Stuart Kauffman suggests that systems reside in attractors at varying distances from a hypothetical edge between order and chaos. Systems near the edge are in shallow attractors and are easily perturbed into new attractors. They are not well adapted to their ecological niches, but they are relatively flexible and able to change with a changing environment. Systems in the ordered regime far from the edge reside in deeper attractors and are more stable (in the dynamical sense). They are better adapted to their current niches, but they are also more rigid and less able to change if their environments are perturbed.

Another way that Kauffman expresses this same idea is in terms of fitness landscapes. This landscape is composed of various peaks and valleys. The peaks represent different habitats or niches and those characteristics of organisms that are maximally suited or adapted to those habitats. Biological evolution tends to move organisms up the peaks. Different species make it to the tops of different peaks. They are specialists that tend to dominate their particular ecosystems. Other species are scattered across the slopes of different peaks. They are generalists that are able to eke out a living in different ecosystems but are not particularly well adapted to any one of them. The specialists are in deep attractors far from the edge of chaos, and the generalists are in more shallow attractors

nearer to the edge. The specialists residing atop the peaks have the advantage as long as the landscape remains unchanged. However, the landscape is itself a vast web or system that will itself be perturbed into phase transitions from time to time as a result of such things as global weather changes, earthquakes, floods, and the invasion of new species from remote ecosystems. When the landscape is sufficiently perturbed, the more flexible generalists will be better able to adapt to the changes and will be able to outpace the more rigid specialists to the tops of the new peaks.

Diversity, whether of species in an ecosystem, baskets of eggs, or stocks in a portfolio, render systems hardy and robust. Complex systems far from equilibrium are less vulnerable to collapse than simple systems close to equilibrium. However, if systems become too complex, then the tables can turn. One tiny perturbation, like a virus in a human body or the addition of one more card to a house of cards, can cause the whole system to collapse. This vulnerability of systems at a threshold level of complexity has been referred to as self-organized criticality.

## THE DYNAMICS OF NATURAL SYSTEMS

Nature affords many examples of dynamical systems. Indeed, all of nature may be considered a vast web of coevolving dynamical systems. For example, a dynamical web of relationships is evident in different species of organisms, such as predators and their prey. Richard Dawkins highlights the example of the coevolution of cheetahs and gazelles. For many millennia, the survival of cheetahs has depended on their ability to hunt gazelles and the survival of gazelles has depended on their ability to elude cheetahs. The evolution of greater hunting skills in cheetahs prompted the evolution of greater elusiveness in gazelles and vice versa. This coevolutionary relationship has been necessary for the survival of both species. If the hunting skills of cheetahs were not counteracted by the escape skills of gazelles, then all of the gazelles would soon be gone and cheetahs would starve to death. Likewise, if the elusiveness of gazelles outweighed the hunting prowess of cheetahs, then the cheetahs would die off, leaving the gazelles to overpopulate, consume all of their food resources, and eventually starve to death. Cheetahs and gazelles are what they are in relation to one another (as well as many other systems).

As noted above with respect to niche construction, organisms change with their environments, and

environments change with the organisms that inhabit them. Organisms and habitats are what they are in relation to one another. One of the most striking examples of the cyclical, coevolutionary relationship between organisms and environments is what has been referred to as the “oxygen holocaust.” For most (about four fifths) of its history, life on earth was invisible, consisting only of bacteria. The metabolic processes of the first bacteria released an abundance of oxygen into the atmosphere. Oxygen is a harsh, corrosive gas, and when too much of it accumulated in the air, the bacteria that produced it began to die off. This oxygen holocaust led to a phase transition in the bacteria. Their metabolic processes evolved to not only withstand oxygen, but to exploit it. Our dependence on oxygen today is testimony to this great transition. So the bacteria changed the environment, which, in turn, changed the bacteria.

The periodic turnover in the diverse species that compose healthy ecosystems exemplifies dynamical stasis in ecosystems. Just as the pattern defining a human face can remain constant despite the constant turnover of the cells that compose it, so the overall features of an ecosystem can remain constant despite a turnover in the species that compose it. The finches of the Galapagos Islands afford another example of dynamical stasis in nature. These islands are inhabited by several species of finches that are differentiated by, among other things, the sizes and shapes of their beaks. Different species are specialized for the consumption of seeds of different sizes. When the climate is moderate, all species of finch may inhabit the islands. However, the climate on the islands can change drastically from year to year and decade to decade, ranging from long droughts to constant rain. As the climate changes, so do the vegetation and the relative abundance of different seeds. When particular seeds vanish, so do the finches that depend on them. Natural selection favors the finches whose beaks are appropriate for the available seeds. Thus, from year to year, different species of finch may dominate the islands. When the climate and vegetation return to a former state, a vanquished species of finch may be resurrected. Thus, over longer spans of time, all species of both plants and finches are represented, so that there is a dynamical stability to the overall pattern and diversity of the ecosystem.

Perturbations like the changing climates of the Galapagos can be beneficial to ecosystems. Research by Reice affirms the value of perturbations in keeping

natural systems robust and alive. Ecosystems that are regularly perturbed by such natural phenomena as floods or fires tend to be rich in species, hardy, flexible, and capable of “rolling with the punches.” Ecosystems that are not regularly perturbed tend to be dominated by a few specialist species. They are mired in deep, rigid attractors far from the edge of chaos and are subject to stagnation and death. When healthy ecosystems do recover from perturbations, there is often a change in the species that compose them. The previously dominant species are the least likely to survive the perturbations. Their niches tend to be taken over by previously subordinate species or immigrants from nearby ecosystems. The turnover of species injects “new blood” into the ecosystem and prevents a dominant species from taking over the whole ecosystem and rendering it vulnerable to stagnation. Again, the ecosystem exhibits dynamic stasis; the inhabitants change, but the overall pattern is retained.

Thus, both whole ecosystems and individual species display many of the features of dynamical systems. Ecosystems that are too stable and too homogeneous are the most vulnerable to the negative arrow of time. Likewise, specialist species that reside atop fitness peaks and dominate ecosystems are the least likely to survive when the fitness landscape is altered by perturbations. Healthy ecosystems and species tend to be those that live relatively close to the edge of chaos and on the slopes rather than the tops of fitness peaks. The idea of fitness landscapes has recently been empirically verified in laboratory studies of bacteria. Cultures of bacteria are allowed to evolve in a particular environmental medium. Some become much better adapted to this medium than others. Those that achieve peak fitness are the specialists that tend to dominate the medium. But when the medium is systematically altered, the specialists falter and the previously subordinate generalists take over. As noted above, this ability of generalists to adapt to new fitness landscapes has been observed in the species of plants that inhabit perturbed ecosystems.

Although complexity and diversity of species in ecosystems generally serve their survival and longevity, they do not render them completely immune to self-organized criticality and fatal butterfly effects. The integrity of complex ecosystems often depends on one or two keystone species. If these keystone species are removed, then the whole system can collapse. In nature, this collapse is often due to the invasions of non-native species. Several invading species from Europe and Asia,

such as cheatgrass, tiger mosquitoes, and zebra mussels, have wreaked havoc on ecosystems in the United States. The integrity of ecosystems also depends on the integrity of their connections to other systems. Ecosystems that become fragmented into isolated patches, disconnected from the webs of relationships to other ecosystems with which they have coevolved tend to stagnate and succumb to the negative arrow of time. Some of the sources of fragmentation are geological, such as earthquakes, and others are human based (e.g., freeways, cities, and farms).

## **The Dynamics of Human Development**

The dynamical framework and its application to natural systems provide a new perspective on human development. We look first at the development, or evolution, of human culture over millennia and then at the life span development of individual humans.

## **EVOLUTION OF THE HUMAN MIND**

### **The Descent of Humankind**

Life on earth has self-organized across many major phase transitions. Nucleated bacteria evolved from non-nucleated bacteria, multicellular organisms evolved from bacteria, and various plant and animal species came and went across various mass extinctions. A global perturbation in the form of a giant meteor is believed to have produced the last mass extinction, the one that led to the demise of the dinosaurs and the evolution of diverse mammals. Thus, as is characteristic of perturbed fitness landscapes, the dominant, specialist species were replaced by the subordinate, generalist species. Then, just a few million years ago in a perturbed, tumultuous landscape in east Africa, a new species of primate, a bipedal generalist, was able to exploit new ways of making a living (e.g., in both jungle and savanna).

Various butterfly effects were involved in human evolution. For example, the upright stance of the first hominids produced a repositioning of the trachea and a more restricted birth canal. The former permitted greater vocal articulation and, a few million years later, the evolution of complex language. The latter required that the babies be born “prematurely” (in comparison with their primate cousins). This meant that brain development continued comparatively long after birth and could be more specifically attuned to

the particular environments in which the babies were reared. Across the millennia, hominids self-organized across various phase transitions involving, among other things, a growth in brain size. Eventually, just a few hundred thousand years ago, anatomically modern humans appeared on the landscape and the remnants of other, more “primitive” humans disappeared.

Jared Diamond suggests that for the bulk of our history, we anatomically modern humans were not particularly remarkable. Our ancestors roamed in small, kinship-based groups, much like other primates. Then, about 40,000 years ago, the first of two grand phase transitions, the upper-Paleolithic revolution, moved us into a new attractor. Our minds underwent a dramatic transition; we became self-reflective, symbolic thinkers. Our potential for complex language was finally realized, and we began to express ourselves on cave walls and invent and make use of a wide variety of tools, weapons, and body ornaments. We continued to follow the hunter/gatherer lifestyle of our hominid ancestors and primate cousins, although we did so with much greater efficiency. Then, only about 8,000 years ago, we stumbled onto an area in the Middle East known as the “fertile crescent” and underwent the second grand transition in our minds and behavior, the Neolithic revolution. We gave up our tried-and-true hunter/gatherer, kinship-based lifestyle and began to settle down in larger, agrarian-based communities. From then to now, cultural and technological evolution has transformed the human mind and the entire web of life on earth.

### Three Natures

It is helpful to distinguish between three basic forms of nature. First nature is material; the whole universe is a web of basic particles and energy. It was the only nature around for most of the 12- to 15-billion-year history of the universe. Second nature is biological. Life appeared on earth some 4 billion years ago. Third nature is ideological. Through the medium of the human mind, it made its appearance with the upper-Paleolithic and Neolithic revolutions. The emergence of first nature from the big bang, of second nature from first nature, and of third nature from first and second natures may be considered the most powerful phase transitions of the entire self-organizing history of the universe. Planet Earth was formed by first nature processes and then massively transformed first by second nature and then, just a

split second ago in geological time, by third nature. We contemporary humans are a composite of all three natures. We are material, biological, and cultural beings. Let us consider in more detail how third nature has transformed the earth and the human mind.

### The Evolution of Third Nature

When humans settled down in communities, the kinship-based clans and social order gave way to a nascent and rapidly growing institutional order composed of various institutions such as polity, religion, law, military, technology, and economy. New ways of making a living emerged, such as politician, priest, policeman, soldier, craftsman, and merchant. Third nature and the institutional order were fueled by the ideas of anthropocentrism and progress, the ideas that humans were a privileged species, capable of and entitled to the ownership and harnessing of the rest of nature.

Prior to the rise of third nature, individual humans were generalists. Everyone knew virtually all there was to know (e.g., about hunting, gathering, and social customs), although some were no doubt more competent than others. However, as the third nature continued to evolve and self-organize, it began to dramatically alter the fitness landscape for humans. People began to be subdivided into the rapidly diversifying niches that defined the institutional order. The third nature landscape has been dynamical and volatile from the start. Those who rise to the tops of the peaks may become marooned in obsolete professional attractors, unable to keep pace with the changing landscape.

Technology and global crises are coevolving systems. Since upper-Paleolithic times, technological innovations by humans have steadily multiplied. The habitats of humans are no longer the living ecosystems of first and second nature. Instead, they are composed primarily of the technological artifacts of third nature. According to Jared Diamond, necessity may be more often the “daughter” than the “mother” of invention. The automobile was a novelty when it was first invented but has now become a necessity in much of the world. The same may be said of television, cell phones, and microwave ovens, among other technological “necessities.”

Most of the “big problems” facing humanity and the rest of the planet today have coevolved with third nature. These problems include overpopulation, environmental degradation, fragmentation of ecosystems, loss of species, and, perhaps, impoverishment of the

human mind. Many of the normal checks and balances of first and second natures that kept the human population under control for millions of years have been diminished by the technological innovations of third nature. For example, if synthetic fertilizer had not been invented some 70 years ago, then the earth would not have been able to sustain the mushrooming human population. Still, the unchecked spread of humanity is taking a severe toll on the earth and its resources. This is especially true of the United States. According to E. O. Wilson, if the entire human population consumed at the same rate as the United States, then the equivalent of four earths would be required to sustain it. Our soaring population and its technological artifacts have led to global warming, the extinction of species of up to 1,000 times the base rate, and countless other global crises.

We may wonder if the dynamics of ecosystems apply to third nature and the human species. Is third nature transforming the entire earth and propelling it into a massive phase transition with unforeseeable consequences? Is third nature so complex that it is near the threshold of self-organized criticality and on the brink of collapse? Are humans the most destructive invading species of them all? Has the human population become so dominant and the diversity of species so diminished that the whole earth is stagnating? Is the human mind itself a casualty of third nature?

## **The Transformation of the Human Mind**

The human mind, like other natural systems, may have been altered by the evolution of third nature. The webs of relationships in which the human is embedded and by which it is defined have been dramatically altered. Whereas we were once connected to and participants in the ecosystems of first and second natures, we now are embedded in and defined by the webs of third nature. In Western cultures, human habitats are technologically crafted. We live in large, electrically powered homes furnished with the latest technological appliances. We spend most of our waking hours connected to televisions, computers, cell phones, and other artifacts of third nature.

Third nature may have co-opted the human mind in the course of its own self-perpetuating dynamics. Our processes of perception, attention, memory, emotion, and learning are all heavily influenced by third nature. Third nature has infused the human mind with the ideas of progress and anthropocentrism, ideas that have fueled the evolution of third nature from the

beginning. The human mind is the medium by which third nature and the institutional order self-perpetuate. Third nature originally arose from the human mind but now controls and defines it. To understand how this may be so, let us now consider the development of individual humans.

## **Development of Individual Humans**

are in relation to the institutional order and other aspects of third nature. We have been shaped and sustained by the dynamics of third nature. Third nature governs our thoughts, our foci of attention, our perceptions, our passions, and our self-concepts. Of course, we still have second nature genes and motivations (e.g., to procreate and develop kinship bonds), but even these have been co-opted by self-perpetuating institutions of third nature (e.g., the fashion, pharmaceutical, and entertainment industries).

When the third nature landscape changes, as it is bound to do from time to time, and our realms of expertise are revised or replaced by new ones, we may no longer have the flexibility to adapt to the changes. In virtually all professions, or institutional niches, there is a steady turnover in the specialists, the “dominant species.” What happens to us when we are no longer vital participants in the institutional order? Is there anything we can do to forestall and abate the negative arrow of time? Are we doomed to be marooned in obsolete attractors and suffer a rapid cognitive decline? Is there nothing of or in us that has not been cultivated and defined by third nature? Can we not fight back?

### What the Future May Hold

The human mind will continue to coevolve with all three natures. Because we are immersed in a complex, chaotic web of relationships with the rest of nature, it is not possible to predict what our futures may hold, both for humanity as a whole and for each of us as individuals. However, if we wish to shape our futures in ways that may benefit ourselves and the earth as a whole, then there may be valuable lessons we can learn from the dynamics of ecosystems. Let us first list five of these lessons and then see how they may apply to both the coevolution of third nature and the human mind and the life span development of individual humans.

*Lesson 1.* The robustness of a system depends on the diversity of its participants. A system dominated by too few participants tends to stagnate and not recover from major disturbances.

*Lesson 2.* In healthy, fluid systems that are continually recovering from disturbances, the more subordinate, generalist participants are more likely than the dominant, specialist participants to survive major disturbances.

*Lesson 3.* Systems that become fragmented and isolated from other systems in the broader webs of life or that remain too long in the same, deepening attractors too far

from the edge of chaos lose plasticity and become vulnerable to the negative arrow of time.

*Lesson 4.* As the oxygen holocaust illustrates, “what goes around comes around.”

*Lesson 5.* Change is constant. Systems that fail to grow along the positive arrow of time will deteriorate along the negative arrow of time.

### Our Collective and Individual Futures

Compared to first and second natures, third nature is still in its infancy and may be suffering growing pains. If it is to survive and continue along the positive arrow of time, then it must heed all five lessons. If third nature continues to kill off the species-rich ecosystems of the earth and fill the vacant niches with a mushrooming human population and artifacts of the institutional order, then it is likely to sever its own lifelines and quicken its own demise. We can only hope that third nature will remain sufficiently flexible so it will be able to adapt and achieve a healthier balance with the rest of nature when the perturbations that it launches travel full circle and come back to haunt it.

Because the human mind is the medium through which third nature survives, the human mind will be either a casualty or a beneficiary of the future of third nature. Will third nature revise the idea of progress to embrace the earth as a whole? Will third nature revive and restore the rest of nature, our sensitivity to it, and our appreciation of it? Or will it continue to replace the first- and second-nature systems with its own artifacts and institutions? Will third nature completely co-opt, define, and control the human mind? Only the arrows of time will tell.

As individuals, there may be little we can do to alter the fate of third nature, but we may be able to apply all five of the above lessons to our individual lives. We may heed lessons 1 and 2 by fostering mental diversity and resisting the temptation to become too specialized. We may heed lesson 3 by reducing our connections with the artifacts of third nature and rebuilding our connections with our first and second nature roots. Otherwise, we may risk becoming isolated in deep, third nature attractors. If we allow ourselves to be totally defined by third nature, then what third nature does to itself, it will do to us (lesson 4). This does not mean that we should disconnect from third nature, but only that we might achieve a more balanced relationship with all three natures. Finally, we may heed lesson

5 by welcoming, even promoting, self-change. One's self identity does not remain constant across contexts and time. The self is an emergent phenomenon that is shaped by the dynamical webs in which it is embedded. Like any other system, it may self-organize across various transitions. A diverse, flexible self, like a robust ecosystem, can survive perturbations and flourish.

## DYSLEXIA

---

*Dyslexia* is a controversial term most often used to describe learners who fail to learn to read quickly, easily, or well, despite exposure to instruction. Historically, dyslexia was understood to be a permanent cognitive deficit, sometimes described as brain damage, minimal brain dysfunction, or congenital word blindness. Currently dyslexia is seen as a specific learning disability, a label that allows students to receive special education services. Parents and teachers sometimes employ the term casually when a student struggles with reading. Intriguing emerging research is demonstrating, however, that most children with reading delays are not brain damaged nor do they have ineradicable reading disabilities. Instead, compelling meta-analytic reading research studies are showing that most young learners with normal intelligence and motivation can learn to read given enough of the right kind of beginning reading instruction, specifically, systematic instruction in phonemic awareness and phonics. Dyslexia, therefore, in most cases, is properly viewed not as an immutable, pathological brain disorder, but as a reading delay that can be overcome with appropriate instruction. Depending on the expert, the study, and the assessment tools utilized, the estimated incidence of dyslexia ranges from 1% to 20% in the general population and from 40% to 70% of adults in the prison population. Adolescents and adults with persistent

difficulty in reading seem to have extreme processing problems and are the most resistant to treatment.

### SPECIFIC SKILL DEFICITS AND INSTRUCTIONAL NEEDS

Delayed readers commonly demonstrate core problems with both phonemic awareness (auditory discrimination of the individual sounds in spoken words) and phonics (sound/symbol correspondences). Typically, a poor reader will hear a spoken word, such as *cat*, as a single sound and will lack the awareness that it is, in fact, composed of three individual sounds (or phonemes): /k/ /a/ /t/. Unfortunately, when learners lack phonemic awareness skills (including sound segmentation, rhyming, oral blending, and other skills), they are unlikely to benefit from formal reading instruction. Teachers in prekindergarten, kindergarten, and grades 1 and 2, and teachers of children with reading delays, should teach phonemic awareness through word play, sound-tapping activities, syllable analysis games, rhyming activities, and the use of alliterative stories, poems, chants, and songs. Students with dyslexia generally require additional practice to master phonemic awareness skills. Behavioral and genetic studies suggest that the tendency to have phonological deficits is heritable.

In addition to deficits in phonemic awareness, dyslexics typically demonstrate catastrophically inadequate knowledge of phonics. Instead of sounding out words, dyslexics memorize words as a whole and guess at meanings from pictures or contextual clues. The most effective method of reading instruction, especially for children with dyslexia, is direct instruction in phonics, not implicit, or discovery methods. Primary grade teachers and reading specialists are advised to provide explicit, sequential, multisensory, fun phonics instruction based on assessment of student needs. Dictation activities, responsive student vocalization, related readings in decodable text, and an encouraging setting are recommended. Phonics experts suggest that phonics instruction be tailored and delivered to homogeneous, not heterogeneous, achievement groups in order to match instructional content to the needs of the learners. Phonemic awareness and phonics lessons are not to constitute the totality of a literacy program, of course. These vital foci are to be integrated with rich exposure to shared literature to develop student motivation, writing practice, and lessons to develop fluency, vocabulary growth, and reading comprehension.

## EARLY INTERVENTION AND TUTORING

Learners with dyslexia are most likely to acquire crucial reading skills if they are identified by the beginning of first grade and receive carefully tailored, sequential instruction, especially small group instruction, individualized instruction, or tutoring in phonemic awareness and phonics. Most school district contracts require classroom teachers to provide appropriate reading instruction for all members of their classes. In practice, though, lagging readers often do not receive individualized instruction from their regular classroom teachers. Some schools require a child failing at reading to repeat a grade. If that strategy fails, the child might be referred for special education. Regrettably, few regular education teachers have the time, training, or resources to provide special lessons for students who lag significantly behind their classmates. Many dyslexics are promoted each year, experiencing frustration and failure as they attempt to follow along with reading instruction, which is increasingly beyond their achievement level. Some elementary schools departmentalize during reading time to enable teachers to meet more efficiently the needs of diverse levels of learners. Intervention services can be provided by recruiting and training members of the community: retired people, high school or university volunteers, paraprofessionals, student teachers, cross-age tutors, parents, or other relatives. Properly selected computer software programs can also provide effective practice in developing phonemic awareness, phonics, and other beginning reading skills. All readers, but especially older delayed readers, need high-interest decodable text in order to practice their emerging reading skills. If students with dyslexia do not encounter targeted, systematic phonemic awareness and phonics instruction in the early years, they tend to fall farther behind academically and often require special education services. They can experience lifelong deficits in achievement and self-esteem.

## BRAIN RESEARCH AND DYSLEXIA

Exciting new brain studies using noninvasive functional magnetic resonance imaging (fMRI) allow reading researchers to measure and record the levels of blood oxygenation in the areas of active brain tissue during the process of reading. Dyslexics have been shown to demonstrate a neural signature or pattern of brain activity in the front of the brain, with some inefficient compensatory activation in other areas, while nonimpaired

readers show activation patterns mainly in the back of the left side of the brain, in the temporoparietal cortex, where the brain analyzes phonological information and processes words for instant recognition. In addition, the latest fMRI studies demonstrate how phonemic awareness and phonics instruction create new neural pathways and actual modifications in dyslexics' brain functioning, while the lack of appropriate instruction seems to cause a deficiency of localized brain functioning and poor reading skill attainment. We now know that students with dyslexia can develop left-side neural networks following effective reading intervention. This line of research shows clearly that targeted instruction works, that the brains of young children with dyslexia can essentially be rewired to function like those of good readers. The fMRI studies indicate that reading problems occur equally among girls and boys, even though boys are more likely to be identified in school, possibly because they are more likely to exhibit behavior that conflicts with social norms.

## THE LETTER REVERSAL MYTH

It is a common misconception that students with dyslexia actually see letters reversed. Studies show that poor readers and inexperienced writers commonly make reversals in their writing, but there is no evidence that the alphabet letters appear visually reversed to these students. Writing reversals and naming errors seem to be artifacts of poor learning. Dyslexics simply have not developed the necessary neurobiological pathways needed to make sense of printed language when they struggle to transform the written code into the oral code.

## CONTROVERSY

Discussion about dyslexia can inspire sharp debate in the reading world. Some maintain that dyslexia is an essentially meaningless term with unfortunate pathological connotations that portray the ordinary poor reader as "disabled." Some scholars grumble that ineffective sight word and whole language reading methodologies are to blame for the large numbers of students with reading problems. They claim that plummeting reading scores and soaring dyslexia statistics are the result of decades of wrong-headed teacher education practices handed down from the ivory towers. Legislators and policy wonks increasingly avoid use of the D-word. Instead, they favor phraseology such as "students at risk of reading failure" and assert that

most dyslexia is preventable and that students with reading difficulty simply need more focused, increasingly prepackaged, teacher-proof, scripted instruction.

Many experienced classroom teachers, reading specialists, and resource teachers view dyslexia as a learning disorder that properly entitles students to extra instructional time and expert professional remediation. They decry one-size-fits-all legislation and point to a tradition of individualized service in special education. They recommend fair eligibility guidelines, attention to individual assessments, and carefully targeted needs-based teaching. These clinicians point out that few classroom teachers beyond the primary grades have the resources or time to go back and provide intervention for students with dyslexia. With or without the label, students with reading difficulties will continue to need the best services of well-prepared, caring, knowledgeable reading professionals, parents, and policy makers.

## Empty Nest

*Adolescence is perhaps nature's way of preparing parents to welcome the empty nest.*

—Karen Savage and Patricia Adams, *The Good Stepmother*

---

## EARLY CHILDHOOD

---

Early childhood is a period of development that spans the ages from 3 to 5 years, between the end of the toddler years and the start of first grade. It is the time in the young child's life when the foundation is laid for physical, linguistic, cognitive, and social-emotional abilities that will expand throughout life. Yet there is an unmistakable quality to early childhood that makes it one of the most interesting and charming periods of human development.

With the start of the early childhood years, babyhood rapidly becomes a thing of the past. The chubby, big-headed body of the baby becomes transformed into the more sure-footed, slimmer, and proportioned physique of the young child. The three- and four-word utterances used for the basic communication of wants and needs now blossoms into grammatically correct and complex sentences. There are great advances in children's thinking about real-world events, which is often expressed in creative ways through pretend play, drawing, and painting. But children's thinking is also characterized by a form of egocentrism in which inanimate objects are given human qualities, such as when young children believe that the moon and the sun follow them when they move, that dreams are movies shown on closed eyelids, and that all activity of the

world ceases when the child is asleep. This type of thinking is endearing and amusing but can also cause young children to have nightmares and irrational fears of monsters in the closet and alligators under the bed and lead to the need to summon imaginary playmates as friends and protectors.

At the same time, there are great advances in children's memory capacity, general knowledge about the world, and self-control that will prepare them for the cognitive and social-emotional demands of the first grade. Continued brain development underlies many of these changes, and these new abilities result from a dynamic interplay between genetic inheritance and experiences in the physical and social world.

A table that summarizes the major developmental milestones achieved during early childhood for each of the following behavioral domains of physical growth, motor, language, cognitive, and social-emotional skills is presented toward the end of this entry.

### PHYSICAL GROWTH: SIZE, PROPORTION, AND BRAIN DEVELOPMENT

From age 3 to 5, children grow in a steady manner, gaining about 5 to 7 inches in height and 8 to 10 pounds in weight, or an average of 2.5 to 3.5 inches in height and 4 to 5 pounds each year. Unlike the infancy and toddler years, when the head is bigger in proportion

to the rest of the body and “baby fat” gives all children a cherub-like appearance, in early childhood children become taller and slimmer as the proportion of torso and limbs to head starts to even out. At age 2, for most babies, the size of the head is about one fourth of their overall body, whereas the size of the head is about one fifth of the body by age 6.

There is great variation among children in physical growth, with boys growing slightly taller and heavier than girls. In addition to gender, good nutrition, physical activity, and health care are leading factors that can promote healthy growth and prevent malnutrition or obesity. The number of children who are obese today is rising, in part due to inactivity associated with more sedentary activities such as television watching and videogame playing, along with eating greater amounts of processed “junk food.” Associated with higher rates of obesity is a serious increase in the number of cases of juvenile diabetes. While many children in industrialized nations acquire unhealthy patterns of nutrition and inactivity, many young children around the world today, and especially those who live in developing nations, are malnourished due to hunger, and malnourishment not only stunts physical growth, it increases susceptibility to disease and illness.

Brain development is an important aspect of physical growth during early childhood. The brain continues to increase in size and weight, although at a slower rate than previously. New synapses, or connections between neurons, continue to form, and previously established connections become stronger. Some synapses that were present at birth will be pruned away due to inactivity, as experience continues to sculpt the brain. The two hemispheres of the cerebral cortex, or the upper layer of the brain, become more lateralized, or specialized, in their functions, with the left hemisphere becoming dominant for many language functions and the right hemisphere dominant for many motor functions. Research shows that there is especially strong electrical activity in the left hemisphere of the brain from 3 to 6 years of age, while electrical activity in the right hemisphere remains at levels constant to those throughout childhood. This increased activity in the left hemisphere may be important for the many advances in language and cognition that appear in early childhood.

Throughout early childhood, the process of myelination, or the appearance of a fatty substance along the body of the neuron, persists and provides insulation to make electrical signals travel faster between neurons. This process continues well beyond early

childhood, but continued myelination of the motor cortex is one factor that helps children to acquire more refined gross and fine motor skills.

## THE ACQUISITION OF GROSS AND FINE MOTOR SKILLS

During early childhood, children gain increased control of their bodies. This new mastery permits them to engage in a wider range of physical activities than before. At the start of early childhood, at age 3, most young children do not have the level of control over their bodies required for highly skilled actions, but by age 5, children are able to start, stop, and change directions with sufficient skill to be able to play physical games such as tag. Researchers have discovered that activity level is higher during the early childhood years than at any other time in development, which gives young children many opportunities to practice and refine their gross and fine motor skills.

*Gross motor skills* involve those actions that are performed by using large muscle groups in the body. Boys tend to jump higher and throw farther than girls, most likely because they have greater muscle strength and higher activity levels. However, girls are better than boys in gross motor skills that require skilled coordination of arms and legs, such as balancing on one foot or hopping. During early childhood, the mastery of basic motor skills becomes coordinated into systems of actions that will eventually permit children to master the basic body movements required for the organized sports and games played in school and for after-school sports, such as youth soccer.

*Fine motor skills* involve actions that are more precise and are performed by using smaller muscle groups, typically in the fingers and hands. Girls tend to acquire fine motor skills faster than boys do and at a higher level of skill, perhaps because girls are less active than boys when it comes to gross motor skills, leaving them more opportunity to focus on the precision of fine motor skills. However, future research is needed to explore this possibility. By the end of the early childhood period, both girls and boys usually have mastered the fine motor skills required for being able to dress themselves, including buttoning, zipping, and tying shoelaces.

## CHANGES IN LANGUAGE SKILLS

Children’s language skills grow rapidly during the early childhood period. Throughout this process, young

children understand the meaning of more words than they can produce. Because of this interesting trend, researchers distinguish between receptive vocabulary, the words that children understand, and productive vocabulary, the words that children can use when speaking. At age 3, on average, children produce between 900 and 1,000 words and have been estimated to understand about 1,200 words. By age 6, when children enter first grade, most have a productive vocabulary of about 2,600 words and they understand over 20,000 words. Researchers estimate that during early childhood most children learn between 5 and 10 new words per day!

It is not just the number of new words that young children learn that is impressive, but also how language permits them to express more complex ideas in ways that increasingly approximate mature language ability. By the end of early childhood, children's speech reflects almost all aspects of adult grammatical forms. For example, during this time children master pronouns (e.g., "I," "me," "you"); possessives (e.g., "Mommie's," "Tommy's"); past, present, and future verb tense; and even plurals, but sometimes young children may over-apply grammar rules, for example, when they say, "I have two feet!" As children gain more experience with hearing and speaking language, they learn irregular grammatical forms, so that these types of language errors typically vanish before the start of first grade.

The structure and rules of language differ the world over, yet there are remarkable similarities in language development during the early childhood years. Despite these similarities, there are differences among children in language acquisition. Many factors influence children's language acquisition, such as their genetic makeup and the extent of experience children have with language, including how much is spoken to them, whether and how parents engage them in conversations, and the degree to which literacy is encouraged through reading books together and structured activities in nursery or preschool.

Because young children learn language at such a rapid rate during early childhood, sometimes they learn words that they don't understand, much to the consternation of parents who quickly learn that swear words spoken in the presence of young children are often repeated, usually at the most inopportune and embarrassing times! Another interesting feature of language use during this age is children's use of already-mastered words to express ideas for which they haven't yet learned the right word. For example,

a young child visiting the zoo and seeing an ostrich for the first time might call it a "giraffe bird," because it has the long neck feature of a giraffe, while also noting that it has feathers like most birds. In this regard, children's language skills also provide insights into their cognitive abilities.

## ADVANCES IN COGNITION

### Representation

Perhaps the most notable feature of early childhood is the progress in young children's ability for symbolic representation, or being able to use words, symbols, gestures, and images to stand in place of, or to *re-present*, people, objects, events, and actions that are not present. Representational ability permits children to move beyond the here and now, such that children can express their memories of past events and entertain the possibility of events that will happen in the future. Representational ability also permits children to think before acting, which often leads to more deliberate planning in problem solving and fewer attempts at trial and error solutions. Three- and 4-year-olds become better at planning multiple-step solutions to problems such as dragging a chair across the kitchen floor to get up onto a counter to open the cabinet door where the cookie jar lives on the middle shelf!

In addition to language acquisition and planned solutions to solve problems, the appearance of pretend play is another example of representation. With pretend play, children progress from using realistic objects, such as picking up a toy phone and pretending to talk to Daddy while he is at work, to using a variety of objects, including a block, a banana, or even a remote control, as a telephone while they fabricate imaginary conversations. Later in the early childhood period, young children engage in dramatic play by constructing scenes with assigned roles, such as "I'll be the baby, you be the Mommy, and Cookie Monster can be Daddy." Children enjoy this type of organized play, and it often functions to let them gain mastery and some degree of control over familiar situations in which they often have little control over what happens.

### Limitations on Reasoning

Greater skill in thinking and reasoning comes with the growth of representational ability, but with these advances, there are also interesting limitations on

young children's logical abilities. More than 75 years ago, Jean Piaget, the famous Swiss developmental psychologist, described children's thought in early childhood as being *preoperational* in the sense that children's ability to reason was not yet fully operational in the use of logic. For example, when Piaget showed 5-year-olds two identical tall, narrow glasses of water, and then poured the water from one tall, narrow glass into a short, wide glass, children reported that there was more water in the tall, narrow glass, even though they agreed that there was the same amount of water in the two tall, narrow glasses before Piaget started pouring, and there was the same amount even when he poured the water from the short, wide glass back into the narrow, tall glass.

Piaget named this situation the conservation-of-water task and explained this surprising response as young children's failure to *conserve* the absolute quantity of water despite its transformation from one size glass to a different-sized glass. This is an example of one type of inflexibility in thinking Piaget identified in early childhood. He suggested that this inflexibility leads young children to focus only on one aspect of a problem at a time. In the conservation of water task, young children focus only on the higher water level in the tall, narrow glass without realizing that the lower water level in the shorter glass is compensated by its greater width. Young children are similarly fooled by appearances when they choose a nickel over a dime because it is bigger, or complain that a sibling was given more ice cream if the same-sized two scoops are put in a bigger dish. The trouble children sometimes have with distinguishing between reality and appearance is a unique aspect of early childhood that declines when older children are able to use logic to discover that reality and appearance sometimes differ. For example, a second-grader would tell Piaget that the amount of water is the same in the different-sized glasses and would prove it by pouring the water from the short, wide glass back into the tall, narrow glass.

Related to young children's inflexibility in thinking is the concept of egocentrism, Piaget's term for young children's tendencies to view the world only from their own unique perspective. If a young child is asked what Mommy might like for her birthday, the child is more likely to suggest a desired toy rather than something more suitable for an adult. Egocentrism also leads young children to animistic thinking—attributing human-like abilities and intentions to inanimate objects such as when they express beliefs such

as the “sun goes to sleep” at night and explain that they can always see the sun or moon in the sky (when it isn't sleeping!) because it follows the child.

These observations suggest that, during early childhood, young children are limited in their understanding of the world and in their thinking skills in unique ways. While other researchers have also observed many of the same interesting early childhood behaviors that Piaget described, they have provided different explanations for why they occur, often focusing on young children's memory.

### Information Processing and Memory

Instead of putting as much emphasis on egocentrism as Piaget did, other researchers explain that young children make errors on various conservation tasks, not necessarily because they are limited in their logic, but because the complexities of the task exceed the amount of information that children can remember and keep in mind long enough to think about. In a typical conservation-of-number task, where two identical rows of six buttons are lined up next to each other, and then one row is spread out in comparison to the other, 5-year-olds will typically say that there are more buttons when pointing to the row that is spread out, even though both rows contain the same number of buttons. When researchers use a smaller number of buttons in this task—three or four buttons instead of six or seven—young children are not fooled by the appearance of the spread-out row of buttons, and they demonstrate conservation of number by reporting that each row has the same number of buttons.

Many researchers today agree that Piaget underestimated the degree to which memory can affect how young children perform on cognitive tasks. This recognition has led to a focus on memory development during the early childhood years. One aspect of memory that develops during early childhood is short-term memory capacity, the amount of information children can remember and use for short periods of time. When young children hear a string of digits spoken out loud and are asked to repeat as many as they can remember, there is a steady increase from being able to remember two digits at the start of early childhood and up to four digits by age 5. In comparison, most adults remember an average of seven digits, or a range between five and nine.

Together, these advances and limitations in thinking and memory make the period of early childhood one of the most interesting. The unique quality of how children think in early childhood also provides a challenge

for those who are brave enough to try to reason with 3- to 5-year-olds! Young children's thinking skills also affect how they form social relationships with peers, gain insight into who they are in relationship to others, and gain self-control over their emotions.

## THE FORMATION AND REGULATION OF SOCIAL RELATIONSHIPS AND EMOTIONS

During early childhood, the great strides that young children make across all areas of development can also be seen in their social and emotional behaviors, especially in the interesting progress that is made in how they view themselves and others as individuals, along with new skills in learning to control their emotions.

### Self-Concept

The initial awareness of the self that emerges in the infant and toddler years becomes further transformed in early childhood. Young children now have the ability to form self-concepts, or to think of themselves in terms of how they look, what they like, and what they can do. For example, when children ages 3 to 5 years are asked to describe themselves, they usually say, "I have brown eyes. I like to play. I can jump as high as that tree! Marisa and Taylor are my best friends." Young children's self-descriptions are usually overly positive and not always grounded in reality, and it is not until they are school-aged that they can move beyond describing themselves in generally positive emotional terms (e.g., "I'm really happy.") to understanding that it is possible to experience both positive and negative emotions at the same time (e.g., "I was happy to play kickball at recess, but mad because I kept making outs").

Another important aspect of the awareness of the self can be seen in how children come to understand the concept of gender and how it guides their understanding of gender stereotyped behaviors, including who and what they choose to play with.

### Gender

At the beginning of the early childhood period, children already can correctly identify themselves as a boy or girl and can also correctly identify the sex of their parents. Once they can do this, they are ready to understand that gender is permanent or that girls become mommies and boys become daddies. Similarly,

young children become experts at figuring out gender-stereotyped behaviors, or the socially acceptable behaviors for boys and girls. Often parents are dismayed by how rigid their child's ideas are about gender-appropriate behaviors, including the belief that boys and girls only play with certain toys, wear clothes of certain colors, and have certain jobs or social roles. However, it takes longer—often not until as late as the second grade—for children to understand that gender remains constant despite outward, physical changes. The strength of gender-stereotyped ideas can lead young children to become confused about a person's gender when, for example, they see a Scottish boy wearing a kilt; they question whether he is still a boy or whether a girl with a very close cropped haircut is really a girl. Simple superficial transformations in appearance, similar to the transformation of water from one size glass to another in the conservation task, can lead young children to be confused about reality. Thus, while young children understand the permanence of gender over time, they do not yet fully understand that gender remains constant despite superficial changes in appearance until sometime after they enter school.

Gender not only guides young children's behaviors, but it also exerts a powerful influence on whom children choose as playmates. As early as age 3, young children not only engage in play around gender-stereotyped activities (e.g., boys engage in group games and rough and tumble play, while girls play more quietly in smaller groups at dress-up or pretend play or with art materials), but they tend to play only with same-sex peers. Researchers found that when given their choice of free play, over 80% of the children observed preferred to play with same-sex peers. The tendency to play with same-sex peers is so strong in early and middle childhood that similar trends have been observed in the United States, Europe, Africa, India, Mexico, the Philippines, and in rural as well as in urban areas.

Although playing with same-sex peers is the clear preference, young children are capable of playing with opposite-sex peers and playmates, especially in situations where there is little choice, such as playing with siblings, or when child care providers or preschool teachers structure mixed-sex group play activities. Despite a clear preference for playmates, the ability to take turns in games, cooperate with others, and develop real friendships with peers blossoms in early childhood. A contributing factor to young children's ability to get along with peers and develop friendships stems from a

**Table 1** Table of Milestones of Early Childhood

<i>Behavioral Domains</i>	<i>3 Years</i>		<i>4 Years</i>		<i>5 to 6 Years</i>

growing competence in recognizing and controlling their emotions.

## Emotions and Emotion Regulation

During the early childhood years, parents are often surprised when their young child wakes up crying from a nightmare or expresses fear over monsters in the closet or alligators under the bed. Recent research, based on interviews with 4- and 6-year-olds, found

that almost 75% of children reported being fearful of ghosts and monsters and being afraid of the dark, bad dreams, wild animals, and getting lost. Many of the fears that young children have may not seem real to adults, but because of their growing representational skills and difficulty in being able to distinguish reality from fantasy, young children are capable of imagining very frightening situations. Such fears can usually be managed with understanding from a sympathetic adult or the intervention of a night light or favorite

stuffed animal or blanket, until children learn strategies to control their own emotions.

The ability to understand and control emotions undergoes significant changes during early childhood. The tantrums of the “terrible twos” decrease in number and intensity, although 3- to 5-year-olds may still have an occasional emotional outburst or tantrum. Instead of the tantrums of the 2-year-old, 3- to 5-year-old children begin to learn strategies for dealing with and controlling their feelings. For example, young children may close their eyes, turn away, or put their hands in front of their faces when they know something scary might be approaching, such as a barking dog or a movie scene. As their language abilities grow, young children also learn to use speech and words to deal with their emotions, from expressing their anger at a parent by shouting, “You’re very mean, Daddy, and I hate you!” to speaking to themselves out loud as encouragement while undertaking a challenging task. Child care providers and parents alike frequently remind young children to “use your words” instead of hitting a playmate in anger over a contested toy.

## SUMMARY

Early childhood is a truly remarkable period of human development. During this time, parents recognize that their child is no longer a baby and is blossoming into an independent thinking, feeling, speaking, and active young child. Along with significant advances in all areas of behavior, early childhood is unique for the emergence of a foundation for the mature behaviors that will continue to evolve throughout development, ranging from skilled actions, language, and reasoning to social relationships. At the same time, early childhood presents an interesting set of unique qualities, such as wild flights of imagination and creativity, irrational fears, and a type of logic that makes reasoning with a 4-year-old nearly impossible, but amusing when not frustrating.

## EARLY INTERVENTION PROGRAMS

---

Early intervention can be both broadly and specifically defined. Generally speaking, the term refers to any specialized assistance provided to very young children, but can be used to define services needed by many, such as immunizations and child care, or it can be specifically targeted to a special population. It might even include programs that are not generally considered to be aimed at children but have a major influence on their lives, such as Medicaid and Food Stamps.

In the most common usage of the term, early intervention is most often recognized to be health, education, and social services and specific or targeted interventions for very young children and their families, with an emphasis on disadvantaged or developmentally delayed children.

Early intervention as we know it today is derived from over 300 years of political, social, and academic influence. Many of the fundamental theories in early childhood development are the foundation for the concepts of today's interventions. Laws have enabled most people in the United States to receive the benefit of these services. Legislation was passed in 1975 to enact the Education for All Handicapped Children Act, known as Public Law (P.L.) 94-142. This law requires all states that accept federal aid for special education to offer all disabled students a free and appropriate education. The year 1990 brought major changes to the original Education for All Handicapped Children Act with the Individuals with Disabilities Education Act (IDEA) or P.L. 105-17.

IDEA specifically provides funding to those early intervention programs targeted to overcome the cognitive, emotional, and resource limitations that may characterize disadvantaged or developmentally delayed children during the first several years of life. This funding allows a broad population to receive treatment regardless of income level or social status.

## TYPES OF EARLY INTERVENTION

Specialized early intervention services are provided to children who are discovered to have, or to be at risk of developing, a disability, or who exhibit a weakness or delay in a particular area. These services begin at any time between birth and 3 years of age and focus on resolving, minimizing, or eliminating existing developmental problems or delays.

Children eligible for early intervention services must be experiencing developmental delays in one or more of the following areas: cognitive development; physical development, including vision and hearing; language and speech development; psychosocial development; and self-help skills. Children may also be eligible due to diagnosed physical or mental conditions (such as cerebral palsy or Down syndrome) or certain family circumstances that put them at risk of having substantial delays.

Early interventions include, but are not limited to: developmental evaluations and assessments, physical therapy, occupational therapy, speech/language therapy, audiology, nutrition services, special education, and psychological and social work services.

Services range from identification—that is, hospital or school screening and referral services—to diagnostic and targeted or direct intervention programs. These direct interventions may include occupational therapy to help an infant learn to hold her bottle, physical therapy to help her learn to roll over, or speech therapy to help her learn to eat. The following are examples of specific intervention therapies.

*Speech and Language Therapy*—Speech and language pathologists provide early intervention services for children with, or at risk for, speech, language, and swallowing disorders.

*Occupational Therapy*—Occupational therapists work with sensory integration disorders, arousal levels, tactile defensiveness, fine motor weaknesses, and oral motor needs. Occupational therapy may be provided in early intervention, early childhood, and school programs, in work settings, and through private agencies, such as Easter Seals.

*Physical Therapy*—Physical therapists work with at-risk children on developmental motor levels (gross and fine), oral motor, neuromusculoskeletal systems, and functional motor skills. The therapist will aid the

family in areas of mobility, positioning, play skills, and handling techniques.

*Nutrition Services*—Nutritionists can provide services to children at risk for certain developmental delays that may be caused by or otherwise impact the child's health through nutrition. The nutritionist analyzes and recommends treatments for anthropometric, biochemical, and clinical variables, feeding skills and feeding problems, and food habits and food preferences.

*Audiology*—Audiologists identify children with auditory impairment, using at-risk criteria and appropriate audiologic screening techniques. They determine the range, nature, and degree of hearing loss and communication functions and provide needed referral for medical and other services for children with auditory impairment. Audiologists also provide auditory training, aural rehabilitation, speech reading and listening device orientation and training, and other services such as selecting, fitting, and dispensing listening and vibrotactile devices.

*Assessment-Based Behavior Support*—Assessment-based or psychological test-based approaches address challenging behaviors associated with developmental delays. Focus is on the development of communication, social interaction, and language skills. Many families rely heavily on this type of support to help them cope with the behavioral difficulties associated with children with special needs. When positive behavior is forthcoming, parents are more likely to spend time teaching and providing intensive care to their child. Families thus are eager to collaborate with professionals in understanding how to guide a child's social and communication development.

No matter which service is provided, the best early interventions are designed to provide a secure, stimulating environment for children to learn and to overcome the challenges that they face.

## ENHANCING CHILD DEVELOPMENT

There are three primary reasons for intervening early with any child who exhibits disability, weakness, or delays. These reasons are (1) to enhance the child's development, (2) to provide support and assistance to the family, (3) and to maximize the child's benefit to society. When properly administered, early

intervention can correct existing developmental problems or prevent potential delays.

Research in child development has established that the rate of learning and development is most rapid in the first 3 years of life. With diagnosis of a delay, disability, or high-risk factors at birth or soon after and the imposition of intervention, developmental gains are greater, and the likelihood of developing further problems is reduced. If this stage of optimal readiness is not taken advantage of, a child may have difficulty learning a particular skill at a later time. Thus, timing of the intervention becomes particularly important.

Researchers have noted that along with early identification of a deficit, the assignment of the appropriate program can best help children develop their full potential. To be most effective, early intervention programs should include these important features: the age of the child at the time of intervention, the amount of parent involvement, and the intensity and structure of the program.

Successful programs are highly structured and clearly specify actions and objectives. These programs closely monitor child and family behaviors and frequently examine the provider's interaction, session plans, and regular activities. In addition to structure, the intensity of the services, particularly for severely disordered children, appears to affect outcomes. Individualizing instruction and services to meet each child's needs also is reported to increase effectiveness.

In any early intervention, the effective outcome can only come from a partnership between the service provider, the child, her family, and the case manager and community resources.

## THE IMPORTANCE OF FAMILY SUPPORT

The family is a critically important and sustaining influence on a young child's development and is considered a major participant in the early intervention process. Intervention efforts are focused on providing the support, resources, and services the family needs to support their child. The main goal of a family-centered approach is to enhance the developmental and behavioral progress of the child and to strengthen and empower the entire family unit.

Both the child and family work together with a service provider to help the child achieve predetermined goals. Service providers such as physicians, diagnosticians, speech and language pathologists, nurses, teachers, early childhood educators, occupational/physical

therapists, and special educators are those usually associated with helping the child and family.

Early intervention services have a significant impact on the parents and siblings of a developmentally delayed infant or young child. The family of the at-risk or delayed child often feels disappointment, social isolation, frustration, and helplessness. This stress may affect the family's well-being and interfere with the child's development. Families of these children are found to experience increased instances of divorce and suicide, and the challenged child is more likely to be abused than are his nondelayed peers. Early intervention can result in parents having improved attitudes about themselves and their child, improved information and skills for teaching their child, and more downtime for leisure and enjoyment of other family members. Parents of gifted preschoolers also need early services so that they may better provide the supportive and nourishing environment needed by the child.

Parents of disadvantaged, developmentally delayed, and gifted children need a variety of support and skills to cope with their child's special needs. A parent's involvement in their child's treatment is especially important, as it affects both the well-being of the child and the entire family. When family members are fully engaged in the intervention, they can expect outcomes to include the ability to implement the child's program at home and a reduction in the stress that impacts the health of the entire family.

## LASTING BENEFITS TO SOCIETY

The long-term goal of early intervention services is the development of a healthy member of society. Intervening as early as possible in a child's life seems to predict a more successful outcome and long-lasting effect. Many years of research on intervention between the ages of birth and 3 years have resulted in evidence of developmental and educational gains for the child. Early intervention increases the odds of improvement for functioning of the family and results in long-term benefits for society. Early intervention has been shown to result in the child needing fewer special education and other habilitative services later in life, being retained in grade less often, and in some cases being indistinguishable from nondelayed peers years after intervention.

Both developmentally delayed and socioeconomically disadvantaged children benefit from early intervention. Results of studies on disadvantaged children showed that children involved in early intervention

programs significantly maintained the gains they made as young children through early adulthood. These children were more committed to schooling, and more of them finished high school and went on to post-secondary programs and employment than children who did not attend the intervention programs. They scored higher on reading, arithmetic, and language achievement and showed fewer antisocial or delinquent behaviors outside of school.

While there is still much research to be done, current measures show that carefully targeted early childhood interventions can yield measurable benefits in the short run and that some benefits persist long after the program has ended. Most of the earliest research involved structured service to disadvantaged children. The children were at risk for delays due to socioeconomic factors rather than specific organic developmental delays. This research was the precursor to the services we know today and is an important part of the overview of early intervention services. Below is a sample of a few of the major research projects conducted over the last 50 years.

## **EARLY INTERVENTION RESEARCH PROGRAMS**

Well-designed, well-funded early intervention programs can have large and significant effects. Designing successful intervention programs includes general guidelines. It is considered optimum to begin intervention before age 3, but intervening at the preschool and school-age level can also be effective. Disadvantaged and developmentally delayed children seem to benefit most from early intervention, and therefore provide ideal target populations. The most important aspect of intervention is the nature of the interaction between provider and child. Several university-based model programs have followed these guidelines and, as a result, have shown desirable long-term outcomes. These include the Carolina Abecedarian Project, the Early Training Project, the Early Intervention Collaborative Study, and the High/Scope Perry Preschool Project. Large, publicly funded programs such as Project Head Start have also exhibited positive results.

### **THE CAROLINA ABECEDARIAN PROJECT**

The Carolina Abecedarian project was started in 1972 at the Frank Porter Graham Child Development Center of the University of North Carolina. The goal of the intervention was to remedy mild mental retardation and improve both academic and social competence for

disadvantaged children. Specifically, the study was designed to examine the relative effects of early education, day care, and other methods of early intervention on intellectual functioning and early academic achievement.

The Carolina Abecedarian Project involved full-day intervention from birth to age 5 and then followed up with an intervention for school-aged children. The Abecedarian Project revealed that, at age 15, those children who had received a preschool intervention scored higher on achievement tests and had lower incidence of special education and grade retention. At age 21, the children who received the preschool intervention were twice as likely to still be in school or to have attended a 4-year college.

### **THE EARLY TRAINING PROJECT**

One of the very first large studies was the Early Training Project directed by Susan Gray in Murfreesboro, Tennessee, in 1962. The motivation for this program was concern over the progressive retardation of low-income children in school. The intervention was designed to improve academic performance through better cognitive performance and achievement orientation.

The Early Training Project showed dramatic reductions in use of special education among youth at age 12, although there were no statistically significant differences between treatments and controls in achievement test scores, grade retention, or high school graduation.

### **EARLY INTERVENTION COLLABORATIVE STUDY**

The Early Intervention Collaborative Study (EICS) is a longitudinal investigation of approximately 190 children with developmental disabilities (Down syndrome, motor impairment, developmental delay) and their families. Participants entered the study during the infant or toddler years at the time of enrollment in an early intervention program. This important national study followed the children in 29 programs. All but 11 children made significant gains. Although those with severe impairments made slower progress, early intervention helped them maintain their skills and prevent regression.

### **THE HIGH/SCOPE PERRY PRESCHOOL PROJECT**

The Perry Preschool Project involved a half-day of preschool every weekday plus weekly 90-minute home

visits over a fairly long time span. Teacher-to-student ratios were 1:6, and all teachers had master's degrees and training in child development. The Perry Preschool Project resulted in positive effects on achievement tests, grades, high school graduation rates, and earnings, as well as lowering crime and welfare use.

The study of long-term outcomes in Perry Preschool has been closely aligned with Head Start in an attempt to promote the benefits of early intervention and to draw attention to the effects of investments in program quality

## PROJECT HEAD START

The most well-known of all early intervention programs, and certainly one of the largest, is Head Start. Initially designed and implemented as Project Head Start in 1965, its chief architects included child development experts Julius Richmond and Edward Zigler. The project was the result of a combination of factors, including public and policymakers' concern about the growing number of children living in poverty in the United States.

The main concern was over subpar educational standards among the inner-city poor. From its inception, Head Start and Early Head Start focused on services specifically geared toward the development of healthy and skillful relationship building between very young children and their parents and caregivers.

A few studies have attempted to follow the children participating in Head Start past elementary grades, and there is evidence that, in the short term at least, Head Start is contributing to school readiness by improving verbal skills and health.

Given the paramount importance of health for very young children, a major focus of the Early Head Start program was to ensure that women received the health services needed to promote a healthy pregnancy and birth and that very young children received early and ongoing well-baby care, immunizations, and other essential health services to support their development. This continues today.

The Head Start program has served more than 15 million children at a cost of \$31 billion since 1965 and, as of this writing, is serving approximately 900,000 children a year.

## CURRENT RESEARCH MODELS

Guided by the results of the programs developed in the 1960s and the ongoing evaluations of even earlier

interventions, researchers have continued to design and evaluate new and more targeted intervention programs. Recent efforts include selecting strict criteria to better identify families and children at risk. For example, scientists are using new research tools such as brain scans to test new interventions. Researchers have recognized that intensive intervention prior to age 2 can result in significant gains for the targeted group of children with autism and related disorders.

The focus on intervention at the earliest ages continues, with many programs in place that start not only with the birth of the child, but with prenatal care designed to provide the child with the best possible life outcome.

## COST TO SOCIETY

What is the long-term cost effectiveness of early intervention? Even though the highly specialized nature of the comprehensive services needed to produce significant developmental gains can be costly, results are generally positive. Researchers have made an effort to quantify the costs of intervention programs and have found examples of significant long-term cost savings.

The total costs of educating a child are actually less if intervention services begin at birth. It has been calculated that the total cost of special services if begun at birth is \$37,273 and the total cost if begun at age 6 is between \$46,816 and \$53,340. The cost is less when intervention is earlier because of the remediation and prevention of developmental problems that would have required special services later in life.

Children with preschool education had fewer years in grades and a higher projected lifetime earning than children without interventions. When schools invest about \$3,000 for 1 year of preschool education for a child, they immediately begin to recover their investment through savings in special education services. Studies have shown improved performance and less need for later intervention, and for every dollar spent on early treatment, \$4.00 to \$7.00 in savings are realized.

## CONCLUSION

For nearly 50 years, researchers, universities, and governments have made significant efforts to close the gap between children with disabilities and those who experience normal development. Children with disadvantaged circumstances are at risk for a host of problems starting as early as birth and persisting through adulthood. Particularly damaging conditions to these

children include, but are not limited to, developmental disabilities and delays, socioeconomic disadvantage, and poverty. Additionally, gifted and special needs children without the associated risk of poverty also benefit from some type of intervention. Early intervention has been based on the premise that children of poverty and, more recently, children with any type of developmental differential can achieve significant improvements in cognitive, academic, and social outcomes. A great deal of progress has been made in our ability to provide effective early intervention for young children with problem behaviors and compromised abilities.

Early childhood—the prenatal period through the beginning of school—is a unique developmental period that serves as a foundation for behavior, well-being, and success later in life. Some children are subjected to stressors during early childhood that impede normal development. These stressors may include insufficient cognitive stimulation, nutritional deprivation, inadequate health care, and maladaptive social interaction. Early intervention to correct these impediments has the potential to promote healthy development in at-risk children.

Program development over the past 25 years has been based on the knowledge that providing highly effective services results in prevention of serious problem behaviors. The challenge now is to continue to create new methods of delivering the highest quality and successful intervention means possible. As new knowledge is acquired, services can be implemented in a consistent and thorough manner and result in effective early intervention.

Family participation and constructive support teams are necessary for meaningful and durable outcomes for both the child and the family. Service providers can identify children at risk and supply services and education to improve diverse developmental issues. Placing emphasis on the important elements of early intervention—diagnosis, planning, program selection, and development—in the first few crucial years results in better experiences throughout a child's life.

psychological health and can have life-threatening consequences. Clinical and scientific interest in eating disorders has increased greatly in the past 20 years. As a result of this growing interest, advances have been made in how these disorders are conceptualized. The abundance of studies in this area has led to an increased understanding of the warning signs, possible causes, and treatments related to eating disorders.

## DEFINITION AND IDENTIFICATION

### Anorexia Nervosa

Anorexia nervosa is an eating disorder that is characterized by self-starvation and excessive weight loss. In order for a health care professional to diagnose an individual with anorexia nervosa, certain criteria must be met. These criteria are outlined in the *DSM-IV-TR*, or the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*, published by the American Psychiatric Association. One of these criteria is a person's refusal to maintain body weight at or above a minimally normal weight for an individual's age and height. Specifically, an individual must weigh less than 85% of expected body weight. In children, there may be a failure to make expected weight gain during periods of growth, which would lead to a body weight that is less than 85% of that expected. Additional criteria necessary to diagnose anorexia nervosa include intense fear of gaining weight or becoming fat, even though the individual is underweight; disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of the current low body weight; and amenorrhea, the absence of at least three consecutive menstrual cycles in females.

Body image refers to the way people see themselves when looking in the mirror or when picturing themselves in their minds. Individuals with anorexia nervosa have a distorted body image. That is, they perceive parts of their bodies unlike they really are, which leads them to feel uncomfortable and awkward in their bodies and to feel ashamed, self-conscious, and anxious about their bodies. Individuals with anorexia tend to overestimate their body size. Some individuals may perceive that their entire body is overweight, while others will recognize that they are thin but perceive specific parts of their bodies to be fat. The word anorexia actually means loss

---

## EATING DISORDERS

---

Eating disorders are characterized by extreme attitudes and behaviors surrounding weight and food issues. Included in this class of disorders are anorexia nervosa and bulimia nervosa. Although each of these disorders is manifested in distinct ways, they both have the potential to result in extreme harm to physical and

of appetite. This definition is misleading, however, because individuals with anorexia nervosa rarely experience loss of appetite. Rather, they intentionally try to lose weight through restricted dieting, purging, or excessive exercise. Anorexia nervosa can be classified in one of two ways, based on the manner in which an individual attempts to limit caloric intake. In anorexia nervosa restricting type, individuals try to lose weight by strict dieting, fasting, or exercise. In anorexia nervosa binge-eating/purging type, individuals engage in regular binge eating (consuming large quantities of food in a relatively brief period of time, accompanied by a perceived lack of control) or purging, or both.

Intervening during the early stages of anorexia nervosa can significantly improve the likelihood of recovery. Therefore, it is important to be aware of some of the warning signs of this disorder. Common warning signs include dramatic weight loss over short periods of time; preoccupation with weight, food, calories, fat grams, and dieting; dieting despite extreme thinness; comments about feeling fat or overweight despite weight loss; development of food rituals or eating very small quantities of food; repeated excuses to avoid mealtimes or situations involving food; excessive, rigid exercise regimens; anxiety about gaining weight or being fat; denial of hunger; withdrawal from usual friends and/or activities or other depressive symptoms; and any behaviors and attitudes indicating that weight loss and dieting have become primary concerns. It is important to note that, by themselves, each of these signs is not definitively diagnostic of anorexia.

## Bulimia Nervosa

Bulimia nervosa is characterized by a secretive style of binge eating followed by behaviors such as self-induced vomiting to compensate for the effects of binge eating. In order to diagnose bulimia nervosa, certain symptoms or criteria must be present, as set forth in the DSM-IV-TR. These criteria include recurrent episodes of binge eating; recurrent, inappropriate compensatory behaviors in order to prevent weight gain, such as self-induced vomiting or use of laxatives, diuretics, excessive exercise, or strict dieting; binge eating and compensatory behaviors occurring on average of at least twice a week for 3 months; and self-evaluation that is overly influenced by body shape and weight.

Individuals with bulimia nervosa may overestimate their body size to the same extent as individuals with anorexia nervosa. While persons with bulimia or

anorexia share some characteristics, such as overestimation of body size, there are also major differences between the two groups. Both diagnostic categories show significant concern about their weight and make attempts at controlling it. Most persons with bulimia, however, maintain weight within the average range for their age and height, while those with anorexia experience dramatic weight loss. Fluctuations in weight may occur in bulimia as a result of alternating cycles of bingeing and fasting or dieting, but dramatic weight loss will generally not occur in these individuals.

Bulimia nervosa can also be classified in one of two ways: purging type and nonpurging type. Individuals who have bulimia nervosa purging type engage in regular self-induced vomiting or regular misuse of laxatives or diuretics. Those who are diagnosed as having bulimia nervosa nonpurging type use other forms of compensation for their overeating, such as fasting or excessive exercise. It has been estimated that as many as two thirds of individuals with bulimia engage in purging, with self-induced vomiting being the most frequently reported method of purging among individuals who seek treatment for this disorder.

Similar to anorexia nervosa, the chance for recovery from bulimia nervosa increases the earlier the disorder is detected. Thus, awareness of the following warning signs can be instrumental in successful recovery: evidence of binge eating, such as disappearance of large amounts of food over short periods of time or the presence of empty wrappers or containers indicating the consumption of large food quantities; evidence of purging behaviors, such as frequent trips to the bathroom after meals, empty packages for laxatives or diuretics, or vomit-like odors; excessive, rigid exercise regimens; swelling of cheeks or jaw area; calluses on hands or knuckles from self-induced vomiting; staining or discoloration of teeth; withdrawal from usual friends and/or activities; and any behaviors or attitudes indicating that weight loss and dieting are primary concerns. As with the warning signs of anorexia, each of these signs by themselves is not absolutely diagnostic of bulimia nervosa.

## PREVALENCE

Most estimates indicate that the risk for developing anorexia nervosa is highest during adolescence and early adulthood. Occasionally, however, this disorder is seen in prepubescent children as young as 7 or 8 years old. Anorexia nervosa primarily occurs in

females, with only 10% of reported cases being male. Estimates regarding the frequency of cases in the population vary. According to the *DSM-IV-TR*, prevalence estimates, or estimates of the actual number of cases in the population at a certain point in time, suggest rates of 0.5% for anorexia nervosa among females.

The number of cases of anorexia nervosa has increased in the past two decades. This increase is likely due to greater awareness of this disorder among the public and among health care professionals. The secretiveness and shame associated with eating disorders, however, is likely to prevent many cases from being reported. Therefore, rates obtained from self-reports in doctor's offices may be underestimates of the true number of cases in the population.

Similar to anorexia nervosa, bulimia nervosa primarily occurs in young females and typically develops in late adolescence or early adulthood. The prevalence of bulimia nervosa, as stated in the *DSM-IV-TR*, is approximately 1.0% to 3.0% among females, while the occurrence of this disorder in males is approximately one tenth that of females. As with anorexia nervosa, bulimia nervosa may be increasing in the population.

## HEALTH CONSEQUENCES

Individuals who have anorexia nervosa subject their bodies to a cycle of self-starvation, which denies the body the essential nutrients it needs to work properly. This causes the body's normal functions to slow down, resulting in serious medical consequences. Among these consequences are abnormally slow heart rate and low blood pressure; increased risk for heart failure; reduction of bone density or osteoporosis; muscle loss and weakness; severe dehydration, which can result in kidney failure; fainting, fatigue, and overall weakness; dry hair and skin; and hair loss.

The recurrent binge-and-purge cycles that are characteristic of bulimia can also have serious health consequences. These cycles can affect the entire digestive system and can lead to electrolyte and chemical imbalances in the body, which influence heart and other main bodily functions. Specifically, these imbalances can lead to irregular heartbeats and possibly heart death. Additional health consequences that may result from bulimia nervosa include inflammation and rupture of the esophagus from recurrent vomiting, tooth decay and staining from stomach acids released during vomiting, and irregular bowel movements as a result of laxative use.

## UNDERLYING CAUSES

Several theories have been proposed in an effort to explain why eating disorders originate, but no single factor has been labeled as the major cause of any type of eating disorder. Most modern theorists believe that biological, social, cultural, and psychological characteristics interact to contribute to the development and maintenance of eating disorders.

### Biological

Research suggests that a person's genetic makeup might increase the likelihood that he or she will develop an eating disorder, although this biological role is thought to be minimal. Eating disorders have been found to run in families. Relatives of patients with anorexia or bulimia nervosa, particularly female relatives, are more likely to develop an eating disorder themselves. Additional evidence for a genetic contribution to the development of eating disorders comes from twin studies indicating that the likelihood of identical twins having an eating disorder may be greater than 50%.

### Familial

Family structure and family functioning have also been identified as possible contributors to the development of eating disorders. Some theorists have argued that anorexia nervosa and bulimia nervosa develop when mother-child relationships are impaired. Negative interaction patterns among family members may also play a role in the development of these disorders. Families of eating-disordered children are likely to lack the ability to manage conflicts appropriately. Children are more likely to develop eating disorders if they are raised in families in which family members are over-protective of one another, overinvolved in one another's affairs, or resistant to family change. It has also been suggested that children develop eating disorders as a means of diverting attention away from family problems, such as marital discord, and toward themselves.

Family processes can lead to an overemphasis on weight and dietary control. Mothers who are critical of their daughters' body weight or who engage in frequent dieting themselves, for example, may unintentionally foster the development of an eating disorder. Parents who are frequently absent, uninvolved, or have unusually high expectations are also thought by family processing theorists to contribute to eating

disorders in their children. Families of adolescents with eating disorders are more likely to be characterized by negative communication patterns and mistrust and to engage in fewer helping behaviors.

The connection between early childhood sexual abuse and eating disorders remains unclear. Some studies of the general population indicate that women with bulimia nervosa are more likely to have been sexually abused as children than women without the disorder. Other studies, however, have not found similar results among individuals with eating disorders. In addition to sexual abuse, other forms of stress or trauma, including physical abuse, being bullied, parental divorce, or concerns over being homosexual have been implicated in the development of eating disorders.

## Social and Cultural

Historically, it was thought that eating disorders occurred only in White, middle-class women. Recently, however, studies have shown that eating disorders exist in minority populations as well. Research has indicated that, in the United States, eating disorders seem to occur as frequently in Hispanic females as in Caucasian females and to be most common among Native Americans. The occurrence of these disorders is less frequent among Black and Asian females.

Anorexia nervosa and bulimia nervosa tend to occur more frequently in industrialized societies. According to the *DSM-IV-TR*, these disorders may be most common in the United States, Canada, Europe, Australia, Japan, New Zealand, and South Africa. It is widely believed that certain features of contemporary Western culture heavily influence eating disorders. In American society, a thin body type is preferred and is considered ideal. This ideal is abundantly portrayed through magazine ads, television shows, and other forms of media. Young girls and women compare themselves to an idealized body image that hardly resembles what most women in our population look like. Alarming numbers of women report being dissatisfied with their bodies and feeling guilty about eating normal quantities of food. At an early age, American girls adopt the cultural focus on dieting and thinness, which is likely to play a role in the onset of eating disorders.

While eating disorders can occur in individuals from any socioeconomic group, females from higher socioeconomic status groups tend to be more concerned with becoming thin than females from lower socioeconomic status groups. White females from

middle- and upper-class societies tend to base evaluations of self-worth and success on outward physical appearance. Thus, eating disorders among individuals in this group serve to restore a sense of satisfaction with physical appearance and self-control.

The fact that eating disorders are far more common in females than in males has been attributed to societal assumptions about what it is to be feminine and what it means to be masculine. Specifically, the focus here is on the belief that girls receive positive attention and reinforcement for being attractive, while boys receive attention and praise for their achievements. Young women tend to base their self-perceptions and identity on the status of their relationships, and these relationships are often heavily influenced by body image and physical appearance.

Subgroups in which there are increased pressures to diet or maintain a thin shape may be particularly susceptible to eating disorders. For example, research suggests that there is a high occurrence of eating disorders among athletes and performing artists. Particular subgroups in which high incidences of eating disorders have been reported are ballet dancers, professional dancers, wrestlers, swimmers, and gymnasts.

## Psychological

The biological, social, and cultural forces mentioned above are thought to contribute to and interact with psychological processes in the development and maintenance of eating disorders. The risk of developing an eating disorder is increased when outside pressures to be thin and attractive interact with internal psychological factors, particularly during times of developmental growth and change. For example, as a result of family or societal influences, a young girl may begin to think she is fat and unattractive as her body develops into a more adult form. In order to avoid the unwanted growth that accompanies the transition into adulthood, this young girl may develop an eating disorder.

Individuals with anorexia nervosa may be described as obsessive, emotionally restricted, approval-seeking, and resistant to change. These characteristics can lead to vulnerability during developmental transitions that involve rapid and notable change, such as puberty. Many persons who seek treatment for anorexia also meet the criteria for one or more personality disorders. Depression and anxiety are common among individuals with eating disorders and are usually manifested near the onset of the disorder. The personality of an adolescent with bulimia is likely to be characterized by

frequent mood swings and lack of impulse control. Abuse of alcohol or stimulants occurs in at least one third of adolescents who seek treatment for bulimia.

Perfectionism may account for the high frequency of depression among individuals with eating disorders. A high need for perfectionism in combination with a high level of daily stress is likely to lead to depression. The likelihood of developing an eating disorder is greater among individuals who have a high need for perfectionism and also think of themselves as being fat or unattractive. In other words, individuals with eating disorders perceive their actual self to be different from their ideal self, so they develop symptoms of an eating disorder in an effort to reach their perceived ideal self.

Adolescents with bulimia or anorexia may believe that limiting food intake and losing weight are means by which to gain control over their lives and to become better people. They may start out with a moderate diet, which will gradually develop into the rigid eating patterns characteristic of anorexia or bulimia. Teenagers may unintentionally initiate a dangerous eating cycle because they are dissatisfied with the way their bodies look, following which their efforts are rewarded by weight loss and a sense of greater self-control. Extra attention from peers may serve to reward dieting behavior and lead to a transition from dieting to a full-blown eating disorder.

## TREATMENT METHODS

Treatment methods for anorexia and bulimia have changed significantly over the past 20 years. Early treatment focused on the need for patients to use insight into emotional traumas to uncover fears surrounding food consumption. The recognition that treatment must involve more than just insight led to the evolution of more sophisticated and comprehensive approaches. Modern treatment approaches, particularly psychological interventions, are leading to more effective outcomes for adolescents and adults with eating disorders. In addition to changes in specific treatment approaches, changes have occurred regarding who treats individuals with eating disorders. The discovery of anorexia nervosa and bulimia nervosa in pediatric populations has led to increased involvement of pediatric psychologists in the treatment of these disorders.

### Anorexia Nervosa

Although anorexia is typically less responsive to treatment than bulimia, progress has been made in the

treatment of this disorder. The treatment of anorexia typically consists of two stages: weight restoration and psychotherapy. The goal of the first stage is for anorexics to restore body weight while under the supervision of a medical professional. This stage may require inpatient hospitalization, either in a general medical unit or a psychiatric unit. During the weight restoration stage, individuals with anorexia are gradually reintroduced to increasing quantities of food until they are able to reach a daily intake of approximately 2500 calories.

Many patients will successfully gain weight while in the hospital, but may return to maladaptive patterns of weight loss and distorted beliefs about food and body image once they are released from the hospital. For this reason, it is important that the second phase of treatment, psychotherapy, be implemented. Through psychotherapy, patients achieve an understanding of their experience with anorexia nervosa, the factors that led to the development of the disorder, how the disorder was maintained, and how to prevent relapse.

Psychotherapy for anorexia nervosa may include behavioral, cognitive-behavioral, and family components. Behavioral techniques can be implemented both during and after the weight restoration stage. Specifically, interventions involve rewarding individuals for positive behaviors. During the weight restoration phase, for example, patients may be rewarded for weight gain by being allowed to participate in hospital activities and privileges. Similarly, patients may be rewarded for weight maintenance once they have left the hospital. These types of behavioral approaches have been shown to lead to short-term success.

The use of cognitive-behavioral therapy to treat anorexia nervosa evolved out of the belief that anorexics have distorted ways of thinking, distorted beliefs, and distorted perceptions. For example, as mentioned earlier, individuals with anorexia nervosa have the faulty belief that they are evaluated based on their weight or body shape. Another example of distorted thinking in anorexia is the tendency to overestimate body size and to believe that eating will lead to loss of control and obesity. Cognitive-behavioral therapies lead to changes in eating behaviors by rewarding or modeling appropriate behaviors and helping patients change distorted or rigid thinking patterns. Although cognitive-behavioral therapy is a popular choice among professionals who treat individuals with anorexia nervosa, few research studies have proven that it is more effective than other therapies in treating this disorder.

For individuals who are younger and still living at home, family therapy is a treatment of choice for anorexia. Family therapy is important because parents are responsible for their children's well-being and can help bring about change by providing assistance in reaching treatment goals while being present in the child's physical environment. Additionally, family therapy serves to restore healthy communication among family members, while eliminating the unhealthy communication patterns that led to the eating disorder in the first place. By involving the entire family, therapists can look at family members' attitudes toward body shape and body image, which may have been interpreted by the child with anorexia as critical judgments.

Group therapy is generally not an effective method of treatment for individuals with anorexia nervosa. These individuals typically have difficulty with social interactions and, due to their preoccupation with weight and negative views of their body, do not welcome group interaction of this sort. Regardless of the type of treatment applied, patients with anorexia have a tendency to deny their illness or to minimize the severity of their symptoms. This denial can stand in the way of progress, regardless of which treatment modality is chosen.

### **Bulimia Nervosa**

Most patients with bulimia nervosa can be treated as outpatients, as they do not typically require the same degree of medical supervision that is required by individuals with anorexia nervosa. Some estimates indicate that approximately 10% of individuals with bulimia nervosa will require inpatient treatment. Inpatient treatment is usually considered when patients have severe medical complications as a result of their eating disorder, are suicidal, or have failed to improve after outpatient treatment. Persons with bulimia also differ from persons with anorexia in that they often seek treatment on their own and are able to acknowledge that they have a problem. Persons with anorexia, on the other hand, tend to be brought in for treatment by their family members and typically deny the severity of their problem.

As with anorexia nervosa, cognitive-behavioral therapy has been used to treat bulimia nervosa by addressing distorted thoughts about eating, weight, and body shape. In treating bulimia, the goals of cognitive-behavioral therapy are to establish more normal eating patterns, change distorted thoughts underlying the disorder, discuss physical and psychological problems related to the disorder, and prevent the disorder from

emerging again in the future. Patients learn to identify circumstances that trigger binge eating and avoid such circumstances. Research has shown significant support for the effectiveness of cognitive-behavioral approaches in treating bulimia.

A type of cognitive-behavioral therapy, exposure plus response prevention, is used to prevent self-induced vomiting in patients with bulimia nervosa. This method involves having a patient eat what they would normally eat during a binge episode. The patient is then guided by a therapist in learning how to resist vomiting and how to deal with anxiety that might result from not being able to purge. A related approach involves having a patient consume small amounts of food, which would typically lead to loss of control and a binge episode. In this situation, the therapist teaches the patient how to avoid or prevent a subsequent binge. After time, the patient will no longer experience anxiety after eating and will no longer feel the need to purge to relieve that anxiety.

Research supports the effectiveness of cognitive-behavioral and behavioral approaches in treating patients with bulimia nervosa. These approaches have resulted in significant reductions in both binge eating and self-induced vomiting. Additionally, these effects appear to remain stable over time, with some studies reporting the absence of binge/purge behaviors for 7 to 10 years following the termination of treatment.

### **Drug Treatment**

Due to the strong association between eating disorders and emotional states like depression and anxiety, attempts have been made to treat these disorders with various medications. Antidepressants and anti-anxiety medications are among the drugs that have been used with eating-disordered patients. Anti-anxiety medications have been used to help patients cope with the anxiety they encounter as a result of having to eat during the refeeding phase. Antidepressants have been used to help patients with bulimia decrease the number of bingeing and purging behaviors in which they engage. Another class of medications, called opiate blockers, is believed to prevent persons with anorexia from feeling euphoric during periods of starvation. The prevention of this euphoric feeling is expected to make starvation less of a rewarding experience for the patient with anorexia and, therefore, may lead the patient to start eating again.

Generally speaking, a number of medications for bulimia nervosa and anorexia nervosa have produced positive short-term effects. The long-term effectiveness

of these medications, however, is unclear. High relapse rates occur once these medications are discontinued. Furthermore, numerous changes in medication are often required over time, and patients tend to discontinue taking medications before they are advised to do so, often to avoid their negative side effects. Thus, while drug treatment does have a place in the treatment of eating disorders, psychotherapy appears to be the preferred method of treatment.

## SUMMARY

Eating disorders are primarily disorders of young females, with those in adolescence or early adulthood being at greatest risk for developing these disorders. Bulimia nervosa and anorexia nervosa, though distinct in certain ways, can both result in serious harm to physical and emotional well-being. Increased attention to these disorders over the past 20 years has led to an increased awareness and understanding of their underlying causes. Most modern theorists believe that biological, familial, social, and cultural factors interact with one another, leading to the devilement of anorexia nervosa or bulimia nervosa in an individual.

Treatments for these disorders have shifted from a focus on insight to more comprehensive approaches, involving behavioral, cognitive-behavioral, and family therapies, as well as drug treatment in some cases. As mentioned previously, the chance of recovery from anorexia nervosa or bulimia nervosa increases when these disorders are detected early and treated promptly. Thus, it is important to be aware of the warning signs associated with these disorders.

Fortunately, social and cultural patterns may be shifting toward healthier norms of eating. This may be due to increasing public advertisements, talk shows, and television shows devoted to discussions of eating disorders and healthier decision making. Nonetheless, many people continue to suffer from the physical and emotional effects of eating disorders, and these disorders can result in mortality if professional help is not sought out.

## ECHOLALIA

---

*Echolalia* derives from the Greek words “echo” meaning “sound,” and “lalia” meaning “a form of speech.” In Greek mythology, Echo is a nymph, an unfortunate victim of Zeus’ jealous wife, Hera, who is punished by Hera and no longer able to use her voice except in the form of echolalia. Echolalia refers to speech in stock phrases that simply involves copying and repeating another person’s utterance word for word. For example, a child might immediately repeat out loud his mother’s utterance “Drink your milk” at the dinner table, or a child might say “Trix are for kids” over and over again, repeating something he or she had obviously heard on TV the day before.

Five stages of expressive speech have been identified in early linguistic development: isolated sounds, syllabic utterances, awareness of one’s sounds, echolalia, and flexible production of meaningful words in context. Echolalia is considered by some to be a

normal developmental occurrence in typical language acquisition. During the echolalic stage, infants characteristically repeat their caregiver's words, which may serve the function of rehearsal and practice for words and language. In typically developing children, echolalia peaks between 2 and 3 years of age, and then decreases. In this context, the term echolalia refers to a typical developmental phenomenon that occurs for a brief period of time during the course of some children's linguistic maturation.

Although echolalia may refer sometimes to a developmental stage in normal speech acquisition, the term is more commonly used to refer to a peculiar and common characteristic displayed by a variety of special needs children experiencing atypical development. In this context, echolalia refers to the apparently noncommunicative and meaningless repetition of another person's vocalizations, commonly found in children diagnosed with various disorders, such as autism, mental retardation, schizophrenia, Gilles de la Tourette syndrome, aphasia, and dementia. Among some children with autistic spectrum disorders who are verbal, echolalia is the only form of speech available to them. For other high-functioning autistic children, echolalic utterances appear sporadically together with more meaningful generative speech.

In these special populations, echolalia is typically displayed with more rigidity, less melodic intonation, and more persistence than that of normal children. Echolalia can be either immediate (i.e., repetition of someone else's words just spoken) or delayed (i.e., repetition of words or sentences after considerable time has elapsed). Also, the utterances repeated can also come from TV or from other media, rather than originating from face-to-face human interaction.

There is debate over the functions of echolalia for children with autistic spectrum disorders and other special needs. Some researchers believe that echolalia has no meaning for many autistic children and that it does not represent an attempt to communicate. Others think echolalia is a way for a child without many language skills to express their lack of comprehension. For some autistic children, echolalic speech is all they have and it does appear to be used at least at times to initiate and maintain social interaction or to regulate one's own actions. For example, a mother may ask the child to say hello: "Say hello, Jim," at which point the child repeats, "Say hello, Jim" and this is the best greeting Jim can produce. The difficult task for family members with a predominantly echolalic child, of course, is to figure

out what the child's echoed utterances might mean. One typically needs to consider both the present situation and many prior contexts of the message being echoed.

In both typical and atypical populations, as language improves, echolalia diminishes by itself. Therefore, the majority of interventions for persistent echolalia in special populations have focused primarily on improving the quality of the child's general expressive speech, rather than discouraging echolalia specifically.

## ECOLOGICAL THEORY

---

There have been many different approaches to explaining development, but one especially has tried to deal with the importance of the environment without ignoring the uniqueness of the individual. Urie Bronfenbrenner, and more recently along with Pamela Morris, has developed what is called an experimental ecology of human development or an ecological theory of human development. Within this model he stresses the importance of the developing person in his or her surrounding environment. He defines the phrase ecology of human development as the study of "the progressive, mutual accommodation, throughout the life span, between a growing human organism and the changing immediate environments in which it lives."

His basic argument is that traditional studies in human development are very rigorous and tightly controlled. While this can be a benefit, the studies are also very limited in scope because many of these experiments take place in settings that are unfamiliar to the

participants and artificial in their construction. In other words, they don't very accurately represent what the real world is about; in Bronfenbrenner's earlier and own words, developmental research has been "the study of the strange behavior of children in strange situations for the briefest possible period of time."

Because he is so concerned with the qualities and characteristics of the environment, part of his ecological model defines a series of structures that are "nested" within one another. In his earliest works, he described four such structures. These structures nest or "fit" within each other, beginning with the microsystem (as he points out much like the stacking Russian dolls that disappear within one another).

The *microsystem* reflects the immediate setting that contains the person. Keeping in mind how our immediate setting changes throughout the day, the microsystem in which we find ourselves changes as well. Although the library might be the microsystem in which we found ourselves late at night, our office or classroom might be the parallel microsystem during the day.

All microsystems have three different dimensions. The first is the *physical space and activities* within the microsystem such as the lighting over our desk or the temperature of the classroom during a test. The second is the *people and their roles* who are part of the microsystem such as our roommate or our classroom teacher. Finally, the third is the *interaction between the people* in the microsystem and the person. At one time, for example, we might be angry with a roommate who does not do his or her assigned tasks. At another time, we might act like best friends.

The second level, called the *mesosystem*, focuses on the relationships between the different settings that the person is in during different times in development. The mesosystem focuses on interrelations among microsystems. For example, the mesosystem for college freshmen might consist of the dining hall, the classroom, home, and the intramural softball field.

The third element is the *exosystem*. Bronfenbrenner believes that the exosystem is a set of specific social structures that do not directly contain the individual, but still have an impact on the person's development. These structures "influence, delimit, or even determine what goes on" in the microsystem of the developing individual. The individual does not participate in these settings, but they do have a direct impact on his or her behavior. For example, an exosystem might be the doctor's office, the teacher's lounge, or grandma's house. These are all places with an indirect impact on the person's development.

The last element or structure in his model is called the *macrosystem*. It consists of all the elements contained in the micro-, meso-, and exosystems, plus the general underlying philosophy or cultural orientation within which the person lives. As Bronfenbrenner says, these are the "overarching institutional patterns of the culture or subculture, such as the economic, social, educational, legal, and political systems of which local micro, meso, and exosystems are the concrete manifestations" (p. 8).

This early model of the ecology of human development helps us in two primary ways as far as understanding human development. First, it places the interaction between nature and nurture in a very clear and easily definable context of one of the four systems discussed above. Second, it encourages us to move away from laboratory-based settings and begins to examine development in the "natural stream" of when and where it occurs. More and more scientists who study human development are emphasizing the qualitative nature of changes and using such methods that reflect that emphasis—away from the more tightly controlled laboratory study.

But, as with all good scientists, Bronfenbrenner has moved on. Along with Morris's help, he has taken the next step and further developed their ideas placing an emphasis on several new and complimentary ideas. The primary change in the ideas presented almost 20 years ago, and now referred to as part of a bioecological model, involves proximal processes (or interactions in the immediate environment).

1. In order for the person to develop, he or she needs to be an active contributor to the environment.
2. These activities and contributions have to take place on a regular basis and over an extended period of time.
3. These activities also need to become more complex over time—doing the same thing as before will not act as the "engine" of development that Bronfenbrenner and Morris emphasize.
4. The process of development is a reciprocal one where each member of a dyad or group influences each other member.
5. While interactions with people are very important, interactions with objects are important as well.
6. The importance and role of proximal processes change over time as the individual and environment change as well.

Bronfenbrenner's original model has clearly expanded to further emphasize the importance of the environment and the interaction between the individual and his or her environment. It is a rich display of ideas and the importance of the role of our social world and its influence upon us.

## EGO

---

The term “ego” is today in common usage. People use the term “ego” in a variety of ways. Because the word is in everyday usage, people assume they know what it means. However, a word such as ego varies in the ways in which it can be used. As Wittgenstein sought to explain, we can think we know the meaning of a word, but it can have a variety of meanings depending on its use. Wittgenstein believed that meanings of words arise out of the social and interactive nature of language. The original meaning of the word is derived from the Latin *ego*, meaning “I” or “self.” While the term ego retains the basic “I” or “self” meaning, it has also come to apply to our sense of identity, our individuality, and our executive and organizer functions as well as the center of our consciousness. We have carried the word ego into the English language and normalized it. We do not say “the I” when we refer to ourselves, but very often we say “the ego” as if to refer to a specific thing or part of our minds.

Today we find that ego, as used in the vernacular, means that some people have an inflated feeling of pride that elevates them above others (superiority). This meaning is usually associated with self-importance, egotism, and pride. We also see the term ego being used in reference to our consciousness of our own identity.

Carl Jung's notion of *anima* in reference to the inner self being in touch with the unconscious is an example of this type of usage. Also associated with this usage is the notion of an alert cognitive state in which you are aware of yourself and your situation. Another use of the term ego comes from the psychoanalytical method of Sigmund Freud. In Freudian terms, the ego is the reality principle. It is the seat of reason and is responsible for our thoughts and feelings mediated by our understanding of social norms and expectations.

The study of the ego or ego psychology began at the turn of the 20th century as philosophy and psychology became two separate disciplines. By the 1930s, the field of ego psychology had earned a respected place in psychological studies. However, a battle between Anna Freud's view and Heinz Hartmann's view of the ego was at the forefront of ego psychology during this period. Anna Freud focused on the defensive nature of the ego while Hartmann focused on its adaptive potential. According to Robert Kegan, these two views were not reconcilable. On the one hand, Anna Freud's view of the ego was a defense mechanism that sought to ward off anxiety that could lead to the ego's breakdown. On the other hand, Hartmann's view of the ego was one that encompassed the process of meaning making. The idea of the ego as a meaning-making agent can be found in the work of Robert Kegan, Carl Rogers, Jean Piaget, and Jane Loevinger, while the idea of the ego as a defense mechanism that mediates the id (or our impulsive desires) can be seen in the work of psychoanalysts such as Sigmund Freud, Anna Freud, Karen Horney, and Eric Erickson.

The basic difference in the Freudian conception of the ego and that of meaning-making psychologists is that in the former the ego arises or develops from an interaction with our social and cultural experiences, while in the latter it is considered to be with us at birth as a process and as such is an active agent in our ability to make sense of our world experiences. Adler, a student of Freudian psychology, departed from Freud's view of the ego. While Freud thought that the ego was derived from drives through processes of frustration and renunciation, Adler understood the ego to provide a reference for the way in which one structures one's world and perceives his or her experiences in the world.

The debate as to the origin and function of the ego is still very much alive today. We have on the one side, those who see the ego as residing in the real world. The ego is driven by the id and attempts to accomplish what the id wants. The ego develops out of our need

to interact with the world and the id's need for a mediator. It is on the foundation of Sigmund Freud's structural ego that Anna Freud's Ego Psychology, Melaine Klein's object relations, Erikson's notion of identity development, and Heinz Kohut's self-psychology were built. On the other hand, other theorists, especially developmental psychologists, view the ego as an innate process that organizes our life experiences. As such, the ego helps us derive meaning from our life experiences and develop our world view.

There are also many philosophers who have contributed to our understanding of the ego and how it develops. George Herbert Mead (1934) developed his understanding of the "I" and "me" in his seminal work, *Mind, Self, and Society: From the Standpoint of a Social Behaviorist*. James Mark Baldwin (1897) in his work entitled *Social and Ethical Interpretations in Mental Development*, discusses the development of the individual (or self) in relation to the evolution of society. In *The Nature of the Self*, Risieri Frondizi (1953) argued that the self is an organic unity and its parts cannot be understood in isolation from each other. This opposed those who treated the self as an aggregate of parts rather than a whole.

The word "ego" has a vast array of meanings and usages. The Oxford Reference Online Library lists 68 definitions for the word "ego" and its associated usages. How one understands the word "ego" depends on which theoretical or philosophical assumptions one makes. Ego is closely tied to concepts of self, identity, consciousness, and way of being. However, the common element in all the meanings is the central understanding that the ego is intimately connected to the "I."

---

## EGOCENTRISM

---

Our everyday conception of egocentrism involves people behaving "selfishly" or failing to be "considerate" of others. While egocentrism does in fact typically manifest itself in failures to take other people's perspectives, it is more rooted in human cognitive shortcomings than in any motivation to be selfish. In both children and adults, egocentrism arises when we fail to recognize the idiosyncratic nature of our own knowledge or the subjective nature of our own perceptions. Such failures describe the child at play who covers his eyes and joyfully exclaims to his parents, "You can't see me!" Likewise, they describe the adult physician who provides her patient with a medical diagnosis that only another doctor could understand.

The Swiss psychologist and biologist, Jean Piaget (1896–1980), pioneered the scientific study of egocentrism. He traced the development of cognition in children as they move out of a state of extreme egocentrism and come to recognize that other people (and other minds) have separate perspectives. Within the framework of Piaget's stage-based theory of cognitive development, the infant in the *sensorimotor* stage is extremely egocentric. During these first 2 years of development, infants are unaware that alternative perceptual, affective, and conceptual perspectives exist. Once they reach the *preoperational* stage (2–7 years), children come to recognize the existence of alternative perspectives but usually fail to adopt these viewpoints when necessary. Using a variety of ingenious tasks, Piaget discovered that children in this stage often do not recognize that another person who is also looking at the same nonuniform object as them, but from a different angle, sees it differently. Piaget's observation that older children stopped displaying such instantiations of egocentrism led him to argue that children overcome egocentrism when they reach the *concrete-operational* stage and come to appreciate that different perspectives afford different perceptions. Piaget's theory of cognitive development posits that by age 7, most of us are

free of egocentrism. Since Piaget, research within developmental psychology on children's *theory of mind* has continued to explore egocentrism in many areas of social and cognitive reasoning, such as perception, communication, and moral judgment. This research has generally maintained its focus on young children's instantiations of egocentrism and the developmental stages at which these are overcome. Another important tradition in psychology that has also advanced our understanding of egocentrism—though largely in isolation from the theory-of-mind tradition in developmental psychology—is the heuristics and biases tradition in cognitive and social psychology. Research on heuristics and biases that affect human judgment has demonstrated that, even well into adulthood, our perceptions are characterized by various egocentric shortcomings. These include the *false consensus effect*, whereby people tend to overestimate the extent to which their own preferences are shared by others; the *curse of knowledge*, whereby experts in a particular domain fail to adequately take into account the level of knowledge of laypeople with whom they are communicating; the *illusion of transparency*, whereby people tend to exaggerate the degree to which their internal emotional states (such as anxiety during public speaking) are evident to outside observers; and the *spotlight effect*, whereby people tend to overestimate the degree to which aspects of their appearance and actions are noticed by others.

Although egocentric biases are generally more subtle in adulthood than in infancy, the persistence of some forms of egocentrism in adulthood suggests that overcoming egocentrism may be a lifelong process that never fully reaches fruition. Opening channels of communication between developmental psychologists, who study theory-of-mind, and social and cognitive psychologists, who study judgmental biases, is likely to generate a host of new and interesting questions while allowing both fields to make important theoretical advances.

## EGO DEVELOPMENT

---

Ego development refers to the evolution of a personality construct that synthesizes experience into a coherent sense of how individuals view themselves. In this way, the ego development is at the center of the investigation of human experience. In another, it is an attempt to fathom the organization of one's own mind; a process one scholar suggested was analogous to "shoveling smoke."

Psychoanalytic thinkers were first to pursue a notion of the developing ego. Highlighting a multifunctional tripartite mind, Freud simultaneously proposed the ego as both helpless mediator of aggressive and libidinal impulses and director of personality functioning. From these seemingly contradictory perspectives, two schools of thought emerged—object-relations theory in Britain (Fairbairn, Klein, Winnicott) and ego psychology in the United States (Erikson, Hartmann, Horney). Both failed to propose a comprehensive theory of ego development and instead relied on the general idea that ego develops via interactions between id and societal realities.

In the work of Piaget and Kohlberg, ego development is dealt with in a far more cognitive and subtle fashion than with psychoanalytic thinkers. Piaget's focus on the development of intelligence—specifically symbolic reasoning—as the ultimate achievement of the species suggests itself as a primary ego demonstration. That is, for Piaget, how one sees the world is a function of intellectual development. Kohlberg proposes similar claims regarding moral reasoning and the expression of ego. Though these descriptions did not bare the hallmark of psychoanalytic interest of the ego as the unifying characteristic of personality, their construction of the

ego as a cognitive entity, in part, offered an alternative framework from which development can occur.

Loevinger (1976), a self-described psychoanalytic iconoclast, was first to offer an explicit structural model of ego development. Merging psychoanalytic interest of ego with a notion of development built on adaptation, she proposed that ego development was a singular, cognitively seated activity demonstrated through impulse control, character, interpersonal relations, conscious preoccupations, and cognitive complexity, among other traits. For Loevinger, ego development occurs through an evolution of stages, each named for functions or characteristics most prevalent for an ego level. First is the Presocial Stage followed by the Symbiotic Stage, Impulsive Stage, Self-Protective Stage, Conformist Stage, Self-Aware Level: Transition from Conformist to Conscientious Stage, Individualistic Level: Transition from Conscientious to the Autonomous Stage, Conformist Stage, and Integrated Stage. That is not to say that ego development occurs in a singular direction from the Presocial Stage to the Integrated Stage. Instead, ego development is an individualized process—though most people are recognized at the Conformist, Self-Aware, or Conscientious Stages. Though Loevinger rejected age norms for stages, earliest stages are largely unseen in adult populations, whereas higher numbered stages are unattainable by children. Most notable of this research agenda is the degree to which stages are supported by empirical data. Using the Sentence Completion Test (SCT), they established a theory as empirically grounded as any other in personality literature.

Challenges to Loevinger include calls that her model, built on interviews and psychometric analysis, is too limited as an approach to the study of something as encompassing as personality and arguments that the stages lack philosophical grounding. Broader criticism is aimed at the use of stages over trait perspectives in the study of personality in general, including ego development. It has been of interest for nearly a century, and its attendants should take comfort in the fact that any psychology claiming to capture human experience cannot exist without a rendering of its current roles and current notions of ego fulfillment, however smoky that may be.

—Sean A. Forbes

## ELDER ABUSE

---

Elder abuse is a term that has both specific and general meanings. Specifically, the term refers to volitional acts (acts of commission) of physical, sexual, or psychological violence perpetrated against individuals over age 65 by family members or other individuals in positions of trust, such as health care providers. The term is not usually used to denote acts of violence perpetrated against elders by strangers. The term is also used, generally, as a cover term to denote, by commission or omission, an array of harmful acts perpetrated against elders by intimate others including neglect, exploitation, and abandonment.

In recent years, researchers have advocated the use of the term “elder mistreatment” as the cover term, reserving the term “elder abuse” to refer to only volitional acts of violence. Some absence of clarity in the literature arises from this lack of distinction. Other definitional issues arise in the literature related to whether the term applies equally to vulnerable elders and non-vulnerable elders, whether cases include situations of self-neglect, and whether the identity of the perpetrator makes a difference in the definition. Because a substantial proportion of elder abuse is perpetrated by intimate partners, some researchers view abuse by spouses under the rubric of late-life intimate partner violence and consider it separately from abuse perpetrated by other family members. In general, how these definitions are applied is defined by individual state statutes.

Estimating the frequency of elder abuse is complicated because of definitional problems and the fact that there has never been a nationwide, population-based prevalence study. However, the National Center on Elder Abuse notes a steady increase in the number of cases reported since 1986. In 2003, reports from Adult Protective Service (APS) agencies estimated 166,019 substantiated cases of elder mistreatment in the United States. There is agreement that the number of substantiated cases reflects a small percentage of

the actual cases, and the discrepancy lies in failure to recognize and report mistreatment by those in contact with elders and the reluctance of many elders to self-identify.

The National Center on Elder Abuse indicates that signs requiring further investigation include bruises, broken bones, burns, abrasions, pressure marks, pressure sores, poor hygiene, and unusual weight loss. Also requiring investigation are sudden withdrawal from usual activities, a change in alertness, sudden changes in financial situations, frequent arguments or tense relationships between elders and their family caregivers, and evidence of belittling or threats. While no one characteristic of elders puts them at high risk for mistreatment, researchers agree that certain characteristics of caregivers should be considered red flags, including alcohol and drug problems; personal problems exacerbated by the caregiving situation; coexisting physical and mental problems; being overburdened by the demands of caregiving mainly due to unrealistic expectations, lack of knowledge or preparation, and dependence issues; the family's social isolation; and previously existing interpersonal conflict.

Treatment for elder abuse is complicated because the autonomy of the elders and their preference for treatment must always be considered. In addition, in some states, treatment options are limited by the availability of resources and affordable, alternative living arrangements. Often the most feasible approach to treatment is the prevention of the next episode through counseling and education. In addition, APS agencies can often place outside workers in the home to act as monitors. In emergency situations, where the elder's life is threatened or the elder is too mentally disabled to make an autonomous decision about a treatment preference, elders can be removed from abusive situations. Whether or not the elder is removed from the situation, in most states perpetrators can be prosecuted.

## ELDER MALTREATMENT

---

Many types of family violence have been recognized, including child abuse, wife abuse, and, more recently, elder abuse. All forms of family violence are at epidemic levels in the United States, yet considerably less investment has been made in reducing elder abuse than child and wife abuse.

### WHAT IS ELDER ABUSE?

Elder abuse, like other forms of maltreatment in families, can take several different forms. The National Elder Abuse Incidence Study (NEAIS) of 1996 defined domestic elder abuse—that is, elder abuse perpetrated by members of the family or household—as including the following forms of maltreatment: (1) *physical abuse*—any form of physical aggression that could result in bodily injury, physical pain, or impairment; unwarranted administration of drugs and physical restraints; force-feeding; and physical punishment; (2) *sexual abuse*—any form of nonconsensual sexual contact; (3) *emotional or psychological abuse*—the inflicting of anguish, emotional pain, or distress; (4) *neglect*—the refusal or failure to provide such life necessities as food, water, clothing, shelter, personal hygiene, medicine, comfort, and personal safety; (5) *abandonment*; (6) *financial or material exploitation*—the illegal or improper use of the elderly person's funds, property, or assets; and (7) *self-neglect*—behaviors by older people that can be injurious to their own health or safety. Although this definition has the advantage of being broad and inclusive, it raises a number of issues that have generated debate—particularly with regard to what constitutes neglect, whether “self-neglect” is a form of maltreatment, and whether using an elderly parent's economic resources for personal gain is abusive. If older adults wish to maintain their autonomy and avoid dependence on adult children, is it correct to say that the adult children neglected them if poor health leads to bedsores and other serious health problems? If older people neglect their personal

care and hygiene, are they being maltreated? Or should terms such as “maltreatment” be reserved for acts committed (or omitted) by someone other than the individuals themselves? Finally, is financial exploitation of elderly parents abusive if those parents feel an obligation to help their grown children?

## HOW COMMON IS ELDER MALTREATMENT?

Estimates of the extent to which elder maltreatment occurs in the United States vary considerably. One important source of information is the NEAIS of 1996, which collected two types of information: (1) official reports on domestic elder abuse from Adult Protective Service (APS) agencies, and (2) reports on personal experience with elder abuse cases from individuals in “sentinel agencies.” APS agencies are the agencies in each state that have the responsibility for investigating reports of elder abuse. Sentinel agencies, such as financial institutions, law enforcement agencies, hospitals, and elder care providers, are agencies that are mandated by law to report suspected cases of elder abuse. Because many more cases of domestic elder abuse occur than come to the attention of professionals, reports from both APS and sentinel personnel are likely to significantly underestimate the actual frequency with which elder abuse occurs in the United States.

Based on information from sentinel agency personnel, approximately 450,000 of the 44 million U.S. residents older than age 60 were abused and/or neglected in a domestic setting in 1966. This number is equivalent to a rate of 11.3 cases of maltreatment per 1,000 elders. Only 16% of these incidents were reported to APS for investigation. This underreporting reflects to a considerable extent the disbelief of mandated reporters that reporting will actually help the victims of maltreatment. When self-neglect, the most commonly reported type of abuse, is added to the definition of elder abuse, more than 551,000 elders were abused in 1996; 21% of these were reported to APS for investigation. Other estimates of the incidence of elder abuse are much higher. For example, the U.S. House Select Committee on Aging suggested in 1991 that somewhere between 1 million and 2 million elders are abused each year in the United States. Given that not all cases are reported, this is likely to be a better estimate of the actual extent of elder maltreatment.

Of the types of elder abuse that are reported and substantiated by APS agencies, the largest percentage is typically for neglect, followed by emotional/psychological abuse, financial exploitation, physical abuse, abandonment, and sexual abuse. Within domestic settings, older men and women may be abused by a variety of family members, including grown children, grandchildren, spouses, and others. Abuse by spouses is more likely to go unreported than reported. Spouses are the perpetrators in only 19% of cases reported to APS, as compared to more than 30% of unreported cases. The rate of abuse by elderly spouses may be as much as 41 per 1,000 elders. As is true of spousal abuse at younger ages, husbands are more likely to hurt their wives than wives are to hurt their husbands. Injuries have been shown to occur in approximately 6% of physically abused elderly husbands and 57% of physically abused elderly wives.

In contrast to spousal elder abuse, the abuse of elders by adult relatives who are entrusted with their care is the most researched and most widely recognized type of elder abuse. According to both reported APS cases and the larger number of identified sentinel cases in the NEAIS, elderly females were more likely to be abused than elderly males. This was the case for every type of use reported to APS except for abandonment, in which males were more likely to be victimized. Finally, several researchers point out that much elder abuse is committed by adult children who are dependent on the elders. These researchers find that in comparison to nonvictimized elders, elders who are abused are more likely to have their adult children dependent upon them in several areas, including housing, household repair, financial assistance, transportation, and cooking and cleaning.

## LEGAL ISSUES

By 1991, all states had elder abuse statutes in their laws and/or had amended their existing laws to bring elders under APS protection. Currently, every state has an intervention agency, usually APS, that handles cases of elder abuse. However, there is little to no uniformity in the laws for, definitions of, or provisions for elder abuse across states. For instance, 46 states have mandatory reporting laws, such that professionals who care for elders must report

suspected cases of abuse. Failure to do so can usually make the reporter guilty of some kind of misdemeanor. The other four states (Colorado, New York, Wisconsin, and Illinois) have voluntary reporting. Of those states with mandatory reporting, 15 require mandatory reporting not only from professionals, but also from *anyone* who suspects elder abuse. Furthermore, in many cases of elder abuse, domestic violence laws (for cases of spousal elder abuse) or guardianship laws (for cases in which a frail elder needs to be removed from an abusive home) are applicable. Despite the existence of mandatory reporting laws, many professionals do not report all the cases in which they suspect elder maltreatment. Physicians appear to be particularly unlikely to report all of the cases of elder mistreatment that they see.

## PREVENTION

More attention has been given to intervention in cases of elder maltreatment (although even in this area resources are inadequate) than has been given to prevention of the problem. When cases of elder abuse are reported to APS, agency workers are responsible for assessing the referred client's level of risk, taking immediate action to protect the client's safety and property, collecting evidence to substantiate abuse, assessing the need for services, providing crisis intervention, arranging for needed services, and serving as client advocates—all forms of intervention that follow an incident of potential maltreatment.

The few available prevention programs generally focus on preventing financial exploitation by family members or others. One of the better known programs is the Fiduciary Abuse Specialist Team (FAST), which originated in Los Angeles. FAST is a multiagency task force established to stop elder financial abuse before it is accomplished. Typical members of FAST include police, public guardians, APS personnel, and probate court representatives. Although other efforts to prevent elder abuse are limited, there has been some effort to develop family-life curricula to help prevent elder abuse in stressed multigenerational families. One curriculum has components on teaching older individuals and their relatives how to cope with common sources of stress and conflict, how to communicate effectively with each other, and how to use family and community resources. There are also recommendations for engaging and empowering elders in an integrative response

to elder abuse—for example, through involving them directly in developing programs, detecting abuse, processing cases, assisting victims, and evaluating programs. Finally, concerned advocates from the American Psychological Association have argued that, to deal effectively with elder maltreatment, it is essential to educate the public more fully about the problem, increase the availability of respite care, increase the supports available for families caring for elders, and encourage counseling and treatment for problems that contribute to elder abuse.

## ELDER NEGLECT

---

Current estimates suggest that 1 million to 2 million American's older than age 65 have been abused, neglected, or exploited by someone with whom they have placed their trust. Although standards may vary across cultures regarding the level of respect, attention, and support provided to the elderly, all cultures recognize the increased vulnerability that occurs with aging. Elder neglect occurs when the increased needs of the elderly are unmet by a designated caretaker. The specific legal definition of "elder neglect" varies from state to state (Table 1). However, all generally define it as the failure of an individual to provide the basic necessities needed for mental and physical health. This includes a failure to provide adequate food, water, clean clothing, medical care, or a safe living environment. Neglect can occur by family members with

legal responsibilities to the elder, or by agencies providing caretaker services to the elder (e.g., in-home nursing, residential retirement centers).

## ELDER NEGLECT

The American Medical Association (1996) defined neglect as the failure to provide goods and services necessary for functioning or to avoid harm. These goods and services include personal care, medications and appropriate medical attention, adequate nutrition, and a safe environment. Neglect has been further defined according to the intent of the abuser. Passive elder neglect often occurs from an omission or failure to act and is often considered unintentional, due to a lack of information or resources. In contrast, active neglect is considered to be an intentional, malicious withholding of adequate goods and services. While the medical definition may distinguish between passive and active neglect, it is important to note that, in most jurisdictions, the legal consequences are the same for neglect by act or omission.

Elder neglect occurs between a vulnerable elder and an individual or organization in a caregiving relationship. The relationship can be through kinship, such as an adult child caretaker, or contractual, such as an employed caretaker. State law determines the age at which neglect of an adult is considered “elder neglect,” usually at age 60 to 65. Conceptually, elder neglect cannot occur if the elder has the capacity for self-care and self-protection. In some states, the legal definition of capacity is the benchmark. Another important distinction is that of self-neglect; the failure of the elder to meet their own basic needs or protect themselves. Self-neglect often occurs in the presence of some form of dementia. The differentiation between self-neglect and neglect concerns whether or not a caretaking relationship has been established. While several federally funded agencies research and provide services to victims of elder abuse and neglect, the legal definition of elder neglect varies and is provided by state law.

## RISK FACTORS

A common misconception is that adult children are more often the perpetrators of elder abuse. In fact, spouses are more likely to commit elder abuse than adult children. This phenomenon has been referred to as “domestic violence grown old,” given that the

**Table 1** Sample of State Law Elder Neglect Definitions by Statute

<i>State</i>	<i>Statutory Definition</i>
California	§ 15610.30 “ <b>Neglect</b> ” includes negligent failure of any person having the care or custody of elder of a dependent adult to exercise that degree of care that a reasonable person in a like position would exercise.
Georgia	§ 30-5-3 “ <b>Neglect</b> ” means the absence or omission of essential services to the degree that it harms or threatens with harm the physical or emotional health of a disabled adult or elder person.
Texas	§ 48.002 “ <b>Neglect</b> ” means the failure to provide for one’s self the goods or services, including medical services, which are necessary to avoid physical or emotional harm or pain or the failure of a caretaker to provide such goods or services.

abuse often begins earlier in life, as domestic abuse, and continues into old age. Several abuser characteristics have also been identified. Studies have found that caretakers with mental illnesses, in particular depression, are more likely to commit elder abuse. Elder abusers also tend to score higher on measures of hostility and also tend to be financially dependent on the victim of elder abuse. While alcohol abuse is very common among elder abusers in general, those who commit elder neglect have not been found to have an increased rate of alcohol abuse.

There are several well-established risk factors for elder abuse in general. Elders with cognitive impairments, such as dementia, have an increased risk for abuse. Shared living arrangements are also an established risk factor, with elders living alone having the lowest risk for abuse. While living alone tends to decrease the risk for elder abuse, strong social networks and ties to the community also decrease the risk of elder abuse.

Adult Protective Services (APS) reports that the majority of elder abuse victims are women. However, given that there are more female elders in the population, it is difficult to determine if gender is a true risk factor. Several studies have actually found more male elders abused than females.

## CONSEQUENCES

There has been little research investigating the consequences of elder neglect. Often, research reports will assess the consequences of elder mistreatment as a whole, rather than differentiating between the effects of abuse and neglect. Additionally, investigating the consequences of elder abuse in general is difficult given the natural decline in health and increase in disease seen during old age. An increased mortality rate is seen in those reported to adult protective services as possible abuse cases. However, this increased mortality rate is not seen until several years postreport. In 2000, the Elder Justice Roundtable Report described our current medical knowledge of the consequences of elder neglect as approximately three decades behind our knowledge of child neglect. It has been suggested that this may be the result of the current medical forensics system in place. If a child dies of unknown causes, the death is investigated fully. However, an unexplained death in the elderly is rarely put to the same scrutiny.

Medical consequences of elder neglect can manifest in many different ways. Multiple decubiti (“bedsores”) are commonly seen in cases of neglect. Decubiti occur from prolonged pressure to certain areas on the body, most commonly from staying in the same position for longer than 2 hours. Malnutrition and dehydration is seen in cases where food and water are withheld. Loss of limb or severe infections can occur when there is a neglect to change bandages or care for wounds. Additionally, a variety of illnesses, and even death, can occur when medications are withheld or given infrequently (e.g., insulin for diabetics). In addition to a marker for physical abuse, burns are also an indicator of potential neglect. A 1998 study at the Fort Sam Houston Burn Unit found that 36% of burn patients over the age of 60 were victims of neglect.

As for psychological consequences, increased rates of depression have been documented in victims of elder neglect, as well as all other forms of elder abuse. Increased rates of alcohol abuse are also seen in neglected elders. Additionally, dementia and psychosis have been shown to be related to elder neglect. However, this is theorized to be more a risk factor for neglect rather than a consequence.

## INTERVENTION

The first step to intervention is the identification of those elders being abused or neglected. The reporting of suspected elder abuse is required by law for many

professions. Several states have mandatory reporting laws for any individual, regardless of profession, if elder abuse is suspected. Suspected cases of elder abuse should be reported to your local APS agencies. However, it is important to note that some states require that suspected abuse be filed at both APS and local law enforcement agencies.

Intervention can occur from one or several different agencies, such as APS, criminal justice, and the health care system. APS investigates reports of elder abuse and neglect and determines what actions are necessary. Most states require an in-person assessment within 24 hours of a report being made. If abuse or neglect is determined to have occurred, APS is responsible for developing a service plan aimed at removing the threat from the elder and ensuring his or her continued safety. Law enforcement officers may be the first to respond to an initial report of abuse and will notify APS if they believe abuse or neglect has occurred. In addition, criminal action may be taken against the abusive caretaker.

Elder neglect continuing over an extended period of time often results in emergency room visits, the most common point of intervention for the health care system. The difficulty lies in differentiating between elders whose health is failing due to old age and those who are victims of neglect. Specialty health fields, such as forensic nursing, have emerged in response to this need. In sum, it is important to note that the elderly provide important contributions to both the family and community and that aging can occur with both dignity and pride if caretakers are responsive to the increased needs required in old age.

## ELDERHOSTEL PROGRAMS

---

Elderhostel was founded in 1975 by Martin Knowles, social activist and educator, and David Bianco, director of residential life at the University of New Hampshire. Knowles had stayed in youth hostels during several years of archaeological expeditions across Europe. He and Bianco discussed the meaningful involvement of Scandinavian elders that Knowles had seen at Scandinavian folk schools. Combining these ideas to challenge prevailing theories of disengagement and social withdrawal in retirement, Knowles and Bianco proposed an “elder hostel” for Americans aged 60 and older. Participants would be housed in unused campus dormitories during the summer while they engaged in 1 week of low-cost classes, field trips, shared meals, and social activities. Noncredit college-level courses in liberal arts and local history would be offered in a nonthreatening atmosphere, with no exams, papers, grades, or previous educational requirements.

Elderhostel’s immediate success and rapid growth validated its founding premise that retirees wanted to be productive and creative and that they would welcome affordable opportunities to develop new interests through intellectual and social pursuits. Programs began in 1975 with 220 participants at five New Hampshire universities and colleges. One year later, word-of-mouth brought 2,000 participants to Elderhostel programs at 21 universities in six New England states. In 1980, more than 20,000 people attended programs in all 50 states and Canada. By 1990, Elderhostel was the world’s largest education and travel organization for older adults, enrolling more than a quarter-million people in hundreds of programs throughout North America and in 80 countries worldwide.

In 1977 to 1978, Elderhostel incorporated as a nonprofit organization, centralized its program registration and administration in Boston, and hired its first president, Bill Berkeley. Seasonal catalogs were

published to meet the increased demand for programs. Elderhostel had been subsidized by corporate and foundation funding and individual donors, but it became fully self-supporting in 1984, less than 10 years after its modest beginning.

Elderhostel, Inc., now operates as a franchise of colleges, universities, parks, museums, and other not-for-profit host institutions that design and conduct programs under its trademark. Elderhostelers age 55 and older stay in hotels, motels, lodges, conference and retreat centers, even on board ships and trains, as they attend programs that range from 1 day to 3 or more weeks in length. Hostellers use their own resources to travel to any of the many individual program sites in the United States, but when the program begins, their Elderhostel tuition covers all lodging, meals, classes, field trips, and related travel until the program ends. Tuition for programs overseas includes round-trip international airfare from a gateway city.

Elderhostel’s mission—to provide high quality, affordable, all-inclusive educational opportunities for older adults—encourages innovative approaches to lifelong learning and, while maintaining a basic set of program standards, gives autonomy of design to providers, who then create a variety in programs that reflects the unique history and culture of their local settings. An extensive array of subjects includes liberal arts, ethnic and cultural studies, visual and performing arts, music and dance, and leisure and practical courses. Elderhostel programs offer thousands of topics each year. For example, hostellers might analyze and read poetry, begin a new language, learn the origins and traditions of southwest civilizations, discuss Jewish thinkers, study religious traditions, or research the scientific discoveries made by Lewis and Clark. They might explore Civil War battlefields, learn new dances, investigate politics and policies, or delve into the mysteries of the solar system. Field trips in Elderhostel programs include visits to places such as historic homes, museums, art galleries, plantations, festivals, theaters, city centers, gardens, lighthouses, presidential libraries, national or state parks, mountains, harbors, or barrier islands.

Continuing surveys of older learners’ interests and motives have spawned new formats as well. These include intergenerational programs, where hostellers share learning adventures with their grandchildren; active programs for outdoor experiences like mountain climbing, bicycling, kayaking, hiking, and birding; and service programs, which combine learning with volunteering for worthy causes worldwide.

A group of Elderhostelers at Virginia Commonwealth University's program at Natural Bridge

To accommodate increasing numbers of retirees who seek the type of lifelong learning that maintains mental fitness, Elderhostel joined with a number of established Institutes for Learning in Retirement (ILR) in 1988 to form the Elderhostel Institute Network, a voluntary association that exists to facilitate the development of new ILRs and provide resources for established ILRs. Acting as a coordinating center for the Institute programs that already existed, Elderhostel also assisted the development of more than 200 new ILRs over the next 10 years.

Now known as LLIs, Lifelong Learning Institutes are campus- and community-based programs that provide noncredit academic courses and related activities for retired adults. In general, LLIs operate like college programs, but each institute's members determine classes, semester schedules, and organizational governance. The Elderhostel Institute Network continues to provide resources to more than 500 college- and university-affiliated institutes and to facilitate the development of new LLIs across North America.

## ELECTRA AND OEDIPAL COMPLEXES

During the third major developmental stage described by Freud, called the phallic stage, the child's psychic energy is invested in the genital organs and the pleasure that is received through organ manipulation. It is also during this period that some of the most profound psychological changes in the child's personality development take place.

As children develop a fairly sound identity of themselves as individuals, they are faced with increasingly sharpened conflicts with parents. The child develops feelings that grow in magnitude to form a complex of interrelated emotions and behaviors termed the Oedipus complex for males and the Electra complex for females. The ultimate importance of this stage is in the resolution or working through of these conflicts and the subsequent development of appropriate gender role identification. Freud believes that the entire dynamic process of child-parent interaction and the resolution of Oedipal and Electra conflicts provides the framework for the basic construction of the superego.

**Table 1** Psychoanalytical Perspective of the Formation of Gender Identity

	<i>Gender</i>	
	<i>Males</i>	<i>Females</i>
Name of conflict	Oedipal complex	Electra complex
Associated anxiety	Castration anxiety	Penis envy
Developmental mechanism for resolution of the conflict	An unconscious fear develops in the male child because of his unacknowledged and unrecognized feelings for the mother. Upon recognition that such feelings are not acceptable, male behavior patterns (such as those displayed by the father) become the acceptable way to vicariously interact with and “possess” the mother.	An unconscious fear develops in the female child because of her unacknowledged and unrecognized feelings for the father. Upon recognition that such feelings are not acceptable, female behavior patterns (such as those displayed by the mother) become the acceptable way to vicariously interact with and “possess” the father.
Result of resolution	Male gender role	Female gender role

The Oedipus complex takes its name and meaning from the Greek tragedy *Oedipus Rex* in which Oedipus kills his father and marries a woman who is, unknown to him, his biological mother. On learning of this transgression, he punishes himself by gouging his eyes out. Freud believes that the desire to possess the mother sexually is characteristic of all males during the phallic stage of development. Parallel to the biological changes that take place during this stage, the male seeks the primary and original love object, the mother, and begins to see the father as a competitive force for the love and affection that only the mother can give. The male child's feelings of inferiority are compounded by the results of a comparison between his and his father's genitalia.

Although the wish to possess the mother physically and psychologically is unrealistic in terms of societal taboos, the male child pursues these irrational desires and eventually is forced to confront his father over who will be the primary recipient of the mother's attention. During this subtle yet profound confrontation, the male child eventually recognizes his father's outrage at his motives and becomes fearful that the father will punish him (through castration) for his incestuous behavior. This fear takes the form of what Freud called the castration complex and specifically results in castration anxiety for the boy. In other words, he fears his father will castrate his sex organs,

which are now the focal point of his maturational and psychological growth.

This fear (which remains at the unconscious level) is so strong that the male child eventually abandons these obviously intolerable thoughts about his mother and realizes that the necessary gratification can be obtained only through identification with the father and through the vicarious satisfaction obtained through father-son interaction via mother-father interaction. It is primarily through this process that (1) the beginnings of the super-ego come into being, because the resolution of the Oedipus complex represents a recognition of societal and tribal mores and values, and (2) the child identifies with his father, leading to successful procreation on the child's part and, indirectly, fulfillment of a very general instinct. The Oedipal conflict is thus resolved.

Freud described a comparable Electra conflict for females but did not elaborate. Many Freudians believe that the process is much more complex for girls than the Oedipal situation for boys. For girls, initially, the young female child does not realize there are any distinct differences between the sexes. Through experience (physical and social/emotional contact with both parents), she realizes she does not possess the same organs the male does. A sense of inferiority over this results in what Freud called *penis envy*. Penis envy amplifies and intensifies her love for and attachment to her father, and there is a corresponding rejection of

her mother. The girl is assumed to unconsciously hold her mother responsible for her lack of a male sexual organ. The dynamics of how gender identity is thought to be formed within the psychoanalytic perspective is shown in Table 1.

However, the girl is thought to realize eventually that the incorporation of a penis is physically impossible and that direct gratification of her desire for one must be channeled into identification with the mother. Freud was much less explicit in detailing the process of the resolution of the Electra conflict than in specifying the course of the resolution of the Oedipal conflict.

The distinction Freud made between the experiences for males and females during the phallic stage of development is often cited as a chauvinistic view. Whereas the male is concerned with the expression of his sexual desires through the manipulation of his genitals, the female is described as being preoccupied with the inferiority of hers. Although both sexes come through the conflict with the same eventual developmental outcome (development of the superego and a gender role), the characterizations of the male and the female through the process have very different connotations.

—Neil J. Salkind

electrodes positioned on the scalp. It has many applications for clinical practice and both basic and applied research. The science of recording, analyzing, and interpreting EEG is part of a larger science called *psychophysiology*, which has its roots in both medicine and psychology. EEG is an important tool in cognitive neuroscience, the field of study that seeks to link human cognition and behavior with specific brain structures and processes. EEG has been used in the diagnosis of epilepsy and other neurological disorders and can also be used as a marker for the presence of numerous developmental abnormalities including, but not limited to, sensory and motor disorders. More recently, EEG has been used to study a variety of biologically based psychological disorders including depression, anxiety, and attention-deficit hyperactivity disorder (ADHD). EEG has also been used experimentally to learn about the cortical mechanisms involved in arousal, vigilance, mood regulation, and even higher cognitive functions such as language and mathematics. With the recent inventions of the related technologies of event-related potentials (ERPs), high-density electrode arrays, and computer-assisted topographic analysis (brain mapping), EEG promises to be a major tool in the neurosciences for years to come.

The biological source of an EEG recording is the postsynaptic membrane potentials of millions of pyramidal neurons that help to compose the human brain, or neocortex. The cells are organized into functional groups called microcolumns, which act as one unit when processing information. Because groups of neurons fire together, their tiny voltages summate and produce enough electrical activity to pass through the resistive mediums of brain tissue, skull, and scalp. Pyramidal cells, named for their triangular shape, are aligned so that their bodies are perpendicular to the surface of the scalp. This orientation means that for cells on the gyri (bumps) and some in the sulci (valleys) of the cortical surface their electrical fields project out to the scalp where they can be recorded.

The basic science underlying the EEG is that whenever an electrical current is passed through a circuit, its amplitude (measured on the y-axis of a graph) can be measured continuously at any point in time (measured in the x-axis) by a device generally known as a galvanometer. Early recordings were made with a few metallic electrodes that were filled with conductive paste and attached to the scalp, with the resultant deviations in voltage plotted with an attached ink pen

---

## **ELECTROENCEPHALOGRAM (EEG)**

---

Electroencephalogram (EEG) is a recording of the continuous electrical activity of the brain made by

on a continuously scrolling drum or sheet of paper. Modern EEG recording is accomplished with multiple electrodes (as many as 256 at once), often positioned with the aid of an elastic cap, and the data are collected and analyzed entirely by microcomputer.

Hans Berger invented the method of human EEG in the 1920s, based upon previous work in animals by Richard Caton in the 1870s. These individuals demonstrated that the brain, like any living system, generates electrical potentials with regular patterns. The dominant patterns are labeled according to frequency and are called delta (.5–4 Hertz [Hz]), theta (4–7 Hz), alpha (8–13 Hz), and beta (13–30 Hz). Berger showed that these patterns are sensitive to both external cues and the internal states of the individual, such as level of arousal. For instance, alpha is present in conditions of relaxed wakefulness and can be suppressed by concentration on a difficult cognitive task. Delta and theta are hallmarks for the deeper stages of sleep, and abnormalities in the frequencies have been demonstrated in children with attention problems, depressed patients, and a variety of other disorders.

The embryo takes nourishment and oxygen and releases waste products through the umbilical cord, which links it with the placenta. The umbilical cord contains three blood vessels through which the embryo's blood circulates to and from the placenta.

The placenta is a disk-shaped mass of tissue 6 to 8 inches (15 to 20 cm) long and 1 inch (2.5 cm) thick and weighs about 1 pound. Implanted in the inner wall of the uterus, it serves as a two-way filter between the bloodstream of the mother and the embryo. It makes it possible for the mother to carry on life functions such as digestion, excretion, circulation, and respiration for the embryo. Into the placenta, by way of two arteries in the umbilical cord, the embryo deposits waste material such as carbon dioxide.

The mass of blood vessels on the mother's side of the placenta then absorbs the wastes into her bloodstream. The embryo receives, through the vein in the umbilical cord, fresh nutrients (oxygen, amino acids, sugar, fats, and minerals) from the mother's bloodstream and hormones, antibodies, and other necessary substances by the same route.

The placenta is a highly permeable membrane that acts as a natural screen to keep out many—but unfortunately, not all—harmful substances. Thus, the unborn child receives only materials with molecules that are small enough to pass through the screen. At the same time as the embryo is taking shape, the amniotic sac is developing into a protective chamber. By the end of the 8th week, this sac completely surrounds the embryo. The watery fluid inside keeps the embryo from being jostled by any sudden movements of the mother or by accidents that may happen to her, such as a fall or a blow. The amniotic sac also keeps the embryo at a constant temperature.

During the embryonic period, three layers of cells are differentiated. The outer layer, or ectoderm, develops into sensory cells, skin, and the nervous system. The middle layer, or mesoderm, becomes the excretory system, muscles, and blood. The inner layer, the endoderm, forms the digestive system, lungs, and thyroid gland.

By the end of the 3rd week of development, the embryo's heart is beating and its nervous system is forming rapidly. After the 4th week, the legs are curled and the eyes have appeared as dark circles. During the 5th and 6th weeks, arms and legs can be seen. After 8 weeks, all of the major body organs are present. The liver is making blood cells, and the kidneys are removing waste products. The mouth, nose, eyes, and head

## EMBRYO

---

During the 46-day embryo stage, the embryo grows to a length of more than 1 inch (2.5 cm). By the end of the embryo stage, many body systems will be in operation and the embryo will begin to appear humanlike.

are clear and distinct. The head is roughly half the total body size at this time. Fingers and toes are blunt, and ribs show under the skin.

The 8-week time span of embryonic development is a particularly vulnerable period in human growth. The embryo can very easily be affected by chemicals, drugs, hormones, or viruses present in the mother's system.

## EMERGING ADULTHOOD

---

When does adolescence end? When does adulthood begin? Traditionally adulthood began when education, whether secondary or higher, was complete; the person would begin a career and settle down, starting a family. In recent decades, the transition to adulthood has lengthened as more people have entered college and graduate school and delayed making major life choices in the areas of career, marriage, and parenthood until their mid- to late twenties. The late teens through the mid-twenties has become a period in which people explore and experience changes in love, work, and worldviews and, ultimately, lay the foundation for their adult lives. Recently, developmental psychologist Jeffrey Arnett has described a new phase in development between adolescence and adulthood called *emerging adulthood*.

### WHAT IS EMERGING ADULTHOOD?

Emerging adulthood begins with the end of secondary school and ends with the attainment of full adult status—usually running the years from 18 to 25, though for many people it may last through the late twenties. Demographic changes have made the late teens and early twenties not simply a brief transitional period between adolescence and adulthood but a qualitatively different period of human development. Emerging adulthood is characterized by change and

exploration of possible life directions, jobs, residences, partners, and worldviews. It is not a universal period of development but exists under certain conditions that have occurred only recently in some cultures.

### SOCIAL CHANGES LEADING TO EMERGING ADULTHOOD

Over the past half-century, demographic shifts have taken place that have changed the nature of adolescence and early adulthood. People are getting married later than ever before. In 1970, the median age of marriage in the United States was 21 for women and 23 for men; by 2002, it was 25 for women and 27 for men. Age of first childbirth follows a similar pattern. The advent of the birth control pill in the 1960s and more widespread acceptance of premarital sexuality and cohabitation before marriage also have influenced the rising ages of marriage and parenthood. Additionally, the number of young people who enter college after high school has risen from 14% in the 1940s to 64% in 2003.

These changes have occurred in most industrialized countries, altering the nature of development during the late teens and early twenties in these societies and making emerging adulthood possible. For most individuals in industrialized societies, the late teens and early twenties are no longer a time of entering and settling into long-term adult roles, but a time of exploration and frequent change.

### FEATURES OF EMERGING ADULTHOOD

Several features make emerging adulthood distinct from other periods in life. Emerging adulthood is a distinct time of demographic variability and identity exploration and is experienced as different from both adolescence and adulthood.

### Demographic Variability

Demographic norms are clear for adolescents and young adults. More than 95% of American adolescents from ages 12 to 17 live at home with one or more parents, more than 98% are unmarried, more than 90% have never had a child, and more than 95% are enrolled in school. By age 30, about 75% of people have married and become parents and fewer than 10% are in school. The time between 17 and 30, however, is a time without demographic norms. Some emerging adults enter college, often attending with stops and

starts, taking more than the traditional 4 years to graduate. Other emerging adults enter the world of work. Most leave home by 18 or 19. Some live in college dorms, others in apartments with friends, others in apartments alone, some cohabitate, some marry, and others live with one or more parents. Variability characterizes emerging adulthood. It is the only period in life in which nothing is normative demographically.

## Identity Exploration

The independence from parents, social roles, and adult responsibilities permits emerging adults freedom to explore possibilities in love, work, and worldviews. The process of identity development may begin in adolescence, but identity achievement is rarely reached by the end of high school. Most identity development takes place during emerging adulthood. It is a process of trying on possibilities and exploring alternatives in order to ultimately make enduring decisions.

Emerging adults often seek life experience for its own sake; sensation-seeking behaviors, in which emerging adults seek out new and intense experiences, increase. For example, many emerging adults experiment with a variety of romantic and sexual experiences. Several forms of risky activities peak in emerging adulthood: unprotected sex, most types of substance use, and risky driving. Each of these risky activities can be understood as part of identity explorations; emerging adults seek a wider range of experiences before making choices and settling down into the roles and responsibilities of adult life.

One important focus of identity development is in the area of love. Romantic relationships are more intimate and serious during emerging adulthood. Instead of group dating, popular among adolescents, dating becomes one on one. Relationships tend to last longer, include sex, and often include cohabitation. Similarly, during emerging adulthood, work experiences tend to become more focused on preparation for careers and adult workroles. Emerging adults try on jobs and career contexts to test their fit. It is not uncommon for college students to change majors multiple times, sampling educational paths that would prepare them for various career possibilities. More people are pursuing graduate school—especially as a way of changing career paths after college.

Worldview, another area in which we undergo identity development, also develops and changes during emerging adulthood. During these volitional

years, people are open to different perspectives and modify their worldview as they grow, change, and learn about the world. By the end of the college years, most emerging adults have established a worldview that is more complex than the one they held when they graduated high school. By the mid- to late twenties, most people have committed themselves to enduring identities in the areas of love, work, and worldview.

## Feeling In-Between

Emerging adults are aware of making the transition to adulthood and of the challenges of measuring up to adult roles and responsibilities. When asked whether they have reached adulthood, the majority of people in their late teens and early twenties will reply, “in some respects, yes, in some respects, no,” reflecting their feeling that they are neither adolescents nor adults, but somewhere in-between.

What does it mean to become an adult? The top criteria for adulthood, as rated by emerging adults, are accepting responsibility for one’s self, making independent decisions, and financial independence. Each of these criteria emphasizes self-sufficiency. During emerging adulthood, people learn to take responsibility and develop these qualities of character as well as develop the skills and acquire the education and experience to become financially independent. Only after these tasks have been completed do they move into young adulthood; typically this is during the mid- to late twenties. In young adulthood, people are self-sufficient and show more stability in work, family, and personal relationships.

## CONTEXT AND EMERGING ADULTHOOD

Emerging adulthood is not a universal stage of development, but a period that exists in contexts that permit it: those that postpone the entry into adult roles and responsibilities until the twenties. Therefore, emerging adulthood generally is found in highly industrialized and postindustrial countries. Not all individuals within a country, however, experience emerging adulthood. Educational and occupational opportunities influence the extent to which the late teens and twenties can be experienced as an experimental and volitional period. Young people from working class and below may have fewer opportunities for the explorations of emerging adulthood than do those with families of higher socioeconomic status. Emerging adulthood is

contextually constructed; it occurs in contexts that permit a gradual entry to adulthood.

## SUMMARY

Emerging adulthood is a newly defined period in human development ranging from the late teens through the mid- to late twenties and is characterized by variability in demographics, a quest for identity development, and a subjective sense of feeling in-between adolescence and adulthood. Emerging adults explore and experience changes in love, work, and worldviews, and, ultimately, lay the foundation for their adult lives.

## EMOTIONAL DEVELOPMENT

---

Emotional development comprises the emergence of the experience, expression, understanding, and regulation of emotions from birth and the growth and change in these capacities throughout childhood, adolescence, and adulthood. The development of emotions occurs in transaction with neural, cognitive, and behavioral development and emerges within a particular social and cultural context.

## EMOTIONAL DEVELOPMENT IN INFANCY

The expression of emotions during infancy promotes the transition from complete dependency toward autonomy. The expression of interest promotes exploration and cognitive development. Social smiles and other expressions of joy promote social interaction and healthy attachment relationships with primary caregivers. The expression of sadness encourages empathy and helping behavior, and the expression of anger signals protest and discomfort. The infant's unique tendency to experience and express particular emotions and the threshold for expressing these emotions is usually referred to as their temperament or characteristic emotionality. An infant's temperament/emotionality emerges at birth as the infant's genes interact and transact with the environment, particularly through early experiences with caregivers.

Currently, researchers generally agree that the neonatal smile is present at birth and that the social smile and the emotion expression of interest appear as early as 6 weeks of age. By 4 to 5 months of age, infants selectively smile at familiar faces and infants and their caregivers begin to share positive emotional exchanges.

Researchers disagree in their explanations of the development and time of emergence of discrete negative emotion expressions. One group has produced evidence of such expressions within the first 4 to 9 months, whereas others have failed to find discrete negative emotion expressions in the first year of life. Apparently consistent with the view that infants express negative emotions in early infancy, scientists have shown that infants perceive and respond differentially to the negative emotion expressions (e.g., sadness, anger) of others by the age of 4 months.

During the second 6 months of life, as infants gain rudimentary cognitive and memory capacities, they begin to express particular emotions based on context. Emotions begin to emerge dynamically as the infant begins to take more of a directive role in the emotional exchanges with caregivers. The attachment bond with the caregiver is increasingly important as infants engage in social referencing to seek support for exploration and look for signals of danger.

## EMOTIONAL DEVELOPMENT DURING TODDLERHOOD AND EARLY CHILDHOOD

During the toddler period, in conjunction with rapid maturation of the frontal lobes and the limbic circuit in

the brain, recognition of the self emerges. As a result, the toddler strives to become more independent and the expression of anger and defiance increases in this struggle for autonomy. The ability to differentiate the self from others also promotes basic empathic behavior and moral understanding. By the end of the second year of life, toddlers respond to negative signals from others and they have specific emotional responses to their own negative actions. The emotions that emerge with a rudimentary conception of the self are often called self-conscious emotions and include shame, embarrassment, guilt, and pride. Some self-conscious emotions, such as pride and guilt, do not emerge until toddlers and young children learn to conceptualize internalized standards for behavior.

As children enter preschool, they begin to label their own emotions and rely on discourse about emotions within the family to facilitate their understanding of basic emotions. Young children first distinguish happiness from negative emotions and then begin to distinguish negative emotions such as sadness, anger, and fear from each other. They begin to recognize these emotions in facial expressions then, as they enter middle childhood, begin to understand situational determinants of emotions. An understanding of emotional subjectivity also develops as children learn that what makes one child happy may not make another child feel the same way.

The emergence of emotional self-regulation is particularly important during early childhood and occurs in the context of family and peer relationships. Open expression of positive emotions and warm, supportive relationships between parent and child promote effective emotional self-regulation. On the other hand, frequent expression of negative emotions in the family and harsh, punitive discipline responses increase the experience of distressing and dysregulated emotions that may lead to psychopathology. Appropriate peer relationships characterized by shared play activities are also important for the development of emotion regulation during early childhood. Children gain emotion understanding and the capacity for empathic and helping behavior from well-regulated emotional exchanges with peers.

### **EMOTIONAL DEVELOPMENT DURING MIDDLE AND LATE CHILDHOOD**

During middle and late childhood, stable self-concepts emerge based on the child's typical emotion

experiences. With the increased capacity for self-reflection, children gain an understanding of their self-conscious emotions. As a result, the consistent experience of patterns of self-conscious emotions has an impact on the child's self-concept. For example, the tendency to experience shame rather than guilt in response to negative transgressions affects the child's emergent self-esteem and tendency to respond with aggression or violence.

Also during middle and late childhood, children begin to understand that a single situation or event can lead to the experience of multiple, mixed emotions. For example, older children understand that a goodbye party for a sibling who will leave for college is likely to be both a happy and a sad event for the child and his sibling. This capacity likely emerges with the cognitive capacity to understand multiple aspects of a situation, called decentration.

Children also learn emotional display rules as they progress through middle and late childhood. For example, a child learns to look happy even though she feels upset when a friend or family member gives her an undesirable gift. The use of display rules tends to increase as children begin to consider what consequences their actions may have for others. Display rules are used judiciously, and the likelihood of suppressing negative emotion depends on a number of factors including the child's gender, the likely recipients of the expression, the specific context, and the child's cultural milieu.

### **EMOTIONAL DEVELOPMENT DURING ADOLESCENCE**

With adolescence comes an additional struggle for autonomy and increased time spent with peers and less time spent with the family. Adolescents become less emotionally dependent on their parents, but this emotional autonomy often emerges after a period of conflict and increased experience of negative emotions. Young adolescents often experience more negative affect than younger children, but the negative affect often decreases during the high school years. However, girls often experience a longer period of elevated negative affect than boys. Adolescents tend to experience more extreme emotions, both negative and positive, than their parents even in response to the same event.

The rise in negative emotion experiences during early adolescence emerges in conjunction with the capacity for abstract thinking. Adolescents often experience emotional distress in response to ambiguous and imagined romantic exchanges, and their capacity to

experience complex and diverse emotions further promotes the development of abstract thinking. As adolescents grapple with increasingly abstract and complex social problems, they often seek a stable peer group as the context for emotion management. Positive peer relationships emerge from the recognition of equality and the tendency to offer emotional support. Adolescents that are not accepted by their peers face numerous risks including school dropout and participation in delinquent activities. Even adolescents who are accepted by peers and have close friends often show an increase in negative emotions such as anger and anxiety in the peer context during adolescence. Overall, positive and supportive peer relations during adolescence promote healthy emotional development and mental health as the adolescent enters adulthood.

Dating relationships also become prominent during adolescence, but young adolescents may still have difficulty understanding that one person can evoke different and conflicting emotional responses. Therefore, dating during adolescence is often characterized by intense emotional lability. Dating partners are also prone to experience jealousy, particularly when they make errors in determining the intent of their partner's actions.

Identity development is important for adolescents as they approach adulthood. When the adolescent or young adult is exploring many identity options, they often have high levels of anxiety but show interest in exploring these options. Adolescents who make an early commitment to a particular identity, usually an identity promoted by their family, have low levels of anxiety and do not experience much conflict in their family relationships. Adolescents who are not exploring identity options tend to have low levels of motivation and often appear bored or apathetic. They have poorer peer relationships and are at greatest risk for mental health problems during adulthood. Finally, young adults who have achieved a stable sense of identity tend to be more empathic and are more successful at managing their emotions.

## EMOTIONAL INTELLIGENCE

---

Emotional intelligence is a relatively new concept within the psychological community and was introduced to the general public by Daniel Goleman's 1995 popular publication, *Emotional Intelligence: Why It Can Matter More Than IQ*. Emotional intelligence, also known as EQ or EI, is characterized as the psychological faculties used to identify, understand, and apply personal and interpersonal feelings. In other words, EQ refers to the ability to understand and manage feelings. Individuals' emotional intelligence facilitates and guides their comprehension and control of appropriate emotional responses across various life situations. It is suggested that high EQ individuals are skilled in identifying and dealing with emotions—both their own and other people's. Ultimately, it is suggested that the possession of emotional intelligence permits the successful use and management of social and communicative skills. Thus, EQ provides the answer to the question: "How could someone so smart be so bad with people?" The deficit lies not with lay person's concept of common sense but rather, technically, with emotional intelligence.

### HISTORY OF EMOTIONAL INTELLIGENCE

The first formal definition of emotional intelligence was formulated by the academic duo, Peter Salovey, PhD, of Yale and John Mayer, PhD, from the University of New Hampshire, as they deliberated about the intermingling of emotion and intelligence: "We define emotional intelligence as the subset of

social intelligence that involves the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions" (1990, pp. 185–211). Their work pioneered and led to the general consensus that there are four basic abilities comprising emotional intelligence. These are the ability to

1. perceive or sense emotions;
2. use emotion to assist thought;
3. understand emotions; and
4. manage emotions.

Incorporating these elements into their definition, EQ experts Bar-On and Parker (2000) more recently defined emotional intelligence as "*a multifactorial array of interrelated emotional, personal and social abilities that influence our overall ability to actively and effectively cope with demands and pressures.*"

## DEVELOPMENT OF EMOTIONAL INTELLIGENCE

The etiology of EQ, how it is developed, has yet to be empirically determined. The only definitive conclusion made at this time is that parents who have high EQ also have children with high EQ. Either socialization/parenting practices and/or genetic factors may account for this finding. It is also unknown whether gains found in children in the area of EQ are actually attributable to any specific interventions or training, for example, education in recognizing and understanding emotions, or whether such gains are part of naturally occurring cognitive and social advances as children develop.

## MEASUREMENT OF EMOTIONAL INTELLIGENCE

Emotional intelligence has been measured in many ways but primarily has been conceptualized as either an ability or a trait. Two particular tests frequently used to measure emotional intelligence exemplify this difference. The pioneers of the concept of emotional intelligence itself, Mayer, Salovey, and Caruso, developed the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT), which conceptualizes and measures emotional intelligence as an ability or a group of emotion-processing skills.

The MSCEIT's scales measure emotional perception (ability to identify emotions), emotional facilitation (ability to translate feelings into emotion), emotional understanding (ability to define complex emotions), and emotional management (ability to effectively include emotion in decision making). For example, a test item might ask an individual to look at a picture of a face and then using a rating scale indicate how that person is feeling. Gender differences on ability-based measures of EQ have been found. Women tend to perform better than men on all four scales of the MSCEIT.

A second commonly used measure of emotional intelligence is the BarOn Emotional Quotient Inventory (BarOn EQ-i) (1997, 2000) created by Reuven Bar-On. This instrument conceptualizes emotional intelligence as a trait and, as such, uses a trait-based approach to measuring it. The BarOn EQ-i is a 133-item self-report measure in which individuals provide self-ratings on categories such as their intrapersonal and interpersonal characteristics, adaptability to stress, stress management through problem-solving methods, and methods they apply to manage mood through self-control and conscientiousness. In lieu of self-report ratings such as those used with the BarOn EQ-i, multiperspective ratings have also been developed to measure emotional intelligence. This method involves having a person's emotional intelligence rated by numerous people well known to the individual such as family members, friends, and employers/colleagues. The results are compiled and said to provide a more objective rating of the individual's EQ.

## APPLICATIONS

When Daniel Goleman, a Harvard PhD psychologist, expanded Salovey and Mayer's academic work on emotional intelligence into the mainstream, emotional intelligence began to gain recognition and widespread use in applied settings as well, particularly in the occupational environment. The EQ concept argues that traditional intelligence (IQ) is too constricted to be the primary predictor of success, and EQ may be able to account for a wider range of abilities that lead to successful work performance. Goleman's research sought to differentiate the impact of cognitive and noncognitive abilities on performance. Goleman also proposes that EQ, unlike IQ, can be learned. In his model for developing EQ, Goleman describes five "domains" of EQ that are trainable:

1. Knowing your emotions
2. Managing your own emotions
3. Motivating yourself
4. Recognizing and understanding other people's emotions
5. Managing relationships, i.e., managing the emotions of others

Current research on EQ in the workplace suggests that compared to low EQ coworkers, high EQ is linked to increased job performance, reduced turnover, and stronger leadership and managerial ability in employment settings. High emotional intelligence has also been found to predict employability. High EQ has also been linked to stronger academic performance and also to general interpersonal behaviors and interactions such as sportsmanship, helping behaviors, and civic involvement.

EQ has been applied to the study of stress and health as well. For example, in adolescents, high EQ has also been found to serve as a protective factor against teenage smoking; and it is suggested that adolescents high in EQ benefit more from prevention programs. Along with concepts such as positive and negative affectivity, optimism, and locus of control, EQ is considered influential in the way that individuals perceive, evaluate, and respond to stress. Research to date finds that workers with high EQ experience less stress and have better levels of health than their moderate to low-scoring colleagues.

EQ has been hypothesized to have potential future implications in clinical work as well. For example, the presence of pathologically low emotional intelligence (PLEQ) may have an important impact in relation to diagnosis, conceptualization, and treatment of emotional disorders. Because it is believed that EQ can be learned and developed via education and experience, emotional intelligence training programs have been established internationally. These programs report that for some individuals, EQ is strengthened through developmental training, thereby improving the health, well-being, and/or performance of the trainees. Additional program evaluation is needed to fully support such claims.

Critics of the emotional intelligence construct note that EQ, as it is currently conceptualized and measured, demonstrates limited incremental utility and predictive value over and above existing traditional intelligence and personality measures. Yet, many believe that the construct of EQ holds much promise, and almost all agree that it is in need of further empirical

investigation. Goleman and others purport that EQ, in fact, predicts work and life success. High EQ is said to promote high achievement in life. Research is needed to fully substantiate such powerful statements, yet the construct of EQ holds much promise and infinite research opportunities.

## EMPATHY

---

### DEFINING THE CONCEPT

The term *empathy* was originally coined in 1909 by E. B. Titchener who, drawing on the work of Theodore Lipps, employed it in his *Experimental Psychology of the Thought Processes* as a translation of the German word *Einfühlung*, a technical term in German aesthetics that literally means “to feel one’s way into.” For Lipps and other scholars interested in studying the emotional responses people have to works of art, *Einfühlung* was employed to explain how people were able to grasp the meaning of aesthetic objects and the consciousness of others. For Titchener, however, empathy referred to an instinctive tendency we have to feel ourselves into the things we perceive or imagine. This early characterization has continued to shape theoretical conceptualizations of empathy to the present day with its acknowledgment that empathy has both affective and cognitive components.

Although widely recognized as a fundamental feature of human social life and moral development, social scientists since Titchener have had difficulty forging consensus regarding a precise and comprehensive definition of empathy and the relationship between its affective and cognitive aspects. Traditionally, the research literature on empathy has been marked by sharply conflicting, even mutually exclusive, conceptualizations of the meaning and nature of the phenomenon, as well as significant disagreements about how it is to be measured or studied. Some authors have made the case that empathy is primarily a cognitive process involving the skill of perspective- or role-taking; others have argued that empathy is a vicariously shared emotion that does not necessarily involve the higher mental processes; still others have attempted to reconcile these two perspectives somewhat by arguing that while it can occur without perspective-taking, the likelihood of empathic response increases in the presence of perspective-taking abilities and skill. Further complicating matters is the fact that clinicians tend to view empathy as a therapeutic technique or process that facilitates effective communication and promotes deepened therapist-client understanding. Ultimately, there may be no one correct or final definition of empathy, just different working definitions.

### EMPATHY, ALTRUISM, AND MORAL DEVELOPMENT

Many researchers have attempted to establish the theoretical and empirical relationship between empathy and altruism, as well as to differentiate between empathy and similar emotional phenomena such as affective role-taking, sympathy, personal distress, and compassion. For example, it has been argued that affective role-taking takes place when we identify with the feelings of another, while sympathy occurs when we respond to another's negative emotional state in ways that are not identical to but nonetheless congruent with that person's feelings; personal distress is the result of self-oriented anxiety or concern over another's feelings. Speaking to the relationship between compassion and empathy, Post (2003) maintains that "compassion requires empathy and seeks to achieve good in the context of suffering." In the minds of many researchers, the basic experience of empathy, an experience of sharing another's emotional state in one way or another, seems to underlie and possibly give rise to each of these other phenomena. One way in which the specific differences

between empathy, sympathy, personal distress, and compassion may be made more clear is by considering empathy as "feeling-with" another person, sympathy as "feeling-for" them, personal distress as "feeling-for-oneself" because of another person, and compassion as "suffering-with" another who is in need. Although this may be a bit simplistic, it is nonetheless a useful heuristic when considering the often subtle distinctions to be had in this particular family of emotional experiences.

Empathy, as a basic conceptual and explanatory construct, has long been employed in social, developmental, and personality psychology. Early in the history of modern psychology, James Baldwin employed the term *ejective consciousness* to characterize the role that empathy plays in the moral development of young children. Later, Piaget proposed that the capacity for empathy was tied directly to the child's development of the cognitive ability to adopt another person's perspective, both of which were fundamental to the development of moral judgment in the child. Following Piaget, Kohlberg (1981) maintained that our role-taking tendencies and our fundamental sense of justice are deeply interwoven and, as such, are closely related to the experience of sympathy and the desire to resolve conflict.

This connection between empathy and moral development has continued to be a central focus of much contemporary research. Some researchers have suggested that an innate capacity to share and respond to the emotional expressions of others may be present from birth. This conclusion is partly based on research indicating that, even when they are only a few hours old, infants are disturbed by the sounds of another infant's distress in ways that they are not disturbed by other sounds—even their own cries. Other researchers have argued that empathy and altruism are just as much a part of basic human nature as selfishness and aggression. It has also been suggested that this natural predisposition to empathic responsiveness ultimately may be what provides the foundation for later development of abstract moral principles such as caring and distributive justice. Indeed, evolutionary theorists have long held that our abstract systems of moral reasoning, ideals of distributive justice, and egalitarian ethics are the result of natural selection and ultimately function to ensure the survival of the species. Although such claims have often been met with strong criticisms (both empirical and philosophical), they nonetheless demonstrate a fairly general recognition of the intimate relationship between empathy and the development of moral sensibilities.

Of similar interest to many researchers has been the relationship between empathy and the development of emotional understanding in young children, in particular young children's abilities to interpret accurately the emotional expressions of others. Much current research indicates that infants and young children are naturally responsive to the emotional expressions of others and are highly motivated to read and understand others' feelings. In this view, the emotional expressions of others provide the young child with important clues about the social world in which they find themselves, thereby helping to enable the child to learn how to react appropriately to the diverse and often changing demands of human social life. For example, the ability to accurately appreciate emotional expressions that convey alarm or distress are obviously important in eliciting arousal and attention in the young child and are therefore quite relevant to the child's personal safety and security. Research in this area also suggests that, contrary to what has often been assumed, infants and young children are not fundamentally egocentric organisms and passive receptors of environmental information, but rather are quite active beings who are very sensitive to the varied and subtle emotional expressions of others in their social world.

## DIFFERENCES IN EMPATHY

Despite the fact that empathy is so basic to human nature, research has shown that not all people experience empathy in the same way or to the same degree—even in the same situations. Indeed, the spectrum of empathic experience extends from those deeply sensitive individuals who feel intense distress in the face of another's suffering to those rare individuals (sociopaths) who seem incapable of appreciating any emotional states other than their own. Typically, though, most people are capable of empathizing with others, and do so to a significant degree—assuming, of course, that they themselves are not experiencing too much distress of their own or are not able to accurately perceive a given situation. This does not mean, however, that human beings are automatically or necessarily empathic toward others. Although there are times when empathy just seems to happen and we experience another person's world without really trying, it is also the case that we seem quite able not only to choose to empathize with another but also to choose to resist such feelings. Although much work in this area remains to be done, it seems clear that the

ability to choose empathic response or to resist empathic feelings is far more defined in adulthood than in either childhood or adolescence.

Although there is no evidence to suggest that empathy is in any way a gender-specific emotion, there may be gender differences in the experience of empathy. Some research indicates that women tend to experience and manifest a greater degree of empathy than do men in most situations. For example, Anderson has shown that among non-Jewish Germans who rescued Jews from the Nazis during the Holocaust there is a two-to-one ratio of female to male rescuers. Research also indicates that females are typically better able than males at accurately identifying the meanings of nonverbal emotional cues, which is presumably an important requirement for empathy. Other researchers, however, argue that gender differences in empathy may have less to do with genetics per se and more to do with differences in the types of socialization males and females experience. Thus, empathy may have different meanings and consequences for males and females. For example, it has been shown that in boys empathy tends to correlate with cognitive skills, whereas in girls it is more often correlated with a positive self-concept and prosocial behavior. Several large scale reviews of research in this area suggest, however, that although females tend to appear more empathic when empathy is measured by asking people to rate themselves, gender differences all but disappear when either physiological change or facial expression is employed as the principle measure of empathic arousal. Such findings seem to imply that what might appear at first glance to be gender differences in empathy may in fact only be artifacts of the methods of measurement employed in the research. What does seem clear, however, is that empathic sensitivity in both males and females can be enhanced or weakened by having (or not having) certain key experiences, particularly during childhood and especially those involving positive socialization, parental examples of affection and generosity, and frequent opportunities to learn about, cooperate with, and assist others.

## EMPTY NEST

---

The “empty nest” refers to the physical and psychological change in the family when a child leaves home or goes away to college. For about 18 years, parents have invested themselves in the emotionally consuming process of raising a family—and suddenly one day the children leave home. As the nest empties, a chapter of parenting draws to a close, often accompanied by ambivalent feelings from both children and parents. The empty space that opens up in parents’ lives can be both exciting and frightening.

Many parents experience deep grief as they prepare to let go of their sons or daughters and the family as they have known it. There are multiple losses including the loss of daily life with children, loss of the sense of family that the parents have built, and loss of the active job of parenting (“I’m out of a job.” “I’m no longer needed.”). These losses can play havoc with a parent’s self-worth, particularly if that parent’s identity has

revolved around child rearing. Grief can be especially deep if it is the first, last, or only child to leave home, if the relationship with the child was especially close, if the child played a critical role in the family, or if there have been other recent losses. This major life passage can coincide with middle age, menopause, and caring for aging parents, as well as issues around finances. It can also bring to light unresolved family, marital, or personal issues that had been put aside while parenting.

Often marriages go through major adjustments after children leave home, as time and energy are freed up from parenting and partners are left alone in the house with each other. Marital relationships have often suffered from lack of attention, intimacy, and nurturance throughout the child-raising years. The adolescent years can severely strain a marriage as well, with the lack of privacy, increased sexuality present in the house, and disagreements between parents about parenting. It is common for long-term problems in the marriage to surface. As partners find themselves alone with one another in a house without children to distract them, marriages often come under scrutiny. This can be an important time to become reacquainted with one another, confront long-term relationship issues that now have the space to surface, and co-create new dreams and projects. It can also be a time when partners find that they have very little left in common; many marriages at this juncture end in divorce. Couples who wait until the children leave home to deal with the long-term problems in their marriages run a much greater risk of divorce.

Parents are challenged to let go of the child they protected and nurtured through childhood. As the young adult is now being launched into the world, parents must assess the job they have done. Parenting is a humbling and challenging experience, and it is rare for a parent to have no regrets. Parents are faced with the reality that they will not have a second chance and that they have prepared their children as best they can. Now it is time to let go of their children. Often the relationship has suffered from the inevitable conflicts of the teen years, and parents may feel a mixture of relief and regret that their son/daughter is leaving home. Parents also know that the relationship is changing; once that child has left home, the relationship will never be what it had been, even if the young adult returns home for a period of time. The parent-child relationship at this stage is much like a dance in which the parents have to be ready to step back as the child steps forward, without stepping back too quickly, as the child may fall. The dance of

supporting children through this transition is a delicate one, needing timing and sensitivity.

It is difficult to predict how the young adult will move through this transition; it can be a rocky time for both parents and children, with the tension straining the parent-child relationship. As they leave home, young adults are struggling with the developmental tasks of searching for identity and independence. They are saying goodbyes, focusing on their futures, and struggling with questions (“Who am I, apart from my family and school?” “What do I believe in?” “What do I want to do with my life?”) and self-doubts (“What if I get homesick?” “What if I chose the wrong college?” “What if I don’t find new friends?”). Many feel ambivalent about leaving home and have fears about the change in the relationship with their parents (“Will they still love me if I don’t make choices they agree with?”). Young adults may feel conflicting pulls between remaining loyal to the family (and its values) and wanting to break free and discover their own beliefs, feelings, talents, and needs. In an attempt to find their own identities and place in the world, over the next few years these young adults will be confronting and reassessing parents’ values, lifestyles, and relationships—with an ever-widening gap between their experiences and the world of their parents. Some children may need to return home for a period of time. This can create stress as the family attempts to readjust while parents and boomerang children deal with feelings of disappointment or even shame.

Children who are leaving home benefit from knowing that parents are dealing constructively with the empty nest and knowing that parents are seeking to find new meaning, intimacy, and possibilities in this new phase of their lives. It is much more difficult for children to leave if parents are unhappy. As parents face the empty nest, they are challenged to re-create their lives and remodel the family system in such a way that it nurtures the newly defined needs of the parents/partners, along with a new relationship with children that embraces, supports, and appreciates them as adults.

Following are some suggestions for parents who are experiencing empty nest:

- Acknowledge the importance of this life transition. Your family is changing, as is your relationship with your child. If you can tend to your own feelings of loss, you can support your child in his/her awkward steps toward independence.
- Get the support of your friends and partner. Reassure them that they do not have to make you feel

better; they can just be with you. Consider starting or joining a mothers support group.

- Review your relationship with your child—what you regret and appreciate, what you left out of your parenting, what you have given your child, what you have learned about yourself. Be willing to honor this phase of your mothering, perhaps through a ritual.
- Make room for the differences in how your family members will deal with this change. Be willing to let go of your expectations and open to things as they are.
- Take time to regularly communicate with your family members about the upcoming changes. Listen to your child; acknowledge his/her fears and anxieties while keeping the bigger picture in mind. Understand that the pressure of separation may strain your relationship and that this may be a time of increased arguing.
- Communicate with your spouse about the changes you both are experiencing in your marriage. Some couples find that they have neglected their marriage while they were raising their children; it is common for long-term problems in the marriage to surface at this time. Many couples find this to be a good time for marriage counseling.
- Explore who you are in the world after your child leaves home. Be open to the emptiness and the possibilities within it. Explore new questions about the direction of your life. Give yourself permission to dream; cultivate interests you may have set aside during your parenting years. Set a goal to initiate at least two new ideas within the first few months after your child leaves for college.

—Alexandra Kennedy

## ENDOCRINE DISRUPTORS

---

Endocrine disruptors are chemicals that disrupt the normal functioning of hormonal systems or the

balance of hormones. There are currently no standardized tests to determine whether or not a chemical should be classed as an endocrine disruptor. Chemicals that alter either the levels of estrogens, androgens, or thyroid hormones or the body's response to them are of special concern because these hormones are very important during development. Laboratory studies show definitively that certain chemicals can have adverse effects on hormone function, which, in turn, produces birth defects, developmental abnormalities, reproductive dysfunction, and cancer. Whether the environmentally ambient concentrations of endocrine-disrupting chemicals create developmental dysfunctions or cancer in humans is still a subject of debate.

There is little debate that wildlife can be affected adversely by endocrine disruptors at ambient concentrations. The classic example is the decline of populations of bald eagles and other birds in the United States. The population decline was reversed after the phase-out of DDT. There are many other examples. Recent laboratory studies have found that amphibian gonad development is altered by the herbicide Atrazine at extremely small concentrations, and other studies have shown that sexual development in fish is negatively affected by estrogenic chemicals found in sewage treatment discharges.

Endocrine disrupting chemicals that act on hormone receptors pose problems for standard toxicology experiments that use high doses and linearly extrapolate the effects to lower doses. The adverse effects to an organism of a hormone or endocrine disruptor are often an inverted-U function; when concentrations are above or below an optimal level, adverse effects occur. Examples are vitamin A (and other retinoids) and thyroid hormone.

A report by the National Research Council concluded that there is evidence that PCBs and the chemicals that accompany them in the environment (dioxins and furans) are correlated with shorter gestation, slower growth, and lower IQ test scores. The panel of scientists could not agree about the source of historical changes in sperm counts, the possible increase in hypospadias (opening of the urethra on the underside of the penis) found in people near toxic waste repositories, and a possible increase in undescended testicles. However, laboratory studies of a number of species of mammals, including monkeys, yield evidence that a variety of endocrine-disrupting chemicals (including DDT, methoxychlor, bisphenol-A, PCBs, dioxins, and dibutylphthalate) induce structural and functional reproductive changes. Some of

these chemicals also appear to suppress immune function in wildlife and laboratory animals.

The National Research Council committee recommended that epidemiological studies be conducted to examine the effects in humans of endocrine-disrupting chemicals that have been shown to affect laboratory animals. The outcomes to be assessed should depend on the outcomes observed in laboratory animals for the specific chemicals. For different chemicals, the outcomes would be reproductive system structure and function, developmental defects, neurobehavioral functioning and social development, immune system, and different types of cancers. Because of the widespread contamination of the environment by endocrine-disrupting chemicals, the committee also recommended the development of assays that will rapidly screen and identify chemicals with potential endocrine disrupting activity, and that the sensitivity of the fetus to delayed effects of such chemicals be considered in developing such assays.

## ENGLISH AS A SECOND LANGUAGE (ESL)

---

English as a Second Language (ESL) is a program in which nonnative speakers of English who live in a country where English is the native language work toward the acquisition of English as a second language. It is referred to as ESL even though English may be the student's third or fourth language. When English is taught as a second language in a country where the predominate language is not English, the program is referred to as English as a Foreign Language, or EFL.

## TYPES OF PROGRAMS

There is a variety of models for ESL instructional programs including Pull-out ESL, Push-in ESL, Self-contained ESL, Sheltered instruction, or SDAIE (Specially Designed Academic Instruction in English), and Newcomer schools. Pull-out ESL programs consist of an ESL teacher who removes children from the mainstream classroom during the day for a limited amount of time and works with them on English language development skills. Push-in ESL programs are mainly used in the elementary grades where there is a small population of English language learners. In these programs, the English language learners remain in the mainstream classroom and an ESL teacher visits the classroom to work with the students and the classroom teacher. Self-contained ESL is found in schools with large populations of English language learners, and the students are grouped into one classroom to learn English skills. English language learners are also grouped together for SDAIE. In this setting, the teacher uses ESL methods to teach students content area materials such as mathematics, English, history, and science. Sheltered instruction techniques may also be used in the mainstream classroom by a grade-level teacher who has had special training. Bilingual education programs focus on dual-language instruction such as Spanish and English. Whereas all bilingual models have an ESL component, all ESL programs are not bilingual.

Newcomer schools are sometimes used to bridge the gap between students' native backgrounds and their new environments. Students who are usually placed in these programs are generally new to the school system, are non-English speaking, or have a limited ability in English. The school provides instruction in language and content to English language learners to help them make the transition to their new environment. After a certain length of time, the English language learners are moved into the mainstream school.

English language learners come from a variety of backgrounds. Some have been well educated in their native country, and some have had little or no schooling. Older English language learners have more of a challenge because although a student may be able to communicate well in English within 6 months to 2 years, the development of academic language may take from 5 to 7 years.

The problem of how to teach students who do not speak a common language and what that common

language should be creates a challenge in a multicultural society. Bilingual education in the United States has been alternately embraced and rejected. For English learners, English-only schooling has often brought difficulties, cultural suppression, and discrimination, even as English has been touted as the key to patriotism and success.

## HISTORICAL BACKGROUND

English as a Second Language has been a part of the history of the United States since Colonial times. Even at that time, the colonies were a mixture of many different nationalities and languages. As the colonies grew, there became a need for a sense of unity, so the leaders began to work for national literacy. Many of the colonies formed schools of their own in which the native languages of the colonists were utilized, but eventually many of these schools became English-speaking. Although Colonial government could not prevent groups from forming schools of various languages, early colonial leaders such as Benjamin Franklin stressed Americanization through education and the teaching and preservation of the English language to strengthen the government. This idea was strengthened with the American Revolution, which emphasized building common bonds and loyalties to build the new nation.

In 1664, at least 18 Colonial languages were spoken on Manhattan Island. Bilingualism was common among both the working and educated classes, and schools were established to preserve the linguistic heritage of new arrivals. The Continental Congress published many official documents in German and French. Early laws in the new nation, such as the Ordinance of 1787, mandated common schools in all of the Northwest Territories. Since this population of settlers included people who were from several European and various other countries, the task of creating common schools was a challenge. Parochial schools for various groups were common in these territories, which prevented some groups from automatically becoming a part of the common culture. Another challenge for the schools was that many of the immigrants were poor and had never attended school or learned to read in any language.

The Territory of New Mexico authorized Spanish-English bilingual education in 1850. The inclusion of a language other than English in the public schools was encouraged by the large population of Germans in

1865, although it was opposed by other ethnic groups. The Chicago School Board agreed to German being taught and, by 1870, 1 in 15 students was receiving instruction in German. Other cities, such as St. Louis, also supported German instruction. As the political power of the German groups decreased, the amount of German instruction in the schools also decreased. The immigrant population changed as immigrants arrived from southern and eastern Europe. Many of the newcomers were illiterate in English as well as their native language. The Compulsory Education Law of 1889 mandated English-only instruction and mandatory school attendance. Many large cities looked to the schools to assimilate immigrants into the mainstream culture, a difficult task for the unprepared schools. Employers also encouraged English language learning to create better educated workers.

In periods of recession, war, or national threat, immigrants, cultures, and languages were restricted and/or forbidden. The diversity of languages in America was further emphasized as World War I began, and the draft registration announcement was repeated in 15 languages. The German-American communities' demands to German instruction in the schools ended as the United States entered WWI and Congress placed language limitations on material printed concerning the war. World War I brought anti-German hysteria, and various states began to criminalize the use of German in all areas of public life. As World War I ended, Ohio passed legislation to remove all uses of German from the state's elementary schools; mobs raided schools and burned German textbooks. In 1917, a new law was enacted to give a literacy test to immigrants. Immigrants were encouraged to learn English so they could learn the laws of the United States and become a part of the American culture. Subsequently, 15 states legislated English as the basic language of instruction and uneasiness toward immigrants continued. Although there were several pockets of acceptance for bilingual education, other areas of the country effectively restricted or even attempted to eradicate immigrant and minority languages. This repressive policy continued in World War II when Japanese-language schools were closed.

ESL and bilingual programs continued to be issues in the political arena. Only as recently as 1968 did Congress signal its first commitment to bilingual education by enacting the Bilingual Education Act as a means of addressing the needs of students whose first language was not English. When the U.S. Congress enacted legislation to begin Title VII of the Elementary

and Secondary Education Act, federal funding became available for bilingual education programs. Almost simultaneously, the courts began to rule that students deprived of bilingual education must receive compensatory services. Beginning in 1970, landmark court cases mandated special language instruction for children with a limited command of English, including a U.S. Supreme Court decision in 1974 citing that Chinese-American children were not receiving adequate education in San Francisco due to the language barrier. However, federal legislation, through continuing reauthorization of the 1968 Bilingual Education Act, has supported the rights of states to restrict bilingual education as seen in Arizona's Proposition 203 in 2000 and California's Proposition 227. Proposition 227 passed overwhelmingly in California on June 2, 1998. The initiative essentially banned bilingual education and called for sheltered English immersion. Students were to be immersed in English for 1 year and then put into regular classes. This program had no research base; it had never been tried elsewhere, but the idea was appealing. The concept was to give students 1 year to learn English and then let them continue with their education.

Periodically throughout history, English has been proposed as the national language such as through the bill titled "Declaration of Official Language Act of 1999," yet this has never been enacted into law. Although the United States has no official language, 23 states have passed laws proclaiming English as official. Because the states reserve the right to dictate educational policy, bilingual education has depended on the vagaries of state law.

## METHODS

Over the years, the methods of teaching second or foreign languages have changed a great deal. Emerging research and philosophical debates have greatly affected the study of how students learn and how a second language is acquired. In second language teaching, methods have moved from teacher-centered approaches to learner-centered approaches that emphasized the student as a whole. Methods have also moved from an emphasis on linguistic competence and grammar structures to communicative competence and learning strategies. Language learning is no longer seen as simply an academic subject to be learned. It is now an act that can transform a person and offer independence.

Communicative approaches, which stress language learning for the purpose of oral and written instruction,

differ from structural approaches, which focus on the structure of the language such as grammar and syntax. Several communicative approaches appeared between the 1960s and 1980s. These approaches reduced emphasis on grammatical structures and recognized the range of language functions and the appreciation of language as embedded in social contexts. Through communicative approaches, teachers and students work collaboratively.

Adult ESL programs use different approaches to language learning depending on the goal of the instruction. Structural approaches are used when the students are preparing for the TOEFL (Test of English as a Foreign Language) for college admission. Communicative approaches are used to train students for social or employment settings.

## EPILEPSY

---

Epilepsy is a medical condition characterized by spontaneous recurrent seizures. Seizures are brief neurological symptoms resulting from abnormal discharge or “firing” of neural brain cells in the cerebral cortex.

Neurons normally transmit information by firing a single short discharge that is conducted from one neuron to another. Seizures result when the discharge is prolonged or recurs rapidly and recruits other neurons. The synchronous discharge of neurons causes excessive expression of the activity normally performed by the discharging brain region.

The symptoms caused by a seizure are determined by the brain region involved. *Simple partial* (or *focal*) *seizures* result from discharge of a small brain region. Seizures arising in the frontal lobe primary motor cortex cause motor seizures. This region contains the neurons of motor control that are eventually connected to muscles in the arms and legs; a seizure arising in the hand region of the primary motor cortex causes jerking of the opposite hand. Simple partial sensory seizures arise in the parietal lobe primary sensory area and cause abnormal sensations. Seizures arising in the occipital lobe primary visual area cause visual symptoms.

*Complex partial seizures* are the most common seizure type in adults. They most often begin in the temporal lobe, which is normally responsible for memory. They are characterized by 1 to 3 minutes of nondistractible staring, often with automatisms of manipulating objects or lip smacking, and are followed by confusion and amnesia for the event.

*Generalized tonic-clonic seizures*, previously termed grand mal or convulsions, are characterized by sudden unresponsiveness, whole body stiffening (tonic phase), and falling to the ground. This evolves to typically less than 3 minutes of rhythmic muscle jerking (clonic phase), followed by deep sleep. “Generalized” seizures begin throughout the whole brain simultaneously. Secondary generalized tonic-clonic seizures start in one brain region, or focus, and spread to the whole brain.

There are other types of generalized seizures. *Absence seizures*, previously termed petit mal, cause 5 to 20 seconds of nondistractible staring, often occurring multiple times daily in children. *Tonic seizures* cause whole body stiffening. *Clonic seizures* cause whole body jerking. *Myoclonic seizures* are brief lightning-like jerks. *Infantile spasms* are brief contractions of the infant's trunk, typically in clusters and accompanied by developmental delay.

Approximately 10% of people will have a seizure. Less than 3% will have epilepsy; 7% will have only a single seizure, often provoked by a transient cause such as alcohol withdrawal, trauma, drugs, or a medical illness.

Any brain disease that affects the cerebral cortex can cause seizures and therefore cause epilepsy. However, “epilepsy” is often reserved for illnesses in which seizures are the primary manifestation. The most characteristic epilepsy syndromes cause generalized seizures from abnormalities of neural transmission without structural brain abnormalities. A few are inherited in a traditional manner but most are sporadic.

Epilepsy with visible structural brain abnormalities can be acquired, for example, from perinatal asphyxia, brain infections, or tumors, or following trauma or stroke. Developmental brain malformations are a congenital cause. The cause of epilepsy is unknown in 50% of patients.

Epilepsy is diagnosed based on the presentation of seizures, but some tests support it. An *electroencephalogram (EEG)* demonstrates spikes in brain-wave activity in about 40% of patients. Brain *magnetic resonance imaging (MRI)* and *computed tomography (CT)* visualize a structural abnormality in a minority.

*Antiepileptic drugs (AED)* are the mainstay of therapy. Effectiveness depends on the seizure type, cause, and epilepsy syndrome. The first AED tried is effective in preventing recurrence of seizures in about 50% of patients. Another 20% will respond to the second or third AED. Approximately 30% remain refractory to AEDs. When seizures arise from a single brain region, surgery to remove the seizure focus is considered. *Temporal lobectomy* is the most common epilepsy surgery, rendering 70% of patients essentially seizure-free. Transient or mild complications occur in about 15%. Vagus nerve stimulation and the ketogenic diet are also treatments.

The previous social stigma of epilepsy being associated with mental retardation or mental illness is dispelled, as most patients are mentally normal. Most state laws prohibit driving for 6 to 12 months after a seizure, which interferes with transportation to work and social interactions, resulting in underemployment, undereducation, and social isolation.

## EQUILIBRATION

---

Equilibration—the process of finding equilibrium or balance—is Piaget’s explanation for how learning grows. Individuals try to balance their present understandings with new events or data they encounter that conflict with what they know, while attempting to maintain stability. When individuals encounter something foreign to their learning structures, the imbalance created is restored through equilibration.

Piaget viewed equilibration as a biological, self-regulatory mechanism for all living things that helps organisms adapt to the external environment by changing internally through learning, rather than by mutation. His theory is largely applied to children’s cognitive growth.

There are four factors in cognitive growth: maturation of the nervous system, social interactions, interactions with the physical environment, and equilibration. Piaget viewed equilibration as the major force tying these together. As children mature biologically and interact with people and objects, they must respond to even simple environmental stimuli, acting on these mentally and physically to understand their encounters in the world. Each encounter involves a constant balancing and rebalancing, resulting in what Piaget called “an ever-widening spiral of knowing.”

*Adaptation* and *organization* are dual psychological mechanisms that lead to learning and cognitive growth. *Adaptation* is the adjustment to the environment, the outside-in aspect. When new events, objects, actions, or ideas are encountered that do not fit existing learning structures, the individual has to *assimilate* the new elements (a taking-in aspect) and modify those organizational structures to *accommodate*

the new information. For example, when a 2-year-old who has only experienced vanilla ice cream is given chocolate and strawberry, he has to assimilate (take in) the different flavors and colors and accommodate (modify) the knowing structure that ice cream is not just white, but varies.

*Organization* is the interrelated internal mental structures, the inside-out aspect. These organizations of rules and principles are also called logical structures, in which elements are continually rearranged and combined to form a strongly interconnected cognitive system allowing for ever more complex thinking. For example, the first time a child uses a computer, a very simple scheme is constructed consisting of rudimentary rules—touching keys makes marks on the screen. After time and practice, the child’s computing structure accommodates word processing, e-mail, Web searches, and so forth. Development of computing principles becomes more complete and may continue to grow. Logical structures allow anticipation and planning for possibilities, leading to ever-higher levels of adaptation. With these structures, computer use becomes a tool for further learning.

## TYPES OF EQUILIBRATION

### Type 1—Simple Equilibration

*Equilibration of object to scheme: for example, balls to a scheme of throwing.* Schemes are mental structures, patterns of thought and action that allow the assimilation of new elements, helping to adapt to the environment. Although Piaget considered schemes to be focused on action (e.g., grasping, eating, drawing), concepts, theories, or ideas can also be thought of as schemes if they have assimilatory power.

### Type 2—Reciprocal Equilibration

*Equilibration between schemes that build sub-systems, rules applicable to several schemes.* When a 6-year-old cuts a snowflake from folded paper and “invents” using it as a stencil, two schemes are coordinated—cutting and coloring. The constructed principle, an insight about multiple uses, could be applied with the question, “What else can I do with it?”

### Type 3—Equilibrations of Totalities

*Hierarchical equilibrations in which the totality is differentiated into parts and then the parts are integrated back into the whole.* Principles that apply to

multiple experiences are constructed. Piaget considered this type “The secret of development and of the transition from one stage to the next.” For example, the child moves to the concrete operational stage of reasoning by constructing the rules for conservation of *identity* (when a ball of clay is transformed into a pancake, if nothing is removed or added, it is the same amount of clay), *reciprocity* (a change in one aspect is compensated by change in another aspect: the pancake is wider *and* flatter), and *reversibility* (the pancake can be returned to the original form).

Equilibration of totalities may occur other than just in stage advances, particularly if applied to adult thought. Expertise may exist in a given area with very advanced, principled structures, highly integrated and differentiated in that domain. There may also be new or far less developed areas of knowing. Thus the individual can function on different learning levels, and there may be several semiautonomous totalities or subtotalities that have the potential to connect to each other.

Gifted and creative individuals develop their mental structures somewhat differently, as there is a constant effort at rule construction and connection among schemes. This allows able learners to be paradoxically better equilibrated because they anticipate possibilities and less equilibrated because there are so many conflicts to present ways of thinking.

## RELATIONSHIP BETWEEN EQUILIBRATION AND STAGE GROWTH

Adaptation through assimilation and accommodation and organization through the evolution of more advanced structures or stages are how equilibration and stage growth are related. This relationship can be expressed by the formula in Figure 1 (Cohen & Kim, 1999).

The relationship between adaptation and organization is complementary (dotted lines). Although they occur simultaneously, the focus can be on one or the other, but not both at the same time. This relationship is also reciprocal (two-way arrows), connected by the inseparable processes of assimilation and accommodation. As the individual’s mental structures become increasingly organized and principled, the ability to adapt successfully increases.

Existing knowing structures are both conserved and enriched as new experiences are encountered and integrated. The stage of development and the level of intelligence influence the achievement of equilibrium, which is always temporary. The seeds of the new

**Figure 1** Cohen's Equilibration Formula

SOURCE: Cohen & Kim (1999).

disequilibrium occur in every equilibration, as there are always new questions or conflicts.

## Conflict

Perturbations, gaps, contradictions, or conflicts to present knowing structures are the stimuli for cognitive advancement and *the dynamic engine* of equilibration. When in a state of disequilibrium, individuals attempt to return to a state of balance by compensating for the imbalance through the constructive process of equilibration. The puzzlement or problem must be real to the individual. It must be moderately novel, not too foreign to the learning structures, nor too familiar, for learning to occur. In other words, the individual must have already constructed preliminary mental structures that can deal with the new aspect. If an element is too foreign, it will be ignored. If it is already familiar, no learning will take place. Ignoring is one way of compensating.

## Compensations

Internal structures are accommodated to moderate novelties by means of *compensations*, actions aimed at canceling or neutralizing disturbances. Compensation is an act that restores the balance in response to a knowledge disturbance. Every equilibration involves both construction and compensation. The compensations needed to accommodate schemes require the balancing of *negations* (constructing what is not visible or present—what the object or idea is not) with the *affirmations* (what is visible, present, evident) in the object. The baby must learn what is blue (affirmations) by grasping what is *not* blue (negations). To do this requires reversibility of thought, the ability to mentally undo an action. Young children do not construct negations very

successfully. Their equilibrations tend to be unstable as they focus more on the positive characteristics. If there is no disturbance or conflict because the assimilation is habitual and requires no compensation, no growth occurs. The levels of compensations are as follows:

*Alpha*—The individual does not deal with the inconsistency and distorts, denies, or ignores it. No instruction can occur at this level until the needed underlying structures and concepts are constructed in order to be aware of the inconsistency or contradiction. *Example*: The year-old baby ignores most of the zoo animals for lack of experience with animals.

*Beta*—The individual attempts to deal with the inconsistency but can only deal with partial modifications (partial accommodation). The novel element is distorted to fit present schemes. Equilibrium is unstable, an optimal level for learning. *Example*: The same baby notices the tiger and calls it “keecat,” distorting the object to fit a familiar cat scheme.

*Gamma*—If the item is not inconsistent to internal schemes, mental reorganization already occurred and the disturbance is integrated easily. *Example*: Two years later, the child easily recognizes most zoo animals and can quickly grasp animal categories when told the gorilla is not a monkey.

## REFLECTIVE ABSTRACTION

Reflective abstraction is the constructive aspect of equilibration. It is the linking and feedback mechanism that moves the individual from one level to the next. It occurs when the individual constructs rules or principles from actions or thoughts, leading to new organization and greater capacity. These relationships are not inherent in the objects or ideas themselves, but must be constructed. For Piaget, reflective abstraction is composed of two inseparable aspects: a reflecting or projecting to a higher level what is known on a lower level (thinking about  $2 + 6 + 9$  or  $9 + 6 + 2$  and the resultant sum) and a reorganization or reconstruction of what has been projected (a conscious rule construction—the order in addition does not matter; the commutative property). When the individual is next confronted by a new but related problem, application of the rule can put the conflicts into a logical relationship.

In sum, equilibration is an open and dynamic balancing between the external adaptive requirements and the internal organization that changes in response to conflicts these engender. It explains the small steps in learning, as in simple equilibrations of object to scheme

or reciprocal equilibration of subsystems. It explains the transitions between stages, when the totality is reorganized and differentiated with new rules or principles. It also provides an overall direction for the development of cognitive structures. Broadly, equilibration is a biological tool by which all organisms adapt to the world and change themselves to do so. Piaget's most powerful contribution and the backbone that holds together all of his work, this concept was evidenced even in his earliest writings. The concept of equilibration can be applied to internal systems of affect and even to social, political, or business systems, which must change internally through learning in order to adapt to the world.

## ERECTILE DYSFUNCTION

---

Erectile dysfunction (ED), sometimes referred to by its old name, impotence, refers to a condition where a man has difficulty obtaining and/or maintaining an erection sufficient for sexual intercourse. It can range from occasional difficulty keeping a firm erection to the total inability to obtain any erection at all. The best estimates suggest that between 15 million and 30 million men in the United States currently suffer from ED.

In order for a man to have an erection, he must possess well-functioning neurologic, vascular, and hormonal systems. Running the length of the penis are

two chambers, called the *corpora cavernosae*. When a man becomes sexually excited due to physical or psychological stimulation, impulses from the brain and local nerves signal muscles in the corpora cavernosa to relax, thereby allowing extra blood into these chambers. As a result, the penis becomes more rigid, allowing for vaginal penetration. This process also requires appropriate levels of certain hormones, particularly testosterone. Any medical condition (e.g., diabetes, prostate surgery) or drug (antidepressants, antihypertensives) that interferes with the hormones, nerve conduction, or blood flow necessary for an erection can result in ED.

The prevalence of ED increases with age, from less than 20% at age 40 to approximately 35% (or more) at age 65. This increase is largely the result of the greater frequency of age-associated medical conditions that can impact sexual functioning, as well as the larger number of medications taken by older men that can interfere with erections. Yet getting older does not necessarily lead to the development of ED. Many men are sexually potent well into their 70s and even beyond.

In addition to medical causes for ED, psychological factors can also interfere with sexual functioning. For example, when a man is depressed or anxious, the body's ability to direct bloodflow to the penis can be compromised.

Fortunately, there are several effective treatments for ED. The most popular are the oral medications (Viagra, Cialis, Levitra) that cause the smooth muscles of the penis to relax, enabling blood to flow into the penis. These drugs, while highly effective, do not work for everyone. Other medical treatments include penile injections of vasodilators, urethral suppositories, vacuum devices, and penile implants. While effective, all of these medical treatments have side effects (sometimes quite serious ones) associated with them. When ED is primarily the result of psychological factors (e.g., stress), psychotherapy alone may be sufficient to remedy the problem.

## ERIKSON, ERIK (1902–1994)

---

Erik Erikson was born near Frankfurt, Germany, and went on to make several important contributions to the field of life span development. After graduating from high school, Erikson traveled around Europe and studied art in Germany. At the age of 25, he was invited to Vienna to teach children whose parents were studying with Sigmund Freud. There he was trained in the psychoanalytic tradition under prominent psychoanalysts including Anna Freud. After failure to obtain Danish citizenship, Erikson emigrated to the United States in 1933 because of Fascism. Despite having no formal education beyond high school, Erikson taught at several preeminent institutions, including Harvard, Yale, and Berkeley.

Although trained as an orthodox psychoanalyst, he extended psychoanalytic theory in several significant and important ways. In contrast to Freud, Erikson conceptualized personality as a life span phenomenon in which personality develops from infancy through old age. Erikson divided the development of personality into eight separate stages across the life span, with each stage characterized by its own crisis and two possible outcomes: (1) trust vs. mistrust, (2) autonomy vs. shame and doubt, (3) initiative vs. guilt, (4) industry vs. inferiority, (5) identity vs. role confusion, (6) intimacy vs. isolation, (7) generativity vs. stagnation, and (8) integrity vs. despair. Erikson paid particular attention to the role that identity played in the adolescent period and beyond.

Erikson referred to the eight crises enumerated above as psychosocial stages of development, emphasizing the important role that social and cultural factors play in personality development (this contrasted with Freud's emphasis on psychosexual factors). According to Erikson, conflicts in each stage arise because societal and maturational factors engender new demands on individuals, and each conflict or crisis must be resolved before individuals are prepared to proceed to the subsequent stage. Based on his work with the Sioux and Yurok Indians, as well as other groups, Erikson believed that the sequence of psychosocial stages was invariant across cultures, but the means by which individuals from various cultures met each of the conflicts varied. Furthermore, he highlighted macro-level factors that affected development including the unique time and historical factors of the larger society.

In sum, Erikson was a synthetic thinker who made several contributions to the study of life span

development. Despite the fact that many of his ideas have been difficult to test empirically, Erikson's life span approach and his work in adolescent development have made a lasting impact.

## ESTROGEN

---

Estrogen is a generic term for a class of steroid hormones that includes 17 $\beta$ -estradiol, estrone, and estriol. Estrogens are synthesized from the hormone testosterone by the enzyme aromatase. Although both men and women produce estrogens, women have more of the aromatase enzyme, so they produce much more estrogens than men. Estrogens are produced in the ovaries, testes, placenta, and the adrenal cortex. In men, estrogens synthesized from testosterone promote mating behavior and bone development.

In women, estrogens are produced in the ovaries in response to hormones released by the brain (luteinizing hormone and follicle-stimulating hormone). Estrogens and progestins (a related class of steroid hormones) are released by the ovaries of postpubertal and premenopausal women in a cyclic fashion. During the menstrual cycle, estrogens promote the maturation of an egg-containing follicle in the ovary, stimulate ovulation, and produce an environment in the female genitalia suitable for fertilization, implantation, and nourishment of an embryo. Estrogens are also involved in the development of female secondary sexual characteristics, female sexual behavior, and maternal behavior. Further, estrogens promote water retention, lipid and calcium metabolism, and bone growth. High levels of estrogens in women have been linked to improved memory function, particularly verbal memory function. Exogenous estrogens are used in oral contraceptives and in treatments for female hypogonadism, primary

ovarian failure, and menopausal symptoms (see below). Because estrogens promote the growth of breast and uterine tissue, antiestrogen drugs such as tamoxifen or raloxifene are used to prevent and treat breast and uterine cancer. These drugs are termed “selective estrogen receptor modulators” (or SERMS) because they prevent the actions of estrogens in certain tissues (e.g., breast, uterus) while promoting estrogenic effects (e.g., on bone and lipid metabolism) elsewhere in the body.

Estrogens are also critically involved in early development. In female animals, an excess of estrogen just after birth can lead to male-like mating behaviors and cognitive function in adulthood. In women, the disorder, termed Turner syndrome, illustrates the importance of estrogens in normal development. Turner syndrome results from the congenital lack of the second X chromosome, which leads to an incomplete formation of the ovaries, a failure to produce estrogens and progestins, and infertility. Without estrogen therapy, girls with Turner’s syndrome fail to undergo puberty. A short stature, hearing loss, kidney dysfunction, and webbing of the neck are often observed in these patients. Turner syndrome patients are also deficient in visuospatial and verbal memory, deficits that can be reduced by long-term estrogen treatment.

As women age, levels of estrogens and progestins decline significantly, eventually leading to menopause (typically around age 50). Menopause is associated with a cessation of ovulation and menstrual cycling and a significant drop in estrogen and progestin levels, which results in symptoms such as hot flashes, mood swings, decreased sex drive, and vaginal dryness. Menopause is also associated with memory loss and increased risk of Alzheimer’s disease. Until recently, the hormone replacement therapy (either estrogens alone or estrogens plus progestins) prescribed to menopausal women was thought to prevent heart disease, osteoporosis, colon cancer, and memory loss. However, recent data from the large multicenter Women’s Health Initiative clinical trial indicate that 5 years of estrogen plus progestin replacement produces a small but significant increase in the incidence of heart disease, stroke, breast cancer, and memory loss (although it reduced the incidence of osteoporosis and colon cancer), and estrogen replacement alone increases the risk of stroke. These data have led to the recommendation that hormone replacement be used to relieve menopausal symptoms only for short durations and in low doses.

## ETHICAL STANDARDS OF RESEARCH

---

The study of behavioral development involves the use of both human research subjects of all ages and animals from chicken embryos to monkeys and apes. Research strategies exist on a continuum that ranges from nonobtrusive naturalistic observation to the direct experimental manipulation of the subject’s internal or external environment. As the range moves from observation to experiment, the potential of lasting impact or risk of harm to the research subjects increases. Throughout the history of experimental science, in the 20th and 21st centuries in particular, researchers, philosophers, and ethicists have reflected on this fact and have offered ethical guidance in the form of principles to be considered during the planning and execution of research. Some principles are general in their concern, while others are more specifically focused on the treatment of either human or animal subjects. In addition, the principles themselves vary in terms of the specificity of their content. Some are quite broad (e.g., respect persons), while others are directly limited in scope (e.g., reduce the degree of risk).

## GENERAL ETHICAL CONSIDERATIONS

1. *Research is the Province of Professionals*. A “profession” obligates its members in ways that go beyond that which is required by other important jobs. For example, members of research professions (a) must

have acquired the specialized knowledge and skills that are required to carry out research activities; (b) must agree to be governed by the relevant codes of ethical conduct (see the American Psychological Association, Society for Research in Child Development for specific standards); (c) are required to police other members of the profession for compliance to applicable ethical codes, laws, and regulations; and (d) have special obligations to protect and improve the “public good.”

2. *Regulation.* Researchers are fully familiar with the relevant law and codes of federal regulation that govern the conduct of research.

3. *Justification.* There is no inherent “right” to conduct research. Research that impacts sentient beings is undertaken to advance the body of important knowledge and the well-being of humans and not to satisfy the personal curiosity of the researcher.

4. *Pre-review.* Researchers seek out review of their research by knowledgeable members of the research community and the general public *prior* to the actual conduct of the research. This process helps to ensure that the research has proper justification, is adequately designed, and contains the proper protections for the designated research participants. Federal law requires that human research be reviewed and approved by the Institutional Review Board (IRB) and animal research by the Institutional Animal Care and Use Committee (IACUC).

5. *Communication.* Researchers work to accurately communicate the results and implications of their work.

6. *Conflicts of Interest.* Researchers who have significant financial conflicts that might influence or bias the conduct or interpretation of their research disclose these conflicts and work to eliminate their impact.

7. *Education.* Researchers ensure that co-workers and students involved in the conduct of research are properly trained and supervised.

## ETHICAL PRINCIPLES AND ANIMAL RESEARCH

The ethical issues that surround the use of animals in behavioral research have a contentious history. The controversy involves two fundamental issues: whether animal research is necessary to understanding human behavior and if animals have what is called “moral standing.” Moral standing refers to whether or not, or to what degree, an entity “deserves” protection by the moral and

ethical norms of a society. Some philosophers have argued that animals have “rights” of absolute noninterference by virtue of their rudimentary sense of self. Others have taken the position that if an animal is capable of feeling pain, this capability must be taken into ethical account when considering whether it is acceptable to use it as sources of scientific knowledge. The current consensus is that since some animal research has contributed to the understanding of human behavior, it must continue until valid alternatives are found. However, since typical experimental animals clearly are capable of experiencing pain and distress, they do require some level of ethical protection. In addition to the general ethical considerations described earlier, research with animals should also be guided by the following principles. The heart of these principles is derived from an important book published in 1959 by William Russell and Rex Burch, *The Principles of Humane Experimental Technique*.

1. *Alternatives.* Researchers strive to replace animals with alternative experimental methods whenever possible. If animals are to be used in research, they must be animals whose behavioral and psychological characteristics are relevant to the purpose of the study. Using animals just as a matter of convenience is ethically inappropriate.

2. *Pain.* The impact of pain and distress on animals must be estimated for each experiment and minimized to the greatest extent possible. Causing unrelieved pain or distress for experimental purposes requires special justification.

3. *Numbers.* If the use of animals is justified, only the minimum number of animals necessary to execute a valid experiment should be used.

4. *Husbandry.* Animals have evolved preferences for types of food, patterns of eating, social relationships, environmental quality, etc. that ought to be accommodated to the extent possible both for the comfort of the animals and the quality of the science.

## ETHICAL PRINCIPLES AND HUMAN RESEARCH

The evolution of the ethical principles of human research is unfortunately a history grounded in examples of the exploitation of vulnerable populations and failure to ensure that subjects were properly informed about the nature of the research and the risks associated with participation. The Nuremberg Code (1947) was published following the war trials of a group of Nazi researchers.

The code emphasized that researchers be adequately trained, risks to participants be minimized, and decisions to participate be voluntary and based on adequate information. In the United States, the revelation in 1972 that a group of impoverished Black men suffering from syphilis had, unbeknownst to them, been part of a study of the long-term effects of untreated syphilis was a reminder that problems in research conduct were not just a matter of authoritarian governments and the environment of war. As a consequence, the National Research Act was passed in 1974, which called for the formation of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. The commission was charged with deriving the ethical foundation of human research in the United States. In 1979, the Belmont Report was published. The report states that human research supported by the federal government is guided by three principles:

1. *Respect for Persons*. This principle emphasizes that showing respect requires that researchers recognize that potential participants are autonomous agents who must be fully informed about the details of the research so that they may validly apply their values to the decision to participate. This responsibility holds regardless of the perceived importance or urgency of the research. Again, there is no “right” to perform research, only rights of subjects to accept or decline to participate. This principle also requires that subjects whose ability to understand and decide may be underdeveloped or impaired (e.g., young children, demented elderly) must be protected from exploitation. When children or incompetent adults are involved as research subjects, their representatives must assume the burden of protection. This principle has led to the specific formulations of the process of obtaining informed consent. The process of informed consent involves:

- a. Disclosure of the purpose of the research and the details of the procedures to which subjects will be exposed.
- b. Ensuring that potential research subjects are competent and understand the disclosed information.
- c. Ensuring that the recruitment environment supports voluntary decisions to participate or not.

2. *Beneficence*. This principle highlights the responsibility to conduct research for a purpose that advances the welfare of people, both with respect to a specific project and to the research enterprise in general. This is accomplished by carefully estimating the risks and benefits and minimizing the risks to the greatest extent possible. This principle has been

formalized as the requirement to create and examine the risk/benefit ratio before initiating a research project.

3. *Justice*. Historically, the poor and underprivileged have shouldered the majority of the risks while accruing few of the benefits of research. Justice is the responsibility to ensure that the burdens of research as well as the benefits are distributed fairly throughout society. Specifically, this principle is reflected in the way subjects are recruited.

—John P. Gluck and Charlene D. McIver

## ETHNIC CLEANSING

---

Ethnic cleansing has two central elements. It is a cultural and political project to construct particular groups of people as dirt and other groups of people as legitimate citizens. It is a military project to remove (or cleanse) the “dirt” in order to allow the “legitimate” citizens to live in an “unpolluted” territory.

People are defined as dirt through campaigns of racist hatred against them that portray them as eternally dangerous to the legitimate community. This racism asserts that they need to be removed not because of what they have done or what they may do but because of who they are. In order to expel whole populations,

it is necessary to create a state of terror. This is achieved by organized mass campaigns of murder, rape, torture, and theft. In order to have a hope of escaping alive, people will leave with what they can carry. Grandparents, the sick, families, men, women, and children—all will leave the place where they live and begin their new lives as stateless, rightless, propertyless seekers of asylum. Logically it is possible to imagine a peaceful ethnic cleansing, but in reality, ethnic cleansing is always achieved through terror.

Ethnic cleansing is a term that was first used during the wars in the former Yugoslavia in the 1990s. The leaderships of Croatia and Serbia aimed to carve out nation states whose citizens would identify with each other on the basis of shared ethnicity. The difficulty, however, was that people with Croat, Serb, and Bosnian identities also lived in interlinking and overlapping territories. The nationalist leaderships aimed to take territory by military force and then to expel those people with the “wrong” ethnicity. Bosnia, a territory with a Muslim majority and with large Croat and Serb minorities, was stuck in between Croatia and Serbia. The Croat and Serb nationalists in Bosnia were successful in taking leadership of “their” communities and, with the help of the respective mother countries, expelled more than 2 million Bosniaks from their homes and killed many tens of thousands. The Serb army and militias also ethnically cleansed much territory of Croats, and Croatia conducted a huge campaign of ethnic cleansing against Serbs, notably in the Krajina region.

Omarska, Kereterm, and Trnopolje were three of the concentration camps set up by Serb forces as part of the campaign of terror against Muslims in Bosnia. Many thousands of people were killed at these camps, and torture, humiliation, mutilation, sexual abuse, and rape were routine. There was also a network of dedicated rape camps where many thousands of Bosnian women were repeatedly abused. In July 1995, between 7,000 and 8,000 Muslim men were separated from the women and children in the town of Srebrenica and executed by Serb forces.

In Bosnia, and most strikingly in Srebrenica, ethnic cleansing was carried out under the noses of United Nations peacekeeping forces. As reports, pictures, and news footage of the terror in Bosnia went around the world, there was an increasing feeling that something must be done to help. There was also a self-interested fear among European governments that refugees expelled from the former Yugoslavia may appear on the frontiers of the European Union looking for asylum. There were many half-hearted interventions into

Yugoslavia by the “international community” that appeared to be offering protection to the Bosniaks. These interventions failed, however, because they refused to use force to prevent ethnic cleansing. By 1999, when the Serb regime turned its attention to Kosovo, there was a different response. Although the United Nations Security Council refused to authorize help because Russia would have used its veto, NATO did act. It did not risk its troops in an operation to prevent ethnic cleansing, but it did carry out a campaign of aerial bombing of Serbia and Serbian forces until the Serbian leadership agreed to allow refugees back into Kosovo under the protection of NATO troops.

Ethnic cleansing will increasingly raise questions of the possibility, advisability, and legality of interventions from outside that aim to defend those at risk. A central question to be addressed by policy makers is how the international community can ensure that states or militias are prevented from carrying out ethnic cleansing in the future. Those who argue for military humanitarian intervention to prevent ethnic cleansing are opposed by those who argue that the principle of state sovereignty is absolute. Others oppose it on the grounds that powerful states are likely to use humanitarian intervention as a cover for imperialist adventures.

Ethnic cleansing may be prosecuted as genocide or as crimes against humanity. Following the Nazi genocide of the Jews in Europe (1941–1945), perpetrators were prosecuted for crimes against humanity at Nuremberg. International humanitarian law established the principle that such crimes were so horrific that they became the business of humanity as a whole rather than of particular sovereign states. It insisted that individuals guilty of taking part in such crimes could not plead that they were obeying orders nor could they argue that their actions were legal under national law. Now they would be held legally accountable for their actions by any state or in an international court. The Genocide Convention (1948) strengthened these principles.

In 1993, the United Nations Security Council set up the International Criminal Tribunal for the former Yugoslavia (ICTY), which grew into an institution capable of prosecuting individuals for their parts in carrying out ethnic cleansing, including Slobodan Milosevic himself, the President of Serbia and the architect of the crime. A tribunal for Rwanda was set up the following year, and currently a permanent International Criminal Court (ICC) is struggling to come into existence. The current regime in the United States opposes the ICC because it fears that American soldiers may be at risk of prosecution for war crimes

and it argues that the United States constitution is more important than international law. Supporters of the ICC argue that if the constitution of the United States is upheld, then there can be no question of Americans committing war crimes.

Although the legal definition of genocide is broad enough to include ethnic cleansing, there is another sense in which ethnic cleansing and genocide may be thought of as distinct. While both involve the racist construction of the victims as unwanted and both involve mass killing and terror, the intent of ethnic cleansing is to remove the people defined as unwanted from a particular territory. The intent of genocide may be understood as a project to kill all of the unwanted people.

Ethnic cleansing is neither new nor unusual. Settler colonial states such as Australia and the United States were established through organized racist and murderous campaigns by settlers against the people who were already living in the territories. The Soviet Union as well as Nazi Germany specialized in using mass campaigns of terror to move or eradicate whole populations. "Ethnic" Germans were cleansed from Czechoslovakia following World War II. More recently there have been Russian campaigns of ethnic cleansing against Chechens, Chinese campaigns against Tibetans, and Hindu campaigns in Gujarat, India, against Muslims. Currently (2004), it is being reported that a million ethnic Africans are being burnt out of their homes in Sudan.

Benny Morris, the Israeli historian, has offered an academic justification for certain acts of ethnic cleansing. He details Israeli acts of ethnic cleansing in 1948 against Palestinians. His argument is that without the expulsion of 700,000 Palestinians it would have been impossible for the Israeli state to come into being and that the Israeli state was necessary to defend Jews from a future genocidal campaign against them. Ethnic cleansing is always presented as self-defense; defense against those who it is claimed pose the real and enduring threat.

Yet Israel is far from unique in this respect. Most nation states were established through an act or a series of acts of ethnic cleansing. Benedict Anderson understood the nation as an imagined community. Contrary to the rhetoric of all nationalists, who insist that nations are natural and timeless communities, he argues that nations are socially constructed through the shared imagining of such communal ties. This is why the first element of ethnic cleansing, the construction of the victims as not belonging, is as central to its understanding as the terror and the expulsions. Before the terror comes the imposition of identity. Before the 1990s, most Muslims in

Bosnia, and also in Chechnya, did not identify their Muslimness as the overriding and defining element of their identities. After they had been defined as Turks, invaders, fundamentalists, and terrorists by the Serbs or the Russians, after they had looked in vain to Europe and America for human rights, and after the Islamic fundamentalists arrived in Sarajevo and in Grozny offering guns, bread, and easy explanations, some people began to think of their identities differently.

Should we use the term ethnic cleansing if we do not agree that the process involves any kind of genuine cleansing? It is a term invented by the perpetrators straightforwardly to describe their project. The term is attractive because of its shocking simplicity. Contained within it is simultaneously an admission of guilt by those who use it and a defiant defense of the indefensible. It is a term that describes very clearly what it means to describe, yet perhaps we can subvert it, somehow, by using it ourselves.

## ETHNIC IDENTITY

---

In our increasingly diverse society, issues of race and ethnicity have become of utmost interest to psychologists. *Ethnic identity* refers to a person's social

identity within a larger context based on membership in a cultural or social group. Research about ethnic identity has come from various disciplines, including psychology, sociology, and anthropology and thus has been conceptualized and measured in different ways depending on the discipline. While sociologists and anthropologists have investigated group level processes related to ethnic identity, psychologists have focused more on the individual and the development of ethnic identity on the individual level.

Current conceptualizations of ethnic identity within psychological research suggest that it is a complex, multidimensional construct, with members of ethnic groups potentially varying widely in their sense of ethnic identity. Within an individual's lifetime, as he or she encounters different situations and other people, ethnic identity can change and become more or less salient for that person depending on the context. Furthermore, societal and political influences (e.g., the Civil Rights era, and increasing immigration to the United States) can play a role in the development of ethnic identity, again emphasizing the dynamic and fluid nature of this construct.

While researchers disagree on the different aspects that comprise ethnic identity, common elements have been identified across ethnic groups. First, ethnic identity includes *ethnic self-identification*, or an individual's self-label as a member of an ethnic group. Feelings of belongingness and evaluations of one's ethnic group, as well as preferences for ethnic behaviors and practices, represent *the affective components* of ethnic identity. *Cognitive components* of ethnic identity refer to an individual's knowledge about his or her ethnic group, such as cultural traditions and history. Finally, *value orientations*, which refer to cultural values associated with a group's ethnicity (such as collectivism and familism), are another important aspect of ethnic identity.

Research about ethnic identity has involved interviews, open-ended questions, and quantitative measures and questionnaires. Findings suggest that members of ethnic groups report ethnic identity to be a defining aspect of their identity. Results also suggest that for some individuals within different ethnic groups (i.e., African Americans, Asian Americans, and Latinos) ethnic identity is associated with self-esteem, though this relationship depends on the individual and ethnic group. Specifically, individuals with more positive evaluations of their ethnic group tend to have higher levels of self-esteem. This relationship is usually stronger for individuals for whom ethnicity is salient, such as members of minority groups within the United States.

Various theories have been proposed to describe the process that individuals undergo as they form their ethnic identity. One of the earliest models of racial/ethnic identity was advanced by William Cross (1971) to describe African American identity development, and this model has since been applied to other ethnic groups as well. In this conceptualization, racial identity development involves a process of four stages: pre-encounter, encounter, immersion-emersion, and internalization. During each of these stages, an individual negotiates the culture around him or her, moving from a goal of assimilating to European American culture to the final stage of possessing a secure African American identity. Janet Helms (1990) has described a model of White racial identity that is analogous to the model proposed by Cross, though it involves six stages of identity development. Finally, Jean Phinney's (1991) model of ethnic identity is based in Erikson and Marcia's psychosocial approach to development. This stage model, which has been studied within adolescents, suggests that as an individual moves from an unexamined identity to searching for an identity to identity achievement, self-concept will increase. Thus exploring the meaning of one's ethnicity often leads to a secure ethnic identity in an adolescent or young adult.

## ETHOLOGY

---

Ethology is a branch of biology that focuses on animal behavior. It originated in European zoology in

the 1930s and revolved around the study of instinctive and fixed-action patterns of behavior. Ethologists study the animal's behavior in its natural environment rather than in a laboratory. Ethology paved the way for comparative psychology. Specifically, ethologists and comparative psychologists use similar methods to study the behavior of animals, human or nonhuman. The main distinction between the two sciences is that ethology is a biological science and attempts to reduce behavior to biological and physiological characteristics whereas comparative psychology is the study of the role of learning as an explanation of behavior.

Karl von Frisch, Konrad Lorenz, and Niko Tinbergen are credited with developing ethology. They were awarded the Nobel Prize for Medicine in 1973. Although the early pioneers of ethology differed from the comparative psychologists in their views of behavior, by the 1960s the two sciences had gained mutual respect for each other's work. The 1970 article by Robert Hinde, "Animal Behaviour: A Synthesis of Ethology and Comparative Psychology," did much to further the cooperation.

### KARL VON FRISCH

Karl von Frisch was curious about the behavior of honeybees after they had found a food source. He developed a way to look inside the hive after a forager bee arrived from ingesting food. He saw the forager bee make a straight run, circle halfway around, then cross to the opposite side in a figure eight pattern. After observing the forager, the worker bees left the hive and ended up at the food site of the "dancing" bee. Von Frisch proclaimed that the dance pattern provided encoded details of the location of the food. He believed the straight line indicated the direction of the food in relationship to the sun while the speed and duration of the dance conveyed the distance to the food.

### KONRAD LORENZ

Konrad Lorenz was interested in social stimulation and motor patterns of precocial birds. Precocial birds are able to leave the nest soon after hatching. Although they are able to feed themselves, the young birds stay close to the mother. They must, therefore, become attached to the mother very soon after hatching or face the possibility of becoming separated and not surviving. Lorenz studied goslings and discovered that they would become attached to any moving object during certain times after hatching. He termed this behavior imprinting, and the

short period of time in which it developed was called the critical, or sensitive, period. He demonstrated that goslings would follow a variety of stimuli as long as it moved. For instance, the goslings became attached to a large ball, a decoy duck, and to Lorenz himself. Many introductory psychology and biology textbooks contain a photograph of Lorenz being trailed by several goslings. Imprinting is found in many species of birds including ducks, geese, chickens, quail, and turkey. Lorenz repeatedly replicated the findings that imprinting occurs only during a very short time, it occurs very rapidly, and it is irreversible.

### NIKO TINBERGEN

Niko Tinbergen was a colleague of Lorenz. He spent many hours in the field observing behavior before moving into the laboratory to study the cause and adaptive function of the behaviors. For instance, Tinbergen studied releaser mechanisms and sign stimuli of instinctive behavior. Unlike the comparative psychologists, Tinbergen believed that certain survival behaviors are innate, and he was interested in finding the mechanism that stimulated these behaviors. For instance, he found that the herring gull chick pecked on the orange spot on the parents' bill. The orange spot, termed the sign stimuli, was the releaser mechanism that stimulated pecking. The pecking, in return, provided the chick with food from the parent.

## EUTHANASIA

---

The term *euthanasia* often elicits a variety of responses from individuals. The reactions may be

related to one's understanding of what euthanasia is, one's experience with end-of-life decision making, one's religious or spiritual belief system, or any number of other factors. This review will attempt to clarify some of the definitions associated with different types of euthanasia, as well as present a historical perspective of the discourse on euthanasia in order to provide a context for the more current developments in the area. Attitudes toward euthanasia found across the major racial-ethnic groups within the United States will be explored. International perspectives on euthanasia legislation will also be discussed. Finally, some of the arguments for and against legalizing euthanasia are offered.

## TERMS AND DEFINITIONS

Before beginning a discussion on euthanasia, it is helpful to review some of the terms that are often associated with this area. *Euthanasia* is derived from the Greek words "eu" and "thanatos" which literally mean "good death." The term has come to mean bringing about a gentle and easy death. *Active euthanasia* entails an active intervention by a physician to end life. *Passive euthanasia* is deliberately withdrawing or withholding medical treatment that would help the person live longer (this may or may not involve the intention of hastening death). Examples of this are removing a feeding tube or withdrawing artificial life support interventions. *Voluntary euthanasia* is euthanasia that is performed at the request of the person who dies. *Involuntary euthanasia* is ending the life of an able person without her or his consent or against the person's will. *Nonvoluntary euthanasia* is ending the life of a person who is not able to give permission. The individual who carries out the euthanasia may do so for the other person's "best interests." *Physician-assisted suicide* is closely related to voluntary euthanasia, but the physician only prescribes rather than administers a lethal drug to the person.

## OVERVIEW OF THE HISTORICAL DISCOURSE ABOUT EUTHANASIA

Prior to World War II, perspectives on euthanasia were significantly influenced by ancient Greek practices and discourse. Euthanasia is generally understood as a hastening of one's own death and thus was often discussed in terms of suicide. Even in ancient Greece there was some disagreement about the acceptability of euthanasia and suicide. Some argued that suicide is an offense against the state and one's family. On the other hand, there also was an ideal espousing the perfect

balance between physical and mental well-being, which was used as a foundation for tolerating euthanasia. Aristotle and Plato endorsed a form of eugenics in order to ensure an optimal state with the worthiest citizens. Furthermore, in areas of ancient Greece in which the state allowed suicide, individuals who sought official permission to take their lives were supplied with poison by the local magistrate. Suicide was also an option for stoics when life was judged as not being in harmony with nature. The disharmony could be the result of illness, physical deformity, or pain. Although there was much disagreement over the acceptability of suicide and euthanasia, the ancient Greeks were perhaps the first to rationally consider the grounds for hastening death. They also suggested that in certain circumstances hastening death was indeed the most humane thing to do.

With the rise of Christianity and through the middle ages, suicide was denounced. Harsh religious and civil penalties were imposed against the body and property of the deceased. Christianity viewed that it was not an individual's privilege to decide how or when to die. That right was reserved for the will of God. With the advent of the Renaissance came the rediscovery of ancient Greek and Roman thought, as well as resurgence in scientific, empirical investigation. There was also an increased interest in facilitating a comfortable and easy death. This led to greater flexibility in thought relating to suicide, although this was primarily confined to philosophical writings.

By the 18th century, the discourse had moved away from being largely confined to the philosophical realm and flexibility in thought was observed in many segments of society. Physicians were discussing the responsibilities to their patients as far as facilitating a natural and humane death. Also, the public stigma against suicide was declining. This is evidenced by the easing of consequences levied against the family, estate, and body of an individual who died as a result of suicide. Hastening one's death was seen as more acceptable when an individual was experiencing an incurable disease or great suffering.

During the 19th century and into the early 20th century, there was increased attention to an individual's right to choose when and how to die. Further, physicians were arguing that attention needed to be given to the needs and desires of terminally ill patients who deserved to have their pain alleviated. Arguments were also made for alleviating the suffering and burden of individuals classified as "hopeless idiots," "imbeciles," and "monstrosities." These pleadings were sometimes made to legislatures in an effort to obtain

state sanction of physician-assisted hastening of death. Although these bills received a significant amount of public support, there were often as many or more opponents to them.

Up to this point, support for euthanasia existed primarily as an option for individuals who were terminally ill, as well as for individuals born mentally retarded and/or severely deformed. When legalization of euthanasia was sought, most bills had provisions for some type of a review of the request by representatives of the state, physicians, and perhaps members of the individual's family, as well as sections delineating limitations on the persons eligible to make the request. In addition to efforts to pass legislation, an increasing number of court cases relating to euthanasia or mercy killings were publicized during this period of time. The consequences for individuals who assisted in the act of euthanasia were often light, as there was mixed concern and sympathy for the individuals due to the circumstances surrounding their actions.

The word euthanasia would forever become tainted by the events that occurred in Germany prior to and during World War II. In Germany, as in other countries including the United States and Britain, the idea that a certain quality of life was not worthy of living became popular. Arguments were put forth that suggested that euthanasia was a humane way to end the suffering of individuals with physical and/or mental "handicaps," as well as alleviating the burden on their families and the state. In Germany, this policy became state sanctioned and was used as a justification for the murder of approximately 100,000 physically and/or mentally handicapped individuals. The methods used to kill these people were particularly brutal, and the actions came to light during the Nuremberg war trials. These events radically influenced the future of the discourse on euthanasia.

In the decade following World War II, there were a number of court cases in the United States involving individuals, often family members, who engaged in the "mercy killing" of someone who was terminally ill or severely disabled. There was a significant amount of public support for these individuals, and several of them were acquitted on bases such as temporary insanity. Those who were convicted of their charges were often given some measure of leniency. On the other hand, there was also significant opposition to euthanasia. Opponents often cited the slippery slope argument, stating that if euthanasia was sanctioned at any level, it could lead to the abuses experienced in Nazi Germany.

They argued that those events started from a belief that there was a life that was not worth living.

The debate continues into the present with passionate arguments on both sides. There have been developments in terms of legislation allowing for living wills and Oregon's Death with Dignity Act, which is the first legislation passed in the United States legalizing physician-assisted suicide. Distinctions have been made between active and passive euthanasia, with passive euthanasia becoming more widely accepted and discussed in terms of end-of-life decision making. In addition, language has changed so that the term is rarely used in the United States because of concern that if people associated withholding or withdrawing treatment with "euthanasia" then these actions would not be requested by people or performed by medical professionals.

### CULTURAL ISSUES RELATED TO EUTHANASIA AND END OF LIFE WITHIN THE UNITED STATES

Individuals from a variety of backgrounds live in the United States and bring with them their own set of cultural values and beliefs that influence end-of-life decision making. This section will briefly discuss differences in beliefs about end-of-life decisions and voluntary euthanasia among five of the major cultural groups in the United States, including European Americans, African Americans, Latinos, Asian Americans, and Native Americans. It is important to note that there is a great deal of heterogeneity within each of these groups. Cultural influences other than "race," including ethnicity, religious affiliation, the region in which one was raised, membership in other groups, and personal experiences with dying and death will also influence end-of-life decision making and views on voluntary euthanasia. When working with individuals from these cultural groups it is important to discuss these issues on an individual basis.

European Americans represent the dominant culture within the United States. Thus much of the mainstream values and discourse about euthanasia are reflective of western European values. These individuals, in general, view euthanasia more favorably than other groups. This is reflective of the values held as a group including a value for achievement and success, material comfort and consumerism, freedom, secular rationality, and autonomy. These values influence the desire for personal control in end-of-life decision making. Furthermore, the values of productivity and

achievement as well as material comfort may influence a greater acceptance of voluntary euthanasia.

As a group, African Americans are generally less likely than European Americans to approve of voluntary euthanasia. Additionally, as a group, they are also less likely to approve of discontinuing life-prolonging treatments. A history of racism is one factor that may influence the views of African Americans about end-of-life decisions. Because of past events, such as the Tuskegee Syphilis Study, many African Americans may experience a distrust of the institutional systems developed by the dominant European American culture, which may be compounded by the documented differences between the groups in terms of access to available health care. This distrust may also lead to a less favorable view of advanced directives and a concern about being allowed to prematurely die if life-sustaining care is not utilized to its maximum.

As a group, Latinos are more likely than African Americans to agree that there are situations in which voluntary euthanasia is acceptable, although the rate of agreement is generally lower than that of European Americans. There are certain cultural values that influence the preferences for end-of-life care for Latinos as a group. In particular, Latinos tend to have a more collectivistic rather than individualistic orientation than European Americans. There is less importance placed on individual decision making and more emphasis placed on the good of the family. There is also a value on focusing on the present rather than the past or the future. This value may hinder planning advanced directives. Finally, there may be a strong religious orientation that may prevent considering anything that may seem like "playing God" near the end of life.

Although there is a good deal of heterogeneity within each of the discussed groups, this is particularly true for Asian Americans. Individuals who come from regions with many different subcultures, languages, and values are lumped together under this label within the United States. This makes it especially difficult to make generalizations about this group. Furthermore, very little research has been performed investigating preferences for end-of-life care. These are limitations to the material presented regarding this group. In many Asian cultures there is a strong family orientation. Therefore, family members may be the ones making decisions about end-of-life care, rather than patient. In some Asian cultures, speaking of death is taboo, and so many Asian individuals may be reluctant to discuss advanced directives. There is also some evidence that

suggests that at least some subgroups of Asians are more likely to request life-sustaining interventions and are more reluctant to withdraw life support than European Americans.

Very little data exist about end-of-life preferences of Native Americans. Much of the research that exists is in the form of case studies. In addition, there are hundreds of tribes, so the same problems with generalizations mentioned in the section on Asian Americans are present here. From the limited research available, there appear to be certain values that influence end-of-life decision making for Native Americans. One example is the value of autonomy. Although Native Americans, in general, value autonomy, there is also an emphasis on cooperation and consensus; thus an individual may yield his or her own decision to the wishes of the group. Participation of cultural healers as well as the incorporation of traditional rituals and practices may also be particularly important when facing end-of-life care. More work needs to be done in order to have a more complete understanding of Native American perspectives on end-of-life care and particularly voluntary euthanasia.

## INTERNATIONAL PERSPECTIVES ON EUTHANASIA

The world's first euthanasia society was founded in London, England, in 1935. In 1976, the first international meeting of "right-to-die" groups occurred in Tokyo when representatives from six organizations gathered. Since then, the international movement has grown considerably, with the World Federation of Right-to-Die Societies being founded in 1980 with 27 groups from 18 countries; there are currently 38 member organizations representing 23 nations. Although there are efforts being made in many countries, the emphasis of this section will be on those nations where euthanasia is actually legal or being publicly practiced. The situations in Germany and Switzerland are complex regarding assistance in dying, and there is lack of clarity about the degree to which voluntary active euthanasia (VAE) versus assisted suicide is practiced; therefore, these countries will not be discussed below.

### The Netherlands

The country most associated with euthanasia is the Netherlands, because for decades this was the only place in the world where euthanasia was practiced

openly by physicians, even though it was not explicitly legal. The movement began in the early 1970s when a physician, Gertruda Potsma, gave her dying mother a lethal injection and was given a light sentence. This led to the founding of the Dutch Voluntary Euthanasia Society (referred to as NVVE) which, in 1975, began aiding members in hastening their deaths.

In 1984, the Supreme Court in the Netherlands approved of VAE under certain circumstances and indicated that if a set of guidelines and procedures was met, physicians would not be prosecuted. In 1994, the Dutch parliament formalized the procedures but kept VAE as a criminal offense. The guidelines, based on recommendations from the Royal Dutch Medical Association, stated that a person could receive VAE if (a) the person makes an explicit request; (b) the decision is well-informed, free from coercion, and enduring; (c) there is no alternative acceptable to the person to alleviate suffering; (d) the attending physician exercises due care in deciding to agree to assist and consults with another physician (who must meet personally with the person); (e) a physician is the one to administer the medication; and (f) the physician reports the death to the medical examiner, who then reports to the local district attorney. Prosecutions would happen only if the guidelines were not followed.

In November 2000, the Lower House of the Dutch Parliament approved a bill allowing VAE and assisted suicide; the Upper House approved the bill in April 2001 but it was not to go into effect until April 1, 2002. The previous guidelines were kept in place with the “due care” aspect being clarified. To meet the due care requirements, the physician must (a) be convinced the decision is voluntary and well considered, (b) be convinced that the person is facing interminable and unendurable suffering, (c) have informed the person about the diagnosis and prognosis, and (d) be convinced that there is no other reasonable solution (and the person requesting VAE must also be convinced of this). Consultation must still take place. Five regional review committees, comprising, at a minimum, a legal expert, a physician, and an expert in ethics or philosophy, review the case to determine if the criteria are met; however, the public prosecutor has the authority to further investigate deaths.

One of the most controversial parts of the bill that was passed was the age of eligibility. After much discussion, it was decided that children aged 16 or 17 could receive VAE or assisted suicide if their parents

are involved in the decision-making process, while those aged 12 to 15 would need parental consent.

It is estimated that approximately 3,500 deaths a year result from VAE, which corresponds to about 2.6% of all the deaths in a given year in the Netherlands.

## Australia

In May 1995, the Northern Territory of Australia became the first place where a legislature passed a law allowing VAE, called the “Rights of the Terminally Ill Act.” The law was amended in February 1996 and put into effect in July 1996; however, because the territory is not considered independent, the Australian Federal Parliament had the ability to vote to rescind the Act and did so in March 1997. Prior to this action by the Parliament, the Act survived two court challenges and a legislative effort to repeal it within the Northern Territory itself.

Before it was rescinded, the amended Act required the person seeking VAE to consult with four physicians—one who would help the person die, a specialist in the person’s disease, a psychiatrist, and a palliative care specialist—and get the first three to sign a request form. The first person to try to use the Act, Max Bell, could not get a signature from a cancer specialist; Bob Dent, who had prostate cancer and died on September 22, 1996, was technically the first person to die under a voluntary euthanasia law. Three others, all patients of Philip Nitschke, did use the Act to hasten their deaths; two others had obtained all the signatures necessary but were unable to use the Act before Parliament acted.

## Belgium

In September 2002, Belgium passed a law similar to the one in the Netherlands. The first report of implementation of the law came from the Federal Commission of Control on Euthanasia in 2004.

## Colombia

In 1997, the Colombian Constitutional Court (the highest court in the country) ruled that it was not a crime to assist a terminally ill person who has given informed consent to die. However, although the Court ruled that VAE is constitutional, the country’s Parliament has not yet developed legal regulations or attempted to amend the constitution to overrule the Court.

## ARGUMENTS FOR AND AGAINST VOLUNTARY ACTIVE EUTHANASIA

Thus far, this entry has focused on the *facts* of euthanasia in the United States and internationally. At this point, it is necessary to outline some of the major arguments for and against VAE as an acceptable practice; as will be made clear, these are based on *opinions* and interpretations of the facts. Entire books have been written arguing either side of the debate, and thus this material is merely a brief review of the points made by proponents and opponents.

### ARGUMENTS IN OPPOSITION TO VAE

*Coercion.* There is significant concern that people may not be making free, fully informed choices. The possibility that people may be coerced into “choosing” VAE, especially because of financial issues or the feeling that they are a burden, is a strong argument against VAE.

*Religious beliefs.* A large number of people believe that only a Higher Power can give life and end it. In fact, religious beliefs are the strongest predictor of opposition to VAE. A related belief is that suffering can have meaning and value to the person and his or her loved ones.

*Slippery slope.* Another concern is that VAE will lead to involuntary euthanasia in general as well as for a larger group of people than would have “qualified” for VAE. This may happen both as a result of losing control as well as habituation to the practice of euthanasia.

*Unnecessary.* This argument is that most people can have their symptoms, especially pain, controlled through the use of hospice and palliative care efforts, thus there is no need to have VAE. A related concern is that allowing VAE would reduce interest in improving palliative care.

### ARGUMENTS IN SUPPORT OF VAE

*Already happening.* The basic idea here is that VAE is already happening, so by legalizing it and bringing it into the open it can be better regulated and problems can be minimized. The argument is supported by the fact that there already exist legal actions very similar to VAE.

*Autonomy.* The most commonly heard argument in support of VAE is that people have the right to decide for themselves the degree to which they want to have power over how and when they die. This is often phrased as “choice” or “self-determination” but ultimately it is about control.

*Just one option of many.* Related to the autonomy argument, this contention is that allowing VAE does not eliminate other options, it merely adds another to the list. Thus, a person could choose VAE or not, but at least it would be available for those who might want it legally.

*Quality of life.* This argument asserts that there is more involved than pain (and even it cannot be completely managed), there are other symptoms that cannot be controlled, there are personal perceptions of dignity, and the basic idea is that quality is preferred over quantity.

## CONCLUSION

There are many forms of euthanasia, some of which are more practiced and more acceptable than others. Although significant attention has been given to euthanasia in a few countries, it is likely that interest in, and attention to, euthanasia will continue to grow wherever technology has advanced to the point where people perceive that they may be kept alive even though their lives have no meaning to them or they are suffering greatly. However, the fact that interest in euthanasia may be present does not mean that legalization is necessarily a good idea or that it is the best option for a given individual.

## EXECUTIVE FUNCTIONING

---

As we grow, our brain continues to develop through adolescence. We know that while different areas in the brain are associated with various abilities, it is with the frontal lobes, located in the newest, outer layer of the brain and which Dr. Elkhonon Goldberg, a leading expert in the field, describes as the instrument, and the agent of control within the central nervous system (CNS), that executive function is most often linked.

Executive function can be conceptualized from a variety of perspectives. Generally there is agreement that executive function includes some degree of cognitive abilities that assists us in engaging in behaviors that are directed toward achieving complex goals. In addition, adaptability to changes and demands within the environment is critical. Other definitions might include (1) the ability to anticipate and plan outcomes, (2) the ability to monitor one's own behavior for desirability or suitability in a given situation, (3) the ability to determine effectiveness of how we solve problems, and (4) the ability to allocate attention.

The frontal lobes, or prefrontal cortex, play a specialized role in orchestrating other brain areas. However, to do so, the prefrontal cortex receives input from many other cortical areas. This synergistic relationship suggests that the prefrontal cortex is dependent on other brain regions for input. To operate to the optimum, the information shared between brain regions must be of good quality.

For many decades, early neuropsychology thought that prefrontal functions did not emerge until late childhood or early adolescence. Due to the prevalence of this thinking, our understanding of the development of executive functions is more recent than our understanding of other cortical areas. A number of various methodological approaches have been used to add to our understanding of how the frontal lobes, hence executive functions, develop. Recent evidence linking CNS maturation and cognitive development provides a framework for understanding brain-behavior relationships through childhood. The frontal lobe seems to develop in growth spurts. Current research in this area suggests that the basic executive functions develop early in life and follow a stepwise progression to maturity in adulthood. Improvement in executive functions appears to be orderly coinciding with these growth spurts. Some experts place the first of these

growth spurts in the frontal regions between birth and 2 years of age. A second growth spurt occurs between 6 and 7 years of age. Welsh asserts through his research that the ability to resist distraction matures at around age 6. Various researchers identify that additional growth spurts occur at about 10 to 12 years of age, followed by spurts in the later teen years.

As children grow and develop, they are better able to regulate their behavior. The ability to plan, set goals, and respond to their environment becomes the basis for behavioral choices that are mediated or regulated by the prefrontal cortex. We may think of executive function, then, as the component that directs attention, monitors and/or regulates activity, and coordinates and integrates information and activity. Goldberg recognizes that the capacity for volitional control over one's actions is not innate, but it emerges gradually through development (Goldberg, 2001).

Let us consider that the difference between the time knowledge starts versus knowledge-based action or behavior appears to be an expression of the development of prefrontal executive function. As a result of her experiments, Baillargeon and her colleagues have demonstrated that infants have knowledge of object permanence—the knowledge that an object continues to exist even though it is no longer present in the immediate environment—months before they are able to utilize that knowledge to guide goal-directed search behavior. Almost certainly the maturation of executive and other systems in the prefrontal cortex between 4 and 9 months of age is necessary for this goal-directed behavior to occur.

Maturation of executive functions is crucial to psychological adaptation and adjustment across the life span. Dealing with the inherent ambiguity is among the chief functions of the frontal lobes. As the individual develops, executive planning involves complicated, means-end problem solving to achieve a behavioral goal and the ability to delay a response. Executive processes required for success in an interactive social environment are much more complex and wrought with ambiguity than the executive processes required when individuals have only themselves to consider.

—D. Tighe Cooke

---

## EXERCISE

---

Exercise is commonly associated with aerobic activity or sustained activity over a period of time that utilizes and strengthens the cardiovascular and pulmonary systems. Aerobic exercise involves repetitive movement of large muscle groups and increased respiration rate. Anaerobic exercise, in contrast, generally involves short duration movements of smaller muscle groups and strength-training exercise, helping to increase muscle mass and build and maintain healthy bones. In the following discussion, the terms physical exercise and physical activity will be used interchangeably to refer to the effects of both aerobic and anaerobic exercise.

### CURRENT RECOMMENDATIONS FOR EXERCISE

The Centers for Disease Control and Prevention (CDC) and the American College of Sports Medicine (ACSM) have provided exercise recommendations for all age groups. Current recommendations focus on healthy, active lifestyles rather than the previous recommendations focusing only on cardiovascular fitness. This is due to recent evidence suggesting that moderate amounts of exercise may contribute to improvements in health and that vigorous exercise is not essential for health enhancement. The CDC recommends that adults engage in at least 30 minutes of moderate intensity exercise (e.g., walking briskly, swimming, or dancing) at least 5 days a week or vigorous activity (e.g., jogging, swimming laps, or high impact aerobics) 3 days a week for 20 minutes. In addition, the CDC recommends that older adults engage in moderate intensity exercise for 30 minutes, 3 to 5 days per week, and also recommends

strength training 3 days per week to help increase muscle tone and prevent falls. To further encourage people to increase their activity levels and to recognize their current level of activity, many different activities are provided by the CDC as examples of moderate activity, such as gardening, heavy cleaning, walking, and jogging. The guidelines recommend daily physical activity for adolescents, with moderate to vigorous exercise for at least 20 minutes, 3 days a week. The recommendation for children is 30 to 60 minutes of physical activity or accumulated play on all or most days of the week.

### DEMOGRAPHICS

In the United States, less than 40% of adults achieve the recommended amounts of exercise and 25% of adults are not at all active. Participation in regular exercise decreases with age and is more common among men than women. One third of older adults age 65 and older are completely sedentary and engage in no regular exercise. People who exercise regularly are more likely to have higher income, more education, and are more likely to be Caucasian.

Exercise patterns are similar for adolescents and younger adults. Nearly 50% of individuals aged 12 to 21 do not engage in regular vigorous exercise. Exercise activity decreases with age from childhood through adolescence. Exercise levels are greater among young men than young women.

### AGE SPECIFIC BENEFITS

#### Children and Young Adults

Among children, regular physical exercise has many physical, social, and psychological benefits. During the years of physical growth, regular exercise helps to build strong, healthy bones and protects against the development of osteoporosis. Regular exercise also builds more lean muscle while helping prevent obesity.

Among young adults and children, there is a relationship between engaging in regular physical activity and engaging in other healthy behaviors, such as maintaining a healthy diet. Young adults who are inactive tend to eat fewer fruits and vegetables. In addition, young adults who engage in regular exercise may be less likely to engage in risky behaviors, such as using alcohol and drugs, and may be more likely to stay in school. Research has suggested that regular

exercise may lead to an increased capacity for learning in children and adolescents, which may, in turn, improve academic performance.

Regular physical exercise also has been found to promote social interaction and psychological well-being, in particular self-esteem. Physical activity in the form of sports participation provides an opportunity for young adults and children to learn about and experience teamwork, self-discipline, leadership, and socialization.

Interventions have been developed to promote regular physical exercise among children and young adults in an effort to help build healthy habits that will last through adulthood. Factors that predict future physical activity among children and adolescents include male gender, intent to be active, a preference for activity, healthy diet, previous physical activity, access to programs or facilities, and time spent outdoors.

## Adults

Regular exercise in adulthood helps to prevent chronic illness and premature death and also helps moderate the effects of stress on the body. Stress is associated with the release of hormones such as adrenaline and cortisol. In the case of an acute stressor, the release of these hormones is adaptive, mobilizing the body for action. However, if the stress is chronic in nature, the hormone response may not be adaptive and can contribute to health problems, including immune dysfunction. Stress also may increase cardiovascular reactivity, as reflected by exaggerated blood pressure and heart rate response following the onset of a stressor, and delayed recovery time following the stressor before heart rate and blood pressure return to resting levels.

Regular physical activity may be an effective tool for stress management and can help to reduce the effects of chronic stress on the body by aiding in the regulation of adrenaline and cortisol, regulating immune system functioning, and reducing cardiovascular reactivity. Regular physical exercise may increase immune activation, thus helping to prevent illnesses, both acute and chronic. Research has suggested that the release of endogenous opioids, or natural pain inhibitors, during exercise also may help to modulate immune activity. Among individuals with chronic conditions, such as hypertension or type II diabetes, regular exercise may decrease the need for medication to control the condition.

Regular physical exercise may reduce symptoms of depression or anxiety disorders in adults. Research has shown that regular physical exercise is associated with as much symptom relief as medication or combination of medication and psychological treatment. In addition, depressed individuals who maintain regular exercise show a decreased chance of relapse as compared with medication or combined treatment. Regular physical exercise can also improve self-efficacy, which may improve mood as well. Regular physical exercise in a group setting provides additional social support and may increase the likelihood that the exercise program will be maintained.

Due to the large number of benefits of exercise, many research studies have explored various intervention strategies designed to increase exercise adherence. Cognitive-behavioral strategies have been used, including contingency contracting, self-monitoring, and goal setting, but have met with only limited success. Other strategies that have been utilized include techniques to maintain behavioral change, such as reminder phone calls, and relapse prevention techniques, such as increasing awareness of obstacles and developing adaptive coping techniques. One reason that intervention strategies have had only limited success may be that they need to be individualized to promote and maintain exercise according to the respondent's stage of change.

## Older Adults

Among older adults, regular exercise helps to maintain healthy bone mass and reduce the risk of fractures and the risk of falling. Exercise may also improve the ability of older adults to live and function independently and may allow older adults to maintain cognitive skills that otherwise show decline with age. Older adults who engage in regular physical activity may show better performance on measures of executive functioning, verbal fluency, and memory, for example. In addition, imaging studies show that aerobic exercise may protect against age-related brain atrophy, particularly atrophy in the prefrontal cortex.

## GENERAL BENEFITS OF EXERCISE ACROSS THE LIFE SPAN

Health benefits of regular physical exercise include a decreased risk of premature mortality and a decreased risk of developing chronic medical conditions, including

type II diabetes, heart disease, high blood pressure, and colon cancer. Regular exercise helps build and maintain healthy bones, muscles, and joints. Exercise also aids older adults in increasing strength, preventing osteoporosis, and reducing risks of falling.

Another benefit of exercise across age groups is the prevention and treatment of obesity. The consequences of obesity for physical health include increased mortality and increased risk of chronic illnesses such as cardiovascular disease, type II diabetes, osteoarthritis, and asthma. Consequences of obesity for psychological health include depression and social stigmatization. Obesity rates are rising across the country in both children and adults. Nearly 61% of adults are either overweight or obese, with a body mass index (BMI, or weight in kg/(height in m)<sup>2</sup>) greater than or equal to 30. Rates of obesity have nearly tripled for children over the past 30 years, from about 5% to about 15%. The demographic pattern of obesity and overweight is consistent with that of regular exercise, as obesity is more common among individuals with lower socioeconomic status (SES) and exercise is more common among higher SES levels. Therefore, one important benefit of regular exercise is to help promote and maintain healthy weight.

## SUMMARY

Regular physical exercise is associated with various physical and psychological benefits among all age groups. Physical benefits include building and maintaining healthy bones and muscles, promoting healthy cardiovascular and pulmonary functioning, regulating body weight, and preventing chronic illness and premature mortality. Regular physical exercise is also associated with reduced feelings of depression and anxiety, improved capacity for coping with stress, and enhanced psychological well-being.

## EXPERIMENT

---

An experiment is a scientific study designed to uncover information about cause and effect through examining the influence of changes in some variable or condition on a measured outcome. In a true experiment, changes in one or more independent variables are tested and the resulting effects on one or more dependent variables are assessed. For example, researchers interested in whether training strategies can help children's memory performance might design an experiment in which they manipulate the type of strategy that is trained and then measure the resulting effects of that manipulation on an outcome measure, such as accuracy of memory performance after the training.

Experiments require some comparison of the effects of the independent variable on the dependent variable. Often one of those treatments functions as a *control* condition. The control condition might be one in which no effect is expected. For example, if studying training strategies for memory performance in children, one might compare a group of children who received explicit training on a strategy with a group of children who received no training. The adequacy of the control condition is important to evaluate. In this example, perhaps a better control condition would be a group of children who received some other treatment that had nothing to do with memory strategy, but gave them the same time and attention that the memory strategy group received.

In an experiment, an independent variable may be a variable that the researcher manipulates, such as the

comparison of various treatment conditions. An independent variable may also be a group difference that the researcher intends to investigate, such as gender or age. These variables are sometimes called *quasi-independent* variables because, although they cannot be randomly assigned, they function as independent variables in the design of the experiment.

The selection of the sample to be tested is an important feature of an experiment. If two or more treatment conditions are to be tested in different groups of people, one strategy used in order to avoid bias is to consider the entire group to be tested and then randomly assign participants from that group to one of the treatment conditions. Any resulting differences between the groups in the outcome of the study can then be attributed to the treatment differences, although it should be noted that there are always potential sources of error in an experiment, such as differences in the groups before the treatment, despite random assignment, or measurement error in the dependent variable.

Nonetheless, random assignment to conditions is a good strategy for experimental designs.

The adequacy of the dependent variable is another important factor in experiments. Does the dependent variable measure what the research intended it to measure, that is, does it have *validity*? And does the dependent variable have reliability, that is, is it a consistent measure of what the researcher intended it to measure?

There are various kinds of experimental designs. For example, an experiment may use comparisons between people in different groups that have been tested with different treatments. This is a *between-subjects* design. Another type of experiment might test one group of people in several conditions and compare the effects of conditions. This is a *within-subjects* design. In research on human development, some studies test the same group of people at different ages in order to assess changes that occur with age. This is a *longitudinal* design. Other studies test different age groups in order to draw inferences about changes that occur with age. This is a *cross-sectional* design.

The opportunity to draw inferences about cause and effect is important in scientific reasoning. Some studies are not true experiments because they do not measure such cause-and-effect influences of independent variables on dependent variables. For example, suppose that a group of high school students' participation in extracurricular activities is measured, and

data from those students are split into two groups, based on whether the student's grade point average (GPA) was high or low. Perhaps the number of extracurricular activities would be greater for the high-GPA than for the low-GPA group. Would it be correct to conclude that GPA *caused* differences in extracurricular activity? No. In this hypothetical example, we can describe a relation between GPA and extracurricular participation, but cannot demonstrate causality. Such studies may be legitimate and informative, but they are not true experiments.

Experiments with human participants and experiments with animal participants are subject to ethical guidelines.

—Marie T. Balaban

## EXPERIMENTAL GROUP

---

To understand the function of an experimental group, one must first know what an experiment is, since that is the context in which experimental groups are found. An experiment is one of the techniques available to researchers in their study of human development. This research method attempts to determine the effect of one (or more) events or treatments on the behaviors of individuals. It accomplishes this by creating two or more equivalent groups of individuals and treating them exactly the same in all ways except for the event or treatment whose effect is being tested. If, after one group has received the treatment or experienced the event, there are now measurable differences between that group and the other(s), those differences are presumed to be due to the event or treatment.

The *experimental group* refers to the individuals who receive the treatment or experience the event that

is of interest to the researcher. The group of research participants that does not receive the treatment is called the *control group*. The treatment or event that is manipulated is termed the *independent variable*, and the participants' responses are the *dependent variable*.

To serve as an example, suppose a researcher is interested in the effects of watching television violence on children's subsequent aggressive behavior. The independent variable is TV violence, and the dependent variable is some measure of the children's aggression, perhaps the number of kicks or punches displayed against an inflatable doll during a 1-hour period. To create an experimental group, the researcher may have several children watch a 30-minute video that includes several episodes of violent acts. The researcher may have a control group of children watch a nonviolent video. The aggressive behaviors of both groups of children would then be observed and recorded, and the researcher would test whether the experimental and control groups differed in a significant way.

Many experiments employ more than one experimental group. For example, if a researcher is interested in what type of TV violence has the greatest influence on aggression, the researcher may have one group of children watch cartoon violence, a second group watch sports violence, and a third watch violence between human actors. A control group may still be included that would serve as a comparison for all three experimental groups.

Experimental and control groups are created to provide a comparison. Turning to our example again, we may find that subjects who watch a 30-minute violent video go on to display an average of 4.5 aggressive behaviors during that next hour. Only by including a control group of children who did not watch a violent video, and finding that they exhibited an average of 1.2 (or 8.9 or 4.6) violent behaviors during the next hour can we infer that the video increased (or decreased or had no effect on) children's subsequent aggressive behavior.

It is critical that experimental and control groups be as equivalent as possible before the independent variable is manipulated. The preferred method for achieving equivalence is to randomly assign individuals into groups. In our example, that would mean making sure that each child had the same probability of being assigned to watch the violent video or nonviolent video. If children are allowed to decide for themselves which video they watch, it may turn out

that children who choose to watch the violent video are more aggressive to begin with.

The experiment is considered the best research method available for inferring cause and effect. Observing naturally occurring behaviors is an effective descriptive technique. But it is the intentional assignment of subjects into equivalent experimental and control groups that makes causal inference possible.

—Jack L. Powell

---

## EXPERIMENTAL METHOD

---

Experimental method is a method in which a variable (independent variable that is hypothesized as a cause; IV) is manipulated by an experimenter and the corresponding change in another variable (dependent variable that is hypothesized as an effect; DV) is observed. To determine whether the change in the DV is caused by the IV, at least two groups are involved: a control group and an experimental group. The two groups are assumed to be identical in all respects except that the control group does not receive the treatment of the IV whereas the experimental group receives the treatment. In reality, no two groups are exactly identical. Therefore, to ensure both groups are identical except for the treatment or experimental manipulation of the IV, all participants are randomly assigned to either the control or experimental group(s). As a result, any innate differences between the members of the two groups are equally distributed.

As an example, consider a hypothetical study investigating the effect of violent TV programs on the

behavior of children. The researcher first randomly assigns a group of children to either an experimental or control group, and then shows a violent TV program to children in the experimental group and a neutral program to children in the control group. After viewing their programs, the children are allowed to play in a room with other children and observed. As a result, children in the experimental condition may exhibit more aggressive behavior than children in the control group. Given the use of a control group and an experimental group, and the random assignment of children to each condition, the researcher may be able to infer that the violent TV program caused aggression among the children since they only differed in the type of program they watched.

Experimental methods facilitate making causal inferences easier. In a well-designed experiment, the relationship between the IV and DV is clear. The experimental method can isolate the relationship among variables, which occurs in a complex environment and is often unobservable. As in the example, the effect of violent TV programs is not easily observed in real settings. By controlling all of the other variables involved, a well-designed experiment makes it possible to discern the relationship between the IV(s) and DV(s). By doing so, experiments can provide grounds for further scientific investigation. In other situations, the relationship between any two variables is weak. Because experimenters can have a lot of control in an experiment, they may maximize the magnitude of the manipulation and thereby have higher power to detect the relationship. In these scenarios, the major concern of the experimenter is the existence of the relationship. Especially at an exploratory step, this kind of evidence may provide a clue as to whether further investigation is warranted.

The experimental method is not without its shortcomings. First of all, its major advantage can often be a disadvantage. An experimenter's control over many aspects of the experiment often makes it hard to generalize the results to other situations. Therefore, the size of the effect in an experiment may not be observed in reality or in other studies. This is intensified because many variables are intertwined with other variables. In this sense, experiments are much simpler than reality. Experimenters may try to include more variables in the design to increase the generalizability of the results; however, often the inclusion of additional variables poses a challenge to experimenters. Experiments typically require more time and effort for each participant. This might be a part of

the reason why experiments are not used to collect longitudinal data. Maintaining control over participants for long periods of time may cause ethical issues, and may even be impossible.

## **EXTENDED FAMILY**

---

Most Americans live in nuclear families, which consist of parent(s) and unmarried children, or simply two adults related by marriage or equivalent partnership. At the same time, most Americans recognize other family members outside their nuclear families. They may be grandparents, uncles and aunts, married siblings, cousins, nephews and nieces, married children, grandchildren, or in-laws. Any family member outside one's nuclear family is called an extended family member.

Yet some Americans, often racial/ethnic minority members, share their households with extended family members. These households are called extended family households. When we examine extended family, therefore, we have to distinguish between extended family members (kins) and extended family households.

While whether or not one lives with extended family members in the same household is a structural question, we also have to examine the nature of the interaction between extended family members. They may help each other in everyday chores, economic aspects, and psychological well-being. Conversely, they may be a source of stress, due to personality conflict, economic burden, or inheritance issues. Therefore, we need to

discuss interactional/functional aspects of extended family as well.

I will examine functional/interactional issues of the extended family first, followed by structural issues.

## EXTENDED FAMILY MEMBERS OUTSIDE THE HOUSEHOLD

Extended family members may get together for holidays or weddings, but otherwise, each nuclear family is quite isolated in everyday life; that's what social scientists believed. When data were first collected from American families several decades ago, however, the results were surprising. Most Americans are in close contact with extended kin, particularly their elderly parents. One research study indicates that as many as 78% of elderly people who do not live with any of their children saw at least one of them in the past week. The proportion was similar in other industrialized countries such as Denmark and Great Britain.

Extended kin also get together for holidays, birthdays, vacations, weddings, and funerals. Even if extended kin live far away, contacts are often made through phone calls, e-mails, and/or letters. In other words, in fully industrialized societies where most people live in nuclear family households, extended kinship network is alive and well. This kinship network is often called *modified extended family structure*.

This modified extended family structure exists in contemporary societies because it serves certain functions. Although each household is supposed to be, and usually is, a self-sufficient unit, it is often necessary to exchange help with extended kin who do not live in the same household.

This support may be economic. Relatively well-to-do parents may rent their residential property for a less-than-market value to their married children. An adult child may financially support his or her elderly parents who are in a nursing home. Retired parents often assist their adult children with child care, free of charge. Adult children may help their parents in everyday chores, personal cares, or transportations, all of which may be substituted by hired services.

Emotional functions provided by extended kin are important as well. Checking up on each other through visits and phone calls provides emotional support, particularly in times of hardship such as illness, death of a family member, family problems, or economic downturn. Even without any hardship, regular contacts by extended kins including visits, phone calls, e-mails, and letters often help stabilize one's emotions.

Modified extended family structure is alive and well because of these functions it provides.

Dealing with extended kins, however, is not always a pleasant experience. Elderly parents may want to interfere with how the children are raised. An adult sibling may keep asking for economic assistance. Married children may cause constant heartaches by getting into trouble with drugs. Friction with in-laws is a well-known source of tension.

Like it or not, we feel a certain degree of obligation to deal with our extended kins. This sense of obligation differs from one individual to another, within each family, and within one's ethnic/racial group. We will revisit this point. In the next section, I will examine structural aspects of extended family, more specifically, extended family households.

## EXTENDED FAMILY HOUSEHOLDS

Approximately 10% to 15% of family households in the United States are extended family households. This percentage, however, is for a particular time period (called cross-sectional data). If you ask, "Have you ever lived in an extended family household?" the proportion would be much higher. This is because each household expands and contracts depending on demographic phenomena such as marriage, birth, and death.

The same is true for historical data on extended family households. While many societies held extended family household as a normative (i.e., desirable) household type, this does not necessarily assure its prevalence. People simply did not live long enough to see their children marry to someone and have their own offspring. Even when someone survived long enough to live with his or her child-in-law or grandchildren, the life span of this extended family household was usually short, so that it may not be recorded in family registry records, etc., making the proportion of extended family households appear smaller.

Thus, whether or not extended family households are formed depends on the demographic force involving that particular household. As is discussed below, extended family household formation also depends on the cultural and economic forces surrounding the household.

## RACIAL AND ETHNIC VARIATION: CULTURE OR ECONOMY

Early sociologists argued that nuclear family households are better suited in industrialized societies. To

**Figure 1** Distribution of Household Types for Each Racial/Ethnic Group

SOURCE: From “Racial and ethnic differences in extended family households,” by Y. Kamo, 2000, *Sociological Perspectives*, 43, 211–229. Copyright © 2000, reprinted with permission of the University of California Press.

live competitively in industrialized societies one often has to move to wherever the new job is located. Extended family households are ill-suited for this, they argued. In many industrialized countries in Asia (i.e., Japan, Korea, and Taiwan), however, there still are many extended family households.

The prevalence of extended family households in certain countries is in part attributed to prolonging life expectancy. The female life expectancy in Japan in 2001 was, for example, 84.93 years, compared with 43.20 years in 1921–1925 (for 5 years combined). A society that has more elderly people is more likely to have a larger proportion of extended family households.

Nevertheless, this demographic force is only part of the story. The prevalence of extended family households in some countries is mostly due to their cultural factors or social norms. Most Asian countries share a Chinese tradition of Confucianism, which emphasizes respecting the elderly and taking good care of elderly parents whether

they can live independently or not (filial responsibility). A typical family norm states that the oldest son lives with his parents for his entire life, taking care of them if or when they become frail or sick.

We have another interesting example of the cultural effect on extended family households in the United States among racial/ethnic minorities. It is natural to expect that Asian immigrants in the United States carried the social norm of their home country regarding family relationship and filial responsibility with them. A recent research study based on 1990 U.S. Census data tells us that Asian immigrants and their offspring are more than twice as likely to live in extended family households than non-Hispanic White Americans (22% vs. 9%; see Figure 1). More specifically, their typical extended family household is composed of the head of household, his wife and children, and his parents. Since this type of household extends

upward from the head of the household, we call this *upwardly extended family household*. Since Asian Americans do not have much longer life expectancy or smaller average income than their non-Hispanic White counterparts, we cannot attribute this racial difference to demographic or economic forces. It is found that those Asians born in the United States are less likely to live in extended family households than those who were born in their home country. This indicates that the cultural force is at least partly responsible for this ethnic uniqueness.

When you examine two other racial/ethnic groups, Hispanic Americans and African Americans, an interesting pattern emerges. First of all, the percentages of extended family households are much higher among both minority groups than among non-Hispanic Whites: 24% among Hispanic Americans and 23% among African Americans, compared with 9% among non-Hispanic Whites (Figure 1).

More specifically, however, extended family households among African Americans are most likely to be downwardly extended (head of household lives with a child-in-law or grandchildren) and those among Hispanic Americans horizontally extended (head of household lives with siblings). This is in contrast to Asian Americans. Similar to Asians' filial responsibility, Mexicans have been long known to honor the idea of "familism," which places priority on the entire family's welfare over individual members' benefits. This cultural norm is undoubtedly related to the prevalence of extended family households. Those who have come to the United States are typically young and haven't established their own households. When they depend on their previously immigrated siblings in residence, we see the formation of a horizontally extended household.

African Americans are also known to have a strong intergenerational tie, often through the maternal line. When a daughter marries or becomes a mother early, she often depends on her parents by living with them, forming a downwardly extended family household. Difficult economic circumstances among young African Americans and a strong intergenerational tie both make this pattern prevalent among them.

Extended family can be examined upon either its functional/interactional significance or its structural characteristics. For the latter, we pay attention not only to demographic but also economic and cultural factors surrounding that particular family, as shown in racial/ethnic variations in the United States.

## EXTINCTION

Extinction is a reductive procedure used to decrease the occurrence of a given behavior. Specifically, extinction involves withholding reinforcement for a behavior that previously received reinforcement. For example, consider the case of a teacher who falls into the habit of laughing at students' jokes. The teacher is reinforcing "joking" behavior by providing positive teacher attention contingent upon the presence of a joke. Extinction occurs when the teacher no longer laughs or responds to students' jokes.

If extinction procedures are implemented consistently, the rate of the target behavior will decrease compared to baseline, or pre-intervention levels, meaning students will make jokes less often if the teacher does not laugh at the jokes.

There are four key features of extinction procedures. First, it is necessary to identify all reinforcers for the target behavior so that all sources of reinforcement (e.g., teacher and peer attention) can be removed. Extinction requires all sources of reinforcement to be withheld when the target behavior occurs. Sources of reinforcement can be determined via direct observations. The intent of these observations is twofold. One purpose is to identify circumstances or events that may set the stage for the target behavior to occur (antecedents). Another purpose is to identify circumstances and events that follow target behavior (consequences) to promote the occurrence of the target behavior. By analyzing the antecedents and consequences associated with the target behavior, it is possible to determine the conditions that are reinforcing the target behavior.

Second, it is important to specify the circumstances when extinction procedures will be employed. The goal is to make sure that all parties (e.g., teachers, students, and parents) are clear about when and if the target behavior is acceptable and the consequences associated with violating the expectations. For example, the teacher would need to talk to the students to let them know that the joking around is interfering with instruction and learning. Therefore, jokes are no longer going to be acceptable during instructional time, but they will be allowed during free-time activities on Fridays. If joking does occur at other times, a negative consequence (e.g., time out or a note home) will take place.

Next, all reinforcement must be eliminated when the target behavior does occur. For example, it is

imperative that neither the teacher nor the students laugh at jokes that are told during instructional time. However, it is fine to respond during free-time activities on Fridays. If reinforcement is occasionally given during instructional time, this is called intermittent reinforcement. Intermittent reinforcement is actually a technique used to sustain a given target behavior. Therefore, consistency is critical. Further, the extinction intervention is not a quick procedure. Consequently, teachers and other professionals must be prepared to continue with the intervention for a reasonable length of time. Before the target behavior is eliminated, an extinction burst is likely to occur. This means that the rate or intensity of the target behavior will likely increase substantially before it gradually declines.

Finally, one should consider using other procedures to teach more appropriate behaviors that are functionally equivalent to the target behavior (e.g., reinforcement techniques). Although extinction, if implemented as intended, is likely to decrease the target behavior, it does not teach students a functionally equivalent replacement behavior. However, other techniques such as differential reinforcement procedures can be used in conjunction with extinction to teach more desirable replacement behaviors.

While extinction is an effective tool for producing lasting decreases in behavior without using more aversive reductive procedures such as punishment (introducing an aversive stimulus when the target behavior occurs), extinction procedures are characterized by a number of limitations. As previously mentioned, extinction takes time to occur and behavior often worsens before it improves (extinction burst). In addition to these limitations, extinction procedures are often associated with (a) a surge of aggressive behavior due to frustration (extinction-induced aggression), (b) imitation of the target behavior by peers, (c) spontaneous reoccurrence of the target behavior (spontaneous recovery or resurgence), (d) limited generalizability to other settings, and (e) difficulty in controlling all sources of reinforcement (e.g., peer attention).

## EXTRAMARITAL SEX

---

Alfred Kinsey sent shockwaves through American society in 1948 when he reported that about half of all married men had sex with someone other than their wives during their married life. In 1953, Kinsey reported that about a quarter of women had extramarital sex by their 40s. Although Kinsey's sampling methods have been questioned, other contemporary studies of marital adjustment indicated similar rates. More recently, the representative General Social Survey conducted by the National Opinion Research Center (NORC) has estimated that 21.5% of men and 12% of women have had extramarital sex, based on surveys in 1991, 1993, 1994, 1996, and 1998. These studies estimate that 5% of men and 2% of women have extramarital sex in a given year. The 1992 National Health and Social Life Survey, also produced by NORC, reported extramarital sexual experience by gender and age: 23% of males and 8% of females aged 50 to 59; 20% of males and 12% of females aged 40 to 49; 16% of males and 8% of females aged 30 to 39; and 10% of males and 6% of females aged 18 to 29.

Two of the most common reasons women report for having extramarital sex are retaliation toward an unfaithful husband and a lack of attention from or general dissatisfaction with a husband. The first reason is more closely associated with brief affairs or one night stands, the second with long-term affairs and an increased risk of divorce. Men are more likely to report opportunistic reasons for having extramarital

sex, along with relief of tension and desire for sexual variety. These reports support the notion that men are motivated by a drive for sexual variety, whereas women are motivated by a search for sexual intimacy.

The more general term used for these behaviors in diverse human cultures and nonhuman species is extra-pair copulation (EPC). The reproductive benefits of extramarital sex to men are more obvious. Men can enhance their reproductive success by fathering children with multiple women, and any genetically influenced tendency promoting this behavior would spread through the population as long as the costs (e.g., being seriously injured or killed by a woman's partner or his kin) did not outweigh the benefits in terms of reproductive success. There are also multiple ways in which EPCs can benefit women's reproductive success: acquisition of material resources; protection against injury or infanticide by the male; high quality genes that enhance offspring survival; "sexy son" genes that would make a son more attractive to females; genetic diversity of offspring as a hedge against changing or unpredictable environments; fertility backup if the woman's primary partner is sterile; replacing a lost partner; and stimulating mate guarding by the woman's partner to reduce chances for the man's infidelity.

Women are more likely to choose men with higher social status and physiological cues of high genetic quality, such as high body symmetry and broad shoulders with narrow hips, for extramarital sex, and are more likely to desire EPCs during the fertile phase of their menstrual cycle. Men are also more likely to have extramarital affairs with women possessing

physiological cues of high genetic quality, such as low waist-to-hip ratios.

## FAILURE TO THRIVE

---

### WHAT IS FAILURE TO THRIVE?

From the day a baby is born, parents will focus their attention on the child's growth and development; their major preoccupation will be connected with the baby's nutrition, health, growth, and contentment. Parents will be eager to see how much weight the baby gains, how well the baby feeds, how the baby responds to their nurturing, and what developmental progress the baby makes.

To grow satisfactorily, the baby needs sufficient nutrition on a regular basis and a quality of care that will make the child feel at ease, comfortable, and secure. In a secure and caring home, and fueled by adequate nutrition, children will thrive, giving parents pleasure and confidence in their parenting. In homes riddled with conflicting stress, chaos, or poverty, or where parents are poorly informed about children's developmental needs, the children's progress may be impaired if nutritional intake and the quality of nurturing are inadequate for the child's age.

During the first year after birth, human growth is quicker than at any other period during childhood,

decreasing rapidly until the end of the third year, then continuing at about one third of its postnatal rate until puberty. However, there are some children who do not grow according to expected norms and who are cause for concern. These children have been described as failing to thrive and, compared with their peers, are significantly smaller and can be expected to have poor outcomes. They can be found in all social classes and levels of society. Without help, one can expect their physical growth, cognitive progress, and emotional development to be negatively affected, and they may be at risk for neglect, abuse, or even death.

### TRENDS AND PREVALENCE

The term *failure to thrive* is applied to infants and young children whose weight, height, head circumference, and general psychosocial development are significantly below age-related norms and whose well-being causes concern. In the United Kingdom, children who fall below the second centile on the Growth and Developmental Charts (and remain there for more than a month) are investigated. In the United States, common practice is to use the fifth centile as a cutoff point for weight. Children who drop down two or more percentile curves on the weight chart over a

short period of time need to be assessed to determine whether there is a medical or psychosocial problem, such as development of a serious illness or trauma (e.g., abandonment, abuse, loss of parents).

The term failure to thrive describes a condition rather than a specific disease, and consequently it can have many causes that can be organic, psychosocial, or a mixture of both. It is conceived as a variable syndrome of severe growth retardation, delayed skeletal maturation, and problematic psychomotor development, which is often associated with illness, inadequate nutrition for normal growth, feeding difficulties such as oral-motor dysfunction, disturbed mother-child interaction (especially during the act of feeding), poor relationships, insecure attachment, family dysfunction, and poverty. Whatever the reason, these children are undernourished in terms of adequate caloric intake. Undernutrition during early infancy can have detrimental effects because the nutritional requirements at that time are most crucial. Given the rapid growth, particularly brain growth, that occurs during the first few years, particular attention should be given to sufficient provision of food.

Failure to thrive is normally diagnosed within the first 2 years of life, although its effects can be seen much later than this. Estimates of prevalence have varied from as many as 10% of children seen in outpatient clinics to 1% of all pediatric hospitalizations.

## RISK FACTORS

Several risk factors have been identified that tend to trigger failure to thrive and maintain the problem if helping strategies are not put in place early on. They are as follows: inadequate intake of food; feeding difficulties; poverty; family stress, such as parental chronic illness; divorce or separation; family violence; substance misuse; single unsupported parenting; low maternal education; limited knowledge about child rearing; social isolation; maternal depression; low parental self-esteem; distorted perceptions about the child; and poor interaction between child and mother.

## PROGRAM OF INTERVENTION

Intervention with failure-to-thrive cases usually falls into two basic categories: (a) immediate (crisis intervention); and (b) longer-term therapeutic and supportive work with more complex cases.

During the assessment period, attention is paid to urgent needs of the child and parents. It is sometimes

necessary to arrange day care (e.g., day nursery for a child if there are developmental delays due to the lack of stimulation or when a child is at risk for being neglected or maltreated). Some families might need assistance with housing, welfare provision, health and addiction problems, employment, family frictions, and financial difficulties. These issues should be dealt with early on to reduce stress and to create an atmosphere in which further therapeutic intervention can take place.

## TREATING INADEQUATE INTAKE OF FOOD

The primary objective of all failure-to-thrive cases is to increase nutritional intake by children in order to achieve subsequent weight and height expansion. Because many children have feeding difficulties, these are treated first in order to help the child to take more food and for the parents to manage better the process of feeding. Some children are simply not given a sufficient amount of food, the feeding formula is wrong, or the interpretation of the child's signals of hunger or satiation is incorrect; therefore, they are instructed and shown how, when, and what to feed. Parent training, in terms of developmental and cognitive counseling, plays an important role in problem solving in such cases.

Frequent home visits by a public nurse to support and monitor the case are very helpful. Much effort is put into making mealtime more relaxing for everybody in the family, but in particular, emphasis is put on the mother-child feeding interaction. Feeding behavior is modeled by the therapist, and food is presented in an attractive, appetizing way to encourage interest in eating and enjoyment of taking food. Because food avoidance behavior is common among failure-to-thrive children, the process of change tends to be slow. Assisting parents for a considerable time to reach successful results is necessary.

## ATTACHMENT WORK

Some failure-to-thrive children are insecurely attached to their mothers, and there is lack of maternal bonding to the child. Interaction in some cases is limited to the bare essentials of care and control and tends to be negative in nature. The child's fear and apprehension when in the mother's company is observable, as is anxiety, anger, or helpless despair on the part of the mother. To bring them closer together and to reduce negative feelings, structured interaction in the form of play, increasing in time, is introduced. Rejective

mothers, and those who have a poor relationship with the child, are encouraged to hold a child, sit the child on the lap for a few minutes several times a day, and talk to the child warmly while doing so. Frequent exposure to close proximity, conducted in a calm and soothing way, tends to reduce anxiety and apprehension in the child and anger or resentment in the parents.

## VIDEO RECORDING AND FEEDBACK

Video recording is a useful technique to increase parents' awareness and understanding of what is happening and how to correct inappropriate responses to the child. Examples of aversive parental behavior are videotaped and then played back to parents so they can see and hear how they behaved. Parents are asked to imagine how they would feel if they were treated in the way they are treating their child. By doing so, it is hoped that they will be able to get in touch with their own and their child's feelings, which, in turn, will help them to recognize the pain and hurt inflicted on the child. Parents are asked to observe the role-play conducted by a therapist demonstrating warm, encouraging, and caring behavior with the child. Then they are asked to play with the child again, using better interaction, which is videotaped, played back, and discussed.

## COGNITIVE WORK WITH PARENTS

Cognitive therapy is used to identify and correct negative dysfunctional or maladaptive cognitions relating to the parenting of the failure-to-thrive child. An essential component of cognitive therapy is that the parents are actively involved. Thus, parents must participate in the exploration of the manner in which their behavior is guided by their own beliefs and information processing. Modeling of alternative methods of interaction or feelings may help parents widen the scope of self-imposed and child-related expectations. Cognitive work points to the successful aspects of parents' lives so that they can take comfort from those aspects and redirect their thinking to constructive strategies to solving problems and feel good about them, thus reinforcing the conviction that they are able to achieve positive change.

## MONITORING FAILURE TO THRIVE

The cases of failure to thrive have to be followed until satisfactory growth velocity is acquired and maintained for at least 2 months. Additionally, parental

confidence on how to deal with various problems and who to turn to if in difficulty is needed for the satisfactory outcomes.

## SUMMARY

Failure to thrive is a multifactorial syndrome that has many routes and, if not identified and dealt with early on, can lead to serious physical and psychosocial consequences. Once a child's weight begins to falter and parent-child interaction is causing concern, action needs to be taken to preempt further deterioration and possible harm.

## FALSE MEMORIES

*False memories* is a broad term used to refer to various aspects of memory errors and distortions that involve not only misremembering specific aspects or details of our experiences but also remembering events that never took place at all. False memories can range from common everyday errors such as when you clearly remember leaving your car keys on the table but you actually put them in your jacket, to much more extreme errors such as remembering as an adult during therapy that your day care provider sexually abused you when you were a young child when in fact no such abuse actually happened. False memories can be very compelling

and seemingly real to the individual, and it is thus difficult for that person or outside observers to determine whether the memory is veridical or false. As such, the occurrence of false memories has widespread implications in legal arenas when allegations are made based on a person's recollections. A wide body of research studies has examined the circumstances under which false memories may occur, the cognitive and social processes involved in evoking false memories, and the types of individuals particularly prone to these memory errors and distortions.

### WHAT FACTORS INFLUENCE THE OCCURRENCE OF FALSE MEMORIES?

Memories are not necessarily veridical recordings of our experiences. However, memory errors and distortions are rarely random. Rather, they reflect principled properties of our memory systems and arise from normal cognitive processes involved in perceiving, comprehending, interacting with others, and remembering. For example, research has shown that people will misremember what they inferred or imagined happened and believe it actually happened, such as when they read a story in which a character dropped a glass pitcher and they erroneously remember having read that the pitcher shattered (which would be a reasonable implication but not necessarily what happened). Similarly, numerous studies have demonstrated that large numbers of people falsely remember having experienced things that were not in fact presented, such as erroneously believing they heard the word "doctor" after having heard a list of words thematically related to the concept of doctor (e.g., "nurse, physician, hospital").

Imagination can have a profound influence on the accuracy of one's memory, and numerous studies have shown that imagining events that did not occur can increase the incidence of people falsely believing they did. For example, people will indicate greater confidence that they experienced a particular event in their childhood (e.g., spilling a punchbowl at a wedding) in relation to the number of times they were induced to imagine the event occurring. Likewise, vividly imagining performing various actions (e.g., breaking a pencil) can lead people to falsely claim to have actually performed those actions. The negative impact of imagination on memory accuracy is particularly marked when the imagined events are plausible and are imagined vividly and with minimal cognitive effort.

There are also important social influences on memory. False memories can arise from listening to other

people's recollections and versions of what happened, with people incorporating erroneous details from the narratives of others into their own recollections.

### MEMORY ERRORS IN EYEWITNESSES

The occurrence of false memories is especially problematic when dealing with eyewitnesses and crime victims. A host of research studies have examined the reliability of eyewitnesses' recollections and have shown that even in naturalistic situations in which the costs of mistakes have serious consequences, people's memories are malleable and not wholly reliable. Such research has shown that people's memories can be influenced by suggestions from others. One manner in which this happens is when subtle changes in the wording of questions bias a witness's recollections. For example, when a question asks about how fast the car was going when it *smashed* into the other car, which implies a higher-speed collision than when the question asks about how fast the car was going when it *bumped* into the other car, people remember higher speeds and even recall seeing broken glass. Another manner in which people's memories are influenced by suggestions from others is when misinformation is provided after the witnessed event. For instance, when people are asked about how fast the car was going when it went by the *stop sign*, when in fact it had been a *yield sign*, they may then misremember having seen the suggested item (the stop sign). This "misinformation effect" is enhanced by the perceived authoritativeness and credibility of the person providing the misinformation, and people can come to believe quite confidently that their erroneous recollections are accurate. The relationship between a person's confidence and the actual accuracy is not very strong in fact.

Another important factor to consider with regard to the reliability of a witness's memories is the stress and emotionality of the situation. The stressfulness of a situation can negatively affect memory accuracy, with increased violence and stress often leading to vivid but not necessarily veridical memories.

At the root of many false memories are source misattributions—that is, when people incorrectly attribute a remembered event to the wrong source, such as falsely believing you had seen something that was in fact imagined or inferred, falsely remembering having heard something that you actually read, or falsely remembering one person having told you something or performed an action when in fact it was someone else.

Memories can arise from many different sources—from our everyday perceptual experiences such as seeing and hearing, to our internal world of thoughts, feelings, inferences, and imagination. Our ability to determine the source or origin of our memories depends in part on the qualitative features that comprise that memory (e.g., perceptual details such as the color of someone's shirt or the sound of his or her voice, contextual details such as the time or place of the event, affective details such as our thoughts, feelings, and reactions), in part on our beliefs about our memories (e.g., "This seems so vivid it must have actually happened"), and in part on the specificity of the criteria we use to judge our memories. False memories therefore can arise when the features of a memory or our beliefs about what memories should seem like provide misleading cues as to the memory's true source (e.g., an event that is plausible and vividly imagined with minimal cognitive effort or attention is particularly likely to be mistakenly judged as real). Furthermore, false memories are more likely when people over-rely on a general sense of familiarity to infer that something really happened.

### WHAT PREDISPOSES INDIVIDUALS TO FALSE MEMORIES?

What factors make particular people vulnerable to false memories? Some research has suggested that individual differences in imagery vividness, absorption, dissociation, and hypnotic suggestibility may be related to the incidence of false memories. These factors can increase the vividness of one's memory and bring about a focus on emotional aspects of one's memories, both of which can increase source misattributions.

Across the life span, there are also some important developmental differences in the occurrence of false memories. Young children are more susceptible to suggestion and generally show increased rates of source misattributions relative to young adults. For example, when young children are questioned repeatedly with leading questions and implanted misinformation, they may incorporate this into their memories and produce reports that can be substantially different than what in fact transpired. Children's increased vulnerability to false memories may be due to several factors, including immature memory systems in the still developing brain, limitations in their ability to conceptualize and verbalize their experiences, and an over-reliance on authority figures.

At the other end of the spectrum is an increased incidence of memory errors and distortion seen in older adults under some circumstances. Older adults tend to make more source misattributions than do young adults (confusions between actions they performed and imagined performing, what they said and what they imagined saying, and what they saw and what they imagined seeing). However, some older adults perform at levels equivalent to their young adult counterparts, whereas others show substantially higher error rates. These individual differences among people of the same advanced age are mediated in part by the overall functioning of their frontal lobes. Several studies have shown that older individuals with impairments in frontal lobe functioning show disproportionately higher rates of memory errors and distortions.

### GENERAL CONCERNS ABOUT FALSE MEMORIES IN FORENSIC SETTINGS

There are several situations potentially involving false memories that are especially relevant to court cases. The overall reliability of the recollections of witnesses and victims is an important factor to consider in light of various research findings regarding the many ways in which memories can be influenced by suggestive questioning and misinformation. The increased vulnerabilities of young children to such factors is especially relevant when their testimony is the primary evidence in court cases (e.g., in cases involving sexual abuse in day care settings). Age-related memory impairments in older adult witnesses are also an issue. Another area of concern involves memories of alleged childhood sexual abuse recovered in adulthood. This is a controversial subject. On the one hand, there are cases in which the allegations are erroneous, having arisen in part from suggestive therapeutic practices such as guided imagery, hypnotherapy, and dream journaling. On the other hand, there are cases in which individuals have apparently forgotten such abuses for extensive periods of time and memories are triggered by some current life circumstance.

## FAMILY SIZE

---

Family size exerts an extremely strong and broad influence on development. The influence is strong in the sense that the effects are long-lasting. It is broad in the sense that it has an impact on many aspects of development, including both cognitive ability and extracognitive (e.g., personality) tendencies. The influence of family size is especially remarkable in comparison to other influences on development. Certainly the school, culture, economic background, and similar factors are notable influences, but the influence of family size is the most direct and probably the more robust. In many ways, those other influences are moderated by the family.

### DEFINITION OF FAMILY SIZE

Family size can be defined in various ways. It may be defined such that all individuals within a household are included. This may include parents and children, but it may also include members of the extended family (e.g., aunts, uncles, grandparents) and sometimes people who are not related by genes. This is, of course, true when there are foster parents or stepparents living with children.

At issue is the definition of *family*, which has undergone enormous change in the past several decades. This has occurred primarily because of the increased divorce rates and the changing demographics of the United States—and the world. In the United States, immigration has increased the population

substantially, and many of the immigrants have brought their own views of family and household to the United States. This holds true in many ways, including such factors as who lives in one household and what is an appropriate family size. The traditional American family from the 1950s and 1960s is no longer the traditional American family.

### FACTORS RELATED TO FAMILY SIZE

Family size is related to socioeconomic status; families in the lower brackets often have larger families. It is, then, an inverse relationship. Associated with socioeconomic status, and therefore also inversely related to family size, are material and educational resources. Simply put, there are usually fewer resources in larger families. Perhaps most important is that family size is associated with family dynamics. Indeed, the impact of family size probably reflects an influence on family dynamics, including communication and discipline. Often, larger families are more authoritarian and less permissive and democratic. This in turn means that children have fewer opportunities to practice making decisions, and they may grow up thinking that their perspective is relatively unimportant.

Family size determines what experiences and resources a child will have and receive, and those in turn influence development. They are strong influences because the experiences determined by family size are repetitious. The effects on cognition and personality are for this reason said to be *overdetermined*.

Family size is in some ways a *nonshared* family influence. It is nonshared in the sense that the different siblings do not share the same family size. A first born, for example, is the only child for a period of time, at which point he or she is in a small family, but only until the next sibling is born. That second born child is never an only child but always has at least one sibling. In that fashion, the siblings do not share certain kinds of experiences. The same thing can be said about each birth-order position and family size. Other nonshared influences on development include socioeconomic status (SES) and parental age. Typically, the first-born child is raised (early in life) in the lowest SES. The parents may achieve seniority of some sort at work, and increase their income, so that siblings born after the first born actually are raised in families in higher SES. Even more certain is that first-born children have the youngest—and least experienced—parents. The parents of a second-born or subsequent

child are always older and more experienced parents than the parents of first-born children.

Much of the research on family structure focuses on one aspect of family size, namely *sibsize*. This represents the number of children (siblings) in the household. Very frequently, children reared in families with a small sibsize—few siblings—have more stimulation and need not share resources. Parental resources and attention are not divided much in smaller families, and children may benefit from adult supervision and interactions. Several cognitive indicators are in fact correlated with sibsize, again in an inverse manner, such that fewer siblings may help each child develop more mature cognitive skills.

These effects are moderated by age gap, the interval between siblings. When the gap is large, the siblings are different because of their levels of maturity, and they need not put any effort into being unique and thus earning parental attention. But when the age gap is small, the siblings may be similar in level of maturity, and they often put some effort into finding ways to be unique. Very frequently, the eldest child in a family is fairly conventional and has a traditional slant to his or her motivations. The eldest might very well excel academically, for example. When this is the case, and if the second-born child is not too much younger—a small gap—the second child tends to go in a very different direction. If the eldest child is in fact fairly conventional, the second born will often be quite unconventional and rebellious. Of course, this may change because of temperament as well as factors such as the sex of the children. If two children are both boys or both girls, they again are quite similar, and there is a tendency to try to be different and unique. If one is a boy and one is a girl, however, they are already different and need not put as much effort into being unique.

The family is quite complicated: age gap, sex of the children, socioeconomic factors, and temperaments all play causal roles and interact with family size to determine what occurs in the family and what experiences will occur.

## KEY TERMS

*Age interval*—the gap between two siblings, usually in years

*Family size*—may include only biologically related individuals, or everyone regardless of relationship, within the household

*Family structure*—defined by family size, age intervals among siblings, and so on

*Family dynamics*—communication, discipline, and other interactions among family members, often determined by family size and structure

*Nonshared family influences*—some experiences within a family are identical for all children within the family, but many (e.g., parental experience) differ for each child

*Overdetermined influence*—many developments and behaviors are influenced by multiple overlapping family factors.

## FATHERS

---

Significant societal shifts in the definitions and role expectations of fathers have occurred within the past 50 years. In the decades of the 1950s and 1960s, fathers' role as the "breadwinners and disciplinarians" was the typical expectation; whereas in the decade of the 1970s, there were expectations that fathers would increase participation in the household responsibilities. In the 1980s, the idea of the nurturing and emotional father was emphasized, whereas the 1990s and the current decade have attended to finding the balance among the many different roles, including stay-at-home fathers and life as a single parent.

Many of these varied roles occurred largely in response to political and economic changes. Beginning in the 1960s and continuing into the 1990s, significant societal changes occurred that have affected the demographics of fatherhood, as divorce and out-of-wedlock births tripled the number of children growing up in homes without a father present. In 1994, 24 million American children were living without their biological

fathers, and in 2002, 40% did not have contact with their nonresidential fathers. Over several decades of research, the diverse effects of father absence on children's development have become clearer, and this research has led to an increased recognition of the unique contribution of a father's role in a child's life. The research has occurred in many disciplines and fields and has illustrated the importance of father roles in the child's development.

Some important differences now being emphasized about the father's unique role include the finding that fathers engage in more physically stimulating play with their children that involves orientation toward specific goals, with less time spent by the father on the caretaking activities. This physical play benefits children in many areas, including providing them with an understanding of their own behavior, helping them learn to regulate their own emotions, and helping them learn empathy skills by recognizing the emotional cues of others. These are all benchmarks of appropriate socialization of children and demonstrate how important a father is to healthy development. During infancy, this paternal style of interaction is shown in the infant being provided with higher amounts of stimulation while the father holds the infant, which may account for the finding that infants sometimes prefer to be held by their fathers. Additionally, children tend to prefer their fathers to act as their "playmates" because of this quality. Research with infants and fathers has also led to the discovery that infants who have involved fathers tend to display less stranger anxiety than those with noninvolved fathers. Furthermore, babies of involved fathers are more responsive socially, demonstrate more resiliency during stressful situations, and perform better on developmental tests. Very young children have also been shown to be able to differentiate between the mother's and father's roles in their lives.

Research has demonstrated that fathers who choose to be present at their children's birth can more accurately describe their baby's moods and temperament and can provide an increased understanding of a child's personality at 3 and 6 months of age. Furthermore, these fathers feel much more drawn to their child (i.e., spending large amounts of time looking or touching their newborn child). When mother-child bonding is emphasized at the cost of the early father-child relationship, there is evidence that some fathers experience their own version of the "baby blues" and that contact with the infant alleviates this. During the past few decades, there have been differing opinions as to whether there was a biological or cultural rationale for the differences between maternal

and paternal interaction styles. The debate is not settled at this time, but the evidence is supportive of both.

Research has also demonstrated that there are many similarities in paternal and maternal interaction styles. As children get older and the opportunities for play activities decrease, fathers tend to engage in more nurturant caretaking, so that this appears to be a shared component between mothers and fathers during middle childhood. Similarly, fathers also are involved with school and extracurricular activities on an equal basis with mothers. Interestingly, the quality of the spousal relationship is predictive of the amount and quality of interaction between fathers and their children, with better quality predictive of more and better father-child interaction.

In addition to the immediate consequences to the child, a father's presence has an impact on the child's life that extends into long-term outcomes. Children who are not raised with fathers present have a significantly higher risk for living in poverty than children with a father and mother, and they are more likely to engage in drug, alcohol, and tobacco use. These children are more likely to fail school, have more emotional and behavioral problems that require psychiatric treatment, and are at greater risk for committing suicide. Male fatherless children are also more likely to become juvenile offenders, whereas females without fathers are more likely to be sexually active than their peers with fathers. Additionally, if fathers actively participate in their children's lives, their sons tend to be less aggressive and more expressive emotionally.

As the research began to demonstrate the negative effects of the father's absence in a child's life, a social movement emerged that involved governmental agencies, researchers, advocates, and policy makers. This social movement has led to the generation of major data collections about the father's role and the establishment of an influx of father-focused organizations.

This increasing support for additional understanding and research into the father's role was demonstrated in June 2002 when Child Trend released a report that included information on parenting practices of fathers, which was a first-of-its-kind report. This significant report provided data about the male role in the areas of fertility, parenting, and family formation. When this was released in 2002, it was the first time statistics were specifically examined regarding provision of parenting by fathers. This research led to some clarification of gender stereotypes. For example, contrary to the belief that fathers are disengaged from their children, the findings indicated that

fathers who reside with their children are quite involved, with close to 68% engaging in an outdoor activity at least once a week.

In addition to increases in data gathering, father-focused organizations have had a significant impact. Several of the organizations have focused on decreasing absenteeism of fathers and promoting the idea of the responsible father. Examples of these include the National Fatherhood Initiative (NFI) and the Fatherhood Project. The NFI has as its mission the goal of improvement in children's well-being by increasing the amount of children growing up with fathers who are involved, committed, and responsible to them. The latter initiative is involved in research and education and has as its aim to support male involvement in child rearing. It is significant in that it began in 1981 and is the longest-running national initiative on fatherhood.

As this social movement has become energized, there have been other significant changes within the past decade, one of which is that the number of fathers being defined as primary caregivers has risen. The 1993 U.S. Census reported that 1.9 million fathers were the primary caregivers to their children. This number is further supported by increasing numbers of conferences for stay-at-home fathers.

Another interesting aspect of the father's role is in the area of male teenage parenting, which has its own set of difficulties. Research has found that although adolescent fathers and their peers who do not have children have similar attitudes, sexual knowledge, and behavior generally, adolescent fathers are quite likely not to live with the mother of the child and consequently feel alienated from the child during pregnancy and especially in the child's younger years. However, if an adolescent father is active in early decision making about the child, he is more likely to be involved both during pregnancy and beyond. Most adolescent males, who had some level of commitment to the mother before the pregnancy, want to be involved in the child rearing, whereas those without a commitment have a lack of interest in establishing a relationship with the child and are usually not involved in raising the child.

## FETAL MEDICINE

---

Maternal and fetal medicine (MFM) is the subspecialty within the field of obstetrics and gynecology that deals with the complications of pregnancy. The problems are varied but can fit into one of several categories:

- Maternal disease: either the disease or the treatment may affect the fetus or pregnancy (e.g., diabetes and hypertension).
- Disease arising as a result of the pregnancy (e.g., preeclampsia and gestational diabetes)
- Abnormalities of the fetus (e.g., birth defects) or of fetal growth
- Genetic disease that has no meaningful effect on fetal life but that may affect the life of the individual after birth (e.g., cystic fibrosis or Down syndrome)
- Abnormalities of the pregnancy (e.g., prematurity)

Fetal ultrasound is a tool that is used in every category listed because it can provide a wealth of information concerning fetal condition, or it can provide guidance for intrauterine tests and treatments. Other tools used in MFM are the tools used by all physicians in the evaluation of a patient, such as taking a medical history, performing a physical examination, using laboratory testing, and using various imaging techniques on the mother.

Training in MFM requires completion of a 3-year fellowship. Completion of a 4-year residency in obstetrics and gynecology is a prerequisite for fellowship training.

MFM specialists practice in a variety of situations. Private practice of the specialty is common, but MFM specialists may be hired by hospitals or managed care organizations and can be found on the faculties of medical schools. The MFM specialist is often involved in teaching and research. Other aspects of obstetrics and gynecology may be practiced along with MFM, and it is not uncommon for the MFM specialists to give complete obstetrical care to patients with specific problems.

Historically, successes in the treatment of pregnancy complications came with the ability to diagnose, treat, and ultimately prevent fetal disease related to Rh incompatibility. Care of the pregnant diabetic woman was begun in the 1930s. The modern treatment of the diabetic pregnant woman began in the 1970s. It was realized then that very tight control of maternal blood glucose could prevent many problems, of both the mother and the fetus, which had otherwise been so devastating. Hypertensive disease in pregnancy remains a problem, but management generally allows a good outcome. The advent of the acquired immune deficiency syndrome (AIDS) epidemic required much research into the factors related to spread of the virus to the fetus.

Increases in the resolution of ultrasound have had a dramatic effect on the methods used. It is now possible to estimate the risk for Down syndrome by visualization of the thickness of the skin of the fetal neck at 12 weeks' gestation, and current research is assessing use of the size of the fetal nasal bone in the first or second trimester for the same indication. Three-dimensional visualization is commonly available, and we continue to try to identify ways to exploit new technology in fetal diagnosis.

Treatment of the fetus is often accomplished with the control of the maternal problem. Although some treatments include delivery of a fetus before complications cause fetal injury, in other situations we may also attempt to prevent a premature delivery. Antiarrhythmic drugs may be given to the mother to control problems with the fetal heart rhythm, and fetal surgery done on the fetus may confer striking benefits in the relatively rare situations in which it is indicated. In some cases, the treatment options are profoundly limited or the situation is judged hopeless. Termination of pregnancy may be deemed appropriate by the parents in these circumstances.

## FETUS

---

During the prenatal period, a human develops from a single cell to a complex array of living tissues and structures. Every experience a prenatal organism has, and every substance it encounters, can potentially alter the course of development. This period of dramatic changes sets the stage for postnatal outcomes, from birth to death. The longest period of prenatal development is referred to as the *fetal period*, during which time the developing organism is called a *fetus*.

### WHEN DOES THE FETAL PERIOD BEGIN?

The first 2 weeks of life are called the *period of the zygote*. This period begins when a sperm and egg unite their genetic material in a single cell. The newly fertilized egg spends the first week of its existence traveling down the fallopian tube toward the uterus. As it travels, the original cell divides into multiple cells. The zygote spends the second week of its existence implanting into the wall of the uterus, which triggers hormonal changes in the mother to help maintain the pregnancy.

Once uterine implantation is complete, the developing organism is called an *embryo*. The *period of the embryo* lasts from week 3 to week 8. During this time, the embryo develops physical features that make it look human, such as eyes, ears, arms, and legs. Inside, the internal organs begin to form and function. The heart begins to beat within the first 3 weeks of gestation.

The final and longest stage of prenatal development is called the *period of the fetus*. This period begins during the ninth week, when bone cells begin to replace cartilage, and will last until birth. During

this time, the fetus will increase rapidly in size, growing from little more than an inch in length to the size and appearance of a newborn infant.

## WHAT HAPPENS DURING THE FETAL PERIOD?

### Physical Changes

At the start of the fetal period, all of the organs have been differentiated. The task of the fetal period is to strengthen and integrate their functioning. In other words, the pieces are in place; all that is left are the final touches. One way to conceptualize these changes is to consider pregnancy as occurring in three trimesters, with each trimester lasting 3 months.

#### *First Trimester*

The first month of the fetal period is the last month of the first trimester. The fetus doubles in length during this time and begins to take on more human characteristics. The head becomes more erect, and the back straightens and becomes less curled in appearance. As the body grows bigger, the fetus's large head looks more proportional, although it is still one third the length of the entire body. Details such as fingernails and toenails are added during the third month. The skin becomes less transparent, and facial structures move into place. Eyelids form, although the eyes will not open until later.

Connections form between muscles and brain, which allows for more coordinated movement patterns. Bone cells begin to manufacture blood cells. The digestive system begins producing insulin and digestive enzymes. The fetus is moving toward life outside of the womb.

#### *Second Trimester*

At the start of the second trimester, gender can usually be determined by ultrasound, the use of high-frequency sound waves that produce an image of the fetus. Sexual development actually begins much earlier, during the embryonic period, when the testes begin to form in male embryos and ovarian follicles form in female embryos. During the third month of gestation, the testes release testosterone, which triggers male embryos to develop a penis and scrotum. Because female fetuses have no testes to release these

hormones, female fetuses develop a vagina about a week after male fetuses develop a penis.

A second important event during the second trimester is the onset of sensory functioning. In mammals, the sensory systems become functional in an invariant sequence. The sense of touch begins at about 8 to 10 weeks of gestation. Maria Fitzgerald at London University has found that fetuses have more irritable nerve fibers than do newborns, which may make them more responsive to prenatal stimulation. Taste and smell begin to function at about 14 weeks. Fetuses show facial responses to sweet or bitter chemicals injected into the amniotic fluid. Fetuses show visible responses to sound as early as 24 weeks, with a preference for high-frequency sounds that will last throughout infancy. Fetuses respond to light by 26 weeks, although the ability to focus will continue to improve following birth. The eyes of the fetus and newborn will remain blue until a few weeks of postnatal light exposure activate the eye pigmentation to create the adult eye color.

Physical details are also added during the second trimester. For example, fingerprints form by the fourth month. During the fifth and sixth months, eyebrows, eyelashes, and hair appear. During this same time period, the fetus's skin is protected from the amniotic fluid by vernix caseosa, a thick, waxy covering. Vernix sticks to the skin because the fetus's skin is covered by downy hair called *lanugo*. Lanugo will decrease in the seventh month, replaced by head hair, whereas vernix will still be visible at birth on the infant and in the amniotic fluid.

#### *Third Trimester*

The final trimester is when the fetus gains the most weight and length. The bones harden, consisting of more bone cells and less cartilage. A layer of fat grows under the skin, which will help the newborn infant stay warm in the postnatal environment. Hair, fingernails, and toenails grow. The fetus is also taking advantage of antibodies in the mother's blood. These antibodies enter the fetal circulatory system through the umbilical cord and provide protection for newborn infants until they can develop antibodies of their own.

The typical length of gestation is 38 weeks; however, babies born before this time can survive. The point at which a fetus can survive outside of the womb is called the *age of viability*. With today's technology, the age of viability can be as early as 22 weeks of gestation, although premature infants often face challenges that

**Table 1** Fetus Developmental Changes in the Three Trimesters

<i>Fetal Period</i>	<i>Developmental Changes</i>
First trimester	<ul style="list-style-type: none"> <li>• Major organs develop</li> <li>• Posture straightens</li> <li>• Body increases in size</li> <li>• Fingernails and toenails begin to grow</li> <li>• Skin becomes less transparent</li> <li>• Facial structures begin to move into final position</li> <li>• Connections form between muscle and brain</li> <li>• Bones begin to manufacture blood cells</li> </ul>
Second trimester	<ul style="list-style-type: none"> <li>• Almost all nerve cells created</li> <li>• Testes or vagina forms</li> <li>• Sensory systems become functional</li> <li>• Fingerprints form</li> <li>• Eyebrows, eyelashes, and hair appear</li> <li>• Lanugo and vernix caseosa appear</li> </ul>
Third trimester	<ul style="list-style-type: none"> <li>• Primary gain in weight and length</li> <li>• Bones become harder</li> <li>• Subcutaneous fat appears</li> <li>• Fetus receives maternal antibodies</li> <li>• Lungs finalize their development</li> </ul>

full-term infants do not face. For example, lungs finalize their development, becoming capable of breathing air at about 26 weeks. Infants born before the final trimester need assistance breathing. The earlier a fetus is born, the more developmental challenges it is likely to face.

## Behavioral Changes

The human fetus is an active creature. It kicks, rotates, and somersaults. The fetus also can turn its head, make faces, form a fist, suck its thumb, and curl its toes. The capability for movement begins during the second month of life; however, much of this early movement is spontaneous rather than in response to environmental stimulation. During the fetal period, movement begins to become more intentional and responsive. By the end of the second trimester, the fetus will make sucking motions in response to a touch on the lips and will shield its eyes in response to a bright light.

Some researchers have argued that behavioral patterns may tell us something about a fetus's personality

or later behavior. For example, Janet DiPietro and her colleagues demonstrated that male fetuses tend to be more active than female fetuses, which is a difference often noted in young children. Fetuses of women who report high levels of stress also exhibit higher levels of prenatal behavior. Each mother may notice a behavioral pattern that is unique to her fetus, with some fetuses being awake and active at certain times of the day and not at others.

Movement can be an important developmental tool because the ability to move increases as a consequence of movement itself. For example, as the fetus swallows and inhales amniotic fluid, it is strengthening the muscles it will use to breathe air in the postnatal world. Bones and muscles gain strength and function through their use, so that movements transition from being uncoordinated to smooth and coordinated.

Movement increases in frequency until about 17 weeks of gestation, at which time it declines. This reduction in movement may be the result of the maturation of inhibitory abilities in the brain. Movement peaks again between weeks 26 and 32, and then declines as delivery approaches. The reduction in movement that occurs late during the prenatal period is most likely due to space restrictions in the uterus. Early in development, the fetus moves freely in its amniotic sac. By the end of late prenatal period, the fetus fills the expanded uterus, and its movements can be seen through the mother's abdominal wall. In preparation for birth, most fetuses move into an upside-down position, with their head pointed in the direction of the birth canal and their face angled toward their mothers' spine.

## Cognitive Changes

The nervous system, which includes the brain, is also rapidly developing during the fetal period. By the end of the fifth month, almost all of the brain cells that a human will have in his or her lifetime are already created. These brain cells are called *neurons*. Neurons that are used will develop connections with other neurons, whereas neurons that are not used will be pruned. One brain area that grows the most is the cerebral cortex, the outer surface of the brain that is more developed in humans than in other species. This growth will continue during infancy and childhood.

Important aspects of brain growth occur during sleep. We now know that fetuses not only sleep, they also dream. Dream sleep, also called rapid-eye-movement (REM) sleep, is the time when neurons form

connections. These connections are even more critical to cognitive functioning than is the number of neurons an individual has. REM sleep is also a time when areas associated with learning show high levels of activity.

Research with both humans and animals has demonstrated that fetuses can learn in the womb. In a classic study by Anthony DeCasper and Melanie Spence, mothers read *The Cat in the Hat* out loud during the last 6 weeks of pregnancy. After birth, their infants could suck on a nipple to hear recordings of their mother reading this familiar story or an unfamiliar story. The infants who had heard *The Cat in the Hat* during the prenatal period sucked on the nipple in order to hear the familiar story. This behavior suggests that the infants remembered what they had heard while they were still fetuses. Prenatal learning may also explain why newborns prefer hearing their mother's voice instead of other voices and prefer hearing their native language instead of other languages.

### WHAT DOES THE MOTHER EXPERIENCE DURING THE FETAL PERIOD?

Although drastic changes are occurring to the fetus, the expectant mother may not feel like she is carrying another person in her body early during pregnancy. Her hormones, however, are already changing her body to maintain the pregnancy. One of the first symptoms she may experience is morning sickness, which typically occurs during the first trimester. Morning sickness may protect an expectant mother by making her more reluctant to eat foods that would be potentially harmful to the developing fetus. Women who experience morning sickness are less likely to miscarry or have a child with birth defects.

At about the 16th week of gestation, as the fetal bones begin to harden, the mother is able to feel the fetus moving. The detection of the first movement is called the *quickening*. First-time and heavier mothers may wait longer to feel this first movement. Early movements feel like a slight flutter or bubbling sensation. As the fetus develops, the movements get stronger, and the space in which to move gets smaller. Thus, later movements feel more recognizable, such as a small person kicking the abdominal wall.

As the fetus grows, the demands on the expectant mother increase. Her heart will get stronger and beat faster in order to supply nutrients and oxygen to the developing fetus. As the fetus grows, it will compress the organs in her chest upward, into smaller and

smaller spaces, leaving the mother short of breath. During late pregnancy, the fetus drops lower in the pelvis. This change in position alleviates some of the pressure on the lungs but increases pressure on the bladder, resulting in more frequent urination.

The growth of the fetus also contributes to weight gain during pregnancy. The average woman will gain 25 to 30 pounds during a healthy pregnancy. Women who are very thin at the outset of pregnancy may gain more, whereas women who are overweight at the outset of pregnancy are often encouraged to gain less. During the final trimester, when the fetus is gaining length and weight, the mother may gain a pound per week. About two thirds of her ultimate weight gain will reflect the weight of the fetus, placenta, expanded uterus, and supporting fluids (e.g., blood and amniotic fluid).

### THREATS TO FETAL AND MATERNAL HEALTH

Prenatal development is a complicated and delicate process, which can be disrupted by harmful substances ingested, inhaled, or absorbed by the mother. These substances are called *teratogens*. The effect that a particular teratogen will have depends on many factors, such as amount, duration, and timing of the substance. Even small amounts of substances that are tolerable to adults may be detrimental to developing organisms. The embryonic period is typically considered the most vulnerable period of development because body structures are being created during that time. The risk for developmental damage is usually lower during the fetal period, yet there are some organs and systems that are particularly susceptible.

Determining the exact results that a substance will produce is a challenging field of research. First, many risk factors occur simultaneously. For example, a woman who is taking illegal drugs may also have poor eating habits, which makes it difficult to determine which behavior resulted in a specific consequence for the fetus. A second issue for research is that genes and environment interact. For example, fetuses with a particular gene and whose mothers smoke are more likely to develop cleft palate. Third, many consequences do not appear immediately. Delayed consequences are called *sleeping effects*. For example, embryos and young fetuses exposed to DES (diethylstilbestrol), a drug given to prevent miscarriage, do not show symptoms until adulthood, when women are at risk for cervical cancer and both men and women are at risk for fertility problems.

## Drugs

The term *drug* can be applied to a wide variety of substances, from prescription medication to over-the-counter remedies to illegal chemicals. Drugs from any of these categories have the potential to be harmful to a developing fetus.

### *Illegal and Prescription Drugs*

Illegal drugs can alter the course of development as well as create a dependency in the developing organism. For example, prenatal exposure to cocaine is linked to premature birth, low birth weight, respiratory problems, and heart deformities. Fetuses exposed to heroin show withdrawal symptoms at birth, including vomiting, shaking, and irritability. Heroin continues to exert negative effects by slowing the rate of motor development.

A classic example of a prescription drug that proved harmful is thalidomide. Thalidomide was widely prescribed in the 1950s and 1960s as a mild sedative and antidote for morning sickness. At that time, doctors believed thalidomide to be harmless to the developing fetus. Unfortunately, thousands of exposed infants were born with limb defects, deafness, facial deformities, dwarfism, and brain damage. Many of these infants died during the prenatal period or shortly after birth. Thalidomide has recently received renewed attention, because of its ability to treat symptoms of nausea, cancer, and leprosy. Controversy exists over whether such drugs can be administered with a guarantee that they will not be made available to pregnant women.

### *Nicotine*

Any form of tobacco (e.g., cigarettes or chewing tobacco) can have negative consequences for both the expectant mother and the fetus. Nicotine interferes with the woman's ability to absorb certain nutrients and also causes her blood vessels to contract. When blood flow is constricted, the fetus receives less oxygen and nutrients. Nicotine has also been shown to disrupt fetal sleep patterns, particularly REM sleep. Women who smoke are more likely to have abnormalities of the placenta and to miscarry. Infants who are born of smoking mothers are more likely to have low birth weight, respiratory illness, or cleft palate. Smoking has also been linked to sudden infant death syndrome (SIDS) and attention deficit hyperactivity

disorder (ADHD). Even exposure to secondhand smoke has been linked to outcomes such as asthma, bronchitis, and ear infections.

### *Alcohol*

According to the Academy of Pediatrics, about 20% of women consume alcohol while pregnant. Some controversy exists about whether small amounts of alcohol are dangerous during pregnancy; however, research clearly demonstrates that large amounts of alcohol consumption are unsafe for the developing organism. One of alcohol's most damaging effects is that it interferes with cell division and cell communication, both critical components of development. Alcohol also decreases the blood supply to the fetus. Because the amount that is considered harmful is not presently known, the best advice for a pregnant woman is to avoid alcohol.

Large amounts of alcohol consumption, considered to be more than 4 ounces several times a week, result in a pattern of deficits called fetal alcohol syndrome (FAS). Children with FAS tend to have slow development, mental retardation, behavioral problems, and heart problems. In addition, FAS results in a small head with an atypical facial pattern of widely spaced eyes, a thin upper lip, an upturned nose, and a flat nose bridge. Children who exhibit these characteristics to a lesser degree have fetal alcohol effects (FAEs) or alcohol-related neurodevelopmental disorders (ARNDs). These less severe effects can include low birth weight, heart and respiratory abnormalities, attention problems, learning disabilities, and behavioral disorders.

### **Infectious Disease**

Pregnant women may be exposed to viral or bacterial infections, such as the common cold or the flu, that do not adversely affect development. However, some infections, such as syphilis, rubella, and toxoplasmosis, can directly affect the development of the fetus. Other infectious diseases, such as gonorrhea and genital herpes, target the fetus as it passes through the birth canal into the postnatal world. Acquired immune deficiency syndrome (AIDS) is a disease that can affect the fetus in the womb and the infant passing through the birth canal.

Syphilis is a fatal disease for the developing organism. About 50% of fetuses of infected mothers die during the prenatal period or shortly after birth. Survivors are at risk for problems with their central nervous system and damage to their teeth and bones.

Rubella, or German measles, has differential effects depending on the time of exposure. Rubella is most damaging during the first trimester, when it can cause a range of defects including blindness, deafness, mental retardation, and heart defects. During the second trimester, rubella is associated with hearing and vision loss as well as language difficulties. Today, most children receive a vaccination for rubella, which means most pregnant women have been protected against the disease.

Toxoplasmosis also has differential effects depending on the timing of exposure. Pregnant women may contract this parasitic infection through eating undercooked meat or from touching the feces of infected cats. During the first trimester, toxoplasmosis causes death or severe eye or brain damage, whereas later exposure leads to less severe damage of the same areas. Pregnant women are advised to make sure that the meat they eat is thoroughly cooked and to avoid contact with any area where cats defecate (i.e., litter or soil).

AIDS is a viral disease that is transmitted to some fetuses, but not to others. The factors that determine which fetuses will contract it are not completely understood. Fetuses that do contract it quickly show symptoms. As young infants, they are prone to respiratory illnesses, fever, weight loss, delayed development, and motor disturbances. Most infants with AIDS die within the first year of life. The only drug currently available (AZT) that reduces the chances of prenatal infection also can cause birth defects.

The infectious diseases discussed thus far have noticeable effects on both the mother and the fetus; however, minor bacterial infections have been identified as one of the leading causes of premature labor. For example, women with gum disease have six times as high risk for premature birth as women without gum disease. Bacterial vaginosis, a disease treatable with antibiotics, also increases the risk for premature birth. For the healthiest pregnancy, all types of infections should be avoided.

**Environmental Hazards**

A fetus can also be at risk because of exposure to natural or man-made chemicals in the everyday environment. For example, a study done on farmers in Wisconsin found that women with higher levels of exposure to pesticides had higher levels of miscarriage and were more likely to have children with leukemia, brain tumors, and other birth defects.

Of recent concern is the amount of methyl mercury found in fish. Methyl mercury exists naturally in the

**Table 2** Threats to Fetal Health

<i>Teratogen</i>	<i>Potential Consequences</i>
<b>Drug</b>	
Alcohol	Low birth weight, arousal and attention difficulties, delayed development, mental retardation, behavioral problems, heart problems, respiratory abnormalities, atypical head and facial features
Cocaine	Premature birth, low birth weight, respiratory problems, heart deformities
DES	Fertility problems, ovarian cancer
Heroin	Withdrawal symptoms, delayed motor development
Nicotine	Disruption of fetal sleep patterns, abnormalities of the placenta, miscarriage, premature birth, low birth weight, respiratory illness, cleft palate, sudden infant death syndrome (SIDS), attention deficit hyperactivity disorder (ADHD)
Thalidomide	Limb defects, deafness, facial deformities, dwarfism, brain damage, death
<b>Disease</b>	
AIDS	Immune system deficiencies, respiratory illness, fever, weight loss, delayed development, motor disturbances
Rubella	Blindness, deafness, mental retardation, heart defects, language problems
Syphilis	Central nervous system problems, teeth and bone damage
Toxoplasmosis	Miscarriage, premature birth, low birth weight, jaundice, cognitive deficits
<b>Environmental Hazard</b>	
Methyl mercury	Motor disturbances, abnormal reflexes, mental retardation, blindness, deafness

environment, and small amounts are not harmful to developing organisms. Levels have risen in recent years because of industrial by-products invading water supplies and being ingested by fish, particularly large fish. Fetuses exposed to methyl mercury through their mother's diet are at risk for motor disturbances, abnormal reflexes, mental retardation, blindness, and deafness.

## Additional Risk Factors

### Age

Increased age at pregnancy is associated with increased risk for developmental problems. Beyond the age of 35, a woman is more likely to have a child with Down syndrome, owing to chromosomal abnormalities in her egg supply. The closer a woman moves toward menopause, the more likely hormonal changes will make the uterus less receptive to implantation by a fertilized egg. In addition, older women are more likely to have health problems, which during pregnancy can lead to complications such as high blood pressure, gestational diabetes, and premature birth.

Having a child early in life may also be associated with difficulties. Adolescents are still in the process of growing and increasing bone mass. Pregnancy takes resources from the adolescent's developing body in order to meet the demands of the growing fetus. One consequence is that adolescent mothers are at increased risk for osteoporosis later in life as a result of sharing calcium during pregnancy. Adolescent mothers are more likely to have infants born prematurely or at low birth weight. Adolescents also have fewer financial resources and are less likely to receive prenatal care than are older mothers.

For most women, the peak of physical health and fertility occurs during their 20s. According to the National Center of Health Statistics, in today's society, an increasing number of women are waiting until later in life to attempt pregnancy, when the odds of conceiving are lower and the odds of problems are higher. The good news is that this behavioral change has prompted better diagnostic tools and infertility treatments.

### Stress

Stress is a normal part of living; however, individual responses to stress may vary considerably. A certain level of stress may seem manageable to one individual and overwhelming to another. The perception of excess stress may cause pregnant women to exercise less, consume harmful substances (e.g., alcohol or nicotine), and eat poorly, all behaviors that can have negative consequences for the fetus.

Stress itself may also create negative consequences for the fetus. During stress, cortisol is released in preparation for a fight-or-flight response. The fetus needs cortisol for maturation of organs, such as its lungs and kidneys; however, chronic stress may lead

to greater amounts of cortisol than the developing fetus needs. Dr. Nathanielsz from Cornell University argues that excess cortisol may direct the nervous system to develop a highly sensitive stress response system that overreacts to even mild stressors. Thus, prenatal experiences may design a nervous system that is easily overwhelmed, leading to a chronic stress experience during adulthood.

## PRENATAL CARE

Even in healthy women, pregnancy creates additional challenges for the woman's body. Early and consistent prenatal care is important to maintain the health of both the mother and the developing fetus. Recent research by David Barker and his colleagues suggests that prenatal experiences may be the most important determinant of overall lifetime health.

### Nutrition

The mother is the sole source of nutrition for the developing fetus. Thus, she must meet her own nutritional needs, while simultaneously meeting those of her child. If the woman is not getting enough nutrients, the fetus takes priority. The mother's body will go without in order to channel more resources to the fetus. The fetus also prioritizes nutrients, with the brain and other essential organs (e.g., heart) receiving the most. As a result, if a fetus lacks adequate nutrients, it may have a head that is proportionally larger than its body.

Pregnant women should increase their caloric intake by 10% to 20%, usually about 400 calories per day. The key to nutritional eating is not eating more, however, but instead choosing the right foods. Some nutrients can have harmful effects in large amounts. For example, vitamin A helps build skin, eyes, and other tissues; however, increased amounts are associated with birth defects in the face, urinary tract, and genitals. Similarly, iron helps create red blood cells, but it also interferes with the body's ability to absorb calcium and zinc.

Nutritional needs change over the course of pregnancy, in response to the developmental demands of the fetus. For example, during the first trimester, folic acid is necessary for proper development of the neural tube, which will become the brain and spinal cord. During the second trimester, calcium is an important nutrient for bones and teeth to develop properly. Protein is important during the last trimester, when the fetus is actively moving and rapidly growing.

Fetuses that do not receive adequate nutrition are at risk for premature birth, low birth weight, physical defects, nervous system problems, and immune system deficiencies. Nathanielsz argues that the nutritional content of the womb may have even longer-lasting effects by providing information to the developing organism about the scarcity or abundance of resources. In response, the developing nervous system alters its metabolism to either conserve or utilize calories, a program that will continue in the postnatal world. A combination of abundant postnatal food supply and a nervous system designed to conserve calories may explain childhood and adult obesity.

## Exercise

Exercise can be beneficial for pregnancy and labor. Good cardiovascular health enables the mother's circulatory system to meet the increased demands of providing nutrients and oxygen to two people instead of one. Exercise is also linked to mood elevation and decreased stress levels, which may help the expectant mother to avoid other methods of reducing stress, such as smoking or drinking. Researchers have shown that exercise is related to higher birth weights and shorter, less painful labor. Shorter labor decreases the risk for complications that can affect the emerging fetus.

Although exercise is known to be beneficial, certain cautions exist. Exercise should not leave the mother feeling breathless, dehydrated, or overheated. If the mother's heart rate gets too high, the fetus is at risk for elevated heart rate and oxygen deprivation. A doctor should always be consulted before a pregnant woman begins any fitness routine because certain conditions may require a modified exercise regime.

## Multigenerational Effects

Poor prenatal care can affect several generations. For example, a malnourished infant may have developmental limitations, which can then affect that individual's reproductive ability and fitness later in life. The notion of multigenerational effects is particularly relevant for female fetuses. A female infant will be born with all of the eggs that she will ever have. Thus, that infant's genetic contribution to her own offspring is formed while she is in her mother's womb. In this way, an unhealthy womb can affect the current offspring and the generation that is housed in that offspring's eggs. As argued by David Barker and colleagues, the prenatal

care a woman received while still in the womb may be a better predictor of her offspring's health than will the prenatal care she gets while pregnant.

## SUMMARY

The fetal period, which constitutes the longest portion of prenatal development, is a time of physical, behavioral, and cognitive changes. The experiences that a fetus has influence those changes and are influenced by those changes. This process of fetal development creates the framework from which the rest of an individual's life emerges.

## FINE MOTOR CONTROL

---

*Fine motor control* refers to the ability to precisely move and position the limbs, extremities, and digits (especially the fingers). Examples of fine motor control include grasping an object between the thumb and forefinger, tying shoelaces, using a spoon to bring soup to the mouth, and typing. Fine motor control is

essential to many activities of daily living (e.g., eating), educational activities (e.g., handwriting), and play (e.g., using a video game controller).

Fine motor control requires a tight link between action and the perceptual information used to prospectively (“feedforward”) and retrospectively (“feedback”) control movement. Although hand–eye coordination is a familiar concept in this regard, during fine motor control, an equally or perhaps more important role is played by *haptic* (touch) perception. Haptic sensory receptors (which are very densely distributed in the fingertips) are sensitive to mechanical stimulation of the skin and deeper tissues. Haptic perception plays a dual role in fine motor control—it provides the actor with *proprioception* (perception of the position and motion of the effectors) and *exteroception* (perception of touched objects or surfaces external to the body, such as a utensil grasped in the hand). Without the continuous, detailed perceptual guidance provided by the haptic system, precision actions such as threading a needle would be extremely difficult.

## DEVELOPMENT OF FINE MOTOR CONTROL

Behaviors that require fine motor control begin to appear early in the course of motor development. By about 1 year, infants can grasp objects in the hand and use a precision grip (i.e., holding an object between the thumb and forefinger). During the second and third years, infants learn to perform actions such as scribbling, drawing, using utensils, and stacking blocks. Fine motor control develops more rapidly after the third year, and actions begin to appear more smoothly integrated and dexterous.

Fine motor control is often contrasted with *gross motor control*—the control of large-scale body movements. Fine motor control development depends critically on gross motor control development because fine motor control requires the ability to control gross body movements and body posture. For instance, a child cannot tie his or her shoe without being able to balance while sitting or kneeling.

Fine motor control development also depends critically on perceptual and cognitive development. Vision and haptic perception must develop sufficiently to support fine motor control development. Cognitive skills, such as the ability to form appropriate behavioral sequences, must also develop sufficiently for fine motor control to develop.

## POSSIBLE PROBLEMS WITH FINE MOTOR CONTROL

Two common problems with fine motor control are developmental coordination disorder (DCD) and cerebral palsy (CP). DCD is associated with general clumsiness and problems with fine motor control. DCD affects about 6% of children in the United States. There is no single cause of DCD. DCD often accompanies other childhood disorders. CP is a cluster of chronic conditions that affects almost 800,000 children and adults in the United States. The most common cause of CP is brain trauma during pregnancy or childbirth.

Physical and occupational therapy are available as interventions for DCD and CP. Physical and occupational therapy can sometimes facilitate fine motor skill acquisition and can help individuals acquire the skills required to write and button clothing, for instance. However, individuals with DCD or CP may experience persistent problems with fine motor control, in which case continued therapeutic interventions are often required to manage the disorder.

## SUMMARY

Fine motor control is expressed during actions such as writing, typing, and tying shoes. Fine motor control development is linked to the development of gross motor control, perception, and cognition. Problems with fine motor control can sometimes be treated with physical and occupational therapy.

## FINE MOTOR DEVELOPMENT

---

One cannot help but marvel at the accomplishments of a skilled pianist, athlete, or craftsman. Even those without exceptional proficiencies display remarkable abilities for fine motor control. As I am typing, my fingers are moving rapidly in varying order and with remarkable spatial and temporal precision. We all perform everyday tasks, such as tying our shoes, with so little effort that we fail to appreciate how complex they are. Performance of these “simple” behaviors far outstrips the abilities of even the most advanced robots.

### MECHANISMS OF FINE MOTOR CONTROL

How are we capable of performing such sophisticated tasks? The most basic units of motor organization are found in the spinal cord. These circuits provide for the fundamental coordination between muscles as well as feedback control of movement. At a higher level, a group of brain structures, the basal ganglia, act as important “amplifiers” of movement. Damage to these structures in the neurodegenerative disorder, Parkinson’s disease, result in paucity of movement. Motor cortex is particularly important for controlling fine movements of the digits. It is the direct connection between motor cortex and spinal motoneurons that enable the fine, independent movements of the fingers necessary for typing or tying shoelaces. However, one could not type, play the piano, or conduct any other rapid sequence of complex movements without premotor and supplementary motor areas of the cortex. These regions are where sequences of movement are “programmed” in advance preparation for movement. Thus, during typewriting, premotor and supplementary motor areas develop a movement plan that is conveyed to the motor cortex, which in turn directs the movements of individual fingers as required. When one “visualizes” execution of a skilled motor behavior, these areas are activated, which is why previsualization and mental rehearsal of complex skills can improve performance. The cerebellum is another major structure of the nervous system of crucial importance for fine motor control. The cerebellum is best thought of as a structure that compares intended behavior, as dictated by motor cortex and the basal ganglia, to the actual output. The cerebellum acts to minimize the error between

intended act and the actual behavior and also ensures proper timing of rapid movement sequences. As one reaches for a coffee cup, the trajectory of the hand is continually being modified by cerebellum-mediated error correction. The importance of the cerebellum is clearly illustrated in the effects of alcohol intoxication, which profoundly affects cerebellar function. The coffee cup gets knocked over instead of being picked up, and typing becomes error prone. Maturation of these different parts of the nervous system are thus of critical importance for the development of fine motor control.

### DEVELOPMENT OF FINE MOTOR CONTROL

#### First 6 Months After Birth

The first 6 months after birth are dominated by spinal reflex mechanisms because brain mechanisms of motor control have yet to mature. So, for example, independent control of the digits is not possible. Instead, touching the palm of the newborn elicits a grasping reflex in which all digits act as a unit. Amplitude, direction, and force of movements are poorly controlled, and there is little evidence of goal directedness. Fundamental rhythms of movement that will later become organized into locomotion and other rhythmic behaviors are present, as are basic patterns of flexor–extensor alternation. Control of movement of the limbs progresses in a proximal to distal pattern, so that maturation of control of the shoulders and hips is more advanced than that of the fingers and toes. Infantile reflexes constitute a large part of the coordinated activity of newborns, but their relationship to later voluntary behavior is disputed. Whether they serve as essential precursors to later behavior, serve adaptive functions peculiar to the neonate, or simply reflect the state of maturation of the nervous and musculoskeletal systems is not clear. At about 6 months of age, most of these infantile reflexes disappear in anticipation of the development of voluntary control of movement. By about 6 months of age, most infants can visually direct their reach toward an object and correct that reach for movement of the object.

#### Development From 6 Months to 5 Years

During the period from 6 months to 5 years of age, there is remarkable maturation of the peripheral and

central mechanisms that control fine movement, which is greatly facilitated by practice and other experiential effects. Among the most notable milestones are the development of language and upright locomotion, both of which typically appear at the end of the first year after birth. It is generally thought that development of cortical areas important for planning and initiating movement and that maturation of the error-correcting cerebellum are crucial for effective execution of those movements. In the progression from crawling (belly on the floor) to creeping (belly elevated during quadrupedal locomotion) to assisted bipedal walking to independent walking, increasing demands are placed on the musculoskeletal system as well as on cerebellar assistance in maintaining balance and responses to perturbations. There is very little evidence to suggest that learning plays an important role in the onset of walking, despite the fact that this accomplishment is referred to as “learning” to walk. However, early walking is typically characterized by lifting and placing of the foot as a whole, rather than by the smooth heel-strike, rolling, and toe push-off that characterizes the adult. In early development, many movements are “mirror-image” movements, in which the intentional movement of one limb is reflected in the opposite limb. These mirror-image movements are thought to be a consequence of immature connections between the left and right sides of the cerebral cortex, which later in life serve to inhibit such movements. It is very clear, however, that after the first year of infancy, practice and learning play a large role in the acquisition and refinement of skills. During locomotion, one sees an improvement in the posture of the limbs and arms, more efficient movements of those limbs, and increasingly differentiated movements, especially of the digits. Thus, the toddler begins to grasp and throw objects. Initial attempts are not very skilled, and the result is not very effective. Toddlers typically begin to throw by stepping forward with the foot on the same side as the throwing hand rather than more effectively stepping forward with the opposite foot. Continued maturation of the motor areas of cortex and cerebellum contribute to these experience-dependent improvements. During this period, there is also increasing control of individual digits. Whereas the newborn uses all digits in unison, as the child matures, increasing control of individual digits becomes possible, so that by about 5 or 6 years of age, most children are able to tie their own shoes.

## Development From 5 Years Into Adulthood

Once the basic sensory and motor controls are in place, experience and increases in muscular strength become the primary factors in the further development of motor skills. Errors in movement are detected visually and by sensory structures in our joints and muscles. Visual feedback generally tells us the effectiveness of the movement, whereas feedback from our muscles and joints tells us how we achieved that end. Both the outcome and feedback from our muscles and joints are used to improve skills. Thus, improvement of motor skills in late childhood and adolescence is dependent on maturation of peripheral tissues (e.g., muscles), but also on improving central and peripheral coordination through practice. Thus, the little league pitcher learns to throw a curve ball, or the pianist learns to play piano compositions of increasing spatial complexity (different combinations of digits) and temporal complexity (rhythms). Sex differences in skilled motor behaviors typically appear during this time and are probably due to differences in peripheral anatomy and physiology that emerge during puberty and to social influences that lead to differential practice of different skills in males and females.

There is little evidence to suggest that there is a “critical period” for learning specific skills. For every childhood athletic prodigy, there is one who did not take up the sport until high school. There is little evidence that taping a tennis racket to a 5-year-old will enhance his or her chances of winning at Wimbledon. Thus, although there are generalized benefits from engaging in skilled motor behaviors in the form of improving strength and hand-eye coordination, specific expert skills can be acquired throughout adulthood. In this context, it is interesting to note that in the past 20 years, it has become apparent that the representation of movement control in the brain is not static, but that continued practice results in increased cortical representation of the associate skill throughout adulthood.

## AGING AND FINE MOTOR CONTROL

As during development, changes in fine motor skills during aging are dependent on changes in peripheral strength and flexibility and changes in central control of those skills. In the normal aging process, the amount of time it takes to preprogram fine motor sequences increases. However, this effect is much less for highly

practiced movements, probably because the earlier practice has made areas of the brain responsible for planning those movements less susceptible to decrement due to age. For example, a skilled piano player who experiences a 20% loss of motor processing ability may experience little decline in piano playing skill relative to the decline experienced for less-practiced skills (e.g., playing ping-pong). Loss of muscle strength may also play an important role in declining motor skills during aging, so that the same little leaguer who could throw a curve ball or fast ball may find a significant loss of these skills during aging. Recent findings are encouraging in that both nervous system controls and muscular strength are responsive to exercise, so that continued engagement in fine motor skills serves to minimize decline of those skills.

## FIREARMS

---

This article is divided into three parts. In the first part we consider the historical background of the development of firearms, in particular the invention of gunpowder and its effect on social structures, particularly in Europe. In the second part we examine the nature of firearms and the categories that relate to their design and use. Finally, in the last part guns in the community and the thorny issue of societal control over possession and use of firearms are addressed.

### BACKGROUND

#### History of Firearms

At its root, the history of firearms is the history of explosives.

Credit for the invention of gunpowder goes to ancient China. Ancient alchemists put minerals and plants together, hoping to make some medicine that would make people immortal. Almost by chance, the alchemists discovered that an explosion would occur if certain kinds of ores and fuel were mixed in the right proportions and heated. Inadvertently, they had laid the foundations, which would lead to the invention of gunpowder.

In November 2003, Chinese archaeologists discovered a network of caves at the Laojun Mountain in southwestern China's Sichuan Province, which was identified as a large saltpeter-manufacturing base, believed to have been used to produce gunpowder more than 1,000 years ago. According to historic records, ancient Chinese found that the mixture of saltpeter, sulfur, and carbon was explosive, which led to the invention of gunpowder sometime before the Tang Dynasty (618–907).

In the *Collection of the Most Important Military Techniques*, edited in 1044 by Zeng Gongliang, three formulas for making gunpowder were recorded, each an explosive mixture of saltpeter, sulfur, and charcoal. These have been identified as the earliest formulas for explosives. The method of powder making was introduced to the Arab world in the 12th century and to Europe in the 14th century. The explosive powder was originally used for making fireworks, but observation that compression of the powder, before ignition, leads to more powerful explosions suggested its use as a mining and demolition tool. Before too long, the capacity to maim and kill was recognized too.

### Invention of Guns

In January 2001, Wang Yulang of Harbin Institute of Social Sciences went to north China's Heilongjiang province to help catalog a collection of locally gathered artifacts. In the collection, he found a blunderbuss, made of copper. The blunderbuss, 38 centimeters long and weighing 5 kilograms (about 11 pounds), was probably made about 700 years ago, possibly sometime during the Song Dynasty (960–1279). It has been confirmed as being at least 100 years older than the previously designated "oldest firearm," a similar blunderbuss, which was probably made in about 1332. The newly found weapon has two Chinese characters carved on its barrel: "Shen Fei," meaning flying magically.

The suggestion is sometimes heard that the Chinese invented gunpowder but only used it for fireworks. The earliest illustration of a cannon dates

from China around 1127, close to 150 years before the development of cannons in the West. The Song also used gunpowder to make fire lances—actually flame throwers—and many other gunpowder weapons, such as antipersonnel mines.

Once the genie—knowledge that igniting gun power that had been compressed at the end of a tube would expel a solid body with massive (and often fatal) force—had been let out of the bottle, there was no putting it back. Guns and explosive devices burgeoned.

And that it was great pity, so it was,  
This villainous saltpetre should be digg'd  
Out of the bowels of the harmless earth,  
Which many a good tall fellow had destroy'd  
So cowardly; and but for these vile guns,  
He would himself have been a soldier.

—William Shakespeare:  
*Henry IV, Part 1, Act 1, Sc.3*

According to one academic, Shakespeare's condemnation of "villainous saltpetre" (I.iii.60) and "vile guns" (I.iii.63) tells us more about contemporary Elizabethan anxieties (*Henry IV, Part 1* was written in about 1596) than about the new technologies of war (guns). Before the mid-16th century, gun powder had been imported to England, principally from France; however, during the reign of Queen Elizabeth I (1533–1603), gunpowder factories had been established in Surrey at Long Ditton and at Godstone in the county of Kent. Although by the early 14th century, there existed rudimentary cannons or "siege engines," historical documents suggest that the Scots were exposed to cannon fire (cannons were referred to as the "crackkeys of war") in one or more battles during the reign of King Edward III (1327–1377). Nevertheless, the actual practice of warfare at the time of Henry IV (1399–1413) still depended more on the skill of archers and their deployment than upon firearms of any kind.

Despite Shakespeare's apparent abhorrence of guns and explosives (a view that continues to be shared by many people in countries around the world), it was the invention of gunpowder that brought the Feudal Age to an end. The kings of Europe used cannons, based on Chinese designs, to alter the social structure of Europe. The existence of such powerful armaments enabled kings to destroy the castles of the feudal lords (who challenged the king's omnipotence). Thus, the development of centralized nation-states was able to take place.

The existence of firearms also changed the nature of warfare forever. Although the development of the bow and arrow had removed some of the immediate need for close-quarters combat, most fighting had been undertaken by swordsmen, halberdiers, and assorted foot soldiers. Thus, the art of war before the existence of guns was easy; all the healthy men of a tribe or a nation could be marshaled and sent into the field to fight, at very short notice.

Consequently, the invention of firearms made the art of war more difficult because the process of making a citizen a soldier required a period of training. Thus, instead of every able-bodied man being ordered out to fight, comparatively small (but trained) standing armies came into being.

## GUN DEVELOPMENT

### Definition

Before we consider the way in which firearms have developed, it is essential that we have a definition to work with. First, the expression *firearm* does not include simple explosive devices, such as bombs, mines, antipersonnel mines, and so on. The problem is, however, that although one may apply the "I'll know one when I see one" logic to the problem of defining a firearm, most countries in the world have a slightly different *legal* definition of a firearm, which seriously complicates matters.

For instance, some legal definitions suggest that there is a distinction between a firearm and a gun, although the term *gun* is often used as a synonym. For example, from a British perspective, the term *gun* *legally* refers only to *smoothbore* firearms, machine guns, and naval artillery, distinguishing it from weapons that are rifled (i.e., have helical [spiral] grooves in the weapon's barrel [bore] that spin the projectile in flight and impart accuracy.) From such a viewpoint, a rifle is not a gun. By contrast, the American National Rifle Association (NRA) suggests that the British practice of restricting the term in such a way is erroneous. The NRA suggests that the term *gun* is properly used for rifles, shotguns, handguns, and airguns, as well as cannons. This is an insoluble semantic debate, which will not be pursued further here.

For reasons of semantic precision, we state that use herein of the term *firearm* does include guns, and offer the following definition based on NRA documents. A firearm is a rifle, shotgun, or handgun that uses

gunpowder as a propellant. The word includes machine guns. Airguns are not firearms.

Strictly speaking, in the United States, by federal definition (under the 1968 Gun Control Act), and in England (by the Firearms Act of 1968), antique weapons are exempt from such legal classification. The exemption is, however, one that relates to ownership and possession. (The word *antique* has different meanings here, too. In the United Kingdom, it refers to artifacts more than 100 years old kept as a “curiosity or ornament,” whereas in the United States, the expression means firearms manufactured before 1899, a firearm for which ammunition is not generally available, or a firearm incapable of firing fixed ammunition. In the State of South Australia, the expression refers to a weapon that was made before 1900 and that was designed to fire breech-loading cartridges and for which live rounds of ammunition are not commercially manufactured; or a firearm that was not designed to fire loaded cartridges and that is used solely for curiosity, display, or ornamental purposes and not to fire projectiles. The foregoing does not alter the fact that such antique items do fall within the general and broad definition of a firearm provided earlier. In an examination of the development of weaponry, it is to a consideration of such ancient weapons and their evolution that we now move.

## Historical Development of Firearms

### *Cannons*

Early cannons, later to develop into the class of weapons known as *artillery* (or *ordnance*), were excessively dangerous. The weapons were muzzle-loaders; that is, they were prepared for firing by inserting gunpowder at the open end of the barrel, compressing it (tamping it down) at the end of the body (the chamber), and then inserting a projectile into the barrel to rest on the powder. A flame or fuse was applied to a small hole (the touch hole) at the rear of the weapon, causing the powder to explode and the projectile to be expelled.

Usually made of iron bars held together with hoops of iron, these early cannons were wider at the mouth than in the body of the barrel and fired stone balls. They had a tendency to explode when fired, and some reports suggest that they were considered so dangerous that convicted prisoners were brought from jail to operate them in times of conflict. By about 1400,

cannons were cast from bronze, and the first cast-iron guns were in use by 1461.

The development of cannons was very slow. Sailors under the command of Admiral Lord Nelson at the Battle of Trafalgar (1805) and soldiers directed by the Duke of Wellington at the Battle of Waterloo (1815) used cannons that had barely changed from those described previously: cast-iron muzzle-loaders, firing balls surrounded in heavy grease clouts (to make them fit the barrel). Each of Nelson’s guns required a crew of at least eight men. When a shot was fired, the gun crew hauled the heavy gun inboard with ropes, swabbed it out, and recharged it.

In 1856, Henry Bessemer (1813–1898) developed a way of mass-producing steel by a process known to this day by his name (the Bessemer process). Steel has a far higher melting point than iron, and as a consequence, it was possible to solve an ordnance problem. Muzzle-loading guns were very energy inefficient. The ball (or shot in hand and shoulder weapons; see later discussion) left the muzzle before the full power of the powder explosion had been used up, and if the charge was too great or poorly compressed, an iron gun tended to melt internally and explode.

Thus, in 1869, staff at the Royal Gun Factory in London designed a large gun with an inner steel tube in place of an iron one. There was a rapid increase in the size of cannons. The first weighed about 35 tons, but that was rapidly followed by cannons weighing about 81 tons and even one that weighed 110 tons.

The change in military capacity brought about by the invention of steel was massive. In Nelson’s time, firing did not begin until ships were within a few hundred yards of one another. However, in World War I (WWI) at the Battle of Jutland (1916), the two sides were 15 miles apart when the battle commenced. Later in WWI, the city of Paris was fired on from a distance of more than 60 miles.

## Loading and Firing Mechanisms

Contemporaneously with the development of cannons, smaller weapons were being developed. Muzzle-loaders like their bigger brethren, the earliest “hand gones” were little more than a small cannon with a similar touch hole for ignition. The user was required to place the barrel of the gun on a stand, bracing it with one hand against his chest. The shooter then used the other hand to touch a lighted match to the touch hole. This gun was notoriously inaccurate (because it was a

muzzle-loader, the shot had to be smaller in diameter than the barrel of the gun and thus, when expelled, tended to wobble about in the barrel, making the direction of the discharge very imprecise). Such guns had an effective range of only about 30 to 40 yards.

For many hundreds of years, arrow makers (fletchers) had known that if, when an arrow was made, the fletchings (usually feathers) were set at a slight angle, it caused the arrow to spin when released from the bow and to travel further and be more accurate. It is not surprising therefore that in the development of handheld weapons, rifling was first used in gun barrels during the 15th century. Nevertheless, it was comparatively rare and was not commonly found until the development of steel gun barrels and of ammunition (bullets) that accurately fit the internal dimensions of the barrels.

Generally speaking, improvements in the design of handheld weapons were mostly in connection with ignition systems.

Firing a weapon by touching a match or fuse to a small hole while at the same time holding the gun steady was excessively difficult. In addition, even if the gun could be held steady, there was no guarantee that the powder would ignite.

Although there were intervening designs, including the match lock (about 1400) and the wheel lock (1517), the key improvement was that the touch hole was moved to the side of the gun barrel, and a cup was placed at the opening with a lid on it. The cup (called a flash pan), which had a small cover to prevent the use of the firearm being affected by the weather, held a small amount of gunpowder that could easily be ignited. When the powder began to burn, some of the fire would go through the touch hole and ignite the gunpowder inside the barrel, thereby firing the gun.

Later ignition systems on guns with a flash pan were designed to ignite the gunpowder in the flash pan automatically at the press of a lever or trigger. This was accomplished by either putting the end of a burning wick into the flash pan or using a flint and steel combination to throw sparks into the flash pan (flintlocks, developed in 1612).

In 1805, the development of the percussion cap was a precursor to all modern firearms. The key feature of this ignition process is that it does not use an exposed flashpan. As a replacement for that inefficient system, the weapon is manufactured with a simple tube at the breach end, which leads straight into the gun barrel. An explosive cap (filled with fulminate of mercury, which explodes when struck) is placed on

top of the tube. The flames from the exploding chemical go down the tube, into the gun barrel, and ignite the powder inside the barrel, expelling the bullet.

This new percussion cap firing mechanism was a significant development in firearms design, improving the reliability of weapons and enabling ammunition design to develop at a significant pace. The development of the percussion cap was the first stage in the development of rotating-block guns (revolvers; e.g., the Colt .45), which could be practically guaranteed to fire. By the late 1800s, commercial production of such multiple-shot side arms was well underway.

## **Small Arms: Handguns, Long Guns, and Machine Guns**

### *Handguns*

Handguns are small, potentially concealable weapons, commonly lightweight. Outside the military world, handguns are the usual armament for the police (in those jurisdictions where the police are usually armed) and, again in some jurisdictions, for possession in public by private citizens where an appropriate license or authority is held. Handguns with a fixed firing chamber are pistols. Pistols are sometimes single shot, particularly when used for target practice, but can also be capable of holding multiple rounds. Most pistols that hold multiple rounds are semiautomatic (a semiautomatic pistol reloads the chamber with a new round automatically once the weapon is fired, without additional action by the user; each shot fired requires operation of the trigger mechanism) or are revolvers. There are a small number of fully automatic pistols (e.g., the Glock 18 and the Mauser C96) in which a single depression of the trigger fires multiple rounds. The revolver holds a number of firing chambers in a revolving cylinder, and as with the semiautomatic weapon, each shot fired requires operation of the trigger.

### *Long Guns*

Long guns fall into one of two categories: rifles or shotguns. A rifle has a rifled barrel and fires single bullets. By contrast, most shotguns are smooth bore (i.e., have no rifling) and fire large packets of shot or, alternately, a single slug.

Rifles are manufactured for accuracy and long-range targets and are usually aimed. Shotguns, which have large impact area with a small range, are usually simply pointed at the target.

A short rifle (commonly with rapid fire capability) is usually called a carbine. The carbine is distinguished from the submachine gun (see later) by its type of ammunition. Carbines use rifle rounds, whereas handguns and submachine guns do not.

### **Machine Guns**

A machine gun is typically a small-caliber fully automatic weapon capable of firing bullets in rapid succession. The trigger does not have to be pulled for each round to fire; the weapon fires as long as the trigger is held down.

Machine guns are divided into two classes: light machine guns and heavy machine guns. Each of these types of weapon has a slightly different practical purpose. The former are used for laying down a wide band of continuous fire (known as a *cone of fire*) in order to suppress enemy activity; the latter are far more accurate, capable of sniping (with rapid fire) over large distances. Weapons known as submachine guns are light machine guns that fire the types of ammunition normally used in pistols.

## **GUNS IN THE COMMUNITY AND FIREARMS CONTROL**

The issue of the presence of guns in the community and whether or not there should be controls on private ownership is a matter of enormous contention. It is not the purpose of this article to support either gun control or freedom to possess guns philosophies. It is merely to report on the two sides of an argument, common around the world, which are summed up in the viewpoints of two American organizations: the National Rifle Association (NRA) and Handgun Control Inc.

According to the NRA, the following data exist with regard to firearms ownership in the United States:

- Privately owned firearms in the United States: more than 200 million, including 65 to 70 million handguns. The number rose by 52 million during the 1990s. (Source: Bureau of Alcohol, Tobacco, Firearms and Explosives)
- Gun owners in the United States: 60 to 65 million; 30 to 35 million own handguns
- American households that have firearms: about 45%

Handgun Control, Inc. simply maintains that these data suggest, particularly when coupled with data on the volume of crime (particularly homicide) in which firearms

are used, that the number of weapons in circulation is excessive and requires restriction.

The U.S. Constitution enshrines the people's right to keep and bear arms in its Second Amendment. It reads: "A well regulated militia, being necessary to the security of a free state, the right of the people to keep and bear arms, shall not be infringed."

In practice, there *are* certain restrictions on gun ownership (e.g., on "assault" weapons—a tricky term in its own right), and the laws governing gun use vary considerably from state to state.

Amending the Constitution to *prohibit* guns is rarely discussed. Many Americans view the right to bear arms as an important civil liberty, but opinion is divided between those who insist on the unfettered right to bear arms and those who advocate stricter controls. However, because the Federal Bureau of Investigation (FBI) estimates (2000) that 66% of the 15,517 murders that year were committed with firearms, and because many fatal shootings in recent years involved teenagers, *gun control* is a source of impassioned debate in U.S. politics.

The core issue is whether or not it is lawful (i.e., constitutional) to impose stricter controls on gun usage.

Proposed gun control legislation has concerned childproof locks, background checks on gun purchasers, the outlawing of some types of assault weapons, and most recently, the creation of a nationwide database of ballistic fingerprints in order to track the movement of the nation's guns.

The influential firearms lobby, headed by the NRA, believes gun ownership to be a personal and moral right and dismisses the link between gun ownership and high gun violence with its slogan "Guns don't kill people, people kill people."

Advocates of firearm control argue that the Second Amendment is anachronistic, belonging to the long-gone days of the frontier. They point to the high levels of gun-related murder and violent crime in the United States to stress the need for reform. Handgun Control Inc. retorts that "Guns don't die; people do."

The issue of removing the number of guns that are already in circulation is rarely discussed.

### **The Problem**

Various (selected) research reports the following information:

- Homicide is the second leading cause of death among 15- to 24-year-olds overall. In this age group,

it is the leading cause of death for African Americans, the second leading cause of death for Hispanic Americans, and the third leading cause of death for Native Americans.

- In 1999, 4,998 youths ages 15 to 24 were murdered—an average of 14 per day.
- Guns are a factor in most youth homicides. In 1999, 81% of homicide victims ages 15 to 24 were killed with firearms.
- A disproportionately high number of 5- to 14-year-olds died from suicide, homicide, and unintentional firearm deaths in states and regions where guns were more prevalent.
- In a study by a Harvard research team, it was stated that across developed countries, where guns are more available, there are more homicides.
- Guns kept in homes are more likely to be involved in a fatal or nonfatal accidental shooting, criminal assault, or suicide attempt than to be used to injure or kill in self-defense.

Such apparently straightforward research findings are strongly criticized (often with some justification) on the grounds of their apparent bias toward the gun control lobby, generally on the ground of methodologic or statistical impropriety. On the other hand, despite such dispute, there is a limited amount of research offering alternative hypotheses.

The real problem here is that almost without exception, such studies are correlational. Correlational studies describe the observed relationship between instances of two events. A systematic pattern can be seen in the occurrences of events that are correlated. The relationship is expressed in the form of a correlation coefficient (a number between  $-1$  [negative correlation] and  $+1$  [positive correlation]). When the events involve observed frequencies of events, a positive correlation means that as one increases, the other increases as well; a negative correlation means that as one increases, the other decreases. Correlation does *not* imply causation in any way.

In other words, just because two events are correlated does not mean that one causes another, or has anything to do with the other—correlations deal only with observed instances of events, and any further conclusions cannot be inferred from correlation alone. Most statisticians accept that a strong correlation, however, does often warrant further investigation to determine causation. Many of the studies to be found in this contentious area do show correlations, but where they are quoted (they often are not), they are weak.

One contentious study conducted by Martin Killias of the University of Lausanne compared, using a database of 18 countries, the numbers of households with guns, the overall frequency of homicide, and homicide using a gun. The latter matrix produced a correlation coefficient of 0.56 (statistically significant but not excessively strong), and its identification was a significant factor in the additional restrictions placed on gun ownership in the United Kingdom. However, it is argued by opponents that there is little meaning in the extant correlation between the number of households with guns and homicides with guns because the correlation with “all homicides” is statistically not significant (0.39). This suggests that the total number of homicides is likely to be unaffected by a restriction on guns in the home; therefore, such a ban is viewed as illegitimate.

Generally speaking, the arguments of the opponents to gun control revolve around the idea that the blame for gun homicide lies with the persistence of violence in the United States, and not with ease of access to guns. Violence is seen as being the consequence of poverty (particularly in the poorer Southern states) based on the cycle of government dependency; broken families; the failure of public education; and the cultural disintegration that has allegedly been taking place for decades. The federal government is seen, from such a perspective, as being largely responsible for this state of affairs.

There is a certain irony in the fact that those who advocate the freedom to own (and use) weapons, who are usually defined as conservatives and are seen as being on the right wing of political thought, use the shibboleths of the liberals (left wing) in their explanation of violence and gun-related homicide.

## FIVE-FACTOR MODEL OF PERSONALITY

---

Personality traits are patterns of thoughts, feelings, and behaviors that are relatively enduring across the life span. The history of personality psychology has witnessed the birth of numerous traits and trait models of personality. In the 1980s and 1990s, the five-factor model (FFM) ascended to popularity and is considered by many personality psychologists to offer a comprehensive trait taxonomy.

The traits that constitute the FFM are extraversion, neuroticism, openness to experience, agreeableness, and conscientiousness. Extraversion, sometimes referred to as *surgency*, is indicated by assertive, energetic, and gregarious behaviors. Neuroticism is essentially equivalent to emotional instability and can be seen in irritable and moody behaviors. Openness to experience, sometimes referred to as *intellect*, indicates an individual’s inquisitiveness, thoughtfulness, and propensity for intellectually challenging tasks; whereas agreeableness is indicated in empathic, sympathetic, and kind behaviors. Finally, *conscientiousness* refers to an individual’s sense of responsibility and duty as well as foresight.

The FFM was developed largely on the basis of the *lexical hypothesis*, which suggests the fundamental traits of human personality have, over time, become

encoded in our language. Following this hypothesis, the task of the personality psychologist is to cull the essential traits from the thousands of adjectives found in language that distinguish people according to their behavioral dispositions. The lexical hypothesis can be traced back to the 1930s, and the advent of multiple factor analysis in that same decade provided an empirical method for culling these verbal descriptions. In the latter half of the 20th century, personality psychologists in fact relied primarily on factor analysis to discover and validate many of their trait theories. A large number of personality psychologists have concluded that the FFM represents the most successful outcome of these efforts.

Three lines of research have provided support for the construct validity of the FFM. First and foremost, the five factors have consistently emerged from factor analyses conducted on numerous data sets composed of descriptive trait terms from a number of languages, including English, Chinese, and German. Second, twin and adoption studies have revealed a substantial genetic component (as high as 79%) to the five factors. Third, the five factors have been applied across the life span. For instance, studies have shown that children use the five factors when freely describing themselves and others, and parents’ natural language descriptions of their children can be classified according to the five factors. Individuals’ relative standings on the five factors have also been shown to be fairly stable across much of the adult life span. Recent efforts have finally sought to explicitly treat the five factors as temperaments that are present from birth, thus placing the FFM squarely in a developmental context.

Despite all of its success, the FFM has been roundly criticized by a number of scholars. One issue raised by these scholars concerns the absence of a comprehensive theory. The lexical hypothesis, while intriguing and rational, is considered far too narrow to qualify as a theory of personality. A related issue regards the generic nature of the factors, which are considered to be too broad to provide a sufficiently rich understanding of human personality. Critics have also raised important methodological concerns, which have revolved around the use of factor analysis as the primary tool of discovery and validation for the FFM. Finally, disagreements among trait theorists have also been prominent in the literature. Some researchers have argued that three traits are sufficient: extraversion, neuroticism, and psychoticism (egocentric, cold, impulsive). Others have argued that a larger number of traits are needed to provide a comprehensive taxonomy.

The FFM will nonetheless likely continue into the foreseeable future as a popular trait model of human personality. The five factors have proved extremely useful to researchers and practitioners in a variety of areas, such as the social, clinical, and industrial-organizational domains. It has unquestionably generated a great deal of research and discussion, and it has played an important role in revitalizing the discipline of personality psychology.

## FIVE-TO-SEVEN SHIFT

---

When you explain to your 5-year-old nephew that his mother is your sister, he stares at you in disbelief. His 7-year-old sister, however, immediately understands that her mother could also be someone's sister. The difference between your nephew's and niece's understanding illustrates the dramatic changes in children's cognitive functioning that occur between the ages of roughly 5 and 7. Developmental psychologist Sheldon White introduced the term *five-to-seven shift* in 1965 to refer to the cognitive reorganization to which many of the changes were attributed.

White conceptualized this “shift” in terms of Jean Piaget's theory of intellectual growth, the dominant paradigm of cognitive development at the time. Piaget, a Swiss psychologist who began studying

children in the 1920s, proposed that cognitive development proceeded through an invariant sequence of stages, whereby each stage incorporated or replaced the previous stage. The five-to-seven shift marked the crucial transition from what Piaget termed the “preoperational” stage, to the stage of “concrete operations.”

Preoperational thinking was characterized by the child's reliance on the perceptual features of a situation. Concrete operational thought enabled the child to distinguish between the changing appearances of things and the logical or physical properties that remain constant. For example, when 5-year-olds are presented with a situation in which liquid is poured from a wide, narrow beaker into a tall, thinner one, they typically assert that there is more water in the taller beaker because the water level is higher. Seven-year-olds will recognize that the quantity of water remained the same, or was “conserved.” When questioned, they will explain that no water has been added or taken away, that if the process were reversed the level of water in the first beaker would be the same, or that the second beaker is taller but narrower than the first.

Piaget's seminal contribution to our understanding of cognitive growth was his recognition that at every point of development, children's performance is an expression of some underlying cognitive structure. He hypothesized that cognitive competence was “constructed” through children's active interaction with the environment. This model of children's intellectual development provided an alternative to the long-standing philosophical and psychological traditions of nativism and environmentalism. Nativists understood intellectual growth as the unfolding of an inborn capacity for reason, as inevitable and predetermined as the child's physical maturation. Environmentalists considered the child at birth to be a blank slate, on which experience etches connections often organized by language and social practices.

Piaget assumed that children's performance on a variety of tasks and in different content areas reflected a singular underlying stage of cognitive competence, which accounted for the parallel changes in their understanding of logic and mathematics, physical properties, biological concepts, and social-psychological phenomena. However, the Piagetian assumption that one underlying structure dictated cognitive activity in different content areas, and that children could be neatly classified as being in one particular stage or another, has become controversial.

Since White originally proposed his theory of a five-to-seven shift, it has been shown that 5-year-olds

are more logical and better problem solvers than many Piagetians claimed, particularly when they are judged on their own terms and in familiar situations. Cross-cultural studies have demonstrated that competence during this period is highly dependent on the kinds of roles and responsibilities that children take on as part of a social group. Others have suggested that if anything underlies the cognitive changes that take place between the years of 5 and 7, it is children's use of language as a tool to manipulate thought. Still others point to the mediating influences of visual culture and information technology on children's development.

Furthermore, many contemporary psychologists and educators are skeptical of the unitary and context-independent aspects of Piaget's theory. It has been demonstrated that children's performance on different tasks and in different content areas is variable, which is inconsistent with the Piagetian stage model of cognitive development. Cognitive growth is currently recognized as being more continuous and incremental, more specific to context and content, and better understood in terms of functionally independent "domains," "frames," or "modules."

The changes that occur between the ages of 5 and 7 are currently understood as a shift in children's characteristic tendencies and preferences of thought, rather than a wholesale reorganization of cognitive functioning. This view reflects the compelling evidence that 5-year-olds are as capable as older children of complex reasoning and remembering, even if they fail to recognize the conditions that require those capacities. In the light of these findings, White has reformulated his understanding of the five-to-seven shift, no longer deeming 7 as the "age of reason," but rather the "age of being reasonable."

## FLAVELL, JOHN (1928– )

---

John Flavell is credited with introducing the work of Piaget to American psychology and founding the field of metacognition.

Flavell is a preeminent figure in modern developmental psychology. Born in Rockville, Massachusetts, he was educated at Northeastern and then earned a PhD in clinical psychology at Clark University. There, he was introduced to Heinz Werner's organismic-developmental theory, beginning a lifelong passion for the study of children's thinking. After a brief period as a clinical psychologist at a Veterans Administration hospital in Colorado, Flavell accepted a teaching position at Rochester and then moved steadily westward, initially to Minnesota, and finally to Stanford University, where he is now an Emeritus Professor.

Three of Flavell's many contributions to developmental psychology stand out. First, his brilliant treatise on the work of Jean Piaget effectively introduced Piaget, and the structuralist approach to children's thinking, to American psychology. So clear and compelling was Flavell's presentation that the Piagetian approach quickly became the dominant paradigm in cognitive development, and it remains a powerful force in that field.

Second, Flavell has written a series of seminal theoretical essays on cognitive development. These now classic essays address, for example, the validity of the "stage" construct in explaining development, the nature of developmental sequences and transitions, the methodological pitfalls associated with diagnosing cognitive competence, the relation of memory to cognitive development, and the nature of metacognition. Flavell further discussed these issues in his highly successful textbook

on cognitive development, the first on that topic to appear in North America.

Third, Flavell has carried out ground-breaking empirical research on children's metacognition (much of it in an extended collaboration with Eleanor Flavell and Frances Green). Just as it is difficult to imagine what the field of cognitive development would look like today had there never been a Piaget, so it is with metacognition and Flavell. He has pioneered research into children's knowledge about memory (which he christened "metamemory"), the development of their perspective-taking and communication skills, their knowledge about perception, their understanding of the appearance-reality distinction, their developing "theories of mind," and their understanding of thinking and consciousness. His discovery of two levels of visual perspective-taking has been especially influential. At level 1 (2 to 3 years of age), children understand that others may not see something that they do and vice versa, whereas at level 2 (4 to 5 years of age), children further recognize that two individuals viewing the very same thing may nonetheless see it differently. Similarly influential is his finding that younger children fail to recognize the distinction between appearance and reality—that, for example, an object may look like one thing but actually be something quite different. Flavell incorporated these and related findings into a persuasive "connections-representations" account of theory-of-mind development.

Flavell is a past president of the Society for Research in Child Development (SRCD). He has received numerous awards, including an American Psychological Association (APA) Distinguished Scientific Contribution Award and an APA Mentoring Award in Developmental Psychology. In addition, Flavell is one of very few developmental psychologists ever to be elected to the National Academy of Sciences. He remains a prominent contributor to the developmental literature.

## FLUID INTELLIGENCE

---

General fluid intelligence (Gf) refers to the ability to solve new problems, particularly when mentally effortful reasoning processes are required (such as inference, induction, abstraction, or synthesis). That is, Gf is involved in working out a novel solution, but not in simply remembering a previous solution. Gf is often contrasted with general crystallized intelligence (Gc), which represents culturally relevant knowledge and skills. Although Gf and Gc are distinct, Gf can support the acquisition of skills and knowledge that contribute to Gc.

Technically, Gf is a statistical construct derived from the factor analysis of mental-test scores. Factors representing the shared variance among particular tests are often interpreted as reflecting specialized latent abilities, talents, or intelligences that determine performance. Gf is typically derived from hierarchical factor analyses, in which the positive correlations among *factors* (rather than correlations among specific tests) specify common ability dimensions at a higher level, or "stratum," of generality. An overarching Gf factor emerges at the second stratum when a test battery produces several reasoning factors at the first (e.g., verbal induction, figural sequencing, and quantitative reasoning). The presence of a Gf factor indicates that people who are skilled at reasoning in one domain tend to be skilled in other domains; Gf represents the shared variance among reasoning domains.

The Gf-Gc theory of intelligence was first proposed by Cattell and elaborated by Horn. It is intermediary between views that intelligence is unitary or general (e.g., Spearman) and views that intelligence is a collection of many independent abilities (e.g., Guilford). One of the theory's primary strengths is in accounting for changes in intelligence across the life span. Whereas Gf rises until young adulthood and begins to decrease thereafter, Gc continues to rise through middle age and either levels off or drops slowly thereafter. A unitary (general) theory of intelligence cannot account for this differential developmental pattern.

The cognitive and neural mechanisms that support Gf are topics of active research. Working memory and the executive control of action are strongly linked to Gf and to the function of the lateral prefrontal cortex (PFC). The lateral PFC appears to be involved more in Gf than Gc: Patients with PFC damage often have normal IQ as assessed by Gc tests, but they show impairment on Gf

tests. Although the specific ways in which PFC and other brain regions contribute to intelligence is less well understood, neuroimaging studies indicate that PFC and parietal brain regions are activated when people perform prototypical Gf tests, including reasoning and working memory. In a study by Gray and colleagues, individuals with higher Gf were more accurate on a working memory task and had greater neural activity during the most demanding components of the task, particularly in lateral PFC and parietal cortex. Thus, working memory, executive control, and the lateral PFC appear to be important cognitive and neural contributors to Gf.

Genetic studies consistently show that general cognitive abilities are partly heritable. Although few genetic studies have examined Gf specifically, fluid intelligence is very strongly related to general intelligence and IQ. Importantly, environmental factors have a greater influence on childhood IQ in impoverished families than in families of higher socioeconomic status. That is, intelligence may be influenced by genetics only when environmental conditions are favorable. Other environmental influences include lead poisoning (negatively related) and the duration of breast-feeding (positively related). Situational factors, including anxiety, can adversely influence performance on tests, especially on tests described as assessing mental ability.

## FORMAL OPERATIONAL PERIOD

---

The formal operational period is the fourth stage of Jean Piaget's cognitive developmental theory. Formal operations incorporate, extend, and complete prior cognitive growth. Individuals begin to demonstrate formal operational characteristics between ages 11 and 15. In each stage, behavior is internalized into cognitive structures or schemes, thereby becoming repeatable and cognitively reversible. Individuals in the preceding concrete operational period use grouping structures, such as class inclusion and serial ordering, whereas formal operational individuals incorporate grouping structures with lattice structures. Lattice structures integrate many problem-related schemes to develop and use inclusional, propositional, and inferential statements about a problem's variables.

Formal operators think more abstractly, from the actual to the possible. They solve problems without using tangible, intuitive, or believable phenomena as they classify and link elements of a problem. In other words, they do not need to experience the world firsthand to generate, reflect on, and integrate information into the problem-solving scenario. This skill supports Piaget's conception of egocentricism, a decentering process that evolves from stage to stage. It also explains why adolescents are more reflective, sensitive to others, and aware of social mechanisms and how they take the emotional perspective of others and understand people's motives.

Compared with concrete operators who employ inductive reasoning, using one incident to generalize about many others, formal operators use a more rigorous and productive form of logic, hypothetico-deductive reasoning. It allows individuals to comprehend many

permutations and contradictions when developing a theory about a problem. To represent factors and factorial relationships in theory development, hypothetico-deductive reasoning employs transformations or 16 propositional statements. Transformations are dependent on the problem type and can be identified by propositional language, such as if-then and either-or.

Formal operators are also more scientific and systematic than concrete operators, who tend to be disorganized. Formal thinkers methodically vary one factor at a time and hold the other factors constant as they keep track of each test result. They use a combinatorial system that fosters perception and organization of all possible factors and incorporates them into transformations. Inefficiency and error in problem solving are thereby reduced. The ability to generate possibilities, to use hypothetico-deductive reasoning, and to be methodical when problem solving explains many of the increased cognitive achievements of adolescents and adults. Consequently, Piaget's theory has greatly influenced educational practice and perceptions of cognitive development.

However, research exploring formal operations has fostered criticism of Piaget's theory. Studies reveal that formal operational skills are not utilized by many adolescents and adults, are more often used in Western cultures than other cultures, are related to formal schooling, and can be taught to children younger than 11. Piaget briefly addressed these issues when he asserted that formal thought was not a universal achievement and that environmental as well as genetic processes were influential in cognitive development. Unfortunately, he did not explain which genetic and environmental factors have influence and how they interact to foster formal skills.

Other studies have shown that formal skills (e.g., use of transformations) are not consistently employed across problem types. Although Piaget asserted that problem type influences the transformations used, he did not match problem type with transformation type. Furthermore, Piaget and his colleague, Bärbel Inhelder, used only scientific problems when exploring and illustrating formal operations, making application of formal skills to nonscientific adolescent problems more difficult. Some, such as Lawrence Kohlberg and David Elkind, have successfully applied Piaget's theory as a foundation for exploring nonscientific problems. Kohlberg built on and revised Piaget's ideas to develop a

theory of moral reasoning, and Elkind used Piaget's views as a basis for exploring his conception of adolescent egocentrism.

Additionally, Piaget's assertion that formal thinking completes the prior stages of cognitive development has been questioned. Some suggest that cognitive development continues into adulthood. However, they often use formal thinking as a basis for describing further development and posit a postformal operational stage, a problem-finding stage, dialectical thinking, or wisdom as examples of adult cognition. A theory can account for certain cognitive phenomena and lay groundwork for further research, but it can not describe all of cognitive development. Regardless of the theory's deficiencies, the formal operational period explains many aspects of adolescent cognition and has provided a strong foundation for research.

## FOSTER CARE

---

Foster care is defined as 24-hour substitute care for children outside of their own homes. It is generally conceived of as a time-limited living arrangement in which a child whose family is unable to maintain a sufficient child-rearing environment is placed with licensed caregivers until reunification with birth parents, adoption, or emancipation occurs. Foster care is a legally binding arrangement in which the state temporarily assumes custody of the child. Reasons for placement into foster care are diverse and include but are not limited to child abuse, neglect, parental substance dependency, mental or physical illness, and incarceration. In the past decade, there has been an increase in the number of reports of child abuse and neglect to child welfare agencies in

addition to higher numbers of mothers and pregnant women with substance abuse problems. Consequently, foster placements are involving younger children and infants more often than in the past, and these children are likely to stay in foster care longer than children placed at older ages.

The number of children in foster care has expanded in recent years, with estimates exceeding 550,000 at any given point in time. Further, it has been reported in numerous studies that these children are experiencing high levels of emotional, behavioral, and medical difficulties. Behavioral and psychological problems among foster children may persist because of caregiver instability, the effects of early maladaptive caregiving, attachment disruption, and insults to developing brain systems. In light of these alarming findings, there has been a movement toward identifying the most effective placements for children who cannot be maintained in the homes of birth parents. The promotion of the child's growth and development through a safe and nurturing atmosphere has become a primary goal of most child welfare agencies. Recent social and political trends reflect our society's efforts to create a foster care system that maximizes children's opportunity for nurturing care in the context of stability.

## **SOCIAL AND POLITICAL TRENDS IN FOSTER CARE**

The emergence of foster care in the United States can be traced back to the efforts of Charles Loring Brace, who in 1853 founded the Children's Aid Society of New York, an organization that established modern methods in child welfare. In the late 1800s, Brace spearheaded efforts to place children from New York City with families from the Midwest and other rural locations, where they were adopted, obliged to work on farms, or both. The system improved many lives, but some of the children were exploited as free labor. Following several scandals, it became evident that more supervision was required by state agencies to ensure that children were not being mistreated. In 1909 at the White House Conference on Dependent Children, Theodore Roosevelt established the first legislation supporting the use of foster families for destitute and neglected children. This helped pave the way for a federal agency devoted to the promotion of child welfare. The Children's Bureau was started in 1912 and has remained as part of the U.S. Department of

Health and Human Services, focusing on foster care, adoption, and child care standards.

Several other landmark political actions have contributed to the development of the modern foster care system. In 1935, the Social Security Act contained provisions for aid to dependent children. Funds were allocated for low-income children and children who were abused, neglected, or abandoned. It was not until 1961, however, that the federal government developed a formal method for disseminating funds for foster care. The Aid to Families with Dependent Children provided financial incentive to qualified individuals to serve as foster parents. An unintended consequence of this measure was that increasing numbers of children were removed from the homes of troubled families without first attempting any sort of intervention with these birth families. In response to the burgeoning numbers of children (nearly 500,000) in foster care and the movement toward family preservation, the Adoption Assistance and Child Welfare Act (AACWA) was implemented in 1980. This legislation provided financial incentives to encourage states to prevent unnecessary foster placements by offering preventative services and programs to reunite foster children with birth families. Initially, there was a dramatic decrease in the number of children in out-of-home placements to about 250,000 in the early 1980s. This law helped to propel the movement toward "permanency planning" by providing set time frames for placement decisions in order to reduce the number of extended foster placements.

Social and political initiatives favoring permanency planning continued throughout the 1990s. In particular, two laws were passed to reduce barriers to expeditious, long-term placements. The Multiethnic Placement Act (1994) responded to concerns about extended placements and poor outcomes for minority children in foster care. The Multiethnic Placement Act prohibited discriminatory placement practices and forbade the delay or denial of foster or adoptive placements because of race, color, or national origin. Another initiative, the Adoption and Safe Families Act (1997), continued to make placement permanency a priority by federally mandating efforts to reduce children's time spent in foster care. Child welfare agencies were commissioned to locate a permanent placement for children within the first 12 to 15 months following admission into foster care. The purpose was to reduce the number of children in long-term foster placements and to promote the adoption of

children unable to return to a safe home environment. The Adoption and Safe Families Act emphasized the safety of children first and foremost, but it also clearly established a timeline for permanency planning.

It is evident that certain aspects of the foster care system remain problematic despite the laudable efforts of our legal and social institutions. As of 2003, the U.S. Department of Health and Human Services reported that the number of children in foster care at any given time is greater than one-half million as a result of neglect, abuse, and other maladaptive parenting practices. Moreover, these children are being identified as having a range of behavioral and emotional disturbances that are more serious than in the past. It is unlikely that political initiatives will completely remedy problems associated with out-of-home placements, and it is equally clear that no simple solution exists. There will likely be continued debate regarding those conditions in which a child benefits from remaining with his or her biological family and those situations in which a child is best served by a temporary or permanent out-of-home placement. Recent initiatives that have placed a priority on children's safety and emotional security while advocating for the permanency of such placements are likely to lead to positive outcomes for many children.

## TYPES OF FOSTER CARE

Foster placements differ on a number of characteristics based on the needs of the individual child and the resources available to meet those needs. Four basic types of out-of-home placement are most prominent: *family foster care*, *kinship care*, *treatment/specialized foster care*, and *group foster homes*.

### Family Foster Care

*Family foster care* refers to continuous 24-hour childcare and supervision by a licensed or approved nonrelative caregiver. These foster parents are typically monitored by private or public child welfare agencies. Although some foster parents eventually choose to adopt, most family foster care placements are temporary. The role of nonrelative foster parents includes providing care, supervision, guidance, and a safe environment for a foster child. Even within this type of foster care, there are different kinds of arrangements. Some families serve as emergency foster families and take children into their homes on very

short notice, often in the midst of a crisis. This emergency placement may last only a short period while another, more stable placement is sought. The most common form is short-term foster care in which foster parents provide a temporary home for children who are ultimately expected to return to their birth homes. Finally, there are some placements that are referred to as long-term foster care because children are not expected to return to their birth families, yet there are also no prospects for adoption. This may occur when an older child does not wish to be adopted. Long-term foster placements are not typical with very young children, especially in light of the push for permanency planning discussed in the previous section.

### Kinship Care

*Kinship care* is another primary type of foster care in which a relative of the child (e.g., grandparent, aunt) or someone with a close emotional tie (e.g., godparent, family friend) assumes the caregiving responsibilities for a child. Kinship care is similar to family foster care in that caregivers are licensed and monitored by child welfare agencies. Children in kinship care differ from children placed in family foster care in that they are more likely to have been removed from their parents' homes because of abuse or neglect. The parents of children in kinship care are more likely to have a drug or alcohol problem and are more likely to be young and never married. Kinship care can be divided into two main categories: *formal* and *informal* kinship care. Formal kinship care refers to arrangements in which kin act as foster parents for children in state custody. Informal kinship care refers to caregiving arrangements that occur without the involvement of a child welfare agency. Kinship care has increased in recent years because it is thought to give children a better opportunity to maintain a sense of family identity, self-esteem, and continuity of family relationships. Moreover, the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 changed the federal law to grant relatives priority when determining with whom foster children should live.

### Therapeutic Foster Care

*Therapeutic foster care* refers to foster family homes that provide specific supportive services that are designed to remediate the behavioral and social problems of challenging foster children who might

otherwise be placed in residential treatment settings. Therapeutic foster parents are licensed to provide specialized services to behaviorally or seriously emotionally disturbed foster children. Therapeutic foster care combines the benefits of a family-centered environment with an array of specialized supportive services. These foster parents are part of a professional care team that provides additional clinical services to the child. Therapeutic foster parents often receive financial incentives for their services that are more substantial than the subsidies of family foster care as compensation for specialized care and training. It is often the case that these foster parents are trained by agencies that provide treatment foster care and subsequently receive contracts to care for children with support from the agency. *Specialized foster care* is similar to therapeutic foster care in that foster parents are licensed to care for foster children with a variety of unique challenges. A distinction that can be made, however, is that specialized foster care usually involves parenting of foster children with certain characteristics (i.e., children with human immunodeficiency virus [HIV] or other medical conditions, drug-addicted infants). It is often the case that specialized foster parents have specific training for dealing with the medical, psychological, or behavioral complications associated with a particular population.

### Group Foster Care

*Group homes and residential facilities* are out-of-home placements in group settings or institutions in which multiple service providers are responsible for the supervision and treatment of foster children. Residential treatment centers or group foster homes are often utilized when severely emotionally or behaviorally disturbed children cannot be maintained in less restrictive settings. Of all foster placements, group settings tend to be reserved for the children with the highest level of problematic behaviors. In many cases, multiple failed placements occur before a child is placed in a residential setting for a long duration. Other times, a residential setting is temporary until a foster or adoptive placement can be arranged.

### FOSTER CARE OUTCOMES

Research evidence about the effectiveness of the different types of foster care placement is limited. Few well-designed studies exist that compare the

different types of foster care with one another as well as control for various confounding influences. Some evidence suggests that children placed in group residential care were more inattentive and hyperactive than those children in the foster family care homes, according to observational and teacher measures collected a year after placement. Other researchers have found that children raised in residential group homes experienced difficulties managing and organizing their lives as adults. Evidence consistently supports the conclusion that children who are adopted generally fare better than children in long-term foster care, who in turn fare better than children reared in group settings or institutions. However, more carefully designed longitudinal research projects need to be conducted to investigate the long-term impact of the different types of foster care on children's later social, emotional, cognitive, and behavioral development.

### ENTRY INTO FOSTER CARE

A child can enter the foster care system through two main routes: voluntary or involuntary placement. Voluntary placement occurs when a biological parent or legal guardian voluntarily agrees to grant the state temporary custody of his or her child. A parent may choose to place his or her child in foster care for a variety of reasons, including lack of housing, incarceration, rehabilitation for a substance abuse problem, or poverty. The parent legally agrees to surrender custody of his or her child for a specified period of time, so that the parent can complete or achieve the stipulated activity for which he or she placed the child in foster care.

A child may also enter foster care through an involuntary placement. An involuntary placement occurs when a report of suspected child abuse or child neglect is filed against a parent or legal guardian. Once a report of child abuse or child neglect is filed with the local department of family services, a social worker must investigate the claim within 24 hours. The social worker will remove a child if evidence of abuse or neglect is found or if the environment is deemed an "imminent danger to life or health." The social worker will then remove the child from the home. The state will assume temporary custody of the child, and the child will be placed with a foster family. Preliminary hearings, fact-finding trials, dispositional hearings, and extension of placement decisions will be conducted to secure the child's safety upon return to the parent.

## EXITING FOSTER CARE

Upon the parent's completion of the stipulated activity, the child exits foster care and returns to the custody of the parent. If the parent is unable to complete the stipulated activity, he or she may ask the court for an extension of time to achieve the stipulated activity. Parents may also decide to terminate their parental rights to the child, which will free the child for adoption. Parental rights must be legally terminated in court before a child can be freed for adoption. The parental rights must be terminated by both biological parents to free a child for adoption. Legal attempts must be exhausted to locate biological parents and inform them of their rights to the child before a child can be freed. If all legal avenues have been exhausted, after a specified time that may vary, the court will terminate a biological parent's rights to a child and free the child for adoption.

Social workers frequently assist parents in their efforts to complete the stipulated activity to support the return of their children. However, many social service agencies are limited in the resources and services that they can provide to families in need. Additional resources exist in some states (e.g., New York, Pennsylvania) to support parents' efforts to achieve their goals, such as Court Appointed Special Advocates (CASAs). CASAs are typically volunteers who work to ensure that a child's stay in the foster care system is as brief as possible.

Although reunification with the biological family is often the goal of foster care, it often does not ensure the future healthy development of children. Children originally placed in foster care as infants and toddlers and then reunified with their biological families are at a high risk to endure future maltreatment and physical and sexual abuse. The U.S. Department of Health and Human Services Administration for Children and Families (2002) found that 77% of children who died from abuse or neglect were younger than 4 years of age. Reunification also threatens the child's attachment relationships with his or her current foster caregivers.

## FOSTER PARENT SELECTION

Individuals who are interested in becoming foster parents usually make contact with a local child welfare agency to apply or are recruited through recruiting drives by these agencies. To become a foster parent, applicants generally first have a telephone interview

and then a personal interview with an agency recruiter. This is often followed by a home study to assess the current living situation, a child abuse and criminal clearance, and training sessions. However, specific requirements vary widely by state. If the state-specific requirements are met, the foster home is licensed and continually monitored by either a public or private child welfare agency.

Currently, there is a shortage of available foster parents. While the number of children in need of foster care placements has risen over the past two decades, the number of available foster families has dropped significantly. Changing family dynamics and women entering the workforce in greater numbers have had a large effect on the decline of available surrogate caregivers. In addition, a number of factors have caused increased dissatisfaction among parents providing foster care services. Because agencies are interested in keeping biological families intact, only children from the most troubled families and those children who have the most severe behavior problems are being placed into foster care. This trend, in combination with changing family dynamics, has led to fewer nonrelative caregivers willing to provide foster care.

On the other hand, there seems to be an increase in the number of kinship foster placements. More relatives of families in need are volunteering to help care for their relatives' children. Interestingly, kinship foster parents often receive fewer services and less frequent home monitoring by social workers than nonkinship parents. Kinship foster parents may be perceived as less in need of attention and assistance than nonkinship parents. However, data do not currently exist to support the claim that kinship foster parents actually require fewer services than nonkinship parents.

## CHARACTERISTICS OF FOSTER PARENTS

Foster families vary widely in terms of structure, ethnicity, and socioeconomic status (SES). National information about specific characteristics of foster parents is not available because no national reporting system regarding foster parents exists. However, several recent, large-scale studies examining foster care in the United States provide some general characteristics of foster care providers. They found that most foster families (about 60%) are headed by two parents, and most others are headed by single mothers. Foster parents are generally between 35 and 55 years of age. Most foster parents have obtained a high school

degree or have attended some college. About one half of foster families would be considered of middle SES based on family income, 15% would be considered of upper-middle SES, and about 35% would be considered low-income families. Additionally, religion appears to be an important factor for many individuals who decide to become foster parents.

Individuals choose to become foster parents for a number of different reasons. Some of the most commonly given reasons for wanting to become a foster parent include the desire to help a child in need, a wish to do something for one's community or society, or an interest in having children, or more children. For most foster parents, money is not a key motivator for becoming a foster care provider. In fact, the stipends that foster parents receive often do not entirely cover the costs of raising the child, and the parents must subsidize the cost of providing care to the child.

## ROLE OF FOSTER PARENTS

Foster parents are commissioned to provide a safe, nurturing home for a child who cannot be maintained in his or her home environment. This is typically a temporary arrangement, although adoption can result if the child's birth parents terminate parental rights and the foster family is inclined to adopt. The role of a foster parent can be emotionally challenging. Foster parents are often faced with dilemmas about what their role is in their foster child's upbringing. Foster parents are responsible for the child's well-being, but also need to work within the constraints of the child welfare agency charged with the child's care. Foster parents and agencies may have different views on what is in the best interest of the child. Foster parents face the prospect of assuming responsibility for a child and not always having the authority to accomplish what is necessary in a given situation. Foster parents must also deal with decisions about reunification and permanency planning, over which they have limited control. To improve recruitment, training, and retention of foster families, unambiguous and consistent guidelines for foster parents' role responsibilities should be established and clearly communicated.

## EFFECTIVENESS OF FOSTER CARE

Children in foster care are presented with a unique set of obstacles to overcome as they mature. They must adjust to disruptions that they experience as they enter

and exit foster care. Some children are placed with foster parents for a brief amount of time and then return home to their biological families. Other children are initially placed with foster care parents who adopt them, whereas other children experience multiple disruptions in care as they move from birth families to foster care families. These disruptions in care disturb the stability and security that caregivers provide to infants as they are shifted from one home to another. Disruptions in care and early inadequate care place the child at risk for developing future emotional, behavioral, and psychological problems. Unfortunately, many of the medical, social, emotional, and cognitive needs of children in foster care are jeopardized by the instability in care that they experience. Furthermore, it is believed that prolonged or unpredictable separations from caregivers are problematic, leading to permanent changes in biological stress systems and adverse influences on brain development. Therefore, it is important to identify children at an early age who are at risk for developing problem behaviors so that interventions can target their specific needs.

Placements into foster care, kinship care, or group foster homes have been associated with high levels of psychological and behavioral problems in comparison to children who are adopted. In response to placements with substitute caregivers, children often demonstrate developmental outcomes that are impaired across a range of social, emotional, and behavioral domains. Evidence suggests that in comparison to children exposed to similar levels of risk, children who experience out-of-home placements demonstrate significantly higher levels of behavioral difficulties associated with impulse control problems, aggression, and attentional deficits. Children experiencing disruptions in care have a higher rate of referral to mental health settings and have more severe attentional and externalizing symptoms than similar children who have not been placed with alternate caregivers.

Such sobering research evidence raises the question, How effective is foster care as an intervention? Many would argue based on research evidence previously cited that the prognosis for foster children's healthy development is grim. "Foster care drift," or the idea that many children remain in foster care even after they are eligible for adoption, is an unfortunate reality. Many policy makers and researchers argue that the foster care system is neither temporary nor effective. Alternatives to the current foster care system, such as keeping parents and children together while providing

services to the biological parents or expediting adoptions, may be more effective in the long term.

Despite the limitations of foster care as a permanent solution for children in need of out-of-home placement, there is evidence that foster care can be delivered therapeutically to enhance children's self-esteem, sense of identity, and personal worth. A number of studies have suggested that many foster parent attributes and service delivery characteristics lead to positive placement outcomes for foster children. Foster parent qualities such as warmth and acceptance, an authoritarian parenting style defined by clear structure and appropriate limit setting, and adequate social support have been associated with positive foster placements.

Studies have also found that foster parent training reduces the number of unsuccessful placements and increases retention of foster parents. Foster parent training ensures that parents possess the skills necessary to deal with children having behavioral and emotional problems. Providing foster parents the tools to handle situations effectively can reduce inappropriate responses and decrease feelings of frustration. Training to help foster parents appropriately interpret foster child behaviors, avoid stress and burnout, and cope with difficult times is important in promoting sustained placements. Respite times, ongoing responsive supervision from child welfare agencies, and social support have also been shown to enhance placement effectiveness.

In general, factors that increase foster parents' efficacy also improve their ability to provide an adequate rearing environment for their foster child. To deal with the unique challenges that foster children present, unique caregiving skills are necessary to provide optimal levels of care. Parents who are warm, are realistic in their expectations, and can manage emotionally and behaviorally demanding behaviors likely provide a foster child with the best chance for a stable and nurturing placement.

## FRAGILE X SYNDROME

---

Fragile X syndrome (FXS) is the leading cause of inherited mental retardation. It is caused by a change (mutation) in the fragile X mental retardation 1 (*FMR1*) gene located near the end of the X chromosome. This change is associated with a broad range of symptoms from speech delay and hyperactivity early in development to mild emotional problems, learning disabilities, and severe mental retardation with or without autism. The physical, behavioral, and intellectual difficulties tend to be greater in boys than in girls.

Although everyone has the *FMR1* gene, those with the mutation have an increase in the number of CGG (cytosine and guanine) repeats at the 5' end of the gene. The increase in CGG repeats is transmitted from generation to generation and is prone to expansion when passed through a female to a child. People who are carriers of fragile X have between 55 and 200 CGG repeats; this is referred to as the *premutation*. When the expansion becomes more than 200 CGG repeats, known as the *full mutation*, the individual will

have FXS. The full mutation is associated with methylation of the repeat region, which results in silencing of the *FMR1* gene and absence of the FMR1 protein (FMRP), causing FXS.

Current estimates are that 1 in 4000 males and 1 in 8000 females in the general population have the full mutation and are affected with FXS. Additionally, 1 in 250 females and 1 in 800 males are “carriers” of the FXS premutation and are typically unaffected intellectually, although they may present with clinical symptoms and carry the risk for having children or grandchildren with FXS.

Studies have documented a subgroup of children who are carriers of the gene mutation that present with mild physical features of FXS; emotional problems including anxiety, obsessional thinking, or depression; and sometimes more severe clinical involvement including mental retardation and autism spectrum disorders. A group of older premutation carriers have been identified as having fragile X–associated tremor-ataxia syndrome (FXTAS), which is characterized by progressive intention tremor, gait ataxia, parkinsonism, and autonomic dysfunction.

The classic physical features of FXS include long face; prominent ears, chin, and forehead; large head circumference; high arched palate; and large testicles (macroorchidism). In addition, loose joints, heart murmurs, low muscle tone, flat feet, and a variety of skeletal problems are often observed. Many of the physical features are associated with connective tissue problems, leading to ear infections, sinusitis, or gastric reflux.

The social and behavioral phenotype of FXS includes impulsivity, attention deficit disorders, hyperactivity, rapid speech, and hypersensitivity to a variety of sensory stimuli. As many as 25% to 30% of individuals with FXS meet the diagnostic criteria for autism and display autistic spectrum behaviors such as hand flapping, poor eye contact, and social anxiety.

At this time, there is no cure for FXS, but there are effective methods for treating many of the symptoms. A combination of special education, speech and language therapy, occupational therapy, and behavioral therapy may be helpful in addressing many of the physical, behavioral, and cognitive impacts of FXS. In addition, medical intervention can improve aggression, anxiety, and hyperactivity.

Because the impact of FXS is so varied, early diagnosis of FXS is important to ensure that both genetic counseling and appropriate treatment are attained as early as possible. Since 1991, highly accurate procedures

for testing have been developed and are widely available. A blood test followed by polymerase chain reaction (PCR) and Southern blot analysis identifies the size of the repeat. This test can identify carriers and those affected and is used for prenatal diagnosis.

## FRAMINGHAM STUDY

---

The Framingham Heart Study pioneered the identification of “risk factors” for heart disease, and this ongoing and ambitious study continues to contribute to the understanding of heart disease and other cardiovascular and related illnesses. Of primary significance to psychology is that findings from this study identify psychosocial risk factors for heart disease and highlight the importance of positive lifestyle change in the prevention and treatment of cardiovascular illnesses.

### WHAT LED TO THIS INVESTIGATION?

A major health shift occurred in the beginning of the 20th century, as cardiovascular disease became (and continues to be) the leading cause of death and illness in the United States. Little was understood about this foremost killer at the time, necessitating the formation of research to examine contributing factors to heart disease. The Framingham Heart Study was a response to this need and was originally designed to investigate the factors that predispose to cardiovascular diseases such as heart disease and stroke.

### THE STUDY: THREE GENERATIONS AND GOING STRONG

The Framingham Heart Study is a longitudinal study that has tapped into three generations of residents

from the town of Framingham, Massachusetts, and has evolved in measurement and primary focus. In the first phase of the study, researchers collected extensive physical and lifestyle data on 5,209 primarily white adult men and women from Framingham, Massachusetts, with follow-up physical examinations every 2 years. Extensive psychosocial measures such as personality, anger, and stress were obtained between 1965 and 1967. During the first 30 years of the study, researchers assessed the relationship of clinical observations with the development of cardiovascular disease and through this process found that factors such as cigarette smoking, cholesterol levels, and psychosocial factors were related to heart disease.

The 1970s marked two important advances in the study: (1) the recruitment of offspring, and (2) new diagnostic technologies. A second generation of subjects was recruited beginning in 1971, with 5,124 adult children (of the original sample) and their spouses participating in the study. The physical examinations conducted were similar to earlier examinations; however, technological advances such as echocardiography and carotid artery ultrasound allowed for more refined observations of the heart.

Currently, the study is in its third phase with the recruitment of children from the offspring cohort. The primary focus of investigation in this phase of the study is the role of genetic factors in cardiovascular disease. In addition, the Omni Study of minorities was launched in 1995 to investigate similarities and differences among minorities from the primarily white cohorts in the Framingham Heart Study.

### WHAT ARE THE RISK FACTORS?

Major risk factors for coronary heart disease identified by the Framingham Heart Study include high blood pressure, high blood cholesterol, smoking, obesity, diabetes, and physical inactivity. Other, related risk factors include blood triglyceride and HDL cholesterol levels, age, sex, and psychosocial issues. Most of the risk factors identified by the Framingham Heart Study can be modified by positive lifestyle change, highlighting the importance of psychology in the prevention and treatment of cardiovascular illness. In addition, psychosocial variables such as type A behavior and suppressed hostility (not discussing or displaying anger) have been identified as independent risk factors for coronary heart disease in both men and women.

### CONCLUSION

Whereas the Framingham Heart Study is best known for its contributions to the understanding, prevention, and treatment of cardiovascular disease, data from this study also have been used to understand diseases such as osteoporosis and arthritis, diabetes, kidney disease, cancer, eye disease, hearing disorders, dementia, and lung diseases. More than 1,200 articles have been published in reputable journals, with more to come as the Framingham Study continues to contribute to our understanding of cardiovascular disease and the importance of lifestyle and psychosocial factors in health.

---

## FRATERNAL TWINS

---

When two fetuses are carried simultaneously and delivered by a woman, it is termed a *twin birth*. Most multiple births are twins. In 1997, 94% of multiple births reported were twins. The numbers of twin, triplet, and higher-order multiple births have climbed at an

unprecedented rate during the past 20 years. Between 1980 and 1997, the number of live births in twin deliveries rose 52%. By contrast, singleton births, or one baby delivered alone, rose only 6% during this time.

Twins referred to as *fraternal* or *nonidentical* (also known as *dizygotic* or *binovular*) are much more common than *paternal* or *identical* twins. They are derived from the development of two eggs that are released from separate follicles at about the same time. They are fertilized by different sperm and become implanted in different places in the uterus. Only rarely do they share the same placenta, and this occurrence is thought to be possibly caused by the use of in vitro fertilization. The embryos have different chromosomal makeups and may or may not be the same gender. They may be as similar or different in characteristics as siblings born at separate times.

The incidence of multiple births in white women has increased more rapidly than among African American women. Because of this, the historical differences in the rates of multiple births between them have been largely erased. For 1997, the twin birth rate for Hispanic women (19.5 per 1,000 births) was substantially less than for non-Hispanic white or African American women (28.8 and 30.0, respectively). The Asian countries of Japan and China have the lowest twinning rates, estimated at 1 in 150 and 1 in 300, respectively.

There are numerous explanations for the increase in twin births. There has been a growing trend for women to begin their childbearing at a later age and to continue to reproduce into later years. The likelihood of multiple births increases steadily with advancing maternal age. A woman in her 30s has twice the chance of giving birth to fraternal twins as her counterpart 10 years younger. Seventeen percent of mothers older than 45 give birth to twins. Of women older than 50, nearly one in nine gives birth to twins. For mothers who have already had one set of fraternal twins, the chances of conceiving another set are four times greater than the average woman, or about 1 in 12. Improvements in the early detection of twin gestations through the use of ultrasound technique, improved prenatal care, and medical advances in the care of neonates have increased the survival rate of twins. Advances in infertility treatments have also contributed significantly to the increase.

All multiple pregnancies are automatically considered high risk. Twins are eight times more likely than singletons to be born at a weight of less than 1,500 grams, or very low birthweight (VLBW). More than

one half of all twins are born with low birth weight (LBW; less than 2,500 grams). This compares with only 6% of singletons born with LBW. Additional risks for these infants include prematurity; underdeveloped lungs, which can lead to respiratory distress syndrome (RDS); cerebral palsy; hearing or vision problems; and developmental delays or learning disabilities. Risks for the mother include preeclampsia (a rapid rise in blood pressure, protein in urine, and fluid retention), anemia (low red blood count), preterm bleeding, preterm labor, gestational diabetes, blood clots, and miscarriage. There are thought to be many more twin conceptions than births because often one or both fetuses are lost during the first trimester owing to miscarriage or vanishing twin syndrome.

As would be expected, families of twins face increases in financial burdens, marital stress, child care issues, and a multitude of other adjustments. With the ever-growing incidence of twins, more and more families are affected.

## FREUD, SIGMUND (1856–1939)

---

Sigmund Freud is arguably the most influential psychologist in history. Born in Freiberg, Moravia (now Pribor, Czech Republic), lived in Vienna, Austria from

about age 5 until his forced exile to London in 1938. Completing his medical degree in 1881, Freud's early interest was in neurology; he studied hypnosis as a treatment for neurosis under Charcot in Paris. Returning to Vienna, he married Martha Bernays, with whom he had six children, and began private practice.

Throughout his career, Freud developed many collaborations, although most of them dissolved acrimoniously. His first, and perhaps most influential, was with Josef Breuer, a Viennese physician treating "Anna O," a young woman suffering numerous hysterical symptoms. From this collaboration, Freud theorized that hysteria stems from conflict in the unconscious and that bringing this material into consciousness allows resolution and relief of hysterical symptoms. Initially using hypnosis to access the unconscious, Freud finally settled on various talking methodologies, including free association, speaking whatever comes to mind with no editing, and dream analysis.

Freud developed the theory of psychosexual development of a three-structured personality (i.e., the id, ego, and superego) that develops as it moves through three conflicts between infantile sexuality and a repressive society (the oral, anal, and phallic stages). Following these three stages, much of this material is repressed, buried in the unconscious; during this latent stage, identification with the same sex parent and socialization into the expected roles of men and women can occur. Around puberty, the fully developed, sexual, adult personality emerges in the genital stage. Although later personality theories have abandoned many of the sexuality factors, most contain elements of the Freudian conceptualization of the id, ego, and superego.

Freud's major contributions to psychology can be summarized as follows:

1. Freud provided the first, formally organized theory of personality development; its controversial nature stimulated the development of alternatives fostering growth in the field of personality development.
2. Although not unique, Freud's insistence that childhood was psychologically unique from adulthood is, today, a cornerstone of developmental theory.
3. Believing personality development largely complete by age 6, Freud was instrumental in showing that events of childhood influence who we are as adults.
4. Freud maintained we have strong feelings for our parents, and these feelings influence how we develop; unobscured by Oedipal fantasies, this notion is seen in much of the work on attachment and parenting today.
5. Freud's ego defense mechanisms, which explain behavior as biologically motivated and often unavailable to conscious awareness, rather than rational and conscious, remain useful in clinical practice today.

—Melinda C. R. Burgess

## FRIENDSHIP

---

### DEFINING FRIENDSHIP

In all cultures, friendships are important relationships throughout the life span. What exactly is friendship? Although there are multiple types of friends, including neighborhood friends, same-sex friends, other-sex friends, and best friends, friendship is generally characterized by five defining features. First, friendship is a dyadic relationship, meaning that it involves a series of interactions between two individuals known to each other. Second, most experts contend that friendship involves a reciprocated, affective, or emotional bond. In other words, friendships are recognized by both members of the relationship and are characterized by a bond or tie of reciprocated affection. Third, these relationships are voluntary. Friendship is not obligatory; two individuals choose to form a friendship with each other. In Western societies, friendships are one of the least prescribed close relationships, with no formal duties or legal obligations to one another. Fourth, friendships are typically egalitarian in nature. Unlike parent-child relationships, for instance, each individual in a friendship has about the same amount of power or authority in the relationship. Fifth, almost all friendships are characterized by companionship and entail engaging together in shared activities. In fact, one of the primary

goals and motivations of friendship is companionship. In addition, adolescent and adult friendships often meet other socioemotional functions, such as serving as sources of support and providing opportunities for self-disclosure and intimacy.

These features differentiate friendship from several related phenomena. The fact that friendships are dyadic relationships distinguishes them from cliques or groups of peers. Of course, many members of cliques are also friends with other members. However, a friendship between two people is not the same as a group of peers. Similarly, having friendships is different from being popular or having a high social status. Individuals who are not popular certainly may have close friendships. Less commonly, a popular person may not have a real friendship. The affective bond that is a component of friendship distinguishes friendship from acquaintanceship. Friends provide individuals with more opportunities for self-disclosure and emotional support than acquaintances. The reciprocal nature of friendship also differentiates actual friendships from relationships in which one person thinks or wishes it were a friendship.

## FRIENDSHIP IN DIFFERENT PHASES OF THE LIFE SPAN

Friendships play an important role in healthy human development and adjustment across the life span. Friendships exist in practically every stage of development, although the form they take varies considerably with age.

### Early Childhood

Although there is no clear consensus regarding at what age children first begin to form friendships, the foundations of such friendships begin to emerge quite early. Toddlers behave in regular, predictable manners in their interactions with well-acquainted peers earlier than they do with unacquainted peers. Within the first 2 years of life, children show stable preferences for certain peers over others; further, they follow different interaction patterns with these preferred playmates than with other familiar peers. By the time children reach preschool age, the existence of true friendships is even more evident.

Children themselves tend to first define friendships in terms of interactions, such as “we play together.” Companionship is generally viewed as the primary

function of friendship among toddlers and preschoolers. Preschool friends have more social contact with each other, talk more, and demonstrate more equality and less dominance in their interactions than they do in their interactions with nonfriends. Differences between friends and nonfriends are particularly evident in social pretend play. By preschool, children also begin to incorporate more emotional and affective functions into their friendships. Preschool friends express more positive affect toward each other and score higher on measures of mutual liking, closeness, and loyalty than nonfriends do. Additionally, even young children frequently become sad or lonely when a friend moves away.

Friendships are not always harmonious, however, and young children may engage in conflict with their friends. In fact, early childhood friend dyads tend to engage in more conflict than nonfriend dyads. Yet, friend dyads also extend more efforts to resolve conflict and are more successful at such resolution than are nonfriend dyads. Conflict resolution is frequently seen as one of the important social skills that young children develop within their earliest friendships.

Additionally, friendships are not always mutual among young children. Although the definition of friendship typically requires reciprocity, unilateral friendships in which only one child of a pair nominates the other as a friend are quite common in early childhood. In fact, about 50% of nominated preschool friendships are unilateral.

### Middle Childhood

Friendships make up an important aspect of development in middle childhood, when much time is devoted to social play and social interaction skills are becoming increasingly important. School-age children spend a great deal of time interacting with peers and thus are presented with many opportunities for extending the friendship skills they acquired in early childhood. Children tend to form friendships with individuals who are similar to themselves on a variety of dimensions. Some research suggests that there is greater similarity between friends on characteristics that are high in reputational salience. For example, school-age boys tend to be especially similar to their friends on aggressiveness. Children at this age are developing increasing independence from their parents, and their relationships with friends may be somewhat less dependent on parental involvement

than was the case in preschool. Children may have more time with their friends outside the direct supervision of an adult. Coupled with the sociocognitive advances of middle childhood, spending time together with a friend may promote the development of shared intimacy, which frequently takes the form of shared secrets, and becomes a defining feature of friendship for children at this age.

School-age friendships are differentiated from early childhood friendships in a number of additional ways. Friendships in middle childhood are more stable over time than friendships in early childhood, yet still typically less so than adolescent or adult friendships. In addition, a much higher proportion of friendship nominations is reciprocated in middle childhood than in early childhood. Although same-sex (versus other-sex) friendships compose the significant majority of friendships in early and middle childhood, there is a sharp decline in the proportion of other-sex friendships in middle childhood. A high proportion of same-sex friendships remains until adolescence.

As in early childhood, school-age friendships are characterized by social contact, talking, equality, positive affect, mutual liking, closeness, and loyalty. In addition, emotion is expressed more readily with friends than with nonfriends by this age; affective reciprocity, emotional intensity, and demonstrations of emotional understanding are all more common. As in preschool, friendships in middle childhood are defined in large part by shared activities, yet in middle childhood, the concept of a friendship as transcending shared activities and having continuity over time emerges more fully. By middle childhood, friendships are frequently more complex and more similar to adult friendships than are children's earliest friendships. Loyalty, shared values, and shared rules become important during the school years, and shared interests, empathy, common understanding, and self-disclosure gain increasing importance by preadolescence. Friends also communicate differently than nonfriends. Conflict remains more common among friends than among nonfriends, as does its resolution.

Friendships still tend to be relatively immature in comparison to adolescent and adult friendships, however. Children at this age are better able to take the perspective of another person, but they are still primarily focused on what they need or want out of the relationship, rather than what their friend may need or want.

## Adolescence

Adolescence marks a critical period in the development of friendships. A variety of factors, such as growth in cognitive capabilities and strivings for increased autonomy from parents, contribute to the formation of close friendships in adolescence. Close friendships involve more affection and intimacy than friendships before adolescence. Although relationships to parents remain important sources of support, adolescents begin to seek more support and advice from friends than in early or middle childhood. Adolescents also spend more time with friends than in earlier ages.

Although adolescents may have some close friends whom they spend a lot of time with and do many different things with, they also begin to develop many friendships that are more specialized in nature. That is, they may have a friend whom they engage in particular sports with, and another friend who is involved in the same school club or activity they are involved in. Neighborhood and school friends can also be relatively distinct groups of peers.

Adolescent friendship is also distinguished from friendships in childhood by the establishment of friendships with other-sex peers. In early and middle childhood, the vast majority of friendships are formed between same-sex peers, and many children do not have any other-sex friends. In adolescence, most friendships are still with same-sex peers, but most adolescents have one or more other-sex friendships as well. Such friendships serve many of the same functions as same-sex friendships, but they also may be differentiated from same-sex friendships on some dimensions. For instance, opposite-sex friendships provide opportunities for learning about the other sex and obtaining the perspective of the other sex. These friendships may also contain some element of sexual tension. Other-sex friends also tend to have less in common with each other, engage in less self-disclosure, and are less stable than same-sex friendships.

Some individuals form friendships with other-sex individuals whom they were initially attracted to, but eventually decided to be "just friends." At the same time, some other-sex friendships evolve into romantic relationships. Even more commonly, these friendships can provide opportunities for heterosexual youth to find romantic partners because an other-sex friend may introduce them to someone who becomes a boyfriend or girlfriend. Although we know far less about the links between friendship and the development

of romantic relationships for homosexual adolescents, some research suggests that for both homosexual and heterosexual youths, other-sex and same-sex friendships may serve as a learning ground for developing the intimacy and connectedness that are part of most adult romantic relationships.

“Friends-with-benefits” is another type of adolescent friendship that seems to be relatively new and relatively specific to Western industrialized cultures. Friends-with-benefits are friendships that involve some degree of physical or sexual intimacy, but are not considered to be a romantic relationship by both parties. Although research is underway on this topic, we currently have very limited knowledge about this specific type of friendship. One possibility is that friends-with-benefits function to meet the physical and sexual desires that develop with puberty and may operate as a basis for some teenagers to learn about sexual experiences.

Adolescence is also marked by the emergence of romantic relationships. In many respects, these relationships can be considered a particular form of friendship. In fact, adolescents and adults often perceive their romantic partner to be their best friend. Just like other types of friendships, romantic relationships are characterized by affiliation and companionship. In late adolescence or adulthood, these relationships may become more distinct from friendships, but even then, companionship and affiliation remain important elements of these relationships.

## Adulthood

Because adulthood encompasses a wide range of ages and life stages, the individual’s stage in the life course is an important factor in considering adult friendships. Life course changes such as the transition to marriage, the transition to parenthood, and the process of retirement affect friendship patterns.

Research on friendship in young adulthood has mostly focused on college students. We actually know little about the friendships of individuals who marry or join the workforce directly after high school. Because of the nature of their environment, college students are likely to have a greater number of friendships than individuals who are not students. College students are surrounded by peers, and at least traditional full-time students have the time and opportunity to develop close friendships. Regardless of whether they are in school or the workplace, young adults who

are more involved in a romantic relationship have fewer friends than individuals who are single.

This trend continues into middle adulthood. In particular, when individuals enter into marriage, both men and women seem to withdraw from friendships. Middle adults generally have fewer friends than college students. In comparison to friendships of younger adults, friendships in middle adulthood also tend to be more homogenous in terms of factors such as age, race, and social status. Adults also tend to have mostly same-sex friendships and thus have fewer other-sex friends than do adolescents. This trend may in part occur because social norms portray other-sex relationships as a threat to marital relationships. The decrease in frequency of friendships and the increase in homogeneity of friends during this period may also reflect the environments of most adults in middle adulthood, with fewer numbers of peers and potential friends. In addition, adults’ lives are typically more multifaceted and more complex, often occupied by family, parenting, and careers.

Friendships among older adults take place in different contexts than friendships in middle and young adulthood. This age and life stage is often characterized by events such as retirement, relocation, widowhood, and deteriorating health. These transitions produce some increases and some decreases in older adults’ ease and ability of forming and maintaining friendships. For example, retirement eliminates work as a source of interacting with possible friends. Widowhood, on the other hand, may encourage individuals to look to friends more often for sources of support and companionship.

## PHASES OF FRIENDSHIP: FORMATION, MAINTENANCE, AND DISSOLUTION

Across individuals of all ages, friendships form, evolve, and sometimes dissolve over time. The length and duration of the various phases of a friendship vary across individuals and across different circumstances.

The formation phase of a friendship is the transition from strangers to acquaintances to friends. During this phase, individuals engage in interactions to get to know each other and to forge the affective bond that characterizes a friendship. Both youth and adults have a tendency to form friendships with others who are similar to them. Even young children are attracted to peers of the same age and sex. Similarity in terms of behavioral characteristics and activity

preferences become increasingly important by middle childhood. As people enter adolescence and adulthood, similarity in terms of attitudes, values, and beliefs, as well as shared interests and activities, may be bases for forming friendships. Adults are even more likely than youths to form friendships with individuals who are similar to themselves in terms of variables such as gender, age, race, and social status.

Why does similarity play a role in the formation of friendships? Environmental variables are one explanation for why individuals tend to form friendships with people who are similar to them. Children and adults frequently spend time with others who are similar to them, and thus have more opportunities to form friendships with similar people. For instance, among children and adults, those who reside in the same neighborhoods are typically similar in terms of socioeconomic status or ethnicity. Peers that children meet at school are likely to have a similar educational status, achievement level, and educational goals, especially as they grow older and are assigned or select classes on the basis of their academic success. Similarly, adults frequently meet and form friendships with colleagues at work who are likely to have similar educational attainment and socioeconomic status. Friends that develop among both children and adults through social clubs or groups commonly share at least one activity or value in common, such as an interest in a particular activity or a political view. Individual characteristics also play a role in explaining why people frequently choose to form and maintain friendships with people who are similar to them. Individuals may find interactions easier with others who are similar in personality, behaviors, values, and attitudes, thus facilitating further interactions and the subsequent development and maintenance of a friendship. Thus, there is strong evidence for the adage that birds of a feather flock together, and little evidence that opposites attract.

The maintenance phase of friendship involves engaging in interactions that serve to sustain the relationship. Friends engage in a variety of behaviors to maintain their relationship, such as sharing interests, doing recreational or leisure activities together, and exchanging support and advice. Friends typically have conversations about topics such as family issues, dealing with other interpersonal relationships, and daily activities. The frequency of interactions between friends is one central determinant of the success of maintaining a friendship. In other words, friendships are not stationary; interactions are required to maintain a friendship.

Convenience is perhaps the most important determinant of the frequency of interactions between friends. Thus, it is easier to maintain friendships with individuals in close proximity (e.g., neighbors) than with those far away (e.g., long-distance friends).

One of the most notable distinctions between a developing friendship and a close friendship is the mutual affective bond. As individuals transition into becoming closer friends, what started out as a mutual liking of each other typically evolves into a stronger emphasis on reciprocal self-disclosure, intimacy, and emotional support. How satisfied a person is with the support and companionship they derive from a friend is an important factor in determining an individual's investment and the amount of effort they put into maintaining a friendship. Interestingly, once a certain degree of an emotional bond has been established, it is more the quality than the quantity of interactions that determine the successful or unsuccessful maintenance of a friendship. In other words, friends who have a long-standing history and who have established a strong affective connection may not need to interact very frequently to maintain their friendship.

Whereas joint satisfaction in the relationship is a part of maintaining friendship, another important component of friendship is managing and resolving conflict. Although the amount and intensity of conflict varies across individual friendships, conflicts do arise in most friendships. In general, conflict is infrequent in the early stages of forming a friendship, but actually tends to increase as individuals become closer friends over time. Some evidence suggests that conflict can potentially serve to strengthen the emotional tie between friends. Because conflict involves self-disclosure and exposing one's own vulnerabilities, successful negotiation of disagreements that arise between friends can actually foster increased trust between friends.

Whereas some friendships will be maintained indefinitely or forever, other friendships will dissolve or break up. Friendships dissolve for multiple reasons and under multiple circumstances. Sometimes the reason can be attributed to circumstances; a friend may move away, and contact becomes harder to maintain. Sometimes friendships may end abruptly. For instance, friends may have a major disagreement that is not resolved. Friendships may also end gradually. In some circumstances, friends share less in common over time or feel less supported by each other.

## FRIENDSHIP AND SOCIOEMOTIONAL ADJUSTMENT

Empirical research has repeatedly found links between friendships and healthy adjustment. It is true both that friendships promote adjustment and that well-adjusted individuals are more likely to develop friendships. First, friendships have an important effect on individuals' socioemotional adjustment throughout the life span. Perhaps foremost, friends serve as a critical source of social support. In childhood, adolescence, and adulthood, social support from friends has significant, positive effects on well-being, such as increasing one's life satisfaction and happiness, augmenting a person's ability to successfully cope with life stress, and even decreasing an individual's vulnerability to illness. Well-being is enhanced by both having friendships and being accepted (vs. rejected) by one's peers. Regardless of social status (i.e., being popular or unpopular), it seems particularly important for healthy adjustment that a person has at least one friendship. Individuals without any friends, particularly individuals who are rejected or bullied by their peers, are at significant risk for a variety of socioemotional difficulties, such as loneliness, depression, and anxiety. Friends can protect each other and provide support for each other against victimization from other peers.

Along these lines, friendship in childhood and adolescence plays a central role in developing an individual's sense of self-worth. Because friends disclose and share personal thoughts and feelings with each other, friendships are an opportunity to receive and provide validation of one's self-worth. Children and teenagers who have friendships have better self-worth or self-esteem than youths who do not have friendships.

Friendship also plays a pivotal role in the socialization of children and teenagers. Although parents clearly are important figures in socialization as well, children and adolescents learn important and valuable information about appropriate behaviors and social norms from peers. Children, and particularly adolescents, have their own cultural norms, most notably with regard to fashion and entertainment. Children and adolescents observe the dress and behaviors of their friends and either strive to be similar or are pressured to conform. In addition to such lifestyle choices, children and adolescents' opinions and attitudes are frequently shaped by those held by their friends. Friendships offer an outlet for discussion and observation of beliefs and attitudes

about such topics as the importance of school, plans for the future, values, activity preferences, and risk-taking behavior. Children can thus learn from their friends what types of beliefs and behaviors are acceptable within a given social context.

Similarly, friendships are children's first experience of egalitarian relationships. In family relationships, parents ultimately have more authority. With friends, however, decision making and power are expected to be more evenly distributed. In effect, these egalitarian relationships provide the necessary opportunities for learning the give-and-take required for effective social interactions. Such experiences teach children how to have mutually rewarding experiences, how to share, and how to resolve conflicts. As emotional intimacy and self-disclosure between friends become more important in adolescence, youth learn about obtaining support from friends, and they also learn how to provide comfort and serve as a source of support for friends.

Although friendships are typically thought to have a positive influence on socioemotional adjustment, it is not just having or not having friends that plays a part in individuals' well-being. The specific effects of friendship on adjustment vary as a function of who the friend is. Thus, having a friend who is deviant or antisocial is likely to foster deviant or antisocial behavior. For example, one important determinant of an adolescent's use of alcohol and drugs is his or her close friends' substance use. Adolescents who have close friends who use alcohol or drugs are more likely to use such substances themselves. In part, this occurs because friendships involve mutual socialization, meaning that friends become more similar to one another over time, perhaps by actively seeking to emulate qualities in their friends, or by trying to strengthen the friendship by emphasizing similarities. Additionally, it is equally true that individuals select friends who are similar to them. In other words, individuals who use drugs are likely to seek out other peers who use drugs.

It is important to point out that just as friendships appear to promote better adjustment, it is also true that well-adjusted individuals are more likely to develop friendships. For instance, children and adolescents who have a secure attachment to their parents are more likely to form friendships and to have more supportive friendships. Similarly, those who are accepted by their peers are more likely to develop friendships.

## GENDER DIFFERENCES IN FRIENDSHIP

Research suggests that there are gender differences in the nature of friendships. Males and females generally stress different factors as being important in friendship. Males often emphasize the importance of doing things together, such as joint activities and shared interests. Women often emphasize the importance of shared intimacy and emotional connectedness in friendships. Such differences begin to appear in children's friendships and may be greater as they grow older.

Why are there differences between the characteristics of males and females? One explanation is that social norms define different expectations for friendships according to gender. Females may be socialized to share feelings and be more emotionally intimate in friendships; thus, they may value and establish these characteristics in friendships. Males may be socialized to be less emotionally expressive; thus, they may value the companionship of friendships more than the intimacy of friendships. Alternatively, other perspectives on gender and friendship contend that gender differences in friendship characteristics are overstated. For example, it has been suggested that males may develop intimacy and connectedness through alternative means, such as activities or shared experiences. From this perspective, gender differences may really be less meaningful than individual differences in factors such as emotional expressiveness and communication skills.

## CONCLUSION

Friendships can be defined in terms of five defining features of friendship—their dyadic nature, an emotional bond, voluntary status, egalitarian structure, and provision of companionship. These features are common across ages and gender, although the form that friendship takes changes considerably over the course of the life span. Regardless of the stage of the life span, friendships play an important role in many aspects of our lives.

## FUNERALS

---

Funerals are the most commonly recognized bereavement ritual linked to death loss. Bereavement rituals can prove helpful for individuals by offering a way to acknowledge the death, remember the deceased, or understand and openly express feelings. These rituals afford the opportunity to say goodbye and form a new relationship with the deceased.

Despite the many therapeutic aspects of bereavement rituals, some have recently argued that rituals have deteriorated in meaning, leading to inadequate grieving and insufficient grief resolution. Although rituals can initiate the grief process, they are not miraculous. Their positive impact comes from individuals' ability to make meaning of these experiences.

Many grief researchers believe that funerals can be the most therapeutic ritual in managing grief adjustment if adequately planned and properly conducted. Irion's multidimensional description of the funeral is the first and most extensive examination of funeral theory. He described funerals as consisting of four dimensions: cultural anthropological, social psychological, psychological, and theological.

The cultural anthropological dimension provides more of a historical, intangible perspective of the funeral. Anthropologists found that individuals attempted to shield themselves from death by controlling it through burial rituals. They appeared capable of body disposal and reorienting bereaved individuals, seemed to preserve and request certain values to be present during the funeral, likely experienced continued connection with the dead after attending funerals over time, and processed through three distinct phases, including separation, transition, and incorporation. The social psychological dimension focuses on the value of the funeral for individuals in the context of their societal group. From this perspective, the funeral involves a relational transition between the mourner and the

deceased, during which the mourners undergo a period of isolation and, subsequently, final reunion with others. Unlike the social psychological dimension that focuses on mourners in the context of their social group, the psychological dimension concerns the needs of the individual. The funeral is psychologically necessary because it provides the opportunity for grief work needed to maintain emotional health and assists mourners by confronting them with the reality of the death to help them understand their various emotional responses. The theological dimension serves as an act of benediction by affirming the ending of an individual's life while also emphasizing the love and respect for this individual. Although Irion concluded that the effectiveness of the funeral increases in direct proportion to the number of dimensions it contains, he explained that funerals containing fewer than all four of the dimensions can still be helpful.

Most of the research conducted on funerals has evaluated attitudes and participation of adults, children, and adolescents. Results suggested that adults value aspects of the funeral reflecting all four of Irion's dimensions. Adults also attributed greater meaning to funerals when deaths were expected. Greater funeral participation by adults was shown to be related to

greater closeness to the deceased and fewer negative symptoms.

In comparison, children and adolescents valued aspects of the funeral reflecting the social psychological and psychological dimensions. Regarding participation, children who attended funerals of unexpected deaths demonstrated more internalizing-externalizing behaviors. Results also suggested that children and adolescents experience lower overall negative symptomatology as a function of their funeral attendance.

## GAMETE

---

A gamete is a cell containing half the amount of genetic material found in a somatic (body) cell that is capable of joining with another gamete and developing into a new individual. In this sense, the joined gametes (zygote) form the earliest stem cell since this one cell will go on to form a completely new organism.

In humans, there are two types of gametes: the sperm and the ovum (egg). After puberty, men can make more than 1 million sperm per day. On the other hand, women release one mature egg about every 28 days. When a sperm penetrates an egg, a zygote is formed. Very shortly following conception, the genetic material from the sperm joins that of the egg to make a cell that contains the correct amount of genetic material, 46 chromosomes, to make a whole new individual.

Each gamete carries one copy of each of the chromosomes. Thus, the process of fertilization is how each new offspring gets one copy of each chromosome from its father and the other half from its mother. Because each parent has two copies of each chromosome, they pass only one of them to each of their offspring, but they do so randomly, allowing for great genetic diversity. Additionally, there are mechanisms in place to ensure that only one sperm and one egg are allowed to

come together during conception. This is important because only the correct amount of genetic material will allow for proper development of the fetus.

If a gamete contains more or less of the number of chromosomes than it should, two outcomes are possible. First, it is likely that the embryo will be spontaneously aborted early in the pregnancy owing to the malformation of the embryo. Alternatively, in some cases, the baby is born with a medical syndrome. The most common chromosomally caused syndromes are Down syndrome (having an extra chromosome number 21), Turner's syndrome (having only one sex chromosome, an X), and Klinefelter's syndrome (having more than two sex chromosomes).

There are many other genetic alterations that can be present in the gamete that are harder to detect because they involve small variations in the DNA sequences of the chromosomes. Whether an offspring will develop a particular trait or disease depends on whether the trait is dominant or recessive and if only one or both gametes bring the allele for the trait. When one considers that there are more than 30,000 genes in the human genome, and that there are multiple variations of each gene, it is easy to see why each person is unique.

**GANGS**

---

The past 15 years have witnessed a dramatic resurgence in youth gang activity in the United States. One of several types of gangs (others include prison gangs, motorcycle gangs, hate groups, ideological gangs, and adult street gangs), youth gangs are not new to the American landscape. Modern youth gangs, however, are more dangerous than their historical counterparts because of the growing drug economy, the decreasing availability of legitimate employment opportunities in urban areas, increased mobility due to the availability of automobiles, and greater access to more lethal weapons. Moreover, gangs are no longer limited to densely populated urban areas but have an increasing presence in suburbs, small cities, and rural towns.

**WHAT IS A GANG?**

There is a great deal of heterogeneity within youth gangs and consequently considerable disagreement over how to define them. Some gangs are loosely knit groups of youth with no specific function, whereas others are highly structured criminal organizations with identifiable leadership. In some regions, gangs are organized around specific geographic locations or turf; in others, however, they are not. There have been several attempts to develop a definition that is broad enough to encompass the varying manifestations of gangs while at the same time specific enough to exclude other youthful groups that may occasionally engage in deviant activities (e.g., fraternities). A commonly used definition identifies youth gangs as groups that (1) consist of more than two individuals within a limited age range (typically 12 to 24); (2) share a sense of identity as evidenced by the use of a collective name, colors or symbols, specific clothing styles, or hand signs; (3) show some sign of permanence, lasting for a year or more; and (4) are involved in criminal activity.

**HISTORY OF GANGS  
IN THE UNITED STATES**

The earliest youth gangs may have originated in Europe or Mexico. Although no one is certain when these groups began to emerge in the United States, there are accounts of youth gangs in this country as early as 1783. The first gangs appeared in large cities such as New York, Boston, and Philadelphia, followed by appearances in Chicago and, more recently, Los Angeles. The first modern criminal gang was the Forty Thieves gang that formed in the Five Points district of New York City in 1820; although primarily an adult gang, it later gave rise to a juvenile group called the Forty Little Thieves. Social scientific study of youth gangs began in the early 20th century and suggested that the earliest youth gangs may have spontaneously evolved from neighborhood play groups as a result of changing social conditions, particularly increasing urbanization, industrialization, and immigration. During the past two centuries there have been four distinct periods of intense gang proliferation and activity in the United States, each of which is also characterized by rapid immigration and population shifts, social and political unrest, and industrial and technological change: the late 1800s, the 1920s, the 1960s, and the 1990s.

**PREVALENCE OF GANGS**

The most widely used estimate of the prevalence of gangs is the National Youth Gang Center's annual survey of law enforcement agencies nationwide. In 2002, there were about 21,500 youth gangs in the United States with 731,500 members. The actual prevalence of gangs may be higher because these estimates represent only those gangs and gang members that are known to law enforcement officials. Official records may particularly underestimate the prevalence of females in youth gangs; there have been reports that law enforcement officials often discount claims of gang membership by females. Estimates from youth self-report studies have indicated that anywhere from 2.7% to 10.6% of American adolescents are involved in gangs. However, these studies are limited by their regional scope, making it difficult to generalize their findings to gangs across the nation.

Although rates of gang membership are higher among Hispanic and African American youth, most gang members are white. Data from the National Youth Gang Center estimate females to constitute

14% of gang members; other studies have produced estimates ranging from 2% to 46%. Most members of youth gangs range from 15 to 17 years of age. Most gang members leave gangs after 1 year, with less than 5% remaining in these groups for 4 or more years. However, the increasing organization of gangs around drug sales provides a lucrative motivation for members to remain in these groups into adulthood.

## ETIOLOGY OF GANG MEMBERSHIP

Research has identified community, family, peer, academic, and individual characteristics associated with gang membership. Gang-involved youth are more likely to live in communities characterized by social disorganization, high crime and gang activity, lack of viable employment and recreational opportunities, and greater availability of drugs and firearms. Gang-involved youth report spending more time with and having closer relationships with peers who engage in delinquency, substance use, or gang activity. Compared with nongang youth, gang members are significantly more likely to live in families characterized by inconsistent discipline, higher levels of family conflict, and lower levels of parental monitoring and supervision and parental warmth. They are also more likely to report having parents and siblings with a history of involvement in gangs or other criminal behavior. Individual characteristics associated with gang membership include endorsing favorable attitudes toward antisocial and sensation-seeking behaviors, exhibiting defiant attitudes and behavior, having low commitment to school and low educational aspirations, and exhibiting a history of academic failure and school-based behavior problems. Common coexisting psychological disorders include learning disabilities, substance use disorders, and conduct and oppositional defiant disorder.

## FUNCTION OF GANGS

In addition to the friendship and support found in typical youth peer networks, gangs meet psychosocial needs that are unfulfilled by other social institutions. Gang members often describe gangs as providing a sense of family, love, and discipline. Indeed, many gangs have rules governing their members' behavior and accompanying sanctions for violating these rules. Gang members also frequently report having joined gangs because of the need for safety and protection in

their neighborhoods. Ironically, though, gang members are more likely to be victimized by crime, particularly violent crime, than are youth who are not in gangs, and female gang members are at greater risk for sexual victimization.

The key feature that distinguishes gangs from other youth peer groups is that gang members have significantly higher rates of involvement in criminal activity, including drug sales, weapons possession, theft, and aggression toward others. Gang members are also significantly more likely to use alcohol, marijuana, and other drugs than are their non-gang-involved peers. Gang-involved youth account for a disproportionate amount of juvenile crime, and although their rates of delinquency and drug use decline upon their departure from gangs, the rates do not reach the low levels shown before gang membership and also remain higher than those of youth who never join gangs.

## PREVENTION AND INTERVENTION EFFORTS

Despite the widespread public concern about gangs, there has been little systematic evaluation of prevention and intervention efforts. Gang prevention efforts have focused on preventing youth from joining gangs as well as interrupting gang formation. The most well-known modern prevention program is the Gang Resistance Education and Training Program (GREAT), a 9-week program for middle school students developed and delivered by law enforcement agencies. The curriculum includes topics such as conflict resolution, goal setting, resisting peer pressure, and the effect of gangs. A multisite evaluation of this program found that it has small but statistically significant effects on reducing gang activity immediately following program participation (9.8% of GREAT participants reported gang membership vs. 11.4% of nonparticipants); however, a longitudinal study found no short-term or long-term effects of the GREAT program.

Intervention efforts have largely focused on reducing the criminal activity of gang members through detached worker programming. Begun in the 1940s, this method involved deploying social workers into communities to provide alternative activities for gangs, including tutoring, weekly club meetings, sports activities, and individual counseling. Evaluation results for such programs have found them to be largely ineffective. Indeed, in some cases, they have resulted in increased gang cohesiveness. Other intervention

efforts have included providing alternatives to gang life, particularly education and employment, establishing truces between rival gangs to reduce intergang violence, and providing alternative recreational activities. In addition to these formal attempts at intervening in youth gang membership, there exist several naturally occurring interventions. Gang members frequently report that the most common reasons for leaving gangs, other than prison and death, include growing too old for the gang (“age-out”), getting married (“marry-out”) or having a child, acquiring legitimate employment (“job-out”), or moving to another neighborhood.

Largely, however, resolution of gang problems has been left to police and law enforcement officials through suppression efforts. Using the combined efforts of police, prosecution, and incarceration, suppression efforts are aimed at reducing the criminal activity of gangs and disbanding them. Suppression programs typically involve dedicating additional financial and workforce resources to combat the gang program, often through the establishment of police gang intelligence units, and enacting legislation that imposes additional sanctions for gang-related criminal activity. These programs have shown mixed results; some have had substantial impact in reducing gang crime, whereas others have shown no demonstrable effect.

## SUMMARY

Youth gangs pose a significant public health concern to the individuals who participate in them as well as to those individuals living in communities affected by them. Current intervention efforts rely heavily on suppression. However, if this social problem is to be adequately addressed, mental health professionals and developmental researchers must become more involved in developing and implementing effective treatment programs.

---

## GARDNER, HOWARD (1943– )

---

Howard Gardner, a Harvard professor, cognitive research psychologist, and prolific author, is best known for his theory of multiple intelligences, first described in *Frames of Mind* (1983) and subsequently refined and extended in *Intelligence Reframed* (1999). Gardner’s work has inspired teachers, school leaders, and special educators to embrace the notion that there is more than one way to be smart.

## THE EMERGING THEORIST

Gardner was born in Scranton, Pennsylvania, in 1943, the son of refugees from Nazi Germany. A studious child, he loved to read, and developed into a gifted pianist. Although he dropped formal piano instruction as an adolescent, finding the practice obligations “onerous,” he retained a lifelong passion for music that contributed to his nonunitary conception of human cognitive capacity.

## FORMAL INQUIRY

Gardner undertook most of his formal training and graduate work at Harvard University, where he studied with noted psychologists and pursued, during his early career, research involving normal and gifted children, as well as brain-damaged adults. He maintained a voracious multidisciplinary reading, research, and writing schedule, and admitted, in later years, to

being a “happy workaholic.” A prolific writer of journal articles and books during his early career, Gardner burst onto the international scene with his sweepingly popular book, *Frames of Mind* (1985).

## THEORY OF MULTIPLE INTELLIGENCES

Faulting earlier unitary models of intellectual ability typically reported as a single IQ score, Gardner detailed a more complex paradigm in which human intelligence comprises eight or more relatively autonomous intellectual capacities: logical-mathematical intelligence, musical intelligence, linguistic intelligence, bodily-kinesthetic intelligence, spatial intelligence, interpersonal intelligence, intrapersonal intelligence, naturalist intelligence (added later), and possibly existential intelligence.

The theory of multiple intelligences became the guide for a multitude of school improvement efforts. Gardner and others promulgated the understanding of diverse student capacities, the need for personalized educational environments, improved interdisciplinary curricular programs, and the use of performance-based assessments. Educators have been inspired to adapt the theory and infuse its essence into school mission statements, curricula, individualized education plans, and instructional practice.

## OTHER CONTRIBUTIONS

Gardner has written more than 20 books on creativity, leadership, discipline, socially responsible work, and ethics and has received the MacArthur Prize Fellowship, the Grawemeyer Award in Education, and a Guggenheim Fellowship. Howard Gardner is the John H. and Elisabeth A. Hobbs Professor of Cognition and Education at the Harvard Graduate School of Education and the Senior Director of Harvard Project Zero.

## GATEWAY DRUG

Although the exact origin of the term *gateway drug* remains uncertain, the use of the term seems to have accelerated sharply in the early to mid-1980s in conjunction with the U.S. “war on drugs.” The notion that the use of certain substances tends to precede the use of other substances, however, predates the widespread use of the term gateway drug. Initial research, for example, found that adolescent substance use tends to progress in four stages: abstinence, use of alcohol and cigarettes, use of marijuana, and use of other illicit substances. Further research suggests that this general progression is apparent among both males and females, although limited research suggests that cigarettes may play a more critical role in the progression among females, among those with and without arrest records, and across numerous nations in both Western and Eastern cultures.

Despite a wealth of empirical research suggesting that the use of certain substances tends to precede the use of others, there remain two separate meanings of the term gateway drug. According to one meaning, a gateway drug is one whose use precedes, but does *not necessarily cause*, the progression to more dangerous substances. According to a second meaning, a gateway drug is one that *both precedes and causes* an individual’s escalation to more dangerous drugs. The distinction between these two definitions is critical for an accurate application of the gateway concept to the social control of substance use. Specifically, the second definition implies that preventing the use of drugs that come earlier in the general sequence would serve to prevent the use of drugs that come later in the sequence. The first definition, however, implies that preventing individuals from using drugs like alcohol and marijuana will not necessarily prevent them from using drugs like cocaine or heroin.

Although much political rhetoric suggests that society should crack down on the use of gateway drugs as a means of preventing individuals from progressing to more dangerous drugs, most research concerning the gateway concept has examined only the first of the above two definitions. Given the absence of widespread research concerning the second definition, political rhetoric concerning the need to crack down on the use of gateway drugs may be based on a faulty premise. Despite the reliable finding that the use of gateway substances *generally* precedes the use of

more dangerous substances, the same research simultaneously finds that the use of gateway drugs *does not always* precede the use of more dangerous substances. Efforts to stem the use of gateway drugs may therefore not serve reliably to prevent the use of more dangerous substances. Following an analogy developed in the research literature, slow and careful driving cannot legitimately be viewed as a cause of reckless driving even though the former almost invariably precede the latter.

Given the limited amount of research that has attempted to determine whether the use of substances early in the typical drug-use sequence actually *cause* the use of substances later in the same sequence, future research will likely be aimed at determining whether the former causes the latter. Establishing such a causal relationship will require the demonstration of an empirical finding that has not yet been demonstrated reliably. In particular, it will require demonstrating that the use of gateway substances increases the probability of using more dangerous substances even after controlling statistically for the influence of other variables that might be said to cause both early gateway drug use *and* the later use of more dangerous substances. Preliminary research, for example, has used longitudinal data from a sample of young adults to demonstrate that the time-one use of marijuana predicts the time-two use of more dangerous substances even after controlling statistically for such variables as age, race, stressful life events, gang membership, and prior hard drug use. Given the limited number of control variables used in such research, as well as its focus on only one gateway substance, further research will be needed before the scientific community will be able to claim with any degree of certainty that the use of gateway substances *causes* hard drug use.

## GAY MARRIAGES

---

Given the recent debate over the legitimacy of same-sex marriage, a discussion on gay and lesbian matrimony is appropriate. In this entry, we provide a brief historical account of same-sex unions, showing the foundation of the ageless debate over gay and lesbian marriage. We also address the present frequency of marriage between same-sex partners, providing the reader with a current account of states that allow for the union of gay and lesbian partners. Additionally, we discuss the social issues surrounding gay and lesbian partnership, highlighting some of the concerns brought forth by those arguing for and against same-sex

marriage. Finally, we conclude the paper with a brief discussion on the legal and political/tax issues surrounding the topic of gay and lesbian marriage. We hope to enlighten the reader about the various facets of this controversial issue.

## HISTORY OF SAME-SEX UNIONS

Despite the recent controversy over the issue of gay and lesbian marriages, same-sex couples have been acknowledged throughout history, appearing in both philosophical and historical documents. Plato thought of the soul as a single entity that, at birth, is separated into halves. Within the possible divisions, Plato explicitly states soul mates could be two male halves or two female halves, suggesting that same-sex couples were recognized in Plato's time. Same-sex unions were at least acknowledged within ancient Greece.

Historical accounts of same-sex unions further support the presence of gay and lesbian marriages by suggesting that some societies formalized same-sex partnerships in ceremonies similar to weddings between man and woman. Although historians have argued over the semantics of these historical documents, evidence suggests that gay marriages were performed in the Mediterranean during the 16th century. Similar accounts of legal unions between lesbians have been recorded in 17th century China; ceremonies marking the cohabitation of lesbian couples were conducted, including legal documentation that allotted a successor to the couples' estate. Additionally, prosperous infertile women of Africa have been noted to buy wives, a process that includes giving the bride's family a dowry and purchasing a house for the newly acquired wife (it is interesting to note that the wealthy woman in these unions is referred to as the *husband*). Finally, gay marriages within Native American tribes have been documented since the 16th century. Timucua, Navajo, and Crow Indians, to name a few, have openly recognized "gay" relationships as legitimate partnerships. Within these formal relationships, one half of the couple takes the traditional role of the male, whereas the other half, referred to as the *berdache*, assumes the role of a traditional Indian wife. Historically, same-sex couples have been recognized across the globe.

## FREQUENCY

Currently, only a few countries formally recognize same-sex couples. The trend started with Denmark's

revolutionary acknowledgment of gay and lesbian marriage in 1989, inspiring a wave of legislation for equality in Northern European countries. States that have followed include Norway, Sweden, Iceland, and Finland. Similar trends have been seen in South America; Brazil and Costa Rica have adopted legislation that allows same-sex couples to have some of the benefits associated with heterosexual marriages. Most recently, Canada adopted legislation to grant gay and lesbian couples marriage rights, whereas the legality of this issue is currently being debated in the United States. There appears to be a global trend towards recognizing same-sex marriages.

## SOCIAL ISSUES

The most common argument against recognizing same-sex marriage is that matrimony is an institution defined by a divine entity, and as a result, public opinion cannot alter the definition. The argument continues that, because there is no conclusive evidence to support the biological basis of a same-sex sexual orientation, granting gay and lesbian couples the right to marry would be unnatural and an abomination against nature. Furthermore, individuals arguing to keep marriage between one man and one woman suggest that this relationship is the moral thread that keeps society together; by altering this historical institution, we will be changing the norms of society.

Individuals advocating to keep marriage between heterosexual couples also argue that recognizing same-sex partnerships would undermine the social value of monogamy, greatly upsetting the institution of marriage. These advocates continue by suggesting that gay men are promiscuous, citing research indicating that gay relationships in Amsterdam last an average of 1.5 years. They further contend that these relationships are marked by multiple extrarelational affairs. However, it is important to note that this research was conducted with an unrepresentative sample composed of gay men attending sexually transmitted disease (STD) clinics and gay organizations, as well as through word of mouth. This greatly compromises the validity of this argument. Nevertheless, individuals arguing against recognizing same-sex partnership suggest that opening the institution of marriage up to promiscuous individuals will lead to polygamous and polyamorous—or group—marriages. This, they argue, would take all meaning out of the institution of marriage, greatly

undermining the social values on which this relationship is based.

Additionally, individuals arguing that marriage should remain between a man and a woman contend that the development of children is dependent on this formal relationship. Gay and lesbian matrimony denies children, should a same-sex couple choose to adopt, the benefits of having a mother and a father. They further contend that it is impossible for gay or lesbian parents to teach a child traditional gender roles, concluding that it is cruel to deny children the benefits of having one male and one female parent. However, research suggests that children raised by gay and lesbian parents are just as well adjusted as those from heterosexual households. The social issues surrounding the debate over same-sex marriage range from the religious to the effects of recognizing gay and lesbian matrimony on children.

## LEGAL AND POLITICAL ISSUES

In addition to the numerous social issues invested in the topic of gay and lesbian matrimony, debate over the recognition of same-sex partnership has ramifications in regard to medical, legal, and political/tax issues. Currently, states failing to recognize the legitimacy of marriage between same-sex couples can deny gay and lesbian partners the right to make decisions about a life partner's medical treatment. This also infringes on a partner's ability to obtain visitation rights to see a partner or a partner's child staying in a hospital. Similarly, under the unfortunate possibility that an individual's same-sex partner becomes ill or even passes on, employers may have the ability to deny the individual the right to take a leave of absence to care or mourn for his or her partner.

Unfortunately, states that do not recognize the matrimony between same-sex couples can also have a detrimental impact on many legal aspects of a gay or lesbian couple's life. A gay or lesbian individual seeking refuge from domestic violence may be denied the right to file for a protection order. Additionally, some states may be able to reject a foreign individual's request for immigration or residency in his or her same-sex partner's native country. Similarly, the surviving member of a same-sex couple does not have the right to determine a partner's final resting place in some states that deny gay and lesbian matrimony. Furthermore, gay and lesbian couples may be denied the ability to obtain joint custody over children the couple may share, giving same-sex parents

considerable legal limitations in countries that fail to acknowledge gay and lesbian marriages.

In addition to the aforementioned legal restrictions encountered by gay and lesbian couples, states failing to recognize same-sex marriage also have the ability to deny gay and lesbian couples numerous tax benefits associated with marriage. Same-sex couples may not be allowed to file joint tax returns, nor can they own property together. Similarly, employers in states that do not recognize same-sex unions may be able to legally refuse to grant a gay or lesbian partner health coverage, as well as restricting them from obtaining other employee benefits. Additionally, upon the unfortunate dissolution of a same-sex relationship, a dependent partner may not be entitled to receive an equitable settlement for property the couple may have acquired during their relationship. Finally, upon the death of a same-sex partner, the surviving member of the relationship is not entitled to the pension benefits of the deceased partner and, if a will was not created, may not be allowed to receive an inheritance. States failing to recognize same-sex unions greatly compromise many of the medical, legal, and political/tax rights of gay and lesbian individuals.

## CONCLUSION

Although it is unlikely that the debate over same-sex marriages will subside in the near future, we hope the reader has become enlightened about much of the debate. We have provided the reader with a brief overview of the historical nature of this controversial topic, while also elucidating the frequency of gay and lesbian marriages. Similarly, we discussed many of the social contentions raised both for and against states recognizing same-sex marriages as a legitimate institution. Finally, we concluded with an overview of some of the legal and political/tax issues associated with gay and lesbian marriages, illustrating many of the rights that may be denied to same-sex couples living in states that fail to acknowledge marriage between gay or lesbian partners. We hope that the reader has been provided with a comprehensive overview of the issue, while also generating further interest in the topic that can be answered in some of the recommended readings offered at the conclusion of this article.

## GENDER DIFFERENCES

---

How men and women, and girls and boys, differ from each other has been the focus of much study in developmental psychology. Numerous newspaper and magazines articles on the topic of gender differences attest to their importance outside developmental psychology as well. *Gender* refers to the societal, social, and behavioral ways that are associated with being male or female. This entry considers issues pertinent to the study of gender differences, examines gender differences and their causes from a variety of theoretical perspectives, and concludes with the social and political implications of these differences.

Discussion of gender differences entails many research issues. Foremost among them is the debate centered on whether the study of gender differences should continue. Arguments against continued study posit that cataloging of gender differences does not reveal their origins and, instead, reifies gender distinctions. Others charge that social scientists accept new discoveries, despite the possible discomfort such politically charged information may cause. Regardless of the validity of these arguments, many researchers argue that research into gender differences, especially with a focus on context, may begin to elucidate origins

of these differences. We will return to this issue in greater depth in the conclusion of this entry, during the discussion of the political and social implications of gender differences.

Given the highly political nature of this topic, a few caveats are worth mentioning. First, when there are differences between girls and boys, the differences tend to be small. In fact, girls and boys are more alike than they are different. There are also large individual differences. For example, a particular girl may not act in a feminine-stereotyped manner. Second, gender differences vary depending on the context in which they are measured. For instance, when playing with same-gender peers, boys are more assertive than girls. Playing with girls, however, boys are no more assertive than girls. Thus, the answer to whether boys are more assertive than girls is contingent on their partner. Third, many sex differences, such as differences in math ability, are disappearing over time. The second two points suggest that gender differences may be magnified and perpetuated more by the cultural context of development than by biology alone. Finally, transgendered and some intersex individuals choose not to identify with either gender. As research continues to evolve on the topic of gender differences, the degree to which gender differences are maintained by the cultural milieu will be understood better.

### DIFFERENCES BETWEEN MALES AND FEMALES

#### Cognitive and Intellectual Achievement

Developed in the late 1970s, meta-analysis enables the statistical combination of the findings of different studies to find an overall effect size. Psychologists have used meta-analyses of previous research to facilitate compilations of gender differences across many studies. Using meta-analytic techniques, Janet Shibley Hyde argues that males and females do not differ in general intelligence. However, Hyde and colleagues found differences in mathematics, verbal performance, and spatial rotation skills.

#### *Mathematics*

In most cases, Hyde and colleagues found that females were slightly superior to males in mathematics achievement, but this difference is small.

Depending on the particular type of math achievement studied, there are gender differences. For example, girls outperform boys in computation once children enter school until they finish high school, but there is no difference between girls and boys after high school. Until high school, there are no gender differences in problem-solving ability. Beginning in high school, however, boys outperform girls in problem-solving ability. In highly selected samples of gifted children, boys tend to surpass girls. Gender differences in math achievement have become smaller in recent years; this change suggests that as girls and boys are given equal access and encouragement in school, gender differences may eventually disappear.

### ***Verbal Ability***

Analogous to mathematics performance, Hyde found that females surpass males in verbal performance. Again, these differences are small. In fact, there is more overlap in scores between girls and boys and women and men than there are differences. Performance differences do not become apparent until age 26, when women surpass men in general verbal performance. When different types of verbal performance are examined, patterns diverge. For example, boys score higher than girls on vocabulary tests in early elementary school, but the difference reverses, with women performing better on vocabulary tests than men after age 19. In early elementary school, girls surpass boys in verbal ability with higher scores on early reading comprehension tests. As is the case with mathematics, differences between the genders are becoming smaller over time.

### ***Spatial Ability***

Marcia Linn found one cognitive difference that is more sizeable, which is the difference in spatial ability. Males surpass females in spatial ability tasks, such as rotating objects in space.

### **Academic Performance**

Focusing specifically on gender, the American Association for University Women examined academic progress. Girls consistently earn better grades than boys across different subject matters. Additionally, girls are less likely to repeat a grade than boys. Women are more likely to go to college than men and

earn 56% of the bachelor's degrees in the United States.

Contrasting with their achievement in good grades, however, girls sometimes perform more poorly on standardized tests than boys. The National Assessment of Educational Progress measures children's school performance via standardized assessments. In reading and writing, girls tend to score higher than boys, whereas in math, science, and geography, boys tend to score higher than girls.

When ethnicity is examined as well as gender, some of the gender differences disappear. For example, Latina girls score higher than Latino boys in reading as well as in math. African American girls score higher than African American boys in reading as well as science. These findings suggest that gender cannot be considered apart from other factors, such as ethnic background. They also underscore the variability that is found between girls and boys of different ethnic backgrounds and the need to understand gender in the context of other variables.

In summary, there are few gender differences in cognitive or intellectual achievement, and there are variations based on ethnic as well as gender differences. Although there are few differences in children's intellectual ability and achievement, there are differences in how children rate their abilities. For example, Jacquelynne Eccles found that girls are more likely than boys to attribute their success in math to effort than ability, whereas boys are more likely to attribute their success in math to ability rather than effort.

### **Social and Personality Differences**

Few differences in personality arise between boys and girls. Some believe that boys are more physically active than girls. However, Eleanor Maccoby argues that activity level is context dependent. Playing alone, boys and girls are equally active. Playing with a same-gender pair, however, boys were more active than girls. That children's behavior changes so dramatically with a peer suggests that children may be constructing gender. Another difference when children play together is that boys are more likely than girls to engage in what Maccoby calls "rough-and-tumble play." That is, boys often wrestle together and will play physically.

In addition to observing larger gender differences, another important reason to study children playing in same-gender pairs is that children segregate based on

gender at a young age. Watching children on a playground or in a classroom, a casual observer notices that children tend to gender-segregate at an early age. Campbell Leaper argues that by the time children are 3 years old they select same-gender peer playmates. In same-gender pairs, girls' talk can be characterized by a collaborative style. Girls focus on social sensitivity and conflict mitigation while interacting with other girls. In other words, girls seem to prefer smooth social interactions with each other. Leaper finds that girls often use suggestions and begin sentences with "let's." In contrast, boy pairs are apt to have a dominant style. Boys tend to be assertive and heavy-handed during conflict. Boys use commands to control other children. However, when girls and boys play together, some of the differences disappear. For example, children are less controlling and domineering when they play with girls than with boys. Girls tend to be more assertive when paired with a boy than with a girl. Thus, children's perceptions of their partner mitigate some of the gender effects.

Some early research suggested that boys were more aggressive than girls. However, more recent research conducted by Nicki Crick and Jennifer Grotpetter suggests that levels of aggression are related to how psychologists operationally define aggression. Boys tend to display their aggression through physical means, whereas girls tend to display their aggression through verbal means, which is called *relational aggression*. For example, girls tease and exclude peers from a social activity with the intent of causing harm.

## Emotional Differences

Exploration of gender differences in emotion has focused on differences in experience and expression. Although the research on emotional experience and expression contains many methodological problems, Leslie Brody's review finds that theorists believe that females, in comparison with their male counterparts, may be more emotionally expressive, shameful, envious, and helpless, and experience and express less anger and guilt. These suppositions are congruent with the widely held stereotype that women are more emotional than men. However, the empirical literature has not always upheld this stereotype.

In general, Brody reviews a sizeable amount of research showing marked differences in the emotional expressiveness of females compared with males. For example, work by Caroline Saarni has shown that

girls are better at hiding negative emotions and are more likely to regulate their expression of emotion to keep in line with the display rules, or cultural standards, of the situation than are boys. Robin Fivush and colleagues suggest that girls place negative emotions, especially anger and fear, in a more interpersonal context than do boys. Consistent with this suggestion is the argument that males are less interpersonally oriented when compared with females. Moreover, Brody finds that males are less likely to express sadness and withdraw more from sad situations, whereas females exhibit their sadness in a more outward way, such as by crying. Fivush consistently finds that girls elaborate more when talking about emotions and generally talk more about emotions than do boys. As adults, women continue to talk about emotions more, and exhibit more intense emotional facial expressions than do men. In contrast, Brody suggests that as infants, boys express emotions—both facially and behaviorally—more intensely than do girls. Although differences in emotional experience and expression are found, these differences do not support the stereotype that women are more emotional than men.

Self-report measures reveal that males and females differ in the intensity and frequency in which they experience emotion. The specific emotions mentioned and the degree to which males and females differ, however, varies from study to study. Generally, females report more intense and more frequent emotional experiences when compared with their male counterparts, especially those associated with negative emotionality according to Stephanie Shields and Fivush. Notably, Brody finds that several studies have reported no significant sex differences in the experience of anger despite its stereotypical association with men.

Why do sex differences occur? Fivush has attributed these differences to various factors, such as the socialization of emotions by parents and peers, emotions being influenced by the culture and society in which one lives, and the situational context. For example, Judy Dunn found that mothers spoke more about emotions with girls than with boys.

## Self-Esteem

Self-esteem refers to how highly an individual evaluates oneself. Although researchers had hypothesized that males would have higher self-esteem than females, Brenda Major's meta-analytic review finds that males have only slightly higher self-esteem than

females. Moreover, this gender difference seems to occur with females of European American ethnicity only. The American Association of University Women reports that compared with boys, girls' self-esteem drops after age 9. In contrast to European Americans, there is no difference between African American females and males. The lack of a difference in African American participants underscores that culture influences self-esteem and its expression.

## Preferences

Anecdotal records suggest that children differ in their toy preferences. Researchers, such as Melissa Hines, have found that girls like to play with dolls and kitchen sets. Boys like to play with trucks and construction sets. These preferences are established by age 2. Similarly, girls and boys like to do different things. Boys prefer to play more actively than girls. Perhaps, the difference in preference for higher activity levels drives boys' preferences for certain toys.

Children endorse gender-typed behaviors and beliefs at a young age. Not surprisingly, boys uphold these beliefs more than do girls. Part of the reason boys may endorse the gender norms to a high degree is that males have more power than females in the society. Moreover, informal observations suggest that boys are more harshly criticized for failing to uphold gender norms than are girls. Consider, for example the negativity associated with the epithet, *sissy*, compared with its relatively less censuring counterpart, *tomboy*.

## THEORIES OF GENDER DIFFERENCES AND DEVELOPMENT

Many theories have been proposed to explain gender development and why girls and boys may develop differently. These theories include biological, social learning, and cognitive approaches.

### Biological Theories

Many biological theories of gender differences focus on hormonal influences. For obvious ethical reasons, we cannot experimentally manipulate individuals' hormonal levels simply to test the effects of hormones on gender development. However, there are "natural" experiments in which genetic conditions alter the amount of hormones to which fetuses are exposed. One such condition is congenital adrenal

hyperplasia (CAH). In this condition, genetic males (i.e., possessing XY chromosomes) and genetic females (i.e., possessing XX chromosomes) are exposed prenatally to excess amount of androgen. As a result of the excess androgens, the genitalia of girls with CAH are often masculinized. At birth, a girl's enlarged clitoris may appear to be a phallus. Before the advent of routine genetic testing, girls with CAH were raised as boys. Presently, however, girls with CAH tend to be raised as girls. Some parents opt for medical interventions to change girls' genitalia. (However, surgery is controversial because it can destroy orgasmic function.)

Studying genetic females with CAH enables researchers to examine hormonal influences separate from biological sex. In her studies of girls prenatally exposed to androgen, Hines has compared girls with CAH, boys with CAH, unaffected girls, and unaffected boys. Although unaffected boys often engage in more rough-and-tumble play than unaffected girls, girls with CAH do not engage in more rough-and-tumble play than unaffected girls. However, Sheri Berenbaum and Hines find that girls with CAH prefer more masculine-stereotyped toys (e.g., playing with balls or guns) than unaffected girls. Hines suggests, thus, that hormonal influences may play a role in children's toy preferences. Of course it is difficult to tease apart social and cognitive factors. Girls with CAH may be aware that they are different from unaffected girls and think that they are more masculine than their unaffected peers. Moreover, that they do not demonstrate more rough-and-tumble play suggests that hormones do not control behavior. However, this is not meant to propose that hormonal influences do not contribute to gender differences. It seems that hormones may act in concert with the social environment to produce differences.

### Learning Theories

According to social learning theorists such as Albert Bandura, children learn behaviors through modeling, reinforcement, motivation, and behavioral enactment. Children learn from modeling by paying selective attention to same-gender models that they imitate. For example, a daughter may decide to wear makeup after watching her mother apply makeup. A son may decide to pretend to shave after watching his father shave. Supporting social learning theory, experimental studies find that children imitate people of the same gender more than the other gender.

Another component of social learning theory posits that children receive reinforcement for performing behaviors that are stereotyped for their gender and receive punishment for performing behaviors that are stereotyped for the other gender. A study conducted by Beverly Fagot and colleagues revealed reinforcement of gender stereotypical behavior in young children. Day care providers were more likely to respond to gestures, gentle touch, and talk from girls than boys. In contrast, they were more likely to respond to physical action, screams, and whining from boys than girls. When the researchers returned to the day care site 11 months later, girls talked more than boys, whereas boys engaged in more negative behavior than did girls. From their findings, Fagot and colleagues maintained that the children developed their behaviors as a direct result of positive reinforcement from caregivers.

## **Contextual and Social Theories**

### ***Role Theory***

Alice Eagly developed role theory, which suggests that personality differences arise from the different roles assigned to women and men. Most of these roles developed as a function of child rearing. She argues that were roles to become similar for men and women, gender differences in personality would disappear.

### ***Social Psychological Theory***

Kay Deaux and Major argue that the display of gender differences is predicated on how gender is negotiated between the perceiver and the target. All people bring beliefs about gender into their interactions that contribute to how gender is perceived and enacted within the interaction. A self-fulfilling prophecy results in the perpetuation of gendered behavior in social interaction. Moreover, perceivers may interpret behavior as conforming to gender norms more than it actually does.

### ***Separate Cultures Theory***

Play segregated by gender facilitates the development of gendered norms in play. Maccoby suggests that these norms perpetuate separate cultures for males and females, which lead to gender differences in behavior.

## **Cognitive Theories**

### ***Cognitive Developmental Theory***

Lawrence Kohlberg proposed a cognitive development theory in which children go through various stages in their development of gender-typed behavior and identity. In the first stage, gender identity, children are able to label themselves, which typically occurs when children are 2 years old. Between 3 and 4 years of age, children begin to understand that gender is stable over time. For example, children realize that when they grow up, they will remain the same gender. Entrance into the third stage, gender constancy, is predicated on the gender constancy or the belief that gender remains constant across situations. For instance, children understand that even were they to engage in cross-gender typed behaviors (e.g., a boy playing with baby dolls), their gender would not change. Kohlberg believes that it is not until children have achieved gender constancy that they engage in gender-typed behaviors. At this point, children identify with their same-gender group and try to act like other members of their gender group.

Critiques of cognitive developmental theory are many. One important criticism is that children act in a gender-stereotypical manner long before they have achieved gender constancy.

### ***Gender Schema Theory***

Building on prior schema theories, Sandra Bem, Hazel Markus, and Carol Martin proposed gender schema theory in the early 1980s. Gender schema theory emerged from cognitive developmental theory and information-processing theory. It applies gender to more general schema theories. Simply put, a schema is a conceptual network that helps people reason more effectively and quickly. Schemas allow people to interpret their experiences, understand their past, and make inferences about behavior. Consequently, in gender schema theory, peoples' theories about gender allow them to simplify a large body of knowledge and to apply this knowledge easily to themselves and to others.

Martin posits that through involvement and observation of cultural practices, children begin to understand that gender is a dichotomous organizer of cultural activities, forming the basis for their gender schema. Once these schemas are internalized, children and adults sort traits, behaviors, and activities into two

categories: one for women and one for men. After sorting these traits, behaviors, and so forth, individuals select the ones that are consonant with their gender stereotype. In an experimental study, Martin and colleagues showed individual children novel objects that were placed in boxes labeled “for girls,” “for boys,” or “for both girls and boys.” The researchers took the objects out of the box and taught children three things about the objects. Children were left alone in a room to explore the objects. A week later, children returned to the university laboratory and were tested about the objects. As expected, children were more likely to explore objects that were labeled for their own gender. Moreover, children remembered more about the objects labeled for their gender. Simply labeling an object for one’s gender is enough to make children prefer an object.

## SOCIALIZING AGENTS

Social learning and cognitive theories similarly agree that children learn about gender stereotypes from interacting with others. Most people accept that children do not develop in isolation, but instead learn in relationships with important others. Thus, it is important to examine what children might learn about gender in their daily lives both by observing others and through actual interactions with others.

### Parents

Children’s earliest and arguably most important relationships begin with their parents. Beginning in infancy, parents treat girls and boys differently. How different, however, is debatable. For instance, a meta-analysis conducted by Hugh Lytton and David Romney found that the only way in which parents treated girls and boys differently was that they encouraged children’s gender stereotypical preferences. Most of the articles they reviewed relied on self-report measures, such as questionnaires asking parents how they treated their children. Leaper and colleagues reviewed studies that actually examined mothers talking with their children. In their review, they found larger differences. For instance, mothers talked more to girls than to boys. Parents may also speak differently to sons and daughters. For example, Harriet Tenenbaum and Leaper examined parents’ scientific explanations to their children during everyday science conversations. Girls and boys did not differ in their math or science grades,

interest, or confidence. Despite the lack of differences between girls and boys, fathers used more scientific explanations with their sons than with their daughters. In contrast, fathers asked more questions of daughters than of sons while discussing an interpersonal conflict. Fathers’ talk may help boys develop more in-depth knowledge about science and help girls develop interpersonal skills.

### Teachers

Much research suggests that girls receive less of teachers’ attention within classrooms than do boys. Allison Kelly’s meta-analysis of 81 studies found that, in general, boys received more teacher attention than did girls. For example, it was found that boys received more praise, criticism, and response opportunities. The only exception to boys’ advantage was that girls were more likely to receive a second chance to answer teachers’ questions. In general, it seems, boys receive more teacher attention than do girls. Moreover, many schools perpetuate children’s differences through practices such as having children forming separate lines or teams during class work.

### Peers

By playing with same-gender peers, children create sex differences. For example, children’s play with same-gender peers may follow gender-appropriate behaviors more strictly than when playing with other-gender peers. Moreover, children police each other’s adoption of gender-appropriate behaviors. Throughout childhood, children may more strictly enforce adherence to gender than other socializing agents.

## SOCIAL AND POLITICAL IMPLICATIONS

Lively debate attests to the social and political implications of the study of gender differences. Foremost amongst the debate is the concern that attention to difference will depict women as inferior to men. This concern stems from women’s societal oppression. Effects of women’s inferior societal position include, but are not limited to, women’s lower wages than men, women’s increased risk for sexual and physical abuse at the hands of men, and that girls are less likely to be educated in much of the world than are boys.

Resulting from this concern, some feminist scholars have argued for the discontinued study of gender

differences. For example, Bernice Lott posits that compilation of sex differences will increase men's power. These concerns are not unfounded. According to Eccles, mothers' endorsement of the cultural stereotypes favoring boys over girls in mathematics ability correlated with mothers' lower perceptions of their daughters' mathematics abilities.

According to Eagly, feminist scholars studying gender differences historically have followed two main research agendas. The first was to render differences as minimal to demonstrate that women and men are basically the same, and thus equal. In this way, psychologists could demonstrate that cultural stereotypes are not based in reality. Because men are viewed as the norm, any difference from men is deficient. The second main feminist agenda allowed for differences between men and women, but viewed women as superior (e.g., more caring, nurturing) than men. These two approaches are so common in scientific psychology that Rachel Hare-Mutin and Jeanne Marecek termed the first a *beta bias*, which is a preference to minimize differences. In contrast, an *alpha bias* is the desire to exaggerate gender differences.

Viewing gender as constructed in social interaction, Marecek debates whether gender is a stable, internal, individual difference characteristic. Moreover, given that generic men and women, girls and boys, do not exist, how can knowing about average characteristics uncover understanding of behavior? Instead, Marecek argues that gender needs to be understood in its sociocultural historical context. Indeed, as mentioned throughout this review, gender differences are not stable across different ethnic and cultural groups.

Another concern raised by feminists, such as Carol Tavris, is that documenting sex differences will not enable understanding of the power differential. For example, given women's higher academic achievement, why do they earn less money than men? Eagly counters with hopes that continued study of gender differences will give rise to an understanding of the causes of gender inequities. This information will then aid feminists in decreasing women's unequal societal status.

## SUMMARY

There are small gender differences in specific cognitive abilities, personality attributes, and emotional expression. Gender differences in preferences are larger. The antecedents and causes of gender differences are not yet fully understood. Continued research

on gender differences, as well as the political implications, will enable a greater understanding of gender in context.

—Harriet R. Tenenbaum and  
Naomi Aldrich

## GENDER IDENTITY

---

All children learn that they are either male or female, but what meaning do they give to the fact that they are one sex and not the other? In all cultures, boys and girls are expected to behave differently, and thus it is likely that children worldwide occasionally reflect on questions such as these: Am I living up to the expectations of my sex? Am I fortunate or am I disadvantaged to be the sex I am? Must I limit my actions to same-sex-typical behavior, or am I free to explore cross-sex options? Children's answers to these questions affect their adjustment and their development.

Here we summarize the ways that children's gender identity has been conceptualized, review the development of several major components of gender identity, and discuss the implications of gender identity for children's adjustment and development.

## WHAT IS GENDER IDENTITY?

Different theorists have conceptualized gender identity in different ways. A classic approach is that of Lawrence Kohlberg, who viewed gender identity as simply knowing one's sex. Gender identity has also been defined as the degree to which one perceives the self as conforming to cultural stereotypes for one's gender, as the degree to which one internalizes societal pressure for gender conformity, or as a fundamental sense of acceptance of, and of belonging to, one's gender.

Susan Egan and David Perry proposed that it is useful to conceive of gender identity as multidimensional. In their model, gender identity has five major components: (1) membership knowledge (knowledge of one's membership in a gender category); (2) gender typicality (felt similarity to others of one's gender); (3) gender contentedness (satisfaction with one's gender assignment); (4) felt pressure for gender conformity (pressure felt from parents, peers, and the self for conforming to gender stereotypes); and (5) intergroup bias (the belief that one's own sex is superior to the other). Thus, gender identity is defined as the collection of thoughts and feelings a person has about membership in a gender category. Note that gender identity concerns more than people's self-perceptions of specific sex-typed attributes, such as competency in math, possession of instrumental or expressive traits, or sexual orientation; it is concerned with the overall sense people make of the fact that they belong to one sex and not the other.

## DEVELOPMENT OF GENDER IDENTITY

The membership knowledge component of gender identity begins early. By age 3, most children attain "basic gender identity," or can answer correctly the question, "Are you a boy or a girl?" However, children do not attain "gender constancy," or understand that their gender is fixed and does not depend on superficial factors such as the clothes they wear or the toys they play with, until about age 6. Shortly after children attain basic gender identity, they show signs of three other components of gender identity—gender contentedness, felt pressure for gender conformity, and intergroup bias. Thus, preschoolers usually voice happiness with their gender, feel it is imperative to behave like others of their gender, and develop "intergroup cognitions," such as hostility toward the other sex and the

belief that their own sex is superior. A few years later, the final component of gender identity—an estimate of one's gender typicality—develops. Gender typicality reflects children's idiosyncratic weighting and integrating of diverse information about their sex typing, with different children of the same sex feeling gender typical (or atypical) for different reasons (e.g., one boy may derive a sense of typicality from athletic prowess, another from competence in math or science). At the same time as children are developing a sense of gender typicality, they usually relax their intergroup bias (i.e., voice less negativity toward the other sex) and relax their felt pressure for gender conformity (i.e., become less inclined to view cross-sex-typed activities as strictly prohibited).

## IMPLICATIONS OF GENDER IDENTITY FOR CHILDREN'S DEVELOPMENT AND ADJUSTMENT

Considerable controversy surrounds the implications of gender identity for children's development and adjustment. Kohlberg argued that gender constancy (attained at about age 6) was necessary before children would show "self-socialization of gender typing," or the tendency to adopt behaviors perceived as appropriate for one's gender. However, it appears that basic gender identity (acquired at about age 3) is sufficient to set in motion a number of sex-typing processes (e.g., imitation of same-sex models, preference for play with same-sex peers) as well as cognitive processes (e.g., intergroup cognitions) that encourage gender differentiation.

Much argument has centered on the question of whether a "strong" gender identity carries positive or negative implications for adjustment. The classic position, beginning with Sigmund Freud, has been that a strong and secure sense of gender identity (a stable and confident sense that one is a typical and adequate member of one's gender category) is good for mental health. Consistent with this view is evidence that children who are diagnosed with gender identity disorder (who have a strong desire to be the other sex and who exhibit marked cross-sex behavior) are decidedly distressed. The source of these children's distress, however, is unclear; it may be that the negative social reactions these children incur (from parents, teachers, and playmates) are the problem.

In the 1970s, a challenge to the traditional position that strong gender identity is healthy was offered by

Sandra Bem, who argued that the more an individual's membership in a gender category is a salient feature of the individual's psyche (i.e., the more an individual conceives of the self as either "masculine" or "feminine"), the poorer will be the individual's mental health. Her argument was that a person who feels strongly masculine or feminine (someone she labeled "gender schematic") must be experiencing strong internalized societal pressures for gender conformity that limit the person's options for happiness and undermine the person's sense of autonomy, thereby undermining mental health.

Evidence bearing on the Bem hypothesis is inconclusive, perhaps because Bem did not directly assess people's felt pressure for gender conformity; instead, she inferred it from the degree to which people fail to perceive both male-typed and female-typed personality traits in the self-concept (e.g., if a person reported many instrumental traits and few expressive traits in the self-concept, it was assumed that the person was experiencing strong internalized pressure to be male typical). Thus, although Bem's conceptualization of gender identity was in terms of felt pressure, her measure of it was closer to a measure of gender typicality. Egan and Perry's work shows that felt pressure for gender conformity and felt gender typicality are uncorrelated. Another problem is that Bem's measures of male and female typicality relied too strongly on self-perceived instrumental and expressive traits. People's self-perceived gender typicality is affected by more than these traits (e.g., appearance, recreational activities, academic competencies).

Recent work on the relation of gender identity to adjustment suggests a more complex picture than that suggested either by a simple "gender identity is good" or a simple "gender identity is bad" hypothesis. Whether gender identity is a favorable or an unfavorable influence depends on the component of gender identity in question. In research in which the several Egan and Perry components of gender identity have been assessed, feelings of gender typicality and of gender contentedness have been found to be favorable influences on adjustment (e.g., self-esteem, acceptance by peers, absence of internalizing symptoms), whereas felt pressure for gender conformity has been found to be detrimental to adjustment. Thus, both the traditional view that gender identity is good and Bem's view that gender identity is bad receive support, depending on the component of gender identity assessed. In summary, children who feel gender typical, who are happy

with their gender assignment, and who do not feel anxious at the thought of exploring cross-sex activities (a combination that might be labeled "secure gender identity") enjoy optimal adjustment.

## FUTURE DIRECTIONS

Contextual influences on gender identity need more study. Some aspects of gender identity are relatively stable parts of people's psyches (e.g., the Egan and Perry components), but contextually elicited gender identity might be important, too (e.g., being the only female member of a group may make being female salient). Situationally elicited gender identity may have consequences, such as causing gender-stereotyped behavior.

Finally, to understand how gender identity affects adjustment and behavior, researchers should assess not only each individual's gender identity components but also the idiosyncratic meanings that each individual accords to gender. If, for example, some girls define being female as being a compassionate leader, whereas other girls define being female as being subservient and dependent, it may be that gender identity will bear different relations to adjustment for the two sorts of girls. For example, feeling content with one's gender assignment may be associated with agentic competencies (e.g., assertion, leadership) for the former girls but with helplessness and depression for the latter. Thus, measuring children's "gender relevance beliefs" (the attributes people view as relevant to each gender role) need to be studied hand in hand with gender identity.

## GENDER ROLE DEVELOPMENT

---

Gender is one of the most central attributes people have and an object of endless interest across all societies. Thus it should not be surprising that children are also aware of gender-related characteristics and quickly come to display those qualities themselves well before their own sexual maturity. What *is* surprising is just how early gender awareness emerges developmentally and just how pervasive its effects are. The present paper summarizes what we know about how gender differences develop over the childhood years, and what theoretical ideas have been proposed as to the basis for gender role development.

### NORMATIVE GENDER ROLE DEVELOPMENT

Diane Ruble and Carol Martin have organized research on gender role development around four major gender-typing components: (1) concepts or beliefs, (2) gender identity or self-perception, (3) verbalized gendered preferences, and (4) display of gender-typed behaviors. They review evidence showing that even in infancy, children are already able to distinguish between the two sexes in rudimentary ways. For example, 7-month-olds respond differently to male and female voices, and by 12 months of age, many infants can distinguish between male and female faces. Similarly, ideas about gender stereotypes regarding toy, activity, and clothing preferences are already evident from about age 2 or 3, and rapidly progress further during the subsequent toddler and preschool years. Knowledge of stereotypes continues to expand in the middle childhood years, but children's advancing cognitive development also leads them to more flexible thinking about gender roles as they further mature during this age period. Children's understanding of gender identity or self-perception likewise progresses systematically during

the toddler and preschool years, moving from a simple ability to label the self as a boy or a girl, to understanding that gender is stable over time (e.g., understanding that a boy can become a "daddy" but not a "mommy"), and finally to a full understanding of the permanence of gender assignment even across clothing and hairstyle changes (gender *constancy*, achieved at about age 5 to 7). Developmental trends for verbalized gendered preferences parallel those for stereotype knowledge, with some preferences beginning to be expressed as early as age 2 to 3, and well established by age 5. Finally, behaviorally, gendered toy play has been found to emerge even earlier, by age 1½ to 2. And by age 3, both sexes show a clear preference for playing with same-sex partners. Research further indicates that gendered differences in interests and activities continue through the childhood years and may even intensify in adolescence.

What might account for such early and pervasive gender role development? A number of theories have been advanced to address this question.

### THEORIES OF GENDER ROLE DEVELOPMENT

Theories of gender role development fall into two major categories, namely, biological and social-cognitive. Biologically oriented theories, such as that of John Money and Anke Ehrhardt, have focused on the many genetic, anatomical, and hormonal differences between the sexes as providing the major basis for the gender role distinctions shown by males and females. For example, biologically based sex-linked characteristics evident from early infancy may predispose boys and girls to favor those activities typically associated with their gender (more muscular, active boys may therefore be predisposed toward risk taking, aggression, and rough-and-tumble play; more verbal girls may therefore be predisposed toward more verbally oriented play). At the same time, intertwined environmental influences cannot be excluded. For example, Eleanor Maccoby has suggested that parents may play more roughly with their more muscular, active sons than with their quieter, more verbal daughters, with such experiences also contributing to children's later gendered development. Money and Ehrhardt's *biosocial* theory incorporates social as well as biological factors by stressing how early gendered socialization experiences combine with the impact of prenatal biological developments, particularly hormonal influences. In support

of such biological perspectives, the large empirical literature on hormonal influences (e.g., with androgenized females exposed to male hormones during prenatal development) demonstrates a wide range of hormonally based effects, but also makes clear the intertwined effects of social experience. A *psychobiosocial* model recently proposed by Diane Halpern has further extended the notion of two-way interactive effects by stressing the impacts that early experience may have on the extent to which neural pathways develop in different parts of the brain.

Although biologically oriented theories do particularly well in spelling out the nature of biologically related influences on gender role development, to find more detailed treatments of socialization factors, it is necessary to turn to the array of theories that emphasize social-cognitive influences. Freud's *psychoanalytic* theory stresses the role of the identification process with the same-sex parent that takes place in the phallic stage of psychosexual development (age 3 to 6). Freud believed that the child identified with the same-sex parent as a way of resolving the conflict associated with having an incestuous desire for the parent of the opposite sex (the Oedipus complex in boys, Electra complex in girls). Because of the more intense threat (fear of castration) experienced by boys, Freud felt that the identification process and subsequent adoption of gender-typed characteristics would be stronger for boys than for girls. Although empirical work has been consistent with Freud's idea that gendered behaviors emerge in the early childhood years, it has not supported many other features of his theory. For example, research by Sandra Bem indicates that children of age 4 to 6 lack accurate understanding of the genitalia differences between males and females, and thus it is difficult to argue for castration anxiety as playing a major role in the conflict experienced at this age level.

A wide range of *cognitively* oriented theories offers another kind of useful perspective on gender role development. These theories all stress the ways in which children engage in self-socialization processes, that is, actively attempt to acquire an understanding of gender roles and their own gender identity. Lawrence Kohlberg's *cognitive-developmental* theory proposed that children progress through three stages in this regard, beginning with showing an understanding of basic gender identity at about age 3, then coming to understand the stability of gender over time, and finally achieving full understanding of the invariance of gender

at about age 5 to 7. He argued that a full cognitive understanding of the constancy of gender was necessary before a child would be motivated to engage in a gendered self-socialization process, only then seeking out and paying particular attention to same-sex others. Although empirical research has supported the idea that children gradually progress through these three stages of gender understanding, the assertion that full understanding is required for gender-typing does not fit well with what we know about the extensive gender knowledge and behavior of younger children. Carol Martin and Charles Halverson's *gender schema* theory proposed a variation on Kohlberg's views by suggesting that *basic* gender identity is sufficient to instigate the self-socialization process in young children, with children then motivated to attend to information about gender and use it to construct organized ideas ("gender schemas") about the two sexes. Young children are believed to first acquire general ideas about what roles and activities characterize each sex ("in-group/out-group" schemas), and then develop detailed notions about those things seen as appropriate for their own sex ("own-sex schemas"). Yet another influential cognitive perspective relates to Sandra Bem's views on the limitations associated with being strongly gender schematic (highly masculine or highly feminine in one's gender typing) and the advantages of *androgyny* (having a blend of both masculine and feminine attributes). Empirical research has supported Bem's assertion that androgyny may often be advantageous for children as well as adults, but the issue of the extent to which gender typicality is a desirable or undesirable attribute remains a subject of debate, and recent findings by Susan Egan and David Perry in fact suggest that it may be a positive factor for children's development.

Albert Bandura's social cognitive theory is likewise strongly cognitive in emphasis, but it also draws on a broad array of other factors, including motivational, affective, and environmental ones. Bandura posits three major types of influences that operate to promote gender role development: (1) modeling (observing gender-relevant conceptions and behaviors from a wide range of sources, including family members, peers, teachers, and the media), (2) enactive or direct experience (gender-relevant learning related to the consequences experienced for the child's own actions), and (3) direct tuition (direct instruction, such as statements about what is appropriate for each sex). These influences affect not only the development of gender-related knowledge and skills in children but

also cognitions centrally involved in behavior regulation (outcome expectancies, self-evaluative standards, and self-efficacy beliefs). Importantly, the child is viewed as playing a very active role in development. Children are not simply acted on by their social environments; they also exert effects on and produce changes in those environments. Specifically, personal, behavioral, and environmental factors are all posited to mutually influence one another in this approach (*triadic reciprocity*). Gender research findings have provided extensive support for the relevance of the components in Bandura's multidimensional approach. Nevertheless, the issue of whether social cognitive theory is sufficiently comprehensive to stand alone as the theoretical framework for gender role development is a subject of debate, and it can be argued that there is much to be gained from continuing to explore alternative perspectives as well.

## INTEGRATION AND FUTURE DIRECTIONS

In summary, gender role development is a central domain that affects children from infancy onward across all areas of their functioning. One theme apparent in the diversity of theoretical approaches advanced to explain gendered development relates to recognition of the important part biological forces have. These forces are viewed not as acting in a deterministic way, but rather as providing biologically based predispositions that operate in intimate concert along with environmentally based influences. A second theme pertains to the frequent stress placed on the role of cognitive processes. The multiple cognitively oriented theories agree in their recognition of the important roles that cognitions play in gender role development, although they vary in the specific kinds of elements and processes given most emphasis.

Integrative approaches incorporating the strengths of the various individual theories in an overall eclectic perspective are likely to best serve advancement of our understanding in this field. Promising directions of future research may be found in every area. Modern theoretical and methodological developments in the neuroscience and evolutionary theory areas are opening up exciting new directions of biologically oriented investigation. In the cognitive theory domain, the same may be said, with new conceptualizations and measurement tools showing the promise of doing much to further advance our knowledge. For example, Liben

and Bigler have made significant new contributions with their work on new gender-typing measures widely applicable across a broad age range. Additional directions of research have also been opened up by the recent work of David Perry and his associates on newly proposed summary-level measures related to gendered representations of the self (e.g., gender typicality, contentedness, and felt pressure for gender role conformity). In conjunction with the increasing use of multidimensional, longitudinal designs, these developments may be expected to add considerably to our understanding of this complex but endlessly fascinating topic.

## GENERALIZABILITY

---

Experiments in human development attempt to identify the influence of variables or events on human behavior. These experiments contribute to the shared knowledge of the community that seeks to understand human development by describing the course of human development, predicting how individual humans will develop, and arranging optimal environments for

growth. Before experiments can contribute to an understanding of human development, they must fulfill two criteria: accuracy and generalizability. How accurate the results of an experiment are can be determined by asking, "How well did the experimenters rule out other possible explanations for the observed results?" If it can be reasonably assured that the results are accurate for a given experiment, we may then begin to ask questions of generalizability.

When an experiment is conducted, it would be impossible (in terms of time, effort, and finances) to measure all of the important behavior of all the world's humans. Instead, researchers observe some important behavior of a smaller group of participants, called a *sample*, in a limited number of settings. *Generalizability* is the extent to which outcomes of observations with a sample represent the performance of the larger population under similar conditions. Typically, consumers of research are concerned with generalizability across different groups, but they may also be interested in generalizability across settings and behaviors.

If a large group of infants was observed to all begin walking by about 10 months of age, would it be appropriate to conclude that all infants learn to walk by 10 months? If mothers reacted with joy and glee each time their babies smiled in a laboratory setting, and the babies smiling increased dramatically when this type of parental response was consistent, would it be appropriate to conclude that all babies learn to smile through social interaction with mothers? If babies do learn to smile from their mother's approval, would it be safe to assume that they also learn other behaviors from their mothers' approval, such as crawling or walking?

These are questions relevant to the generalizability of results. They are important questions because it is crucial to be able to apply what is learned under one set of conditions in the past to many of the important situations occurring in the present. Nevertheless, the tentative nature of science suggests that the answer to all of the questions above is "No." Infants raised in cultures other than those represented in the original study may not learn to walk until they reach 12 months. Mothers may respond to smiling in different ways outside of the laboratory setting, and other important infant behaviors may develop independent of parental social interaction.

Increased generalizability can be obtained in one of two ways. The first involves replicating studies (i.e., doing them again) with different participants, in

different settings, or while measuring different behaviors. This method is direct in that similar analyses are replicated across relevant new dimensions. The second involves including a large and diverse sample of participants, settings, or behaviors into the initial experiment. Generalizations of findings from samples to populations are made with the most confidence when the critical dimensions of the population are equally represented in the sample; this is usually achieved through systematic sampling and assignment techniques. Ultimately, generalizability, the successful extension of findings to people and situations beyond those of the original experiment, is achieved by assessing the impact of the same or similar variables on an ever-widening subset of participants, behaviors, and settings.

## GENERALIZED ANXIETY DISORDER

---

The Diagnostic and Statistical Manual of Mental Disorders characterizes generalized anxiety disorder (GAD) as a problem attributable largely to excessive worry. In recognition of the heightened levels of worry and anxiety common to all anxiety disorders, some have considered GAD a core anxiety disorder. Although worry is central to GAD, additional necessary features for the diagnosis include the following:

- Difficulty controlling the worry
- Combinations of three or more physical and emotional concomitants of the worry (i.e., restlessness, easily fatigued, concentration and attention problems, irritability, muscle tension, and sleep disturbance)
- Worry is not due only to another primary psychological problem (i.e., worrying about having a manic episode in the case of bipolar disorder).

- Significant impairment in social, occupational, or role functioning
- Worry and associated disturbance is not due to effects of a substance or other medical problem

## ETIOLOGICAL FACTORS

Although worry is considered a core feature of anxiety disorders, and GAD is considered a classic anxiety problem, there is little consensus regarding the etiologies of both worry and GAD. In general, individuals with GAD have high trait anxiety, which is the stable tendency to respond to stress with high levels of anxiety. One etiological model proposes that GAD arises from several, largely genetic, predispositions. These genetic predispositions are associated with a general anxious vulnerability, composed of the following elements:

- *Processing bias*: the tendency to view neutral or ambiguous stimuli as threatening, and a corresponding tendency to conclude there are no alternatives to exposure to threat
- *Avoidance*: a coping style that is excessively reliant on avoidance of the threatening stimuli as a means of managing anxiety
- *Arousal/emotionality*: refers to the heightened physical arousal, interpreted by the individual as anxiety that accompanies the processing bias

A closely related etiologic explanation of worry in general, and GAD in particular, involves avoidance theory. Central to this perspective is the counterintuitive premise that worrying shields the individual from experiencing even greater levels of anxiety associated with anticipated poor coping and a resultant negative outcome. At a basic level, chronic worriers have been found to have significantly less physiological arousal when worrying (a predominantly verbal activity) than while imagining a scene associated with the worry. Additional evidence suggesting that worriers have a basic assumption of poor coping ability shows that individuals with chronic worry also perceive themselves as less effective when faced with challenges and responding to stress.

Problematic in conceptualizations of GAD and worry is the role of worry in everyday life. Worry is a common experience, and many have suggested it is essential for some tasks, particularly certain types of problem solving where the individual has lower confidence in their ability to meet the challenge posed. Investigators have speculated that GAD is a fairly

common disorder (lifetime prevalence between 4% and 7%), but drawing a clear distinction between normal (and possibly intense) worry compared with pathological worry has been difficult.

## TREATMENT

The availability of empirically supported treatment for GAD is fairly recent. Most of the research investigating how to manage excessive worry has involved a combination of cognitive and behavioral interventions. These interventions have been varied, ranging from individually applied relaxation or biofeedback to comprehensive treatment packages such as multicomponent cognitive behavioral therapy (CBT) or anxiety management training. A recent review of the available treatment literature supports CBT as producing the best outcome (both immediate and with maintenance of gains).

CBT, as it is currently applied for GAD, involves identifying specific errors in thinking that contribute to worry, including faulty beliefs about the likelihood of catastrophe and a pessimistic view of one's chances of coping successfully. However, unlike in the case of obsessive-compulsive disorder (OCD), individuals with GAD appear to have a wider range of cognitive distortions. Some common distortions are as follows:

- *Fortune telling*: in the absence of supporting evidence, the specific belief that the future events will turn out negatively
- *Negative filtering/positive discounting*: an increased focus on negative outcomes, while downplaying positive events as trivial
- *Overgeneralizing*: applying the negative outcome from one event and assuming it will occur the same way for all other events
- *Black and white thinking*: placing all events into either all positive or all negative categories, with no intermediary conditions

These common distortions may contribute to worry, although none of these is pathogenic of worry, and can be readily identified in other conditions. So what makes these cognitive distortions particularly relevant in the case of worry? Notice that in most of the cognitive distortions, there is a future-oriented negative outcome. This is one fundamental distinction that can be brought to bear for anxiety conditions in general, and for worry in particular.

Treatment using CBT involves systematically identifying which of these distortions best apply to

someone with worry. Once this has been established, the client and therapist engage in a collaborative effort to determine how to challenge these spontaneously occurring distortions and to apply these challenges in situations that give rise to worry.

As noted, CBT is a comprehensive treatment package. Other important components include training GAD sufferers in more effective problem solving than chronic worrying and exposure to reduce the naturally occurring avoidance that worry produces. Problem solving involves developing a systematic approach to understanding the common problems that individuals face and determining ways of best resolving the situations. These analogue problems can then be applied to problems common to the client. This frequently includes managing emotional responses when faced with difficult situations and understanding that not all problems are readily solved. With repeated practice, adaptive coping responses would be strengthened, particularly for some ongoing problems that require periodic management.

Although CBT has been found to be an effective treatment for GAD, the most recent research suggests that interpersonal functioning must also be addressed in order for GAD sufferers to achieve a long-term positive outcome. Preliminary evidence from one treatment outcome study suggests that individuals with GAD who receive an additional treatment component focused exclusively on interpersonal functioning have improved progress. The mechanism of action for the improved outcome associated with interpersonal functioning among worriers is not clear. However, it has been speculated that improved interpersonal functioning also improves perspective taking (frequently addressed in CBT via challenging cognitive distortions) and increases the GAD sufferer's sense of effectiveness.

## GENERATION GAP

---

The concept of the generation gap is one that has become part of our cultural vernacular. Reputedly coined by renowned anthropologist Margaret Mead, the simplest definition of the concept is the differentiation (or gap) of values, attitudes, or behaviors between members of an older generation and a younger generation. Typically, the concept of the generation gap is used as an explanation of conflict between parents and children within individual families. The concept gained particular notoriety during the 1960s and 1970s, when numerous articles and books commented on the differences between baby boomers and their parents.

The gaps between generations can be considered in two particular ways. The first is when comparisons are made at different times between generations at similar ages, such as comparing a parent's high school experiences relative to his or her child's high school experiences. The classic example of this is the popular saying by older family members, "when I was in school, I walked a mile in the snow." The second approach is to examine across groups at the same point in time. For example, parents and adult children may experience conflict about child rearing, whereby the gap may be defined in terms of current differences in child-rearing beliefs between children and their parents. Most studies from the 1960s and 1970s were based on the latter approach.

Generation gaps emerge out of the differential experiences of what demographers refer to as *birth cohorts*. Birth cohorts are groups of individuals born

within a similar time, typically 10-or 20-year intervals. Typically, cohort members have *unique* experiences that affect their human development in similar ways. This uniqueness of birth cohorts is linked directly to the level of social change within a given society. The greater the degree of social change (i.e., immigration, economic development, political instability), the more unique birth cohorts become. Thus, the characteristics of birth cohorts influence generation gaps in two key ways. First, they emphasize the distinctiveness of different birth cohorts. Second, through shared experiences and memories, members of the same birth cohort form deep bonds with each other, often reinforcing that which makes them unique to other generations.

What are the implications of the generation gap? At the family level, generation gaps may increase ambiguity and discord between parents and their children. At the societal level, researchers and policy makers are concerned that increased parent-child discord may potentially alienate aged parents from their families, essentially making them more dependent on governmental sources of support in old age.

As our population ages and as the nuclear family continues to undergo radical transitions, there has been a renewed interest in the generation gap. This interest has been translated into the development of intergenerational programs that are aimed at reducing divisions and ambiguity between generations. Intergenerational programs are most frequently found in schools, child and adult day care programs, community centers, and civic organizations and youth groups, but federal and state initiatives also exist. However, we still do not know how effective these programs and initiatives have been on larger social and cultural processes that produce the generation gap.

## GENOTYPE

---

The term *genotype* refers to the specific genetic makeup, unique genetic constitution, or hereditary “blueprint” of an organism. An individual’s genotype is his or her genetic identity.

A genotype can mean the full complement of genes that an organism possesses, or it can refer to the DNA bases at only one position in the genome. Often the term is used to describe a characteristic subset of genes, and the linkage relationships between them, that define an individual or group of individuals.

The term *allele* refers to the specific string of base pairs (i.e., the genotype) at a particular genetic locus. A *locus* is the physical position or address in the genome that a particular gene occupies. The term genotype may refer to the sequence of bases at a single locus (i.e., an allele), or it may refer to an organism’s entire set of alleles.

The term *polymorphism* means the existence of two or more different forms in a population. In biology, its uses include describing variable forms of proteins or other chemical compounds, whole organisms, and genotypes. Genetic polymorphisms may be differences in single nucleotides, or they may extend over a number of nucleotides, examples being polymorphic repeat sequences. Polymorphism frequencies may vary in different subsets of the population. Common polymorphisms are most useful in mapping studies. Single nucleotide polymorphisms (SNPs) probably occur every several hundred base pairs in the human genome. With current technology, SNPs are found at about every 1,000 base pairs.

An individual may possess two copies of the same allele on both homologous chromosomes and be a homozygote or homozygous. An individual who carries two different alleles at a particular locus is a heterozygote or heterozygous. Strictly speaking, any difference in base pairs (i.e., genotype) between two alleles at a particular locus is heterozygosity. Sometimes the concept is used to signify only differences that lead to different gene products with significantly different functional capabilities. An example would be an individual who is heterozygous for a disease-causing mutation. On the other hand, a single base pair difference that occurs commonly and does not have any detectable effect on the gene product and/or its function (i.e., a polymorphism) also may define a

heterozygote. Such an individual would be heterozygous for a genetic polymorphism.

A group of two or more linked genotypes is called a *haplotype*. A haplotype may refer to a series of polymorphisms within a single gene, but more commonly, it refers to a series of genes or alleles that extend over a portion of a chromosome (i.e., genotypes at linked loci). Whereas allele refers to a particular genotype at a single gene locus, haplotype refers to a series of genotypes over a stretch of DNA that may include several genes. When a haplotype (i.e., a series of linked genotypes) tends to be inherited intact more often than expected, given its chances for recombination, it is said to be in *linkage disequilibrium*. Haplotypes, as well as single polymorphisms, are useful genotypes for mapping studies.

An organism's genotype is commonly thought to determine its outward characteristics (i.e., the phenotype). The fact is, however, that individual phenotypes actually result from not only the products of gene expression (i.e., the genotype as expressed through transcription and translation) but also complex interactions involving the environment and chance.

## GERONTOLOGICAL SOCIETY OF AMERICA

---

The Gerontological Society of America (GSA) was founded in 1945 to promote scientific study of aging

and to encourage exchange of the resulting knowledge among scientists, teachers, practitioners, and decision makers in an aging society. GSA was the first scientific organization in the United States to promote a distinctive interdisciplinary focus on the study of human aging, a focus that continues to be reflected in its major journals—the *Journal of Gerontology: Psychological and Social Sciences* (published monthly); *Journals of Gerontology: Biology and Medical Sciences*, and *Gerontologist*, which focuses on applied research and policy issues (published bimonthly).

GSA maintains a membership of more than 6,500, and its annual meetings attract more than 3,500 participants in its interdisciplinary scientific programs. A special Committee on Humanities and Arts has broadened GSA's scope in recent years. Information about GSA's objectives, special events, and annual scientific programs is available on the Web at <http://www.geron.org>.

Although GSA historically attracted primarily academic scholars and investigators in gerontology, the organization has maintained an interest in promoting sound gerontological practice and in translating scientific information into effective social policies. Since 1960, an Emerging Scholar and Professional Organization program has promoted and facilitated development of careers in gerontology. In 1974, GSA leadership responded to a new federal initiative in aging, the Older American's Act, with the creation of what became the Association for Gerontology on Higher Education (AGHE). AGHE focused on training materials and programs designed primarily for smaller academic institutions and initially worked independently before reintegrating administratively with GSA in 1999. AGHE provides more than 350 member institutions consulting service for developing programs promoting careers in gerontology; guidelines for developing training programs; a national directory of training programs; surveys assessing the effectiveness of career training programs in aging; and a broad range of training materials. AGHE's annual meetings showcase current information on key issues in effective promotion of careers in gerontology. Current information on AGHE's services, publications, and annual meetings is available at <http://aghe.org>.

GSA has issued over the years a number of timely publications addressing issues of gerontological research, education, and public policy and for more than two decades has conducted a postdoctoral research training program for younger academics with career interest in aging. In the 1970s, GSA also

provided summer research training institutes for college and university faculty. From time to time, GSA administers foundation-supported fellowships in special areas, such as research in biomedicine and social work.

GSA has continually related scholarship and research on human aging to assessment of alternative policies for an aging society. The society is a founding member of the Leadership Council of Aging Organizations, a coalition of more than 40 national aging organizations that meets regularly to review the status of aging policies and to recommend national strategies. GSA's policy institute, the National Academy on an Aging Society (NAAS), was established in 1994 to add a new dimension to GSA's interest in aging policies. NAAS conducts research identifying challenges and opportunities in an aging society and presents policy-relevant findings from research to the public, the press, and policy makers. Published reports, research briefs, and fact sheets are made available to the press and Congress. NAAS's *Public Policy and Aging Report* is distributed regularly to more than 2,500 policy makers, investigators, and members of the media. Effective ways to promote civic engagement in the interest of moving aging issues onto the civic agendas of communities is an example of the NAAS's initiatives. For information about NAAS research and publications, see <http://agingsociety.org>.

GSA is a founding member of the International Association of Gerontology (IAG), an organization that brings together every 3 years scholars, scientists, and practitioners in gerontology and geriatrics from more than 50 countries worldwide. IAG has played an important role in advising the United Nations and periodic World Congresses on Aging on aging issues in both more developed and less developed countries. The presidency of IAG, which rotates among participating countries every 3 years, was the responsibility of GSA leadership from 1982 to 1985; in 2005, IAG leadership is from Canada. For current information on activities and plans for the next international congress, visit <http://sfu.ca/iag>.

## GERONTOLOGY

---

From the time of conception onward, humans are constantly aging, developing, and getting older. Although not a new area of investigation and study, gerontology (operationally defined as the scientific study of the aging process) has until recently taken a back seat to many other areas of scientific investigation. One reason for this is that many individuals do not want to think about aging and getting older, although these processes are inevitable. However, the study of aging and gerontology (as well as geriatrics) has taken center stage within many areas, including biology, psychology, sociology, and education, among others. Questions about how we age, why we age, why some age faster (or slower) than others, and diseases and deficits associated with aging and gerontology are now issues of vast importance worldwide. Related issues concern quality of life as we age, nursing home placement, and therapeutic interventions to slow down or halt the aging process to name but a few. Gerontology is now a "hot" topic and one worthy of continued investigation. One need only consult sources on sociological and demographic information to realize that people are living longer and that with this increase in longer life comes more risk for age-related disease and disorder. Understanding the aging process (gerontology) is of critical importance on many levels.

### WHAT IS GERONTOLOGY AND WHY SHOULD WE STUDY IT?

As mentioned previously, gerontology is considered the scientific study of aging and the aging process. As with many English words, the derivation comes from Greek, with *ology* meaning "the study of" and *gero* meaning elders. A similar, but different, term is *geriatrics*, which is typically referred to as a specialty area of study within various health care fields (e.g., social work, medicine). Gerontology is multidisciplinary, with many areas contributing to its knowledge base, including psychology, sociology, education, social work, and medicine. The multidisciplinary nature of gerontology makes good sense because to understand gerontology and aging is to reveal how several of these areas interact with each other and influence how and why we age. Several theoretical views of aging and gerontology also advocate this interactive nature of the aging process, suggesting that gerontology is best viewed from several

different contexts (historical, cultural, societal). For these reasons, gerontology has become one of the fastest growing areas of study in the United States and, more important, the rest of the world.

### WHAT FACTORS HAVE INCREASED THE POPULARITY OF GERONTOLOGY?

Radical changes have been slowly evolving with regard to aging and gerontology, and these changes relate to several factors, including dramatic increases in the proportion of older adults older than 65, a lowered birth rate, advances and increases in how long a person can live (life expectancy), and the graying of the current baby boomers. Because of these (and other) factors, it is estimated that within the next 20 to 25 years, about 1 in every 4 older adults will be 65 years of age or older. Additionally, one of the faster growing segments of the population is the so-called old-old, those individuals 85 years of age and older. In fact, another fast-growing group is those who live to be 100 and beyond (the so-called centenarians). Because women historically tend to outlive men, these increases will be especially relevant for women as they get older. One downside of such longevity is the undeniable fact that age is the number one risk factor for several age-related diseases and disorders, including Alzheimer's disease. It is estimated that 50% of individuals age 85 and older have some form of Alzheimer-type dementia. The paradox, then, becomes what to do with an advancing aging population that shows increased risk for a number of age-related diseases and disorders. Adequately addressing and dealing with this paradox is precisely where gerontology fits in to the larger picture of aging and geriatrics.

### THEORETICAL ISSUES IN GERONTOLOGY

Like any science, gerontology is rooted in and driven by a number of theoretical issues that highlight the somewhat controversial nature of the aging process. These controversies exist because there is no one crucial factor or variable that causes aging and gerontology. In fact, some argue that the aging process is akin to a disease, whereas others argue that aging and gerontology are normal processes. Because of the interactive nature of aging and gerontology discussed earlier in this entry, it is not surprising that such controversies exist. Although some would argue that such controversies are not healthy for the study of aging and

gerontology, in fact it is precisely these controversies that are making the scientific study of aging more of an accepted discipline worthy of continued study. One such theoretical view that has shown continued popularity is the life span model of aging. It is this model that accurately outlines aging and gerontology as a contextually dependent and highly interactive series of stages or processes that result in aging. The life span model possesses seven distinct criteria—that aging and development are lifelong, multidimensional, multidirectional, plastic, multidisciplinary, and contextual, and include issues in growth (gains) as well as decay (losses). This theoretical model has been the dominant view in aging and gerontology for the past 20 years and shows no signs of decreasing in its popularity with a variety of researchers, teachers, and doctors.

### HOW DO YOU STUDY GERONTOLOGY?

Like any other science, several methodologies and statistical techniques are available for the study of aging and gerontology. The two most typical methodologies used in aging and gerontological research are the cross-sectional and longitudinal methods. Both have costs and benefits, and the type used is actually related to what specific hypothesis (or hypotheses) a researcher is interested in. For instance, many gerontology studies (typically) compare a group of young adults (usually ages 18 to 22) and a group of older adults (usually age 65 and older) on some series of tests or experimental manipulations. This cross-sectional method is efficient and less time consuming than the longitudinal method and is frequently used. However, the issue of cohort effects is always potentially confounding because these types of designs are not good at controlling for these effects. Longitudinal studies are more cumbersome to complete, especially because the researcher is testing the same person (or persons) over an extended period of time (usually years). Problems like subject attrition, subject death, and cost are usually factors that prevent researchers from using a longitudinal type of methodology. However, similar problems exist for the longitudinal methodology as well, and confounding cohort variables are also possible. Sequential research designs, however, are possible alternatives to cross-sectional and longitudinal methods, and the age cohort effects can be teased apart. One method is not better than another, and it is primarily up to the investigator to decide which methodology offers the most

benefit with the least amount of cost. Some of the most prominent and classic studies in gerontology, however, are longitudinal studies and include the Baltimore Longitudinal Study of Aging and the Seattle Longitudinal Study of Adult Intelligence.

## SUMMARY AND FUTURE DIRECTIONS

This brief review has highlighted what gerontology is, how it is studied scientifically, and what these results mean in the grand scheme of things. However, the current status of aging and gerontology also begs the question of what the future holds for these topics and their associated challenges. First, the issue of dramatic increases in the numbers of older adults diagnosed with Alzheimer's disease (and other age-related disorders) will need careful (and immediate) attention. Training more professionals in the areas of aging and gerontology will be a priority in the coming decades across a number of disciplines. Likewise, and somewhat related, are how attitudes and perceptions of age and aging can be changed to a more positive view. Older people face discrimination, ageism, and prejudice all because of their age. This is especially problematic for older women and older women of color. This negative view is not universal, and it may be possible to integrate the more positive aspects of aging from other cultures into ours. These are the challenges posed by the field of gerontology and are challenges that can and should be taken up by the current and future generations of gerontological scholars who study, examine, and interpret the vast age differences and age similarities that exist.

—F. Richard Ferraro

## GESELL, ARNOLD (1880–1961)

---

Arnold Lucius Gesell was among the first psychologists to establish quantitative measures of child development, based on his extensive observations of New Haven children, whom he filmed through one-way mirrors in the laboratory. Born 1880 in Alma, Wisconsin, a small town that still refers to him as the most famous graduate of Alma High School, Gesell in 1899 graduated with a bachelor's degree from Steven Point Normal School. In 1906, he earned his PhD from Clark University, specializing in child development under his mentor G. Stanley Hall (1844–1924). After earning his PhD in psychology, Gesell worked briefly in an elementary school before taking up the post of assistant professor at Yale University in 1911. There he founded the Yale Clinic of Child Development. At the age of 30, Gesell decided to study medicine, and in 1915, he received his MD from Yale University.

Using his observational studies, Gesell established developmental norms from birth to adolescence. These scales were not measures of Intelligence Quotient (IQ); rather, they described behaviors in four areas: personal-social, neurological-motor, language development, and overall adaptive.

The primary aim of Gesell's Developmental Assessment was to observe children's overall behavior in order to compare their developmental level with their chronological age. These assessment scales were used to assess children's school readiness and to identify abnormal patterns of development that might necessitate further investigation. Gesell was also influential in adoption issues. Gesell believed that adoption posed a risk or was inappropriate for some children. He therefore advocated the use of his scales to determine whether children were suitable for adoption and to match their abilities to the abilities of the prospective adoptive parents.

The basis for Gesell's theory of child development is rooted in the principle that development is influenced by two factors, the environment and genes, and that although development unfolds in a fixed sequence, the rate of development varies. Hence, he believed that children can only be taught a skill once they are ready for it and that each child is a unique individual and so cannot be classified on the basis of chronological age alone; rather, children have to be examined in the context of their sociocultural background. Gesell was aware

of, and often referred to, the fact that children's development needs to be assessed by examining various sources, such as cultural or social influences and observations by teachers, as well as taking into account measurements carried out in his laboratory. Nevertheless, he was criticized for the fact that the norms that he established were based usually on white middle-class children from well-educated backgrounds. Additionally, Gesell's use of the concept of "normality" was criticized. It was considered too imprecise in that children who performed below established norms were still "normal," according to Gesell, but just slower in their development. He wrote and coauthored many books and chapters, which are still in use today.

## GIFTEDNESS

---

Giftedness can be conceived as unusually high ability or potential in any domain. Views of giftedness are culturally shaped, and society deems which domains are recognized, valued, and nurtured. Historically, the term *gifted* was primarily applied to high intellectual abilities, although it has also been applied to high ability in areas such as the arts. From a psychometric perspective, the term *gifted* refers to performance at 2+ standard deviations above the mean on an IQ test (130 or 132 IQ). IQ tests are intended to measure verbal abstract reasoning, logical-mathematical reasoning, and general knowledge, as well as certain types of social awareness and spatial abilities. Unintentionally, they also measure such things as test-taking skills, self-efficacy, and the effects of the testing situation.

IQ tests have been criticized because they evaluate a narrow range of human abilities. Many theorists assert that giftedness should also be recognized in additional areas, such as creativity, task commitment,

"street smarts," interpersonal skills, and so on. The Marland Report informed the U.S. Office of Education's definition of giftedness (P.L. 97-35). Six areas were targeted: general intelligence, specific academic aptitude, creative thinking, leadership ability, visual and performing arts, and psychomotor ability. Across these domains, the defining characteristic of giftedness is extraordinary potential or performance.

Teacher recommendations, academic achievement, and behavioral checklists are commonly employed methods of screening students for gifted programs, and most gifted programs include IQ tests as part of their strategy for identifying participants for gifted programs. Recently, new methods of recognizing giftedness have emerged to complement these traditional methods. For example, alternative approaches to the use of portfolio evaluation and dynamic assessment have been proposed as methods that show promise for addressing a serious problem plaguing gifted education: the underrepresentation of certain minority groups in gifted programs. Instead of simply measuring the products of learning, both of these methods evaluate the processes of new learning.

How giftedness is defined matters. It has implications for the identification and selection of students for programs. It also determines the scope and character of gifted programs.

## EDUCATION OF GIFTED STUDENTS

In his 1972 report to Congress, Marland asserted that if they are to attain their potential, gifted children need educational programming that goes beyond what is provided in the regular classroom. More than 20 years later, another U.S. Department of Education report described the state of gifted education as being in a crisis. Misplaced perceptions of egalitarianism may underlie the slow progress many schools have made toward developing and implementing successful gifted programs.

A survey of teachers documented the practices employed in the education of gifted students. These included acceleration, or increasing the rate at which students progress through material; enrichment, or increasing the depth and breadth of students' knowledge base; using various student grouping practices; and independent work. In addition, individualized instruction such as private tutoring, distance learning, and home schooling are noted in the literature on gifted education.

The most successful gifted programs employ differentiation, individualization, and teachers trained in giftedness. Differentiation refers to curricula that are suited specifically to how gifted students learn. Although differentiation can be provided within the regular classroom in theory, in practice, little or no real differentiation seems to occur in most such situations.

Most agree that gifted students benefit intellectually, and without social detriment, from accelerated learning opportunities. However, the research on enrichment-based program outcomes is mixed. Gifted students may benefit from independent projects and the like, but given the opportunity, might prefer working with other gifted students rather than working in isolation. Mixed-ability grouping practices, which are effective for many students, may not serve gifted students well. From both an academic and a social perspective, placing gifted students together is the preferred method of grouping for this population. Although it is not as effective as grouping gifted students together in separate classes or schools, from an achievement perspective, pull-out gifted programs are better than within-class gifted programming. Many pull-out programs employ generic enrichment models, however, and fail to individualize curricula. Like their counterparts enrolled in special education, gifted students, especially highly gifted students, have special needs that may be best addressed in a case-by-case manner.

Not all gifted children show gifted performance in the typical school setting and may fail to achieve at levels commensurate with their abilities. Gifted children can become disenfranchised, hide their giftedness, underachieve, or dedicate their energies to socially acceptable activities, such as athletics. To avoid such negative consequences, gifted children need both to be challenged and to be around like-minded peers. Without sufficient opportunities to interact with other gifted children, these children can feel very “different” from their classmates and very alone.

## SOCIAL AND EMOTIONAL ISSUES

In general, the gifted have fewer mental health problems than most. This advantage may not apply to some subgroups. For example, those who are exceptionally gifted in verbal ability, creativity, or the arts may suffer disproportionately from mood disorders and problems with self-esteem.

Gifted children’s self-concepts are generally at average or above-average levels. Their high *academic*

self-concept may be in part responsible for these findings. Gifted children’s *social* self-concept scores are not generally found to be similarly enhanced.

Gifted students tend to have good social relations but may have distinct perceptions concerning their relationships and social status. They may not be as satisfied with their peer relationships, even when from the outside those relationships seem positive. With extreme ability, problems can arise from not being synchronized with peers. The extremely gifted choose to spend a great deal of time alone and may be inclined toward introversion or isolation. Indeed, the extremely gifted may feel extremely lonely.

Giftedness, for some, is a social liability. They feel they cannot be themselves and must hide their gifts. Gifted children also perceive themselves as *different* from others and feel that others treat them differently and see them as different. Feeling different can include both positive factors, such as being curious and capable, having additional resources, and feeling proud, as well as some negative factors, such as feeling isolated and feeling out of step with one’s peers.

Although gifted individuals feel things very deeply, their emotional intensity is not associated with adjustment problems. Young gifted children have a passion for their domains of ability. Being inclined towards perfectionism, the gifted often expect a great deal of themselves. Others, too, expect a great deal from them. These children may be given the message that they should do extraordinary things (which rarely happens)—and if they don’t, they are somehow failing.

The adults in the lives of gifted children need to be sensitive and responsive not only to their educational needs but also to their social-emotional needs. Although some gifted subgroups, such as the extremely gifted, may be at increased risk for adjustment problems, in general, the gifted are well adjusted. Gifted children, nevertheless, have some atypical responses and face some unique social-emotional challenges.

## SUMMARY

Gifted individuals are, by definition, exceptional owing to having extraordinary abilities. Regardless of the domain of their giftedness, they have atypical needs. They need differentiated and individualized education provided by trained teachers, and they need opportunities to work and play with other gifted children.

—Catya von Károlyi

and a visiting professor at the University of Cambridge affiliated with the Centre for Gender Studies.

Gilligan received a bachelor's degree in English literature at Swarthmore College, a master's degree in clinical psychology from Radcliffe College, and a PhD in social psychology from Harvard University in 1964. She began teaching at Harvard in 1967 and worked with both Erik Erikson and Lawrence Kohlberg. While studying with Kohlberg, Gilligan became interested in his research on moral development. In the next few years, she conducted studies that led to her seminal work, *In a Different Voice: Psychological Theory and Women's Development* (1982), which described women's point of view on development in terms of their caring effect on human relationships. Her studies on women and gender issues resulted in five coauthored books with her students: *Mapping the Moral Domain* (1988), *Making Connections* (1990), *Women, Girls, and Psychotherapy: Reframing Resistance* (1991), *Meeting at the Crossroads: Women's Psychological and Girls' Development* (1992), and *Between Voice and Silence: Women and Girls, Race and Relationships* (1995). *Meeting at the Crossroads: Women's Psychological and Girls' Development* won the *New York Times'* Notable Book of the Year award. In addition to being a prolific author, Gilligan has been honored by receiving a Senior Research Scholarship award from the Spencer Foundation (1989–1993), a Grawemeyer award for her contributions to education (1992), and a Heinz award for contributions to the field on human conditions (1998), and was named one of the 25 most influential Americans by *Time* magazine.

Gilligan was a member of the Harvard faculty for more than 30 years and was named the first Professor of Gender Studies in 1997, where she was the Patricia Albjerg Graham chair. While still a professor at Harvard, she was honored with the distinction of becoming the Pitt Professor of American History and Institutions at the University of Cambridge (1992–1993). In 2002, she became University Professor at New York University, where she continues to work. Also in 2002, her book *The Birth of Pleasure* was described by *The Times Literary Supplement* as a “thrilling new paradigm.” Gilligan teaches courses on gender issues, psychology and culture of democratic societies, and adolescent psychology.

## GILLIGAN'S THEORY OF FEMININE MORALITY

---

Carol Gilligan was born on November 28, 1936, in New York City. She graduated from Swarthmore College in 1958, majoring in literature. She received her Masters in clinical psychology in 1960 from Radcliffe University and her PhD in social psychology from Harvard University in 1964. She began teaching at Harvard in 1967, becoming a full professor there in 1986.

Gilligan's primary focus was the moral development of young women. In 1970, she became a research assistant for Lawrence Kohlberg, whose stage theory of moral development is now well-known. Gilligan's interest in moral development was deeply affected by her interviews with young women contemplating abortions in the 1970s.

Over time, Gilligan began to question Kohlberg's methodology and the assumptions that grounded his theory. First, the participants in his studies were all privileged white men and boys. Gilligan felt that this biased his theory against women. Second, Kohlberg privileged the consideration of individual rights and rules over the consideration of the importance of caring in human relationships. Gilligan took this to represent the privileging of a male perspective over a female perspective.

Research by Constance Holstein (1976) appeared to support Gilligan's claim that there is a gender bias in Kohlberg's theory. Holstein's longitudinal study found that female participants typically scored at stage 3 of Kohlberg's moral stages (which emphasizes interpersonal relationships and issues of social duty and obligation), whereas male participants typically

scored at stage 4 (which emphasizes abstract issues of rights, laws, and social contracts). According to these results, males are generally more morally developed than females. However, Gilligan argued instead that these results show that Kohlberg's stages are unfairly biased in favor of the kind of moral reasoning in which males, but not females, typically engage.

Consequently, Gilligan became one of Kohlberg's most outspoken critics. Her criticisms of Kohlberg's theory were published in her 1982 book, *In a Different Voice: Psychological Theory and Women's Development*, which Harvard University Press described as "the little book that started a revolution." Translated into 17 languages with more than three-quarters of a million copies sold, it continues to inspire political debate, new research, and initiatives in policy and education. *In a Different Voice* was followed by several other coauthored or edited books: *Mapping the Moral Domain* (1988), *Making Connections* (1990), *Women, Girls, and Psychotherapy: Reframing Resistance* (1991), *Meeting at the Crossroads: Women's Psychology and Girls' Development* (1992), and *Between Voice and Silence: Women and Girls, Race and Relationships* (1995).

### REVIEW OF KOHLBERG'S MORAL STAGES

In 1969, Kohlberg published his stage theory of moral development. He argued that moral development occurs through a series of invariant stages, in a manner similar to Jean Piaget's cognitive development stages. Kohlberg's model is not only descriptive of how moral development occurs, but also prescriptive of how moral development *should* occur. Insofar as each stage represents a higher level of moral reasoning (i.e., a stage that is more adequate, stable, and "ideal"), people should strive to attain the highest stage of moral development.

Kohlberg identified three levels of development with six stages, two stages per level, as follows:

Level 1—Preconventional (concrete individualistic perspective): stages 1 to 2

Level 2—Conventional (member-of-society perspective): stages 3 to 4

Level 3—Postconventional (prior-to-society perspective): stages 5 to 6

Although Kohlberg's stages vary in what factors are salient to people engaged in moral reasoning, each stage involves what Kohlberg called "justice reasoning."

Thus, each stage of development revolves around how best to adjudicate interpersonal conflicts, balance conflicting claims and competing interests, and most fairly distribute goods and rights (the “benefits and burdens” of social life).

## GILLIGAN'S THEORY OF FEMININE MORALITY

Gilligan challenged Kohlberg's claim that all moral reasoning is “justice reasoning.” She argued that Kohlberg's stage theory makes assumptions—for example, that the moral ideal is attained through an abstract, impersonal, individualistic “prior-to-society” perspective—that do not respect the experiences of women, who prioritize interpersonal relationships. Kohlberg's theory thus estranges women from the process of moral development.

Gilligan argued that women's moral judgments necessarily include feelings of compassion and empathy for others, as well as concern for commitments that arise out of relationships. Women engage in “care reasoning,” not “justice reasoning,” and thus consider their own and other's responsibilities to be grounded in social context and interpersonal commitments.

Gilligan identified two moral voices that arise from two distinct developmental pathways. According to Gilligan, the male voice emphasizes independence (“separation”) and responsibility for oneself, whereas the female voice emphasizes interdependence (“connection”) and responsibility to others. Males are encouraged to be active agents, females to be passive recipients. When faced with moral problems, males seek solutions that are just and fair; females seek solutions that are caring and benevolent. For males, moral wrongness is linked to the violation of rights and justice; for females, moral wrongness is linked to a failure to communicate and to respond. For males, moral interactions take place primarily at the political and legal level, in the realm of abstract laws and social contracts; for females, moral interactions take place primarily at the level of personal relationships, in the family and the social network of the community in which they live.

Like Kohlberg, Gilligan identified several stages of moral development.

### Level 1: Self-Oriented

Focus is on the needs of oneself. Here, the survival of oneself is of sole concern. The transition to level 2 begins with the recognition of the conflict between

one's own needs and the needs of others (i.e., what one owes to oneself vs. what one owes to others).

### Level 2: Other Oriented

Focus is on the needs of others. Here, the self adopts the traditional conception of feminine goodness, the maternal morality of self-sacrifice, whereby the good is equated with caring for others. Consequently, one's own needs become devalued. The transition to level 3 begins with the recognition that the self cannot be left out, but must also be an object of one's caring.

### Level 3: Universal Oriented

Focus is on the universal obligation of caring. Here, care is a self-chosen principle that condemns exploitation, violence, and neglect and demands active response to suffering. Caring for oneself and others is seen as intertwined because the self and others are recognized as interdependent. Thus, all acts of caring are seen as beneficial to both self and others.

## EVIDENCE FOR GILLIGAN'S THEORY

Nona Lyons (1983) interviewed 36 people using real-life moral dilemmas. Responses were coded as either “rights” (justice) oriented or “response” (care) oriented. Three fourths of female respondents displayed the response orientation, whereas only 14% of male respondents displayed this orientation. On the other hand, 79% of male respondents displayed the rights orientation, whereas only 25% of female respondents displayed this orientation.

Gilligan and Attanucci (1988) found that 65% of males used a justice-only orientation, 32% used a justice and care mixed orientation, and none used a care-only orientation. In contrast, 35% of females used a care-only orientation, 35% used a justice and care mixed orientation, and 29% used a justice-only orientation. Gilligan and Attanucci concluded that both men and women can use justice and care orientations, but men tend to gravitate toward a justice orientation, whereas women tend to gravitate toward a care orientation. They further concluded that women appear to be more willing (or able) to use a justice orientation than men are willing (or able) to use a care orientation.

As further evidence for her theory, Gilligan pointed to the overwhelmingly male population of the prison systems and the preponderance of women in educational

and caretaking professions. Rhetorically, she asks: if there are no gender differences in empathy and moral reasoning, then why are there such easily recognizable gender-specific behavioral differences?

### CRITICISMS OF GILLIGAN'S THEORY

Some argue that Holstein's study failed to provide unequivocal evidence for gender bias because, although some results did suggest a gender bias, other results did not.

Indeed, Gilligan's claim that Kohlberg's theory is gender biased has found little empirical support. Lawrence Walker's (1984) empirical meta-analysis found that gender differences in moral reasoning stages are extremely rare: of 108 studies, only 8 showed clear gender effects, many of which were confounded by educational levels or occupational status. Likewise, James Rest's (1979) meta-analysis also found that gender effects are extremely rare. Also, Walker (1989) found that most of the gender effects that have been reported are nonsignificant.

Kohlberg's response to Gilligan's critique was to distinguish between two different ways of thinking about morality. Morality is sometimes concerned with what it takes for a judgment to be moral (i.e., whether or not it is impartial, universal, and prescriptive; whether or not it is motivated by a desire to adjudicate conflicts, and so on). However, morality is also sometimes concerned with human relationships and what they must include to be moral (i.e., whether or not they involve adequate concern for another's well-being; whether or not they are motivated by feelings of obligation and responsibility, and so on). These are two ways of *thinking about* morality, Kohlberg argued, not two different moralities. Consequently, he proposed a moral continuum that possesses a justice orientation at one end and a caring orientation at the other.

---

## GLASS CEILING

---

The term *glass ceiling* was introduced in the 1980s to refer to an informal but effective limit on how high women could rise in a work organization. This ceiling was “glass” in that women could see above this transparent barrier, and in fact might not realize it was there, until they found they could go no higher. This ceiling is understood to apply to women as a group who are kept from advancing not because of their individual deficiencies, or because of the funnel of fewer opportunities at higher levels, but *because they are women*. When the Federal Glass Ceiling Act was passed by Congress in 1991, the term was expanded to refer to artificial barriers that prevent the promotion of women or minorities; in current usage, it may refer to limitations on women or people of color. More precisely, a glass ceiling is indicated by a disproportional lack of advancement that cannot be accounted for by productivity and that increases at higher organizational levels.

Support comes first from data showing underrepresentation at high organizational levels in proportion to presence in the workforce. For example, although women constitute about half the managerial workforce, Catalyst's survey in 2000 showed that only 12.5% of

the top corporate officers in Fortune 500 companies are women. At the very top levels—chairman, CEO, president, or executive vice president—only 6.2% are women. In 2003, Catalyst reported that only 13.6% of the directors of these large companies were female, but this was an overestimate of numbers because often the same individual was appointed to more than one board. Most of the 500 companies had *at least one* woman on their board, but 54 had *no women*.

Additional support for the concept comes from longitudinal sociological analyses. D. J. Maume has shown increasing disadvantage in advancement for women and minorities over time when productivity is taken into account.

In the early 1990s, the Department of Labor published a report on the glass ceiling. Subsequently, Title II of the Civil Rights Act of 1991 (“The Glass Ceiling Act”) set up the Glass Ceiling Commission. This 21-member bipartisan body was charged with studying the glass ceiling and making appropriate recommendations “to eliminate artificial barriers” . . . and “increase opportunities and developmental experiences of women and minorities.”

Its 1995 report identified barriers at three levels. In *society at large*, the “supply barrier” of lack of opportunity and the “difference barrier” of stereotypes and bias were noted. *Government barriers* included lack of vigorous and consistent monitoring and law enforcement, weaknesses in the collection of employment-related data, and inadequate reporting of glass ceiling issues. Barriers *internal to business structure* included inadequate outreach and recruitment, hostile or unsupportive corporate climates, and problems in moving women and minorities through the internal pipeline to upper management.

The Commission’s final report recommended several things that could be done by government and business. The Federal government should lead by example and improve data collection for tracking the progress of underrepresented groups. It should more strongly enforce antidiscrimination laws and develop ways to make demographic statistics currently being collected by federal agencies publicly available on a voluntary basis. Recommendations to business included demonstration of CEO commitment to workforce diversity. Businesses should include diversity in all business plans and hold managers accountable for meeting advancement goals for underrepresented groups, committing to affirmative action as a tool in this process. Women and people of color should be actively prepared

for senior management positions and the corporate workforce should be educated about glass ceiling issues. Family-friendly work-life policies are needed, as well as high-performance workplace standards to encourage autonomy and initiative in all employees.

—Rosemary Hays-Thomas

## GRADE RETENTION

---

Grade retention, also recognized as “being retained,” “being held back,” “nonpromotion,” and “flunking,” refers to the practice of requiring a student who has attended a given grade level for a full school year to remain at that same grade level in the subsequent school year. The practice of grade retention has become increasingly popular over the past few decades and particularly amidst the current sociopolitical zeitgeist emphasizing educational standards and accountability. In contrast to the abundance of research during the past century suggesting that grade retention is an ineffective and discriminatory policy, grade retention rates have increased during the past 30 years.

Current estimates indicate that between 7% and 9% of children in the United States are retained annually,

resulting in more than 2.4 million children every year. Considering the research investigating the effectiveness of grade retention as an intervention to address academic, social-emotional, and behavioral problems, the increasing use and expense in the United States has led to numerous debates. Research provides essential information regarding (1) individual, family, and demographic characteristics of retained students; (2) the effectiveness of grade retention in addressing academic, social-emotional, and behavioral problems; (3) long-term outcomes associated with grade retention; and (4) the perceived stressfulness of grade retention from students' perspectives.

### **CHARACTERISTICS OF RETAINED STUDENTS**

Research has examined gender and ethnic characteristics of retained students, revealing that boys are twice as likely to repeat a grade as girls and that retention rates are higher for minority students, particularly African American and Latino children. Retained students generally have lower achievement scores relative to the average student in a classroom; however, it is important to consider other characteristics of retained students because low achievement in isolation is not a distinguishing characteristic among retained and promoted students. Compared with equally low achieving and promoted peers, research reveals that retained students do not consistently have lower IQ scores. However, children who are retained are more likely to have mothers with lower IQ scores than a matched group of promoted children. Moreover, parents' involvement in school and attitude toward their child's education also play a significant role in determining whether a student will be retained.

Those students who are retained are often reported as being significantly less confident, less self-assured, less engaging, and more "immature," and as exhibiting more behavior problems compared with their similarly low achieving, but promoted, peers. Teachers have also reported that the retained students are less popular and less socially competent than their peers. Thus, available research indicates that retained students are a diverse group of children with an assortment of challenges that influence low achievement, behavior problems, and poor classroom adjustment.

### **EFFECTIVENESS OF GRADE RETENTION**

Comprehensive reviews and examinations of grade retention research published between 1925 and 1999 have provided a synopsis of the findings of this research. These comprehensive reviews inform researchers and practitioners alike of the overall, cumulative results of these grade retention studies. Examinations of these studies that result in a negative number indicate that an intervention (grade retention in this case) had a negative or harmful effect relative to the comparison groups of promoted students. The larger the negative number, the more harmful the intervention. These comprehensive reviews examining the effectiveness of grade retention have included academic achievement, behavior problems, and social adjustment.

#### **Effects on Academic Achievement**

Overall, research does not demonstrate academic advantages for retained students relative to comparison groups of low achieving promoted peers. One comprehensive review of 63 grade retention studies revealed that 54 yielded negative numbers with respect to the effect that grade retention had on achievement for retained students. Of 9 studies revealing positive short-term achievement effects (during the repeated grade the following year), the short-term benefits diminished over time and disappeared in later grades. The overall negative effects on achievement outcomes found in this comprehensive review was  $-.44$ . This number indicates that grade retention was not found to be a beneficial intervention, overall, in the studies examined.

The most recent comprehensive review of 20 studies, published between 1990 and 1999, revealed that only 5% of 169 analyses of academic achievement outcomes resulted in significant statistical differences that favored the retained students, whereas 47% resulted in significant statistical differences favoring the comparison groups of low achieving peers. Of the analyses that did favor the retained students, two thirds reflected differences during the repeated year (e.g., second year in kindergarten). Moreover, these initial gains were not maintained over time.

Analyses examining the effects of retention on language arts, reading, and math yielded moderate to strong negative effects ( $-.36$ ,  $-.54$ ,  $-.49$ , respectively). Notably, decisions regarding grade retention are often

based on reading skills; however, research reveals that grade retention appears to be an ineffective intervention to improve reading skills. Thus, grade retention appears to be contraindicated for children with reading problems.

These findings indicate that across published studies, low achieving but promoted students outperformed retained students in language arts, reading, and math. Altogether, the results of comprehensive reviews examining more than 80 studies during the past 75 years, including nearly 700 analyses of achievement, do not support the use of grade retention as an early intervention to enhance academic achievement.

### **Effects on Social Adjustment and Behavior**

Relatively fewer studies have addressed the social adjustment and behavioral outcomes of retained students. The results of these studies indicate that grade retention fails to improve problem behaviors and can have harmful effects on social-emotional and behavioral adjustment as well. A comprehensive review that examined more than 40 studies, including 234 analyses of social-emotional outcomes, concluded that, on average, the retained students displayed poorer social adjustment, more negative attitudes toward school, less frequent attendance, and more problem behaviors in comparison to groups of matched controls. Another comprehensive review examining 16 studies generated 148 analyses of social-emotional adjustment outcomes of retained students in comparison to a group of low achieving but promoted students. Based on this comprehensive review, retention was found to have an overall moderately negative average effect on the social adjustment and behavior outcomes of retained students. Related research reveals that retained students may be teased or have difficulties with their peers. Overall, results of comprehensive reviews of more than 300 analyses of social-emotional and behavioral adjustment (from more than 50 studies during the past 75 years) do not support the use of grade retention as an early intervention to enhance social-emotional and behavioral adjustment.

### **Long-Term Outcomes Associated With Grade Retention**

There is a considerable amount of literature examining high school dropout that identifies grade retention as an early predictor variable. Grade retention has

been identified as the single most powerful predictor of dropping out, even when controlling for other characteristics associated with dropping out. A comprehensive review of 17 studies that examined factors associated with dropping out of high school before graduation supports the findings that grade retention is one of the most robust predictors of school dropout. All studies of school dropout that included grade retention found that it was associated with subsequent school withdrawal. Several of these studies included statistical methods that controlled for many individual and family level variables commonly associated with dropping out (i.e., social-emotional adjustment, socioeconomic status, ethnicity, achievement, gender, parental level of education, and parental involvement). Research indicates that retained students are between 2 and 11 times more likely to drop out during high school than nonretained comparison groups of students and that grade retention increases the risk for dropping out between 20% and 50%.

In addition to increasing the likelihood of dropping out of high school, grade retention is associated with other long-term negative outcomes. The results of longitudinal research provide evidence that retained students have a greater probability of poorer educational and employment outcomes during late adolescence relative to a comparison group of low achieving but promoted students. Specifically, retained students are reported to have lower levels of academic adjustment at the end of 11th grade, are more likely to drop out of high school by age 19, and are less likely to receive a diploma by age 20. They were also less likely to be enrolled in a postsecondary education program, received lower education and employment status ratings, and were paid less per hour.

### **STUDENTS' PERSPECTIVES ON GRADE RETENTION**

It is also important to consider children's perspectives regarding grade retention. In a study published in 1987, students in first, third, and sixth grade were asked to rate 20 stressful life events that included such occurrences as losing a parent, going to the dentist, and getting a bad report card. The results indicated that sixth grade students reported only the loss of a parent and going blind as more stressful than grade retention. This study was replicated in 2001, and it was found that sixth grade students rated grade retention as the single most stressful life event, higher than both the

loss of a parent and going blind. A developmental trend was noted in both studies, with the reported stress of grade retention increasing from first, to third, to sixth grade. Thus, research indicates that children perceive grade retention as extremely stressful.

## SUMMARY

Cumulative evidence converging from research during the past century examining the effectiveness of grade retention consistently indicates the potential for negative outcomes. Considering this cumulative research evidence, it is important to consider evidence-based alternatives to promote the social and cognitive competence of children at risk for academic failure.

## GRANDPARENTS

---

Multigenerational families have increased in number because of the extended life span of individuals. This increased longevity also has led to an increase in the number of older adults in our communities. Census reports of the past decade identify adults age 85 and older as the fastest growing population group. There has been an approximate 12% increase in the number of individuals age 65 years and older during the past decade. Predictions of continued growth among this age group over the next decade are attributed to the large number of baby boomers (those born from 1946 to 1964) who will turn 65 years old in the upcoming years.

Given the expansion in the numbers of older adults, the numbers of grandparents and even of great grandparents is expected to increase. In addition, the time spent in the grandparenting role and the likelihood of having adult grandchildren has also increased. An American Association of Retired Persons (AARP) study estimated that 56% of Americans 65 years and older have at least one adult grandchild. This figure is particularly striking when compared with data from two decades ago, when adolescents were unlikely to have known both of their grandparents. Today, 70% of older adults are grandparents. On average, grandparents are endowed with their new status at about age 45 years, but grandparents can range in age from 30 to 110 years old.

The lives of older adults and their progeny are inextricably connected and illuminated by today's changing family structures. Grandparents' entrenchment

in contemporary family structure has received the attention of the most recent U.S. Census. Multigenerational families tend to include grandparent, parent, and grandchild, with either the grandparent or parent having the responsibility as householder. There are 3.9 million multigenerational families in the United States (about 3.7% of all households). Although the definition of the multigenerational family encompasses householders who care for both their parents and children, in an estimated 2.6 million multigenerational families, the grandparents are the primary householders. Demographic factors such as increases in life expectancy, rates of divorce, and rates of remarriage contribute to changes in family structures and by extension changes in the very nature of the grandparenting role.

### GRANDPARENTING ROLE

*Grandparent* is a term generally used to refer to one's ancestor. The term connotes caring, kindness, preservation of family values, and the like. Scholars lack consensus on the definition of the grandparenting role but agree that the role can be enacted in a variety of ways. The manner in which a grandparent assumes the grandparenting role is as diverse as the individuals holding the role.

During the preindustrial era, grandparents traditionally held roles of authority and high status in the family. Over the years, the grandparent role was influenced by societal changes, and the authoritarian role became less frequently held. Its absence was replaced with a more formal but friendly grandparent-grandchild relationship.

Older adults can simultaneously provide assistance to their offspring and play a meaningful role in their descendents' lives. The grandparent-grandchild relationship largely is devoid of the burden of parental responsibilities because grandparents often prefer to function as mentors and role models. A traditional classification of the grandparent role includes three dimensions: formal, fun seeking, and distant. Grandparents often opt for a fun-seeking (pleasurable) relationship with their grandchild.

The 20th century ushered in a new focus on the role of grandparents, highlighting its diversity and complexity. Grandparent roles vary according to geographic location and ethnic group membership. Furthermore, grandparents who live far away from their grandchildren are less able to offer instrumental

assistance in terms of caregiving. They also visit with their grandchildren less often. Recently, grandparents have become a focus for anthropologists, sociologists, and other scholars in their efforts at understanding human evolution and behavior. For example, some studies attribute the decrease in mortality rate of toddlers (Gambia) and the increase in the fertility and life span of Kashi women (India) to the active roles of grandparents in those societies. Regardless of the pliability of the grandparent role and its susceptibility to sociocultural influences, the importance of grandparents seems to cut across class, ethnic, and cultural dimensions.

### GRANDPARENT-GRANDCHILD RELATIONSHIP

The grandparent-grandchild relationship is unique because it is exempt from the emotional intensity and responsibility common to the parenting experience. Grandparents may relate to their grandchild on three dimensions: exchange of services, influence over grandchild, and frequency of contact. One classification of the grandparent's style of relating to the grandchild included the categories of (1) detached, (2) passive, (3) supportive, (4) authoritative, or (5) influential according to their level of involvement. Although the degree of involvement is low on all three dimensions for the detached styles (detached, passive, authoritative), a high level of contact with the child characterizes the influential and supportive styles. An example of the influential style is the active parent-like role (whereby grandparents provide caregiving assistance to parents and have frequent contact with the grandchild).

Another method of characterizing the styles of grandparenting focuses on different dimensions, including (1) centrality (role of grandparent is central in the grandparent's life); (2) valued elder (grandparent is the prized holder of tradition); (3) immortality through clan (grandparent's identification with grandchild as well as feelings of responsibility for family members); and (4) reinvolvement with personal past (reliving their own lives through their grandchildren).

Grandparenting styles have not escaped the purview of the emotional realm. Characterization of the grandparent-grandchild relationship has focused on measuring cohesion among the different generations of the family. Intergenerational relationships have been classified using six dimensions, including

(1) emotional closeness, (2) level of contact, (3) frequency of agreement, (4) importance of familial obligations to members, (5) geographic proximity, and (6) function helping behavior.

Scholars have also maintained that the grandparent-grandchild relationship is influenced by relational factors. Strained family relationships may impinge on the relationship between the grandparent and the grandchild. Relational quality between the parent and grandparent can determine the quality of the relationship between the grandparent and the grandchild. These intergenerational interactions are key because the parent brokers the initial grandparent-grandchild relationship.

Intergenerational bonds are also dependent on the degree of disruptions in the families' lives. Life cycle changes due to separation, divorce, and remarriage have differing impacts on the preservation of the grandparent-grandchild relationship. For example, grandchildren often become estranged from the parents (grandparents) of the noncustodial parent. For these grandparents, who had an established relationship with the child before the divorce, the loss can be profound. Often, the only recourse for noncustodial grandparents is to pursue legal measures to ensure a continued relationship with their grandchildren, and even this is not always successful. It is important to note, however, that divorce also may result in more reliance on custodial grandparents for support, and subsequently closer ties develop between that grandparent and the child.

Other predictors of the relational dyad include factors such as frequency of contact, gender of grandparent, kinship position, and age of the grandparent. The amount of time spent together also contributes to the child's experience of having a close relationship with the grandparent because grandchildren who live closer tend to have more contact. Grandchildren report more contact with their grandmothers relative to their grandfathers. Consequently, they also report feeling closer to their grandmothers than their grandfathers. Because the grandmother often is younger and lives longer than the grandfather, this contributes to the greater closeness with the grandmother. Contact alone, however, is an inadequate determinant of closeness in grandparenting relationships. For instance, when given a choice, grandchildren tend to select their maternal grandparents as the preferred one regardless of geographic proximity. However, when only one grandparent is alive the maternal-paternal divide (i.e., kinship position) loses its significance. The living

grandparent is reported as the one with the closest relationship by default. A lack of closeness between grandparent and grandchild is also reported among grandchildren whose grandparents are older and have health problems relative to grandchildren with younger and healthier grandparents.

Moreover, as grandparents become more socially removed from the grandchild's world, relationships become increasingly remote. This particular dynamic is prominent among immigrant families in which there is a gap in the social values between acculturated grandchildren and their grandparents. For example, embracing mainstream values and language can create a cultural divide within the Latin American family. Grandchildren who speak Spanish are closer to their grandparents and are more likely to live with them, whereas grandchildren who speak only English are more likely to move away in an effort to establish an independent identity.

Grandparents stand to benefit from a close relationship with their grandchildren. When the relationship is close, grandparents experience a greater sense of well-being and improved morale. Some grandparents even admit to having a preferred or favored grandchild. The close grandparent-grandchild relationship helps to mitigate feelings of helplessness that can accompany the attainment of senior status, thus enhancing mental health. When the intergenerational significance of the grandparent's contribution is considered, the instrumental as well as expressive support to the family is inescapable. Grandparent relationships serve as a reliever of stress, provide needed caregiving assistance, and aid in the child's ego development. Grandparents also offer children a sense of security and a vision for the future.

If deprived of a close grandparent relationship, an individual stands to lose additional nurturing, emotional security, and a cultural and historical sense of self. For example, grandparents participate in feeding, caretaking, and mentoring their grandchildren. For grandchildren, the significance of the relationship also extends into their adulthood. Adult grandchildren continue to value their contacts with their grandparents and are influenced by their presence. Usually, adult grandchildren assume responsibility for maintaining their relationship with their grandparents, but for most, the frequency of their contact is reduced. Nonetheless, grandparents strongly influence their adult grandchildren's ideology by creating realistic examples of older people.

## DEVELOPMENTAL PERSPECTIVE ON GRANDPARENTS

Stages in an individual's adult life can be grouped into periods of time spent in courtship, marriage (with or without children), family life (with children at home), empty nest, grandparenthood, and beyond. Some rewards of aging include retirement, an absence from active parenting once children have grown, enjoyment of leisure time, availability to pursue traveling opportunities, and the pursuit of abandoned personal goals during child rearing. In addition to these, the customary grandparent role usually provides much joy and gratification, and makes this an eagerly anticipated stage in the development of the individual.

Grandparenting traditionally has been identified as occurring along the developmental trajectory from middle to late adulthood. A hallmark of middle adulthood is for the individual to develop a genuine concern for the welfare of future generations and to contribute significantly to the world of family and work. Developmental theorists such as Erikson have identified the key developmental task central to this stage as the resolution of conflict between generativity and self-absorption. The essence of successful grandparenthood is embodied in self-choices promoting generativity. Grandparents' caring behavior toward their grandchildren can be interpreted as supporting the continuity of their lineage. This support manifests itself in the form of child care, financial assistance, and the support of the leisure activities of their grandchildren. We often underestimate the extent to which grandparents contribute to the development of their grandchildren indirectly through their emotional, physical, and financial support of their children (the grandchild's parents). Thus, support from grandparents can be seen as contributing both directly and indirectly to the survival of the grandchild, which undoubtedly contributes to the survival of the grandparent's line of descent.

Grandparenting offers a natural outlet for attainment of one's middle adulthood developmental milestones. For example, two of Havighurst's seven major developmental tasks (helping teenage children to become responsible adults and having a social civic responsibility) can be attained through having a close relationship with your grandchild. Through the relationship with a grandchild, grandparents can provide guidance and instruction to their younger family members while contributing to the development of society's next generation.

## INTERSECTION OF THE GRANDPARENTING ROLE AND SOCIETAL CHANGES

The reality of societal changes has had an impact on the role of grandparents. Contemporary grandparents are working later in life. Even after retirement, today's grandparents are more likely to pursue a lifestyle that precludes the assumption of child care duties. Grandparents are also less likely to live close to their children, which affects the role of the grandparents in the grandchild's life as well as the kind of assistance offered. Baby boomers who are becoming grandparents and retiring expect to have a higher standard of living than the economy is able to support. Consequently, more of their resources may be directed toward maintaining an expected standard of living, and therefore fewer resources will be available for their grandchildren. In addition, longevity has been extended for older adults. The possible subsequent economic requirement for long-term medical care can tap resources grandparents might otherwise have used to support their younger family members. Another consideration is that newly developed technological entertainment in the form of the Internet, video games, and television all capture the attention and time of youngsters. Grandparents are often challenged to compete with these diverse technological attractions for their grandchildren's attention. Grandchildren as young toddlers are computer active. As a result, grandparents have been encouraged to learn to surf the Internet and play video games so they can engage with their grandchildren. Grandparents have learned to use e-mail as a tool to improve contact and communication with their grandchildren. In general, a mutual lack of appreciation for the different things that the grandchild and the grandparent consider to be important could result in distancing the child from the grandparent. The grandchild might experience the grandparent as nonsympathetic to the child's perspective and also might not be responsive to the grandparent's concerns.

## SURROGATE PARENTING BY GRANDPARENTS

Grandparent status was traditionally thought of as a much awaited privilege that generally occurred later in life. Today, the grandparent status is no longer relegated to late life but may occur more frequently at earlier times in one's life cycle. In addition, the

grandparental role may merge with the parental role owing to a set of unfortunate circumstances. Grandparents attain surrogate parental status for a variety of reasons that might include parental death, drug use, AIDS-related illness, incarceration, or the termination of parental rights (often resulting from neglect and abuse). Unlike grandparents who develop traditional relationships with their grandchildren, grandparents who act as surrogate parents have the added responsibilities that accompany the parental role.

Grandparent caregivers not only attend to the child's daily care, they are also responsible for the intellectual and emotional development of their grandchildren. Often, the child's needs require grandparents to accompany him or her to weekly appointments with medical, mental health, and school professionals. In other words, attending to the child's well-being is an active, rather than a passive, endeavor for these grandparents. Intergenerational differences may make it difficult for grandparents to negotiate issues pertaining to the child's development, including academic life and peer interactions. For grandparent caregivers, a traditional perspective of grandparenting is simply unattainable because the circumstances resulting in caregiving dictate otherwise. Moreover, these caregiving situations tend to be a long-term commitment, at times requiring as long as 5 years.

The number of grandparents who are currently providing primary care for their grandchildren is on the rise. During the past three decades, the number of grandchildren being raised by their grandparents has increased by more than 1 million, from 2.2 million (1970) to 3.9 million (1997). More recent census reports estimate the number of households with coresident grandparents and children younger than 18 is 5.8 million (2000). About 2.4 million of these households constitute grandparents serving as the primary caregiver for their grandchildren. Most of these grandparent caregivers were younger than 60 years old.

Although there are a significant number of white (non-Hispanic) grandparents raising their grandchildren as surrogate parents, African American and Latino grandparents are disproportionately represented in this group relative to their white counterparts. Although population estimates suggest only 3.6% of individuals age 30 and older coreside with their grandparents, the rates of minority coresident grandparents differ substantially, relative to their white counterparts. Compared with 2% of the white population, higher numbers of coresident grandparents were

found among Asian Americans (6%), Native American and Alaskan Natives (8%), African Americans (8%), Latinos (8%), and Pacific Islanders (10%). Of these coresident grandparents, 35%, 52%, and 56% of Latinos, African Americans, and Alaskan Natives, respectively, were primary caregivers for their grandchildren. Only about 20% of Asian American grandparents were primary caregivers.

For many grandparents, the short-term shock of their unexpected propulsion into the primary caregiving role is less traumatic than their assumption of parental responsibilities for their grandchildren and its long-term impact on their own development. Researchers on family issues characterize the grandparent-grandchild relationship of grandparents who are primary caregivers as significantly different from traditional grandparent-grandchild relationships. They found that parenting responsibilities adversely affect such more typical grandparental developmental milestones as retirement, as well as their social functioning (which include social interactions and leisure activities). Grandparent caregiver studies have found that parenting has a primarily negative and inhibitory effect on grandparents' lifestyle and on their relationships with friends, family, and spouses.

During the past decade, researchers have steadily increased the amount of available information on grandparent caregiving. The grandparent caregiver role is complex, and researchers have evidenced both costs and benefits associated with this type of grandparenting. In many ways, the relationship is thought to be deleterious to grandparent's well-being. Among African American grandparents, stresses from caregiving result in heightened physical ailments, alcoholism, smoking, depression, and anxiety. Latino grandparent caregivers are also predisposed to experience depressive symptomatology. Custodial grandparents also experience predominant feelings of guilt, self-blame, obligation, and a sense of betrayal. Generally, grandparent caregivers' mental and physical health is poorer relative to their noncaregiver counterparts. Specific areas of stress for grandparent caregivers include social isolation; difficulties negotiating the legal, financial, and educational systems; family conflicts; and limited resources.

Health risks for grandparent caregivers are notable and marked by poor health care behaviors. Grandparents are likely to suffer from hypertension, insomnia, and alcohol and cigarette consumption. Moreover, grandparents who care for their grandchildren as well as their elderly parents were particularly

vulnerable to the negative physical and emotional effects of stress. However, the stress of parenting can be mediated by informal supports from friends and family members. One must consider that, for previous studies, conclusions drawn may only emphasize the cost or burden associated with the grandparent caregiving experience. Undoubtedly, for the grandparent caregiver, the task of caring for one's grandchild may seem emotionally overwhelming and at times physically daunting. The stresses associated with caregiving tend to exacerbate existing medical conditions and allow grandparents little private time. However, despite these problems associated with caregiving, the parenting experience could prove gratifying and maybe even pleasurable for some grandparents.

Most research has focused primarily on the difficulties of the grandparent caregiver experience, and few have discussed the benefits. As such, it is important to note that some grandparent caregivers report they experience a greater purpose for living. In addition, grandparents report rewards such as a chance to raise a child differently, to nurture family relationships, to continue family histories, and to receive love and companionship from their grandchild.

## SUMMARY

Undoubtedly, demographic changes due to extended life span have increased the likelihood of adults spending a large portion of their lives in the grandparenting role. Moreover, increased longevity increases the number of multigenerational family structures. Families diversified by sociocultural influences, including divorce rates, remarriage, and other variations of blended families, have also added to the diversity of the grandparenting experience.

Subsequently, the grandparent role has become more complex, reflecting the changing family structures. Grandparents' roles have evolved from a more traditional one largely void of parental responsibility to roles that vary in increasing degrees of responsibility for their grandchild. Grandparents are often required to expand their role to include providing a financial base for their children in the case of divorce and other financially stressful situations. In other instances, they assume full caregiving responsibilities for their grandchildren. The influences on the relationship are as diverse as the roles grandparents assume. Grandparents' relationships with their grandchildren hinge on a variety of factors, including the strength of family ties, frequency of contact with

grandchildren, gender of the grandparent, kinship position (maternal vs. paternal grandparent), the amount of time spent together, and the degree of acculturation of the grandchildren. All of these factors contribute to the experience of closeness between the grandparent and the grandchild.

Grandparents stand to benefit from relationships with their grandchild by experiencing a greater sense of well-being and morale. In addition to instrumental supports acquired during the child's early life, grandchildren gain a sense of self and security from their relationship with their grandparents, which extend into their adulthood. Regardless of the dimension, role, or style of grandparenting, the definition of grandparenthood is embodied in the self-choices grandparents make promoting generativity.

## GRAY PANTHERS

---

The Gray Panthers is a national organization founded in 1970 by social activist and educator Maggie

Kuhn in response to insidious ageism within American culture. Ageism is the negative stereotyping, stigmatization, and segregation of people based on age. Through the national organization and coordination of local networks, the Gray Panthers functions as an inter-generational advocacy group dedicated to facilitating social change by combating inequities in a broad range of issue areas, including affordable and adequate housing, health care, work and retirement, nursing home abuse, and many others. The Gray Panthers seeks to unite younger and older people alike in grassroots change through social activism. The organization is known for its use of a variety of techniques to facilitate social change, for example, petition drives, demonstrations, letter writing and telephone campaigns, and large-scale educational programs.

The year was 1970, and Maggie Kuhn was involuntarily retired from her job. She wasn't ready to be put out to pasture, and neither were five friends who were experiencing the same involuntary retirement. Thus began a movement by a woman, her friends, and the addition of college students who were, at the time, opposed to the Vietnam War. This network of friends gathered under the early name Consultation of Older and Younger Adults for Social Change. Shortly thereafter, this new, highly action-oriented group was nicknamed the Gray Panthers, a name that has remained associated with a mission to lead advocacy and activism for social equity and justice on issues affecting older adults.

Combating the effects of ageism has always been at the heart of Gray Panther activities. *Ageism*, a term first coined by Robert N. Butler in 1968, was originally defined as the systematic stereotyping of and discrimination toward older people as individuals and a population group. Ageism reflects extremely negative images of older people and subsequently manifests in the treatment of older people in inappropriate, unfair, and undignified ways. The Gray Panthers actively adopted a visionary counter position to ageism, actively advancing positive images of older people as well as social systems and institutions that were proactively responsive to their needs rather than based on a disease, disablement, disempowerment orientation. For example, in 1973 and 1974, the Gray Panthers New York City Network organized two events that were intended to call into question ageist medical treatment. These events were alternatives to the American Medical Association (AMA) conference and focused attention on health care as a human right. In another bold move,

the Gray Panthers in 1974 staged guerrilla theater outside the site of the 123rd AMA annual meeting. Health care inequities, lack of adequate housing, the need for long-term care, mandatory retirement, and the impact of demeaning stereotypes in the media were just some of the "causes" that the Gray Panthers actively sought to ameliorate throughout the latter half of the 20th century.

Maggie Kuhn died on April 22, 1995, at nearly 90 years of age and just following the 25th anniversary celebration of the Gray Panthers. Her leadership was central to the inspiration and determination of all who were involved with the Gray Panthers. Following her death, the national organization struggled and then moved forward under the leadership of a dedicated board of directors and its chairperson. A 5-year strategic plan was prepared, and, in 1997, the Gray Panthers held their first national convention since Maggie's death.

Since the 1990s, the Gray Panthers has continued to launch activist efforts targeting universal health care, Medicare, education, economic justice, family security and community safety, job and worker rights, social security, and other national issues that affect the basic ethical and human rights of older people.

## GROSS MOTOR DEVELOPMENT

---

Gross motor skills have traditionally referred to motor activities that move the body through the environment or use the large muscles of the torso, arms, and legs to transport or displace an object in some

way. By contrast, fine motor skills have typically been described as involving the arms, hands, and fingers in acts of manipulation. For example, psychometric assessments of gross motor skills include balance, crawling, walking, running, jumping, climbing, and hopping, but may also include throwing or other ball-handling or hitting activities. However, this distinction has more recently been recast with respect to the underlying dynamics of the behavior and the ecological fit between dynamics and the information available to the actor.

A dynamical systems perspective on motor development provides a set of fundamental principles for characterizing gross and fine motor skills in terms of action systems. These are very general functional classes of behavior that have evolved in response to particular environmental pressures. The focus here is on three action systems: basic orienting (maintaining a functional orientation to gravity and to the surfaces and media of the environment), locomoting (moving from place to place by using disequilibrium to initiate motion), and performatory acts that displace objects by producing large forces or contain objects that approach the body with large forces. The development of these three action systems throughout the life span is proposed as the underlying basis for the observation of age-related improvements in the traditional gross motor skills of balance, locomotion, and physically displacing objects. Exceptionally skilled performance by adults during performatory acts, such as juggling, reveals clues about the fundamental principles of coordination. Moreover, the problems of balance experienced by aging adults illustrate the relation between basic orienting and other skills, especially locomoting.

## BASIC ORIENTING

All of the action systems consist of several functionally specific components of orienting: obtaining a relatively persistent orientation to the environment, supporting the body's weight, balancing forces acting on the body and limbs, and keeping the perceptual systems attuned to available information. These components of orienting are clearly at play in the development of sitting and standing during the first year, skills that require control of destabilizing forces acting on the body. There are two notable trends in the development of sitting and standing. First, achievement of postural stability makes it possible to anticipate and counteract muscular forces. During sitting, for example, coordinated

activation of the extensors and flexors of the trunk and hips allows the infant to control upper body sway. With improved trunk balance, there is a narrowing of the base of support as the legs are brought together and extended at the knees. Similarly, during standing, infants learn to control rotations about the ankles by applying torques (rotational forces) at the joint. Second, the achievement of postural control opens up new possibilities for perceptually exploring the body's capabilities, such as manipulating objects with hands freed from the task of support.

## LOCOMOTION

The locomotor action system builds on this foundation of basic orienting: between 15 and 18 months, standing infants allow the body to sway forward in order to initiate walking. Force plate measurements demonstrate that once infant walkers reach a steady-state velocity, their step-cycle organization is virtually identical to that of mature walkers. The step cycle consists of four phases. Swing phase (toe-off to heel-strike) is divided into F(lexion) and E(xtension) phases. The F begins at toe-off and ends as knee extension begins during swing. The E1 phase begins at knee extension and ends at heel-strike. The stance phase (from heel-strike to toe-off) consists of E2 and E3 phases. The postural instability that promotes a transition from stance to walking is also apparent in the developmental transitions in coordination of gait. Detailed longitudinal kinematic analyses indicate that for newly walking infants, intralimb coordination of shank and thigh motion is unstable, but attracted to a consistent phase angle. By 18 months, a reciprocal arm swing and heel-strike are present. Mature gait, as assessed by single-limb stance duration, step length, ratio of pelvic to step width, and progression velocity is well established by age 3. Walking velocity and stride length increase throughout childhood, and stride width is becoming narrower.

When the step cycle is placed in the context of its ground support, it becomes apparent that the muscles do not supply all of the forces used for locomoting. When a pulling or pushing force stretches a material (such as biological tissue), the energy stored in the material will provide potential energy for an elastic force that tends to return the material to its original state. Infants younger than 1 year of age will learn to harness the elastic forces stored in a spring as they bounce vertically. Walking proficiency improves in

toddlers as step frequency and length, head and trunk stability, amplitude of hip flexion, and coordination of lower limb movements reflect a dynamic integration of postural equilibrium and forward propulsion. During running, both gravitational potential energy and forward kinetic energy reach a minimum in the support phase, and both go through a maximum as the body takes off and flies through the air. Once toddlers begin to run, they may begin to harness the elastic potential energy at particular moments in the step cycle.

Developmental levels of hopping and jumping illustrate how further improvement in the child's ability to harness properties of the body and its relation to gravity enable them to safely use greater forces to propel the body away from support surfaces. During hopping, each of the four limbs, which characteristically behave like harmonic oscillatory systems, appears to become mutually entrained so that they act as a single "spring." Developmental changes are attributed to changes in the dynamics of the system. For example, in developmental level 2, called *fall and catch*, forward lean allows the body to fall forward of the support foot, the swing leg is inactive, and balance is recovered in the landing. Here, the force of landing on the support foot is quite high. In level 3, called *projected takeoff*, the swing leg pumps up and down to assist in takeoff. The basis for the developmental transition is a change in a dynamical parameter of the body, namely, stiffness. Rather than continuing a jarring, potentially injurious manner of hopping, the body reorganizes its movement, lowering the stiffness setting in the landing leg (perhaps through central regulation of the stretch reflex).

Jumping is another means of using the considerable force production of the body to escape the pull of gravity. It is used throughout the life span for projecting the body into the air in a way that achieves a wide range of skilled performance, including dance and athletics. Descriptively, jumping develops by increasingly taking advantage of the propulsive power of the shoulders and arms. The youngest children use no arm action, and leg action is usually a one-foot takeoff. Next, there is some shoulder flexion, but the arms remain immobile. Finally, children use shoulder flexion at the time of takeoff to achieve a complete and efficient arm action. Interestingly, even though position and magnitude measurements of the lower extremities change between the ages of 3 and 9 years, delay in peak extension velocity for hip, knee, and ankle remains highly consistent. This suggests that the

support aspect of the jump that maintains orientation to the ground remains stable and that developing the capacity for propulsion of the body into the air is a process of introducing disequilibrium against a background of postural stability.

## **ACTIONS ON OBJECTS**

The performatory act of propelling an object by means of perceptually guided release or brief contact with parts of the body (e.g., throwing, hitting, or kicking a ball) requires postural support on the ground that can withstand changing disequilibrating forces. Children may first begin to push a ball from a seated position, but once they have gained standing stability during the toddler period, rudimentary throwing patterns appear. The developmental pattern is one in which there is a rapid transfer of support in muscle groups so that a flowing sequence of muscular action produces propulsive force at a single point of contact with the ball. Throughout childhood and into adulthood, throwing velocity and accuracy increases, and individual differences in skill become apparent in games involving throwing, hitting, or kicking a ball. Early skilled performance in using the two hands, as in clapping, and expertise in coordinative skills, such as juggling, may have an underlying basis in the ability to detect regions of stability in dynamics and to time actions of upper body so that they are only intermittently stable. Coordination on the "edge" of stability in the phase relation of both hands introduces a degree of flexibility to adapt to the even tiny fluctuations inevitable in each catch and throw.

The dynamics of movement relative to balance and postural support is also the basis for age-related declines in walking performance by older adults. Beyond about age 60, walking velocity decreases, there is less vertical excursion of the center of gravity, and disturbed coordination exists between upper and lower extremities. During the seventh and eighth decades, there is often a further loss of the normal arm–leg synergy, an overproduction of "unwanted" movements, and diminished flexion in the swing phase. At the approach of the century mark, there may be rapid disintegration of the gait pattern, arrhythmia in step rate, and absence of any arm swing movement. The similarities between motor patterns in early childhood and senescence, respectively, suggest that both periods in development experience instability in postural equilibrium. In the former case, such disequilibrium comes to be used in the

service of development of new motor skills. It remains to be determined whether advances in 21st century technology will assist older adults in preventing such disequilibria from becoming incapacitating.

## HABITUATION

---

Any unconditioned response that is elicited in response to an unconditioned stimulus will show habituation if the stimulus is repeated. That is, measures of the response will show orderly decreases in magnitude as the stimulus is repeatedly applied. Habituation can be seen in the withdrawal responses of protozoa to tactile stimulation, in the freezing-defensive responses of rodents to auditory stimuli, and in the orienting responses of human infants to complex auditory and visual stimuli; it is one of the most fundamental properties of behavior. More simply put, habituation is a process in which a stimulus loses novelty and in which decreases in responsiveness to the stimulus are seen when the stimulus is presented repeatedly or for an extended time period. An organism ceases to engage in attending or otherwise responding to the stimulus; the stimulus comes to be ignored.

One of the most apparent trends in recent psychology has been the attempt to redefine basic behavioral processes in terms of more complex cognitive processes; as a result, habituation used to be considered *nonassociative learning* because only one stimulus was involved but has been termed *implicit learning*

by some writers, implying that “implicit memory” may be involved.

### WHAT ARE SOME OF THE PROPERTIES OF HABITUATION?

The formal study of habituation goes back nearly a century, being described by writers in the early 20th century and with the basic properties being outlined in the 1930s and again in the 1960s and 1970s. Some nine basic features of habituation were formally outlined and have come to serve as a formal definition of habituation:

1. If a specific stimulus elicits a response, repeated presentations of that stimulus result in decreased response or habituation; the decrease is typically an orderly function of the number of stimulus presentations.
2. If the stimulus is subsequently withheld, the response showing habituation will tend to return or recover with the passage of time, termed *spontaneous recovery*.
3. If the habituation experience and subsequent opportunity for recovery are repeated in a series, then habituation will progress more rapidly.

4. With all other variables held constant, the higher the frequency of stimulation, the more rapid and pronounced is habituation.
5. With weaker stimulation, habituation will progress more rapidly and be more pronounced.
6. The effects of habituation training may progress below baseline measures of the response.
7. If habituation occurs to a specific stimulus, then habituation to similar stimuli through stimulus generalization also occurs.
8. Presentation of an irrelevant stimulus will result in the recovery of the habituated response, termed *dishabituation*.
9. With repeated presentation of the dishabituating stimulus of number 8, the degree of resultant dishabituation is decreased or shows habituation itself.

A modified list of defining features has also been put forth, with the following additional defining characteristics:

1. The process of habituation will be disrupted by any unpredictable changes in the eliciting stimulus.
2. Habituation will occur more slowly to stimuli that are presented in a varying manner relative to stimuli presented in a constant, unchanging manner.
3. Spontaneous recovery may occur faster after more rapid rates of stimulus presentation relative to slower rates of stimulus presentation.
4. Spontaneous recovery may be incomplete recovery in that some habituation will persist over a long time period.
5. Habituation will be observed for most if not all animal species; habituation occurs in response to most stimuli, including events without ingestive consequences such as lights and noises. The rate at which habituation will be observed will differ as a function of the species, the stimuli employed, the responses being measured, and the individual subject.

As defining features, any behavioral stimulus-response contingency is said to display habituation if the response decrement shows these properties.

### HOW IS HABITUATION STUDIED IN INFANTS?

In general, studies of human infant habituation employ variations of some basic themes. In measuring

the rate of a reflex such as the sucking reflex, researchers measure the initial baseline rate of sucking to a pacifier equipped with transducers to measure muscle contractions applied to it. Then an auditory stimulus is presented, such as a human voice uttering a speech phoneme such as “ba.” In response to a novel stimulus such as this, the rate of sucking will predictably increase but come to decline to baseline levels as “ba” is repeatedly presented, showing habituation. If the phoneme “pa” were to then be presented, the rate of sucking would again increase, demonstrating that the infant can discriminate between these two stimuli.

To measure more complex responses, slightly different procedures are used. When an intense or novel stimulus is presented, an orienting response is elicited, and an infant (or any person) turns to look and fix the gaze at the source of a visual stimulus or turns the head toward the source of an auditory stimulus, as well as shows changes in heart rate, electroencephalogram (EEG) patterns, and other autonomic responses. Initially, infants show this orienting (or orientation) response to a stimulus, but after repeated trials of stimulus presentations, infants no longer respond to the stimulus, showing habituation of the orienting response. Researchers in human development have used measures of the orienting response as assessment tools of complex human development, described in the next section.

### ROLE OF HABITUATION IN HUMAN DEVELOPMENT AND LEARNING

Habituation procedures have increasingly been employed to assess the covert-behavioral abilities of preverbal infants to study the development of perception, remembering, and what is termed *information processing* as part of basic developmental research. In addition, the performance of infants on habituation tasks has been shown to be a reliable and independent predictor of long-term development. Indexes of the speed or efficiency with which infants show habituation have been shown to predict outcomes in behaviors such as language acquisition as well as more general behavioral outcomes such as verbal and nonverbal intelligence. Infants who show difficulty during habituation or habituate at slower than normal rates have been found to be at increased risk for a range of significant developmental delays. Populations of infants with Down syndrome, teratogen-exposed infants, malnourished infants, and premature infants have been studied.

Some researchers have found that at an age of 16 months, high-risk infants show rates of habituation comparable to newborn infants. Full-term infants have been shown to have more favorable measures of habituation indices than did preterm infants (birth weight < 1,750 grams) at 5, 7, and 12 months. Despite its widespread use, some writers have argued that the precise psychometric parameters of habituation need to be established before any definitive and significant dialogue on the predictive value of habituation can be conducted. Some such studies have also been criticized for using highly artificial events as stimuli, such as an artificial voice box, instead of a stimulus with higher ecological validity, such as recordings of actual human utterances as auditory stimuli.

Despite cross-study comparisons being obfuscated by procedural differences as well as in the response being measured, and despite that normally developing infants show a range of individual variations in habituation, acceptable measures of test-retest reliability have been obtained for some measures of habituation. Unfortunately, few such data exist for populations of high-risk infants, among whom the pertinent data would be of greater interest.

### WHY AND HOW DOES HABITUATION OCCUR?

The observation that habituation is so catholic points to an obvious and basic adaptive significance. Constantly responding to meaningless stimuli would be taxing and wasteful to any organism; learning to not respond to biologically irrelevant events while still responding to events that are biologically significant has clear survival value.

For some stimulus-response contingencies that show habituation, the physiological mechanisms have been identified, and although habituation has 9 (or 14) defining features, only one established physiological process has been elucidated. In studies of simple reflexes of invertebrates, such as a defensive-withdrawal reflex to tactile stimulation, the organism ceases to respond as the repeated stimulation causes a sensory neuron receptor to no longer release the necessary neurotransmitter to an effector motor neuron for the response to occur. The sensory neuron will continue to release its neurotransmitter in response to a different stimulus, and the reflex will still occur to a different stimulus but not to the stimulus to which habituation has occurred. That is, the observed change in responsiveness will be

stimulus specific but show stimulus generalization to physically similar stimuli.

In terms of identifying the biological bases of habituation in vertebrates, less progress has been made, but research so far points to similar neural events taking place in distinct lower brain areas depending on the sensory modality of the stimulus and the nature of the response undergoing habituation. Little if any research has been conducted into the biological basis of habituation in humans, but the infrahuman models of habituation are considered more or less applicable.

### SUMMARY

Habituation is a ubiquitous behavioral phenomenon, seen with virtually every response of a wide range of organisms to repeated stimulation, and because it is so universal, it has been argued as having adaptive value. Whether it merely reflects basic behavioral processes such as learning or more complex actions such as attention or memory is debated. Researchers in human development have studied habituation both for purposes of basic research and as a possible diagnostic mechanism to map and possibly predict developmental delays and disorders. Habituation will continue to be the subject of human development research for many years to come.

## HALL, G. STANLEY (1844–1924)

---

Granville Stanley Hall is commonly known as the father of American developmental psychology, and his contributions in the developmental field and in psychology in general are numerous and invaluable. Born in Ashfield, Massachusetts, Hall grew up on a farm and was initially intending to become a minister. He graduated from Williams College and studied theology at the Union Theological Seminary. Religion, morale, and Jesus later became topics of his books. Hall studied under William James at Harvard, and in 1878 was the first person who ever obtained a PhD in psychology in the United States. After finishing his PhD at the age of

34, Hall followed his dream to go to Germany and study psychology with Wilhelm Wundt in Leipzig (1878–1880). Coming back to the United States, Hall was a lecturer at Harvard and later accepted a position at Johns Hopkins University in 1882, as lecturer and later professor of psychology and pedagogy. Hall followed Wundt's methodology and opened a psychological laboratory at Johns Hopkins University. Advancing the scientific study of psychological phenomena, Hall adopted the experimental method in his laboratory using surveys, controlled observation of children and their families, and fostering the development and application of scientific tests. When Clark University in Worcester, Massachusetts, opened in 1889, Hall transferred to Clark and became its first president. In 1909, Hall organized a conference that was attended by Sigmund Freud and Carl Jung. Hall devoted his life's work to understanding the process of development and stayed at Clark University until his death in 1924.

It's no exaggeration to state that Hall is the father of American developmental psychology. Particularly, Hall focused on the study of children, development, and education in his pioneering studies "Adolescence" (1904) and "Educational Problems" (1911). He also founded the Child Study Association of America in 1888. Some people see Hall not only as the founder of American developmental psychology but also as the father of scientific American psychology. Impressively, by 1898, Hall had supervised 30 of 54 U.S. PhDs in psychology. He mentored graduate students and founded the first psychological journal in the United States, the *American Journal of Psychology* in 1887. As his passion was great and his vision steadfast, he had also started other journals, such as the *Journal of Genetic Psychology* in 1891, the *Journal of Religious Psychology* in 1904, and the *Journal of Applied Psychology* in 1915. A lifetime achievement in and of itself, Hall was instrumental in forming the American Psychological Association. He became the organization's first president in 1892 and was re-elected shortly before his death in 1924.

Hall's (1904) research interests focused on education, child development, and evolutionary theory, topics that are still relevant and at the heart of development to this day. His theory was influenced by Darwin's evolutionary theory and is based on the assumption that ontogeny recapitulates phylogeny. He viewed human development as a recapitulation of the biological and cultural history of humankind. According to Hall, the child repeats cultural evolution in his or her play. Hall developed a stage model of development and argued

that before the age of 8, a child ought to be free in expressing his or her spirits, and only after the age of 8 should formal learning occur. He had also proposed that it is later in adolescence that the child becomes ready to deal with moral issues and service for others. According to Hall, the curriculum should follow the needs and interests of children in their specific stages. Besides his main interests in development and education, Hall had other interests and efforts in gender differences, racial issues, emotions, hypnosis, basic psychological processes, and social and industrial psychology, to name a few. He has left his indelible mark in the fields of psychology and developmental psychology, and people during his lifetime and still today are impressed, indebted, and grateful to him.

## HARLOW, HARRY (1905–1981)

---

Harry Israel was born in Fairfield, a small rural town in Iowa. He was the third of four boys and grew up in a family that placed a premium on the value of education. Upon completion of his bachelor and doctoral degrees at Stanford University, his advisor convinced Harry to change his surname from Israel to Harlow owing to concern over possible discrimination because of his name. In 1930, Harlow began work as a comparative

psychologist at the University of Wisconsin in Madison and remained there for his entire career. Among numerous honors, Harlow was a member of the National Academy of Sciences, was elected president of the American Psychological Association, and received the National Medal of Science from President Lyndon B. Johnson in 1967.

Although Harlow studied complex information processing and curiosity in nonhuman primates, it is his work on nonhuman primate affectional systems that has had the most lasting impact. He was one of the first researchers to study love scientifically, but this was not the intent of his original work. In nonrelated work, Harlow separated infant rhesus monkeys to decrease the spread of disease, especially tuberculosis, in the animal colonies with which he was working. After observing the infants' unusual social behaviors that ensued following the separations, Harlow serendipitously began his exploration of affection.

Infant rhesus monkeys, when separated from their mothers, exhibit behaviors including withdrawal and emotional discomfort as well as atypical social and sexual behaviors. Curiously, however, these monkeys seemed to become attached to cloth items in their cage. *Contact comfort* was a phrase first coined by Harlow to describe the fact that the infants clung to cloth surrogate mothers placed in their cage, particularly during times of distress, rather than to nourishing surrogates. The results of Harlow's studies supported the work of ethological attachment theorists such as John Bowlby who held that attachment relationships are primary, not secondary, to the food that nonhuman primates' mothers provide to their young, as psychoanalytics and behaviorists once believed.

Harlow's ingenious work with infants and surrogate mothers had widespread impact, influencing attachment theorists and psychiatric treatments as well as the general scientific perception of affection. His own work and the research of his students have had a lasting impact on the field of psychology.

## HATE CRIMES

Crimes against people and property can be motivated by many different things, including greed, anger, and a desire for revenge. The subset of crimes known as hate crimes are those unlawful acts that are motivated by prejudice against a group that the victim is believed to belong to or identify with. U.S. law classifies crimes based on bias against a victim's perceived race, religion, sexual orientation, disability, and ethnicity or national origin as *hate crimes*. Some states have also added gender to the groups that can be classified as victims of hate crimes.

Victims of hate crimes are not limited to individuals. Businesses, institutions (such as a church or a mosque), communities, or even society as a whole can be a victim of a hate crime. Likewise, there is a range of offenses that are perpetrated against hate crime victims. Crimes against persons include intimidation, aggravated assault, rape, and murder. Crimes against property include vandalism, arson, theft, and robbery. Although offensive to many, certain types of hate-based behaviors are protected by U.S. law. Actions such as the creation of hate literature or the public expression of hateful speech are allowed until they cross over into making direct threats against identifiable people, organizations, or institutions.

### PREVALENCE RATES

Since 1991, incidences of hate crimes in the United States have been compiled on a yearly basis by the Federal Bureau of Investigation (FBI). For the year of 2002, law enforcement agencies recorded 7,462 hate crime incidents. Racial bias was the motivator for most of these offenses. Table 1 provides a breakdown of the type of bias for all reported incidents.

Hate crime offenses are more than twice as likely to be crimes against persons as crimes against property. Table 2 provides a breakdown of the type of offense for all reported hate crimes in 2002.

Many experts agree that these figures underestimate the actual number of bias-motivated crimes. The FBI relies on reports from local law enforcement to compile the national hate crime statistics. Inconsistencies in reporting or nonparticipation may artificially decrease the totals. By their very nature, hate crimes are designed to intimidate and may keep the victim from reporting the attack to authorities. There is evidence that victims

**Table 1** Types of Bias for Reported Hate Crimes

<i>Type of Bias</i>	<i>No. of Incidents</i>	<i>Percentage</i>
Race	3,642	48.8
Religion	1,426	19.1
Sexual orientation	1,244	16.7
Ethnicity/national origin	1,102	14.8
Disability	45	0.6
Multiple biases	3	<0.1

of nonbias crimes are twice as likely as victims of hate crimes to report their victimization.

### PERPETRATORS

It is a common perception that perpetrators of hate crimes are members of organized hate groups such as the Ku Klux Klan. In reality, only about 5% of known offenders are members of such groups. Most attackers are otherwise law-abiding citizens.

The most vicious hate crimes do tend to be committed by people with a history of antisocial behavior and ties to organized hate groups. For these individuals, prejudice and hate are the major focus of their lives, and they are actively involved in recruiting and indoctrinating new members. Although this group represents a small minority of actual perpetrators, organized hate groups facilitate wider disturbance by providing information and encouragement to anyone who wants it.

Most perpetrators are so-called dabblers, for whom hateful behavior is a part-time affair. These people do hold prejudiced beliefs that they express through behavior but typically keep these hidden in areas of their lives. For example, at work, they may keep their beliefs to themselves but on the weekends get together with like-minded friends to harass people who they perceive as being different.

Young people represent a significant number of hate crime offenders. Of known hate crime perpetrators, 33% are younger than 18, and 29% are between the ages of 18 and 24. The high rate of teenage and young adult participation in these crimes is one reason why most intervention and prevention programs are school based.

Two other groups of people are not active perpetrators of hate crimes but do encourage an atmosphere in which such actions can take place. Although they may

<b>Crimes Against Society</b>	<b>49</b>	

\*The number of offenses exceeds the number of reported hate crime incidents because an incident may include more than one offense type.

never act on their beliefs, sympathizers agree with the ideology of perpetrators. Sympathizers typically express their beliefs only at the verbal level, but these acts show support for more serious hate acts. Furthermore, sympathizers are unlikely to cooperate with efforts to stop hate crimes. The second group of people who help facilitate a hate-accepting environment are spectators. These are people who may disagree with prejudiced speech or behavior but are unwilling to stop it. Others may view their silence as approval and so draw encouragement from spectators.

## CAUSES

Hate crimes are certainly designed to hurt or intimidate the victim but are also meant to send a message to the victim's community: you are not welcome here. Such crimes share a basis of negative beliefs about groups of people who are perceived to be different in a significant way. But what motivates individuals to act on these prejudices varies. Hate crime perpetrators can generally be divided into four main categories of motivation: ideology, thrill, defense, or peer dynamics.

## Ideology

Ideology perpetrators draw strongly on their bigotry for motivation. They have a very rigid view of the world and believe themselves to be maintaining or restoring social order and morals. An ideology offender may believe, for example, that interracial relationships are wrong and threaten the morals of society. By drawing on perceived support in the community, the offender may attack a person who is part of an interracial couple to enforce these beliefs.

## Thrill

The main motivations of thrill seekers are to experience excitement and power. These assailants are usually young people, often groups of teenage boys, who crave respect and attention. They themselves are marginalized in some way, be it economic, educational, or social. For thrill seekers, hate crimes bring excitement to otherwise idle time and give them a sense of importance and strength by putting others down.

## Defense

Defense-motivated crimes occur when the offender feels threatened by a hated group. For example, an African American family may be targeted after they move into an all-white neighborhood, or a male assailant may attack a gay man because he feared that the man would make sexual advances toward him.

## Peer Dynamics

Individuals who are motivated by peer dynamics participate in hate crimes to gain respect from friends. These people are searching for acceptance and engage in hate crime primarily as a means to please others and prove their toughness.

## PREVENTION

Hate is learned. Whether through direct teachings of parents or subtle attitudes of society, individuals encounter messages of intolerance from the outside environment. The ideal way of preventing hate crime is to prevent the development of prejudice. A common factor among people who have resisted participation in hate activities, such as individuals who helped Jews escape Nazi Germany, is the existence of a role model who respected diversity.

A secondary solution is to alter those prejudiced beliefs that have already developed. The major way to change misconceptions about others is through purposeful exposure. Whereas simple contact between groups may encourage stereotypes and lead to bias crimes, cooperation between people is related to a decrease in negative attitudes. By working cooperatively with others, individuals gather information that challenges their previous beliefs. They also begin to see similarities between themselves and people they used to see as being very different. After one's attitudes are changed about a specific person, those positive feelings generalize to the group to which that person belongs. U.S. organizations such as Partners Against Hate, the Southern Poverty Law Center, and the Anti-Defamation League have developed numerous educational materials that teach accurate knowledge about different groups and facilitate interaction and understanding between peoples.

Because we have not yet reached the ideal of completely preventing the development of hate, programs that resolve intergroup conflict are needed. The Community Relations Service of the U.S. Department of Justice is an organization that provides information and free mediation services to communities that have experienced a hate incident or conflicts between people based on differences in race, ethnicity, or national origin.

## SUMMARY

Hate crimes are based on learned attitudes of prejudice against groups that are perceived to be different. Perpetrators of these crimes are typically otherwise ordinary citizens who use their hate to gain power, thrill, or acceptance. Prevention of hate crimes begins with developing attitudes of tolerance and acceptance instead of prejudice and discrimination.

## HEAD START

---

Head Start is the oldest, largest, and most widely known early intervention program for young children and families living in poverty. Created in 1965 as an 8-week summer program, it soon grew to a full-year preschool program. Head Start center- and home-based programs reside in all 50 states, the District of Columbia, Puerto Rico, and the U.S. territories, and serve more than 900,000 young children and their families. The principal components of Head Start include health care, education, nutrition, social services, parental involvement, and employment and career development. The primary goal is to foster healthy development (cognitive, social, and emotional) in low-income children.

## HISTORY

In 1964, President Lyndon Johnson declared “War on Poverty” in his State of the Union Address and named Sargent Shriver head of the War on Poverty program. Under Shriver’s direction, the Office of Economic Opportunity formed a Head Start Planning Committee composed of 13 scientists, including pediatricians, psychiatrists, psychologists, nurses, educators, and social workers. Because of the diverse backgrounds represented on the Planning Committee, the focus of Head Start went beyond education to include other aspects of early childhood development. The Committee proposed seven major goals for the preschool program: (1) improving children’s physical health and physical abilities; (2) facilitating the emotional and social development of children by encouraging self-confidence, spontaneity, curiosity, and self-discipline; (3) training children’s mental processes and skills with particular attention to conceptual and verbal abilities; (4) establishing patterns and expectations of success that foster confidence for future learning efforts; (5) expanding children’s capacity to relate positively to family members and others while also

strengthening the family's ability to relate positively to their children and their children's limitations; (6) developing in children and in families a responsible attitude toward society, and fostering constructive opportunities for society to work together with disadvantaged families in solving their problems; and (7) increasing the sense of dignity and self-worth of children and families. In these ways, Head Start aimed to break the "cycle of poverty" by providing a comprehensive program that targeted the cognitive, emotional, social, health, nutritional, and psychological needs of low-income children.

In 1965, the Office of Economic Opportunity launched Head Start as an 8-week summer program in more than 2,500 communities, serving more than half a million children younger than 7 years of age. Head Start transitioned from a vision to a functioning program in just a few months. A year later, Head Start expanded to a full-year program serving 350,000 children at 10,000 child care centers. In this brief time, more than 30,000 teachers were trained, and Head Start was enthusiastically welcomed by parents, community leaders, and educational and child development specialists across the nation. Described succinctly in this way, the program might sound like a Utopian intervention, which it clearly was not. In many programs, most of the teachers and other employees were parents of Head Start children who were themselves undereducated and underqualified for the program responsibilities that they assumed. There were then, and remain today, many financial, logistical, and technical challenges to the viability of the program, but a start had been made.

Head Start has undergone many changes under the leadership of Dr. Julius B. Richmond, a prominent pediatrician who served as the first director of Head Start, and Dr. Edward F. Zigler, a distinguished academic psychologist from Yale who was appointed as the first director of the Office of Child Development. In 1969, Head Start was transferred from the Office of Economic Opportunity to the Office of Child Development in the U.S. Department of Health, Education, and Welfare (later renamed the Department of Health and Human Services). Amendments to the Economic Opportunity Act of 1969 allowed participation in Head Start to children from more affluent families if they paid for those services, but that system was dismantled after 1 year owing to problems in its implementation. In 1972, another amendment was made to the Economic Opportunity Act calling for expansion

of Head Start program opportunities to handicapped children. The legislation mandated that handicapped children constitute at least 10% of the national Head Start enrollment. A year later, program directors created the National Head Start Association to serve as a lobbying agency for Head Start. In 1974, a Congressional Act reallocated Head Start funding priorities to encourage research, demonstration and pilot projects, and ongoing evaluations of Head Start programs.

In 1975, Head Start Program Performance Standards were issued. Recognizing the uneven quality of programs nationwide, Dr. Zigler feared that the benefits of high-quality Head Start programs would be "washed out" by their underperforming counterparts. In the same year, the Child Development Associate program started offering training and credentialing to child care workers, and more than 50,000 Head Start employees have earned their associate's degrees since 1975. In 1994, Congress passed legislation signed by President Clinton that required the Head Start Program Performance Standards to be revised and published in 1996. In 1998, the Head Start Reauthorization Act mandated expansion of Head Start to a full-day, full-year service. To date, Head Start has served more than 22 million children and their families.

Today Head Start is housed in the Administration on Children, Youth and Families at the Department of Health and Human Services. It is locally administered by community-based nonprofit organizations and school systems in all 50 states, the District of Columbia, Puerto Rico, and the U.S. territories. Head Start serves urban and rural children and families from many different ethnic backgrounds. In the year 2003, there were more than 900,000 children enrolled in Head Start, with 19,200 centers in operation, although even today, not all 3-year-olds can be accommodated who wish to enroll. (Four-year-olds are usually given preference for enrollment because 3-year-olds will still have another opportunity when they are a year older.) Of the children served currently by Head Start, 28% are white, 32% are African American, 31% are Latino, and about 9% are Asian/Pacific Islander or Native American. At least 90% of Head Start children must come from families with incomes at or below the federal poverty line, which currently allows about \$30,000 of income for a family of four. The primary exception to the poverty rule is that the 10% of children who are handicapped may come from more affluent families. Some Head Start programs have difficulty complying with the 10% guideline because many handicapped

children cannot reliably be identified before 5 years of age, but the program nationally has been successful in identifying and serving preschoolers with special needs, and 12.5% of the national enrollment in 2003 consisted of children with disabilities.

Head Start programs comprise the following main components: health care, education, nutrition, social services, parental involvement, employment, and career development. Health care provides immunizations, medical and dental checkups, eyesight tests, and mental health services. The Head Start founders believed that unhealthy children have difficulty performing in school; therefore, making health care a primary objective should equip children better to handle the later challenges at school. Educational curricula are designed to provide important learning experiences that low-income children might not otherwise receive; such provisions foster intellectual, social, and emotional growth.

Between 1997 and 2000, the Families and Child Experiences Survey (FACES) examined the quality of Head Start classrooms using measures of quality consistent with the Head Start Program Performance Standards. More than 70% of classrooms studied scored in the “good” or “excellent” range, and very few in the “minimal” range. Most Head Start teachers used the Creative Curriculum by Teaching Strategies program or the High/Scope curriculum, but 41% used another curriculum. Most teachers liked their curriculum for a variety of reasons, including that it covered multiple domains, was easy to use and adapt, involved parents, allowed room for teacher creativity, and provided adequate learning materials.

Besides educational resources, Head Start provides or arranges for social services that might be needed, including community outreach, referrals to other agencies, family needs assessments, recruitment and enrollment of children, and emergency assistance and crisis intervention. A critical objective of Head Start is to encourage parent participation, such as assisting teachers and social workers as paraprofessionals, serving on policy councils and committees, and attending classes and workshops on child development. In 2003, 28% of program staff members were parents of current or former Head Start children, and more than 880,000 parents volunteered in their local Head Start programs. These figures underline a common misperception: Head Start is *not* solely a program for children; it is a program for families as well. Through their involvement, it is intended that parents learn from Head Start how to teach, train, and nurture their own children. The

last Head Start objective is to foster employment and career development. Most staff members are recruited locally and are offered training and credentialing opportunities, in hopes of improving child care quality and career prospects through the additional training. The FACES study found that nearly 60% of teachers received training in their curriculum from their own programs, 14% received this “technical assistance” from the developers of the curricula, 10% from a Head Start Quality Improvement Center, and the remainder from other sources.

About 1.4 million people volunteer their time to Head Start programs and projects. Volunteers include parents and grandparents of Head Start children, high school and college students, senior citizens, and homemakers. Volunteer opportunities range from being a front desk receptionist, to serving as a classroom aide, to assisting with special events.

## PROGRAM EXTENSIONS

Beyond the center-based Head Start program, several program extensions have evolved through the years since its inception. Some prospered and continue to operate, whereas others fell by the wayside, but many of the features of Head Start that have proved to be valuable and effective started out as experimental ventures by teachers, parents, or program directors.

The first offshoot of Head Start, Project Follow Through, was implemented in 1967 by the Department of Education. The purpose of this program was to extend the Head Start vision into elementary schools, thus creating a more gradual transition into public education. Follow Through began as a pilot program in 40 school districts and was expanded to full-scale within 1 year. Unfortunately, the program did not receive the funding necessary to implement the comprehensive Head Start curriculum; thus, no universal model of Follow Through was adopted. The program continued to operate into the 1990s, but only as an experimental program in newly formed elementary schools.

Health Start, a summer medical screening program for impoverished children, was introduced in 1970. In addition to general medical screening, children received referrals, dental care, and follow-ups throughout the year. This program was in operation for 2 years but was discontinued for lack of success. Three years later, Home Start was initiated, providing home-based Head Start services by paraprofessionals, the rationale being that Head Start skills could be brought home and

delivered to parents and other siblings. This program was particularly well received in rural areas where great distances to child care centers hindered families' participation. There are now more than 500 Home Start sites in operation, and more than 47,000 children have participated in Home Start services.

In 1991, the Head Start Transition Project received funding to partner Head Start with elementary schools to provide services in four different areas: (1) developmentally appropriate and continuous Head Start curriculum, (2) health services, (3) facilitation of parental involvement, and (4) social services to participating families. This program operated in 32 sites. Although this program is no longer active, the effort to coordinate transitional support to Head Start children is still a priority.

In 1995, the first Early Head Start grants were awarded to provide services for pregnant women and children birth to age 3. Four years later, Early Head Start served about 45,000 children through such program services as comprehensive early child development, health, and family support in both home- and center-based care. Thus far, the research evaluation conducted by Mathematica Policy Research, Inc. shows that Early Head Start is improving cognitive, language, and social-emotional development in the participants at age 3, and increasing parental involvement.

## EVALUATION OUTCOMES

Because Head Start is a nationally recognized, federally funded preschool program, there are plentiful reasons to study the magnitude of its effects on the children and families it serves. Over the years, many notable studies have been undertaken. The first studies evaluating the efficacy of Head Start primarily focused on "graduates" between first and third grade. The Westinghouse National Evaluation Study in 1965 matched former Head Start participants in grades 1 through 3 with classmates from similar family backgrounds. This was a quasi-experimental study that tested the academic achievement scores of these children. Two investigations with similar designs and findings include the Educational Testing Service (ETS) Longitudinal Study in 1969 to 1971 and the New Haven Head Start Study, 1968 to 1969. Finally, the National Longitudinal Survey Child-Mother (NLSCM) conducted between 1979 and 1989 compared language test scores of children who attended Head Start against those of their siblings who did not attend.

Regarding long-term effects, the general consensus of these studies was that Head Start graduates had higher achievement test scores than non-Head Start participants in grade 1, but that this difference was no longer significant in grades 2 and 3. This phenomenon has been termed the *fade-out effect*, whereby the cognitive benefits of Head Start are evident immediately but diminish gradually within 1 or 2 years. The NLSCM study found the fade-out effect among African American and white children, but actually found a "fade-in" effect for Latino children. It appeared that, for Latino children, having attended Head Start produced a progressively beneficial effect on academic achievement.

Despite the immediate benefits associated with Head Start, the fade-out effect brought into question the value of the program. In 1985, the U.S. Department of Health and Human Services issued a contract to synthesize the results of 210 Head Start research studies. The findings confirmed the fade-out effect, concluding that immediate cognitive gains were significant, but diminished within 2 years after exiting the program, in the absence of intervention beyond preschool.

Simultaneously, Head Start advocates began questioning the legitimacy and validity of the research being conducted. For instance, the Westinghouse National Evaluation Study was conducted 3 years after Head Start was initiated; thus, the non-Head Start subjects were assigned to the control group *after the fact*. Typically, an experimental study assigns participants to each group randomly *in advance*, to avoid bias in interpreting the results. Consequently, it is difficult to conclusively attribute any effects—favorable or otherwise—solely to the Westinghouse intervention. Second, the instruments used to measure the social competence outcomes were not validated ahead of time. Unlike the well-standardized cognitive competence measures, the measures of attitude or emotion were developed informally by the evaluators of the program, which elicited substantial criticism from experts. The research findings also brought into question whether the outcomes measured could truly determine the efficacy of intervention programs. Ultimately, certain outcomes may be more useful in shaping public policy (e.g., cognitive and social competence), and other outcomes may provide more useful feedback for curriculum improvements, medical and dental care, and parental involvement. It is worth noting that the bill for the Head Start program—now approximating \$7 billion annually—must be paid through legislative action, an intensely political enterprise.

Given the limitations of previous research, Head Start supporters began looking to other program evaluations. Between 1984 and 1993, the High/Scope Perry Preschool Project conducted follow-ups of its participants and nonparticipants at ages 19 and 27. Regardless of the outcomes in the elementary school years, the follow-up results indicated that the preschool participants showed increased employment and graduation rates, less dependence on public services, and reduced crime and arrest rates, when compared with nonparticipants. These significant findings were dubbed the *sleepers effect*, meaning that the effects of the preschool program became evident later in the participants' lives, most prominently in the areas of social behavior, self-sufficiency, and moral conduct.

Owing in large part to the notoriety of the Perry Preschool Study, the Long-Term Benefits of Head Start study (LTBHS) was initiated in 1987 and 1988. In this study, former Head Start children were followed up 17 years after participation in the program and compared with non-Head Start subjects of the same age in Colorado and Florida. Compared with the nonparticipants, Head Start graduates achieved significantly higher elementary school grades and showed a trend toward higher rates of general equivalency diploma (GED) or high school completion, employment, and enrollment in school. However, there were no significant improvements regarding teen pregnancies, use of public assistance, or rates of crime and arrests.

A subset of the Florida Head Start sample received a model Head Start program based on child development theory, known as the High/Scope preschool model. This subset of Head Start graduates was compared with the Head Start graduates who received the regular curriculum, and significant improvements were found regarding grades in elementary, middle, and high school, and in lower crime and arrest rates. Although no significant improvements were found in rates of GED or high school completion, employment, enrollment in school, or teen pregnancies, the significant findings did, to some degree, replicate the Perry Preschool finding that preschool intervention has lasting effects beyond the commonly measured domains of cognitive and social competence in early childhood.

Several research studies were initiated to evaluate programs developed as offshoots of Head Start. In 1968, a study of program effectiveness for Project Follow Through found only moderate effects on the children's academic achievement. However, these results were not surprising, given the haste and disorganization in

launching the program and the lack of curriculum consistency across sites. Home Start was evaluated after its inception in 1972, and the results indicated that the program was equally effective in all areas, except that it did not provide the same quality of health services as center-based Head Start. Finally, the evaluation of the Head Start Transition Project determined that participating children were able to reach national norms in most academic areas.

## SOCIAL AND POLICY IMPLICATIONS OF EVALUATION FINDINGS

Since its inception, Head Start has received strong financial support from the federal government. The congressional appropriation increased dramatically from \$96.4 million in fiscal year 1965 to \$349 million in 1967, owing to the early enthusiasm for the program. However, the ensuing negative evaluation reports led Congress to decrease the appropriation to \$325 million in 1970. At that time, the Office of Management and Budget floated a plan that would have phased out Head Start over a 3-year budget cycle. This phase-out plan never took place, owing to protests from parents and other advocates who supported Dr. Zigler's arguments. He acknowledged that, although it is straightforward to base policy decisions around easily measurable effects like achievement scores, the importance of other Head Start objectives may be overlooked, such as improved health, promotion of social skills and moral conduct, and reduction in arrest rates and crime. Not only did the phase-out plan not take place, but also, in 1971, Congress appropriated \$35 million more than the previous year's allocation.

Between 1977 and 1983, the Consortium for Longitudinal Studies (CLS) published a series of reports reviewing the long-term effects of 11 preschool interventions, including Head Start. CLS has been pivotal in publicizing the importance of early childhood interventions and in drawing outside support. The perspective that emerged from those reports drew on the plausible argument that the long-term effects of early childhood interventions do not stand alone. Rather, these interventions have an interactive relationship with their social context and with the families and educational experiences surrounding the children. During the Carter administration, from 1977 to 1981, the annual appropriation for Head Start nearly doubled, and in 1984, the Head Start budget exceeded \$1 billion dollars. The total appropriation for Head Start in fiscal year

1995 was \$3.5 billion; it rose to \$5.3 billion in FY2000; and it reached \$6.8 billion in FY2004.

Most of the congressional appropriation for Head Start is awarded to public or private nonprofit agencies to fund local Head Start projects. Grants are awarded by the Department of Health and Human Services regional offices, except for the American Indian and Migrant programs, which are administered in Washington, D.C. The remaining funds are used for training, technical assistance, research, demonstrations, and program evaluation.

In addition to policies affecting Head Start, the following two examples illustrate the profound effect that Head Start has had on policy decisions throughout its existence. In 1971, the Comprehensive Child Development Act was created to provide access to quality child care for all working mothers. Low-income mothers would receive the service for free, whereas other families would pay for the service on a sliding scale. Simultaneously, the Nixon administration was working on its welfare reform package known as the Family Assistance Plan. The plan was designed to provide women with job training and child care in order to reduce their dependence on welfare. The next step in support of the Comprehensive Child Development Act and the Family Assistance Plan was to specify what would be considered quality child care. Dr. Zigler and his staff drafted a set of federal standards based on their experience with Head Start, and Secretary Elliot Richardson approved those standards. Although the two bills failed to pass, the National Association for the Education of Young Children (NAEYC) eventually adopted the standards proposed by Dr. Zigler in its system for evaluating and credentialing child care programs across the country. NAEYC is still in existence and continues to influence child care standards across the nation.

## FUTURE DIRECTIONS

Head Start has remained active for almost 40 years and receives significant funding from both federal and state sources. This investment in Head Start is founded on the complementary relationship between program evaluation results and public policy. In order for Head Start to survive in the future, this relationship must be nurtured, to ensure that current research appropriately drives future policy decisions. In 1998, Congress authorized the first national evaluation of Head Start (the National Reporting System) since the Westinghouse

study, contracting the Administration on Children, Youth and Families (ACYF) to direct the research.

The National Reporting System (NRS) is grounded in President Bush's *Good Start, Grow Smart*, Early Childhood Initiative. It includes provisions in the Head Start Act to create a new national database that monitors the progress of 4- and 5-year-old Head Start children in specific areas of child development. Programs will administer this NRS assessment to more than 525,000 children (all 4- and 5-year-olds) at the beginning and end of the program year, to assess the skills with which they enter Head Start, their levels of achievement when they leave Head Start, and the progress they have made during the year. The assessment information collected through the NRS will be used to strengthen Head Start program effectiveness. This assessment will monitor the following five learning indicators, as mandated by Congress in the Head Start Act of 1998: (1) understanding and using language to communicate for various purposes; (2) using increasingly complex and varied vocabulary; (3) in the case of children whose native language is not English, progressing toward acquisition and mastery of the English language; (4) identifying at least 10 letters of the alphabet; and (5) awareness of numbers. To counter the skepticism generated by the flaws in the Westinghouse study, the NRS evaluation has employed an experimental design using random group assignment and validated performance measures.

Although it is still early to evaluate the NRS, it is *not* too early to praise the magnitude of the undertaking or the enormity of its promise for our understanding of early childhood development. This program has the potential to cure a chronic deficiency in our knowledge about children raised in poverty, and about our understanding of what works best, for whom, and under what circumstances to mitigate the pernicious effects of poverty in our nation. That deficiency is the lack of a national database of norms against which to compare developmental progress of poor children in all of the important areas of growth. The cost of the NRS program and the scope of the undertaking are simply staggering, but the potential benefits from the program, if well executed, are even more impressive.

The future of legislation pertaining to Head Start is also in transition. The funding of Head Start is gradually shifting to the states, and as a federally regulated program, Head Start must continue to build ties to state and local agencies. Already, most states in the country sponsor similar preschool programs, albeit usually of

lesser cost and sometimes lesser quality than Head Start. Local school districts are also moving in the direction of expanding their preschool offerings, especially for low-income families. Recent changes in our national welfare systems have mandated a high priority on quality child care, in order to support the requirements of further education and employment, especially of low-income mothers. Since 1990, ACYF has financially supported several partnerships between Head Start and state-operated agencies, aiming to coordinate early education, child care, and health care. These partnerships are vital because it has been suggested that the widely documented fade-out effect may diminish if children's educational and social environments improve as well.

There are pervasive and persistently adverse influences on child development that are associated with extreme poverty in our society. Poor American children spend at most 40 of their waking hours in school settings each week, but half again as many waking hours in impoverished homes and neighborhoods that typically breed very different behaviors, attitudes, skills, and values than those promoted in Head Start. Therefore, if children graduate from Head Start but remain in impoverished neighborhoods and enter public schools without any compensatory assistance, this would present much greater challenges for those children to make strides academically or psychologically.

A second step that has potential impacts on children's prospects is an alliance with public elementary schools. Developed in 1995 at Yale University, the School of the 21st Century program provides services associated with Head Start to children and families through their elementary schools. Such services include on-site preschool, before- and after-school care, and family outreach. In keeping with the Head Start policy model, the Department of Education funded an evaluation of this program, to be conducted by the Yale Bush Center in Child Development and Social Policy. The results are still pending, and Head Start advocates believe that this will help bridge the transition of Head Start children to public schools.

A prospective policy funded by state and federal agencies that may have an impact on the future of Head Start is the trend toward universal access to preschool education. This may instigate competition between preschool programs, leaving Head Start to defend its need for future funding. Thus, the future of Head Start may lie in targeting the younger age bracket, including infants and toddlers, an effort that is already underway

within the Early Head Start program. An evaluation of the effectiveness of Early Head Start is in progress, and results thus far appear promising. In the future, we may see a larger proportion of the Head Start budget shifting toward Early Head Start and other progressive programs in very early childhood.

## HEALTH INSURANCE

---

Health insurance often seems confusing and can be difficult to navigate for even the most knowledgeable consumer. It is one of the most talked about topics in political elections and has received considerable media attention because of the rules and restrictions

placed on people who have insurance and the plight of the growing numbers of uninsured Americans.

The primary feature of health insurance is to pay for the cost of medical events that a person cannot afford. Insurance intends to pool for groups of people the financial risk of expensive, unforeseen medical events. Lately, however, the trend has been to use health insurance to pay for routine and ordinary health care as well as those catastrophic events. As a result, the cost of health insurance is rising for everyone.

Insurance as a concept is easy to understand. It is simply a mechanism for pooling financial risk within a community so that no single person has to bear the burden of a substantial expense. When members of a community or a company insure against health risk, everyone puts money into a collection, and the cost of their health care is paid for, in part, from that pool. No individual person is responsible for overwhelming medical costs because they all share the burden of each other's costs.

Insurance in practice is more difficult to navigate. To participate in insurance plans, a consumer must enroll in a plan either through his or her employer, through programs run by the federal or state governments, or individually with an insurance company. The enrollee pays a monthly payment called a *premium*, which goes to fund the risk pool. When insurance is accessed through work, the employer frequently pays all or part of this premium, and any remainder is paid by the employee using pretax wages. When insurance is accessed through public programs, little or no money is required of the consumer for the premium; however, funds are deposited by the government to fund a risk pool just the same.

Insurance companies offer different health insurance plans, each of which maximizes benefit or minimizes cost to the enrollee. Often, this means that plans that are the most financially appealing to the consumer because they cost less in premiums will have greater restrictions when the insurance is used and health care is sought. Health maintenance organizations (HMOs), preferred provider organizations (PPO), and point-of-service plans (POS) are plans that cost less in premium dollars than traditional, more expensive health insurance plans, but they also have more restrictions and guidelines that the consumer must follow in order for their care to be paid for by the insurance plan. The rules and guidelines of these types of insurance plans are often the basis of many complaints about health insurance today. It seems that in theory, health care is easily accessed and less costly with these types of health insurance plans;

however, in practice, people find the rules and restrictions difficult to manage and to navigate.

Once enrolled, an insured person is able to go to any provider such as a doctor or hospital that accepts their particular insurance plan, and the provider will be paid for the care delivered by the insurance company. Providers are free to accept or to deny particular insurance plans, and consumers are usually provided with a list of participating providers by their insurance company. Also, depending on the rules of any particular insurance plan, an annual deductible and a co-pay or co-insurance may also be required of the enrollee. That means that the consumer is responsible for paying for a portion of the cost of the care out of his or her own pocket in addition to what the health insurance plan will pay for the care that is provided. It is important to understand that in most instances, insurance does not cover the entire portion of the cost of care, and consumers are increasingly being called on to make health care decisions based on greater responsibility toward the cost of their own care.

Access to health care providers looks about the same for anyone who has insurance, whether it is private, employer-sponsored insurance, or a public insurance program. However, if a provider is unwilling to accept your health insurance plan, then you must either find another provider who is willing, or pay for the care out of your own pocket.

People without health insurance have much greater difficulty gaining access to providers who are willing to treat them. Most providers will accept full cash payment from individuals without health insurance; however, the cost of health care today is much more expensive than most people can casually afford. Most people today are unaware of the full costs of an office visit, for example, and are often unable to pay unexpectedly for such visits out-of-pocket. As a result, uninsured people tend to go without medical care until such time as their illness or disease creates a major disturbance in their lives. Alternatively, they access health care through the emergency room of the local hospital. Either instance illustrates a critical issue in our health care system today. If someone waits too long to be treated because they lack health insurance, then their illness can be far more serious and more costly to treat when they finally do seek treatment. Also, when someone who is uninsured needs to access basic, routine health care through the emergency room, then the cost of their care is much greater, and the encounter is wasteful of health care resources. Either way, prompt,

appropriate, and affordable health care is denied through a lack of health insurance.

Most Americans, about 60% of the population, get health insurance through their employer, whereas about 25% of the population gets health insurance through the federal government (Medicare) or the state government (Medicaid, State Children's Health Insurance Program [SCHIP]). Also, at any given time during a year, there are between 20 and 40 million people, or up to 15% of the population, who are without health insurance, either because they are between jobs, their employer does not offer health insurance as a benefit, or they are unable to purchase health insurance on their own. Many of these uninsured Americans are working, wage earners; some will pay a substantial portion of their total income on medical costs out-of-pocket.

Women and children who are unable to access health insurance through an employer program, or for whom insurance is too costly to purchase, are often eligible for health insurance through state-run programs such as Medicaid and SCHIP. Medicaid is a state-run insurance program that provides health insurance to low-income families. Families must meet income guidelines proposed by their state to qualify for Medicaid insurance. Once enrolled in Medicaid, recipients are covered for a broad range of health care services from providers willing to accept Medicaid. The federal government outlines a list of required services that Medicaid will pay for from willing providers. These include, among others, inpatient and outpatient hospital services, physician services, prenatal care including nurse-midwife services, vaccinations for children, nursing facility services, family planning services, home health services, laboratory and x-ray services, pediatric and family nurse practitioner services, and early periodic screening, diagnostic, and treatment services for children younger than 21. Some states also elect to provide optional services, including prescription drugs and optometrist services, among others.

For little or no cost to families who make too much to qualify for Medicaid, but for whom health insurance is beyond their financial reach, SCHIP is a new program that enables states to insure children younger than 19 years for doctor visits, hospitalization, emergency room visits, and immunizations. Exact program components vary from state to state, and information about coverage can be obtained from any state's Department of Health.

Nationwide, the SCHIP outreach and enrollment activities have increased the screening and evaluation

of many uninsured families, and many states have reported that SCHIP has had a significant impact on their Medicaid programs. The result has been the identification and enrollment of children who may have been eligible for some time into either the Medicaid or SCHIP programs.

Even with these significant improvements in access to health insurance for our nation's children, however, a significant number of children across many states continue to remain uninsured. During the 10-year period from 1988 to 1998, the proportion of children insured by Medicaid increased 4.2% (from 15.6% to 19.8%), and yet in the same time period, there was also an increase in the number of uninsured children (from 13.1% to 15.4%). It seems that the changes facing employer-sponsored health insurance in the quest to contain the costs of health insurance are substantially cutting the insurance benefits to many employed people. As a result, employed, previously well-insured Americans will become less well insured or even uninsured. Development of alternative insurance programs for the United States' most vulnerable populations will continue to be an important issue at the state level. However, while states continue to test the viability and success of the Medicaid and SCHIP programs, it will not be without increasing cost, which the taxpayer will have to bear.

## HEMOPHILIA

---

Hemophilia is a blood disorder characterized by unusually low levels of clotting factor, which prevents normal blood coagulation. As a result, people with hemophilia bleed for longer periods of time but not at a faster than normal rate. It is a recessive genetic disorder that is carried on the X chromosome, and so it affects predominantly males. The diagnosis of hemophilia in women is very rare. There are two forms of hemophilia. Hemophilia A results from a deficiency in clotting factor VIII, and hemophilia B results from a

factor IX deficiency. Hemophilia A is more common, occurring in 1 in 10,000 male births, whereas hemophilia B occurs in about 1 in 34,500 males. About one third of hemophilia cases occur through spontaneous mutation with no inheritance of the gene.

Severity of the disorder can be classified as mild, moderate, or severe with differing symptoms. Symptoms of hemophilia include pain, bruising, spontaneous bleeding, bleeding into muscles and joints with associated pain and swelling, blood in urine or stool, and prolonged bleeding from minor cuts or abrasions. People with mild hemophilia are most likely to experience problems due to surgical procedures or major injuries, whereas people with severe hemophilia may experience spontaneous internal bleeding into muscles and joints.

For some cases of hemophilia, treatment consists of regular injections of the missing clotting factor. Mild cases of hemophilia may require injections only when bleeding occurs. The clotting factor either comes from human plasma or is made synthetically. Because so many donors are required to process one dose of factor, transmission of viruses from donor to recipient was a significant problem until the early 1990s. The risk involved in contracting viruses through human clotting factor has been drastically reduced in recent years, practically eliminating the risk for contracting human immunodeficiency virus (HIV) and hepatitis from clotting factor derived from human plasma.

Psychological functioning of children with hemophilia has been found to be similar to children with other chronic illnesses, with a display of more internalizing and externalizing behavioral disorders. However, there are certain aspects of hemophilia that are quite different from other illnesses. For instance, psychological difficulties may arise from the restrictions that people with hemophilia may have to place on their lifestyle. In particular, people with hemophilia have limitations and require close monitoring with regard to physical activity. Participation in contact or high-impact sports can potentially be very dangerous for a child with hemophilia, owing to the likelihood of joint and muscle bleeds.

Children may become frustrated and bitter with the limitations of hemophilia. Children may have to repeatedly explain to other children why they cannot be involved in activities. People with more severe cases of hemophilia have greater limitations and can often experience more loneliness. Education of the family and friends of those with hemophilia can help boost the

self-esteem of those suffering from hemophilia by creating a greater understanding of the illness. Children can also be helped if alternative activities are provided for them. As children enter into adolescence, they face not only the same psychological issues but also possible physical changes as a result of the bleeding. Those with hemophilia may have to deal with medical issues before they are developmentally ready and in some cases before they can adequately care for their illness. Fortunately, treatment centers have begun to address these issues by creating a multidisciplinary approach that stresses education, proper medical care, and adjustment to living with a chronic illness.

## HETEROSEXUALITY

---

Heterosexuality is ubiquitous to modern Western sensibilities. It is often seen as the natural, timeless, and logical arrangement of the mating pair bond. For most people, trying to describe the role of heterosexuality in life is like trying to describe walking upright or using opposable thumbs; you never really think about it until it is challenged. Heterosexuality is not even questioned unless the concepts of homosexuality or bisexuality are mentioned. However, as recent as a little more than 100 years ago, if you had asked someone if they were heterosexual, they would either not know what you were asking or be highly offended.

The term *heterosexuality* has its origins in pathology. It first appeared in print in medical journals as a malady related to the obsession with nonprocreative

sexual activities, just as homosexuality was mentioned as obsession with same-sex (obviously nonprocreative) activities. It was not until the 1930s that heterosexuality began to lose its stigma and take on its mainstream position in the Western consciousness.

Even though the term heterosexuality may have a recent and varied history, the concept is older than recorded history itself. As soon as men and women began to divide themselves into separate spheres of activity and the realization that sexual intercourse was how procreation was achieved, the concept of heterosexuality was born. This concept is rooted in sexual duality of the binary sexual categories of male and female.

Originally tied to reproduction and division of labor, heterosexuality has grown to encompass attraction or desire, behavior, and identity.

## **ATTRACTION**

Heterosexuality is often currently defined as “sexual orientation toward persons of the opposite sex.” This definition starts with the premise that there are only two sexes, male and female. However, in nature, there are many species of plants and animals that are hermaphroditic, possessing the gonads and sex organs of both sexes. There are also some insects and reptiles that are single sexed. Even in the human population, we find that about 1 in 2,000 births has some form of sexual ambiguity that makes it difficult to determine the child’s sex at birth.

However, for most humans and animals, there are just two sexes. Based on the sexual reproduction paradigm, roughly half of the species carry gonads that produce eggs, and the other half carry gonads that produce seeds or sperm necessary to fertilize the eggs and produce genetically variant new offspring. It is this drive to reproduce that is at the center of the heterosexual paradigm. To reproduce, an animal (or human) with the egg-producing gonads must unite with a partner who carries the sperm-producing gonads and join in a sexual union. Likewise, the same drive exists in the sperm-producing creature to locate and secure an egg-producing partner to accept his sperm and thus produce the next generation.

For many animals, the quest stops there. Once the eggs are fertilized, interest in the opposite sex ends. However, in most warm-blooded animals, at least one partner (usually the egg-bearing one) remains behind to nurture the offspring. In other cases, the partners form

a pair bond; the pair either takes turns in caring for the offspring, or one partner cares for the young while the other gathers resources such as food and provides protection for both the partner and the offspring.

This pair bond is what is central to the concept of heterosexuality. Among humans, the pair bond exists even when procreation is not the central concern. Human pair bonds can develop before procreation is possible and continue long after reproduction has ceased. Even when reproduction is a prime concern, the heterosexual union is often more than just the matching of gonad-producing organs; there is also a balance of sexual energies that is frequently sought.

Thus, the attraction of a mate takes on the quest for certain physical and relational traits that one would find desirable in a mate. Interestingly, even in modern information age societies, many of the traits that are considered most desirable in a mate are those traits that would be advantageous in producing and rearing offspring. Often men are attracted to physical attributes that indicate a woman is healthy and likely to be able to bear children. These include things like clear skin, youthful appearance, widening at the hips, developed breasts, and so forth. Women also seek attributes in men that might indicate good genes but also attributes that indicate that the male has access to resources that could make him a good provider for her and her offspring. Women will also look for men that make good companions. Although these markers of attraction may be conscious or unconscious, they are central to heterosexual attraction.

## **BEHAVIOR**

If the most common definition of heterosexuality is sexual orientation toward the opposite sex, the second most common definition could be “sexual activity with the opposite sex.” Originally, this activity focused on the procreative nature of sex; that is, sex was for reproduction. Thus, activities associated with sex were supposed to be for producing offspring. There were (and still are) many ancillary activities that go along with producing and rearing offspring that have led to a division of labor between the sexes. Because bearing children is the sole province of the female, the male then has been relied on to assist by providing food, shelter, and protection for the mother and offspring. In fact, during the gestation period, or pregnancy, the human female becomes more incapacitated and thus more dependent on the male or at least the extended family.

Even when she has recovered from the delivery and has regained much of her strength, the human female still needs assistance in caring for the newborn, owing primarily to the immature development of the human offspring. It takes several years before the human child can function independently, and even then the child still requires protection and guidance in social and intellectual development.

Because nurturing this young child typically falls to the female, providing resources and protection falls to the male. This has led to different realms of activities for each sex tied to the maintenance of the child and the social unit, the family. As humans advanced from wandering hunter-gatherer societies to agrarian ones, the realms of activities remained, even as the activities themselves changed. The main difference is that in agrarian societies, the activities occurred closer to home, and thus the male was around more often. Also, because the types of activities changed, some no longer requiring brute strength, the lines between male and female behaviors also began to change.

It is at this point that division of labor took on a more sociological meaning, rather than being based primarily on physical abilities and attributes. Thus, activities of men and women became proscribed as inappropriate for one sex or another. This gave rise to the concept of gender role—that is, the assignment of a set of activities to males and calling it *masculinity* and another set of activities to females and calling it *femininity*. From this time to the present, the division of heterosexual behavior has taken on hegemonic overtones concerned not with simply providing for the family but also with maintaining the social structure of the family and larger society (as locally arranged).

Each society has its own definitions of which activities are relegated to women and which to men. In most patriarchal societies, men who engage in work deemed “women’s work” are mocked, and it is considered an affront when women venture into areas reserved for men. In both cases, the person’s status as a man or woman is frequently called into question when this occurs. This is true even when the behaviors have little or nothing to do with the reproduction or rearing of children.

Even in today’s postindustrial society, the vestiges of this distinction remain. Although men and women can engage in activities previously deemed inappropriate, they do so at threat to their status as masculine or feminine and, in some cases, as a direct threat to their very lives. In the United States, it is considered perfectly masculine for a man to cut men’s hair for a

living and be called a barber. However, if a man chooses to focus on women’s hair and be a beautician or stylist, his masculinity will be called into question. Likewise, a woman, if she is strong enough, can do construction work or even drive 18-wheeled delivery trucks, but there will certainly be questions raised about her femininity.

This is true for a whole host of activities, even leisure activities. Men are still encouraged to engage in high-energy, even dangerous, leisure activities, whereas women are often relegated to the role of observer and supporter. Leisure time activities that are more home centered are still the realm of women. Even though it has been some 40 years since a retired professional football player mentioned publicly that he enjoyed knitting as a form of relaxation, there has been no mass movement of heterosexual men to take up the craft. Likewise, quilting, cross-stitch, and beadwork are still seen as feminine, and males who participate in these activities have their masculinity questioned. The same could be said of women who engage in woodworking and metal die and tool work. Women can and do participate in these activities, but not in large numbers and not without questions being raised about their femininity.

Finally, when we move back into the area of sexuality, the appropriate roles for men and women are also dictated. The influence of Victorian era mores still lingers in modern ideals about appropriate sex behavior. Men are supposed to be the pursuers and women the prize. Men are to be the aggressors and women more passive. Men who have many sex partners are raised in esteem, whereas women who engage in similar behavior are looked down on. These attitudes are changing slowly but still persist.

## IDENTITY

Throughout much of Western history, it was assumed that boys grow up to be men and girls grow up to be women. Occasionally, there would be a notable person who attempted to buck this trend, but for the most part, men were considered men and women considered women. Even if they engaged in what would be considered by today’s standards homosexual behavior, they were still considered to be men and women and for practical purposes heterosexual. That is to say, that merely participating in certain acts did not change one’s identity.

It was not until the late 19th century when science turned its eye to the study of the human mind that the discussion of individual differences emerged and that

homosexual behavior began to be seen as more than just activity but an identifiable malady. Thus, males with a propensity toward same-sex erotic behavior were seen to be suffering from sexual introversion. As with the naming of many diseases, the person soon became the disease. Men with this “condition” soon became known as “introverts.” The focus was still on behavior, but the behavior now defined the man.

Recall that during this time, even heterosexuality or nonprocreative sex was considered a malady. It was the expansion of the “sex for pleasure” ideology and possibly one entertainer’s play on words that helped to usher in the modern heterosexual identity. By proclaiming to be a raging heterosexual in a vaudeville routine, a comedienne helped bring heterosexuality out of the closet, so to speak. The drive and growth of the identity was probably more as a reaction to the growth of homosexuality as an identity. After the Kinsey report revealed that a large number of men have participated in at least one homosexual act in their lifetime, many men felt driven to proclaim their heterosexuality and deflect any doubt by engaging in masculine activities and establishing a solidly heterosexual lifestyle.

This pressure greatly increased after 1969, and the Stonewall riots gave rise to “gay pride.” This, along with the women’s liberation movement, challenged men who were not gay, or who greatly feared even the remote possibility of being mistaken for homosexual, to assert their heterosexuality. During the past 40 years, there has been a decided shift in which activities are considered masculine and which activities are considered feminine. Thus, it has become increasingly difficult for males in the United States to firmly establish their heterosexual identity. For women, too, there has been some confusion in this area. Does she really want to give up the privileges that came with being able to stay at home with the kids or the other benefits of the previous gender role expectations? Does he want to take on the roles that men have played for the past 150 years of the industrial age and join the “rat race”? One response for both sexes is to retreat to the standards of an earlier day. Try to reestablish the nuclear family with mom at home and dad in the workplace. In some cases, this has caused men to become misogynistic and shun all things feminine. In other cases, society has had to redefine what it means to be a man. Taking care of one’s family has become a hallmark of “manhood” on par with obtaining sex from several women, being strong and athletic, or earning lots of money.

As the earning power of women has grown and some women have moved into becoming the chief

wage earners in their households, some men have become the caretakers of children. These men fight a daily battle to maintain their identity as virile heterosexual males. It is not enough to say that you are married and that you have fathered offspring (although for some men that is enough), men in the 21st century are having to reestablish what exactly is the masculine identity. In similar manner, women are having to decide just how far they are willing to encroach on previously defined male territories and how much traditional femininity can they bring along and how much they have to give up. In these days of diminishing division of labor, sex for pleasure versus procreation, and individuals even deciding not to procreate, the definitions of heterosexuality may have to revert to the orientation toward the opposite sex. As acceptance of other forms of sexual relating (e.g., homosexuality, bisexuality, transgenderism) continues to grow, maybe even the ubiquitousness of heterosexuality will wane to the point at which it is just one option among many.

—Herbert L. Coleman

## HETHERINGTON, E. MAVIS (1926 – )

---

Eileen Mavis Hetherington is Professor of Psychology, Emeritus, at the University of Virginia. Her distinguished career of more than 50 years is highlighted by contributions to research on childhood psychopathology, personality and social development, and stress and coping, but she is perhaps best known for her work on the effects of divorce and remarriage on child development.

Hetherington received her PhD from the University of California at Berkeley in 1958. She taught at Rutgers University and then at the University of Wisconsin before arriving at Virginia. Although she retired in 1999, she has continued to be an active scholar, writing and speaking around the world. Hetherington is quick to note that her accomplishments came at a time when it was not common for women to excel in academia, and that her path was smoothed by her parents, her husband John, and their three children.

Hetherington began her research career looking at sex role stereotyping in families, documenting fathers' influences on their children. This sparked her research in father absence in the early 1970s. In 1972, she began the 20-year Virginia Longitudinal Study of Divorce. Hetherington and her colleagues reported the somewhat controversial findings that, although divorce is certainly harmful to children, it is not as devastating as most theorists assumed. Her claims that children in divorced and stepfamilies can continue to function within normal ranges continues to provide fodder for discussion, as evidenced by the reaction to her 2002 book, *For Better or Worse: Divorce Reconsidered* (coauthored by J. Kelly). Recently, she collaborated with Robert Plomin and David Reiss on the Nonshared Environment of Adolescent Development study investigating biological influences on family processes and individual differences.

An eminent teacher and scholar, Hetherington has received numerous honors, including the State

of Virginia's Professor of the Year award and the G. Stanley Hall Distinguished Scientist award from Division 7 (developmental psychology) of the American Psychological Association (APA) in 1986, the APA's Distinguished Teaching in Psychology Award in 1987, the Distinguished Scientist Award from the Society for Research in Adolescence in 1989, the Distinguished Scientist Award for Research Contributions to Family Therapy from the American Family Therapy Association in 1992, the William James Distinguished Scientist Award from the American Psychological Society in 1993, and the Burgess Distinguished Scientist Award from the National Council on Family Relations in 2000, among others. In 2004, she was awarded the APA's Distinguished Scientific Contribution Award (at the same time, her former student, Thomas G. O'Conner, received the Award for Distinguished Scientific Early Career Contribution to Psychology, a fact that pleased her very much).

## HIGH BLOOD PRESSURE (HYPERTENSION)

---

High blood pressure (hypertension) is a sustained elevation of blood pressure greater than 140/90 mm Hg. With hypertension, the pressure within the arteries of the body is too high and causes damage to the eyes, kidneys, brain, and heart. The damage can be prevented with proper treatment, consisting of diet, exercise, weight loss, and sometimes medications.

Hypertension affects 50 million Americans (one in four) and 1 billion people worldwide. Of the 50 million Americans with hypertension, 30% do not know they have the disease, and only one fourth sustain adequate blood pressure control (less than 140/90 mm Hg). One reason that people with hypertension may not be aware that they have the disease is that high

blood pressure generally has no symptoms unless it is extremely high. For this reason, it is often called the “silent killer.” The first indication of long-standing hypertension may be symptoms of damage already done to the body, such as a stroke or heart attack.

Hypertension increases with age. It is more common among African Americans than whites. As the American population ages and obesity reaches epidemic proportions, the incidence of hypertension is predicted to rise. Obesity is thought to be a major contributing factor to hypertension in children and adolescents, and the incidence of obesity in children has risen sharply in recent years.

## CLASSIFICATION OF HYPERTENSION

A blood pressure reading consists of two numbers. The top or higher number, known as the *systolic blood pressure*, measures the pressure in millimeters of mercury (mm Hg) within the arteries when the heart is pumping or contracting. The bottom number, or *diastolic blood pressure*, measures the pressure when the heart is at rest. Elevation of either the systolic or the diastolic blood pressure (or both) constitutes hypertension. Elevation of the systolic blood pressure is associated with more complications than elevation of the diastolic blood pressure. Historically, it was believed that an elevated systolic blood pressure was “normal” as individuals grew older and that an increased diastolic blood pressure carried a worse prognosis. However, recent studies have proved this to be false. These studies show that elevation of the systolic blood pressure causes more damage than elevation of the diastolic blood pressure.

Blood pressure readings in any individual vary depending on time of day, psychosocial factors, and degree of physical activity. One elevated reading does not mean that a person has hypertension. Instead, the average of two or more readings made several weeks apart must be elevated in order to confirm the diagnosis.

Individuals with blood pressure readings averaging less than 120/80 mm Hg are considered to be “normal” or “optimal.” Those with blood pressure readings averaging between 120 and 139 for the systolic or 80 and 89 for the diastolic are labeled as *prehypertensive* because about half of these individuals go on to develop hypertension. Stage 1 hypertension is defined as a systolic blood pressure of 140 to 159 or a diastolic blood pressure of 90 to 99. Stage 2 hypertension is blood pressure averaging greater than or equal to 160/100 mm Hg (for either number or both).

## CAUSES AND RISK FACTORS FOR HYPERTENSION

In about 95% of all cases of hypertension, no cause can be found. This type of hypertension is known as *primary hypertension*. In the other 5% of cases, *secondary hypertension* occurs, in which a specific cause can be established and in many cases treated or corrected. After the treatment of secondary hypertension, the person no longer has the disease. Examples of secondary hypertension include pregnancy-induced hypertension, thyroid disorders, and narrowed arteries leading to the kidneys.

Most affected individuals have *primary hypertension*. Although no exact cause has been established, certain risk factors have been identified that are associated with the disease. Individuals who possess one or more of these factors have a higher chance of developing hypertension than those who do not. Risk factors for hypertension include age (hypertension increases with age), gender (hypertension occurs more frequently in men younger than age 55 and women older than age 55), family history of hypertension, obesity, race (African Americans and Mexican Americans have increased rates of hypertension), physical inactivity, smoking and other tobacco use, diabetes, and excess alcohol intake (more than two drinks a day for men and one drink a day for women). Experts disagree on the role stress plays in the development of hypertension. Now it is generally believed that it is not the degree of stress, but how one handles stress, that contributes to hypertension. Although some risk factors cannot be changed, many are modifiable, and altering them can decrease the chances of developing hypertension. For example, if an obese individual loses weight, that person may never have an increased blood pressure.

## COMPLICATIONS OF HYPERTENSION

If untreated, hypertension can lead to debilitating complications or even death. In general, the higher the blood pressure, the greater the number of complications in the body. The damage usually occurs in four target organs: the brain, eye, heart and blood vessels, and the kidney.

### Brain

Uncontrolled hypertension is a leading cause of stroke in the United States. Sustained high blood pressure weakens the walls of arteries in the brain

causing a rupture of a blood vessel. This rupture causes a cerebral hemorrhage or stroke. Hypertension also causes hard, rough, irregular deposits on the interior of arteries. These rough areas promote the formation of blood clots, which can block the blood supply to certain areas of the brain and cause a stroke.

## Eye

Tiny blood vessels in the back of the eye (retina) can rupture with uncontrolled hypertension, leading to decreased vision or blindness. Individuals with hypertension should have a dilated eye exam by an ophthalmologist at least once a year to determine whether damage is occurring. Laser treatment can often correct this condition.

## Heart and Blood Vessels

Uncontrolled hypertension can lead to a heart attack or heart failure. When the blood vessels become damaged with hardened and rough deposits (called *arteriosclerosis*), blood flow in the heart and the rest of the body decreases. The heart must pump harder to meet the needs of the body. Eventually, the heart enlarges to try to meet these demands, and it may become exhausted and fail to pump adequately. This condition is called *heart failure*. Symptoms of heart failure include shortness of breath, cough, and swelling of the legs.

When the blood vessels in the legs are narrowed, the person may experience pain in the leg muscles when walking. The pain may then disappear with rest. Narrowed arteries in the neck vessels promote the formation of clots, which can travel to the brain and cause a stroke.

## Kidneys

Hypertension can cause narrowing or rupture of blood vessels in the kidneys. When this happens, the kidneys are unable to filter wastes and kidney failure may result. The person will need dialysis (removal of body wastes by a machine) several times a week or kidney transplantation.

## TREATMENT OF HYPERTENSION

Although hypertension can cause life-threatening damage to the body, treating and controlling hypertension lessens or eliminates complications. The goal of therapy is to reduce death and disability by sustaining a blood pressure less than 140/90 mm Hg. In

people with kidney disease or diabetes, the goal blood pressure is less than 130/80 mm Hg.

To attain these goals, the person with hypertension should immediately begin lifestyle modification efforts: consume a diet low in sodium and rich in potassium and calcium, stop using tobacco, exercise 30 minutes a day, and consume moderate amounts of alcohol. Often, lifestyle modifications alone are enough to bring the blood pressure down to the goal. But if they do not, medications may be added. Several types of antihypertensive medicines effectively reduce blood pressure. Medication selection will be based on several factors, including the presence of any other diseases, such as diabetes. Often, a diuretic, a medicine that reduces fluid in the bloodstream, is the first one chosen. Most people require two or more types of drugs to reach the target goal. These medications do not cure hypertension, but they lower the blood pressure so that damage to the body does not occur. Therefore, blood pressure medications must be taken for life.

The evidence for treating hypertension to avoid complications is quite compelling. Why, then, do many individuals remain untreated or undertreated for hypertension? First, they may not know they have the disease. They do not feel ill because there are usually no symptoms of hypertension. Next, people with hypertension may not be able to afford the medications. Many people in the United States lack adequate health insurance and must pay full price for all prescriptions. These can be quite expensive in some cases. Sometimes, blood pressure medications make the person feel weak or dizzy. Because most people do not feel ill to begin with, they see no reason to take a medicine that may make them feel bad. Then, many people fear impotence from taking blood pressure medications. In fact, the incidence of this side effect is extremely low. If it does occur, the category of medicine can be changed to another type less likely to cause problems.

Adequate public education should focus on the dangers of hypertension and the lifestyle modifications to prevent it altogether. Screening programs should target persons of lower socioeconomic status who rarely seek health care because they lack health insurance. These measures are the best preventive health care to avoid damage from this very common disease.

## HIGH-RISK INFANTS

---

Tremendous advances in medical technologies and the emergence of neonatology as a medical specialty have led to the increase in the number of surviving high-risk infants. The developmental status of these children is of great concern to a wide range of professionals. Special educators, school psychologists, developmental psychologists, early childhood educators, and speech and language pathologists are now dealing with a new category of special children. Although the physician is primarily concerned with mortality and morbidity factors, other professionals are interested in developmental performance, family concerns, speech and language development, and later school achievement.

### DEFINITIONS, FACTORS, AND INCIDENCE

The term *high risk* encompasses a class of infants who have been exposed to any one of a number of medical factors that may contribute to later developmental delay. These are infants who have been subjected to a potent array of potentially debilitating conditions. Children are identified as being at high risk for developmental difficulties if they experience problems before, during, or after birth that are known to be associated with later difficulties in development. Reviews of the high-risk population can be confusing because of the multiple and overlapping factors that place an infant at risk.

### Clarification of Terminology: Birth Weight and Gestational Age

Gestational age and birth weight are most often mentioned in high-risk issues and are defined using World Health Organization criteria. These are barometers for developmental risk and provide an objective means of establishing risk status. A full-term infant is one born between 37 and 41 weeks of gestational age, and infants who are born before 37 weeks of gestational age are defined as premature. Premature infants usually weigh less than 2,500 g (5 lb, 8 oz) and constitute 12% of all births in the United States. Infant mortality rises from five times normal at 37 weeks of gestational age to 45 times normal at 32 weeks of gestational age. Most of the problems associated with prematurity occur in infants with birth weights of 1,500 g (3 lb, 5 oz) or less, usually in those born at less than 32 weeks of gestational age. Incidence rates for neurological and developmental delay for this group range from 18 to 80%, depending on the assessments used.

Birth weights of less than 2,500 g are labeled low birth weight, and very low birth weight is designated for infant weights less than 1,500 g. Together, birth weight and gestational age provide a more accurate means of determining an infant's risk status. Infants born before term are usually also low in birth weight. It is important to distinguish between those infants whose birth weight is close to what would be expected, given their early delivery date, and those whose weight is lower than would be expected. In addition to classifications of appropriate for gestational age (AGA) and low birth weight (LBW and VLBW), another classification of small for gestational age (SGA) combines the two terminologies. Full-term infants may also be SGA, and therefore at risk for postnatal difficulties. Risks are greater for SGA babies than for babies born early but appropriate in size. Generally, the risk for infant mortality increases as birth weight and gestational age decrease.

Extreme prematurity and very low birthweight are known to be associated with developmental problems. Developmental problems may be temporary delays or impairments associated with illness or environmental conditions, or they may be indications of long-term developmental conditions. Researchers have noted that roughly 15% to 40% (depending on how the group is selected and what kind of problems are considered) of extremely premature infants have

significant, long-term medical or developmental problems.

In summary, a high-risk infant is an infant who, because of low birth weight, prematurity, serious medical complications, or adverse environmental conditions, has a greater than average chance of displaying developmental delay or later cognitive or motor deficits or a combination of these in the neonatal or postnatal period. The definition of the risk is necessarily broad because there is increasing evidence that the quality of familial, medical, therapeutic, and educational care that is provided to the child immediately following birth has great influence on the quality of that child's life.

### Incidence of High-Risk Infants

Before the advent of the neonatal intensive care unit (NICU), the risk for neonatal death was 30 times greater for low-birth-weight infants. The NICU has greatly modified the concept of risk because many more infants now survive because of the environment it provides immediately following birth. This is reflective in the changes from neonatal mortality statistics (death within the first month of life) in the 1960s (21 deaths per 1,000 births); the 1970s (15 deaths per 1,000 births); the 1980s (18 deaths per 1,000 births); and the 1990s (5 deaths per 1,000 births). The creation of the NICU has reduced the neonatal mortality rate but at the same time increased the number of surviving infants who are at risk for developmental delays. Saving very small and very sick infants results in a greater incidence of handicapping conditions. Estimates of incidence of high-risk infants range from 5% to 15% of all newborns, depending on the classification criteria. The inclusion of congenital anomalies in the description helps to differentiate between earlier and later babies, with the incidence of anomalies at 2.3% for babies born at 40 or 41 weeks and 30% for babies born before 28 weeks of gestation.

Infants at risk for delay also tend to come from nonwhite families, and this is related to socioeconomic status. For example, in the new millennium, black infant neonatal mortality rates (13%) continue to be almost twice the rate of white infants (8%). These statistics reflect the lack of prenatal care available to low-income families in the United States as well as the risk factors related to mother's age and behavior during pregnancy; these will be discussed later in this entry.

**Table 1** Survival Estimates for Infants in Intensive Care

<i>Completed Weeks of Gestation at Birth</i>	<i>Survival (%)</i>
21 and less	0
22	0–10*
23	10–40
24	40–70
25	50–80
26	80–90
27	>90
30	>95
34	>98

\*Most babies born at 22 weeks of gestation are not resuscitated because survival without major disability is so rare.

### Survival

Many factors increase an individual baby's chances of survival. The most important of these are the baby's gestational age and weight; the absence of breathing problems; the absence of congenital abnormalities; and the absence of other severe diseases, especially infection. In the smallest infants, gestational age is usually most important because it determines whether the infant's organs, particularly the lungs, have developed enough to allow the baby to live within the limits of current technology.

General estimates of survival for live-born infants who receive neonatal intensive care in the United States in the new millennium are noted in Table 1.

## ASSESSMENT

### Immediate Neonatal Assessments

There are special exams conducted in the NICU that examine a high-risk infant's behavior to get a picture of how he or she acts and reacts to stimuli and the surroundings. What is learned from the exam can be used to make the baby's world fit his or her own special needs. The exams assess if and how quickly the baby becomes awake and alert; how the baby soothes himself or herself when upset and how easy it is for an adult to soothe the baby; the baby's movement patterns; and how much handling the baby can tolerate without becoming upset.

The Apgar scoring system measures a newborn infant's physical responsiveness, development, and overall

state of health shortly after birth. The exam measures heart rate, breathing, muscle tone, reflex response, and color, which reflect the newborn's adaptation to life outside the womb. Because of their early birth, high-risk premature babies are more likely to have lower Apgar scores. Depending on the maturity of the infant's lungs, the newborn may have trouble breathing. Breathing and heart rate can be assessed using a cardiorespiratory monitor. Incubators are also used to warm premature babies who have less body fat.

The Brazelton Neonatal Behavioral Assessment Scale (NBAS) is an interactive assessment of the newborn's behavioral repertoire and neurological responses during the neonatal period. Assessments of physiological, motor, state, interactive and attentional, and self-regulation functions are made, and observations of the infant's communicative signals are included.

Routine developmental screenings during the first 2 years are then plotted from the infant's estimated due date rather than the infant's birth date. The Denver Prescreening Developmental Questionnaire, the Denver Developmental Screening Test, and the Gesell Screening Inventory are all examples of standardized developmental tests. These forms of screening do not replace neurologic examinations. Because of this, standardized examinations, such as the Neonatal Neurodevelopmental Examination, have been developed and are used primarily by developmental pediatricians and pediatric neurologists. The Neonatal Neurodevelopmental Examination assesses postural reflexes and muscle tone, cranial nerve and motor function, sensory responses, and behavior.

### Long-Term Assessments

For long-term developmental assessments beyond infancy, it becomes difficult to make a list of definitive developmental milestones that must be met by a certain date. The range of how children do things and when they accomplish developmental tasks becomes broader, largely owing to the increasing influence of culture and experience. The results from testing infants and young children do not reveal how they may do at school age or later in life. There are a number of reasons it is difficult to predict later levels of functioning from testing done with infants and young children, including the fact that the most critical skills tested in older children and adults do not yet exist in infancy.

Another reason why infant tests cannot predict future success involves the importance of later events

in determining a child's progress. For example, a young child may have a sensory impairment or motor problem that would profoundly affect performance and limit access to what he or she knows. Later correction or adaptation for the impairment (e.g., glasses, hearing aids, braces) may provide a dramatic difference in the course of the child's progress.

Finally, developmental problems tend to emerge slowly over time as higher levels of brain functioning are called into use. Injury to areas of the brain important for later functioning may not be apparent in an infant or very young child. It is important to look at high-risk children frequently over time to identify delays in their development compared with age mates. Identifying delays early allows for investigation into causes and referral to therapies that may be able to improve or stabilize skills. It is also helpful to compare a child's current performance to his or her previous pattern of development to document the rate of change and recovery being made.

In general terms, developmental evaluations assess how well a child is developing for his or her age. A child's test scores are compared with the average scores for children of the same age. The areas tested include language skills, attention, social behavior, thinking and problem solving, and fine and gross motor skills. These evaluations should also take into consideration the quality of the child's performance, including completion, approach, ease, frustration, and general response, which can help in understanding how the child may be helped most successfully.

### PHYSICAL COMPONENTS OF HIGH RISK

The initial physical elements of high-risk status are often discussed as risk factors. Risk factors are defined as characteristics of the infant, the caregiver, or the life situation that have the potential for harming development. When risk factors are in operation, the result may be poor socialization, later problems with mental health, and poor school performance. Risk factors usually occur in multiples, making it difficult to discover the nature of their effect on the infant's development. Certain risk factors tend to be accompanied by specific other factors, which is termed *comorbidity*. For example, a baby with fetal alcohol syndrome is often being cared for by a mother who continues to abuse alcohol, and the mother's negligence and abusiveness are comorbid with the infant's

physical condition. Not all the risk factors for an individual are necessarily present at birth or even at age 2. Although early risk factors can be powerful, later events can play a real part in determining how well a child or adult functions.

### **Birth Risk Factors**

Although many factors may place an infant at risk for developmental disabilities, those related to the birth process are most closely associated with later difficulties. Infants born too soon or too small are at risk for a number of problems. First, they may have difficulty adapting to the postnatal environment owing to their less mature body organs, especially their lungs. Second, they may have restricted growth potential. Third, they may exhibit certain biochemical or physiological disturbances that place them at risk for brain damage. Finally, they may be born into an environment in which certain socioeconomic factors combine with the physical factors of prematurity to double their chances of risk.

### **Maternal Factors**

Maternal histories that include premature births, repeated miscarriage, cervical incompetence, still birth, uterine and placental abnormalities, intrauterine growth retardation, blood group problems, unexplained fetal or neonatal death, and genetic disease or chromosomal disorders may lead to higher risk potentials. Substance abuse (including smoking and alcohol use) and malnutrition are other factors that have been well linked to poor birth outcomes. Medical conditions can also contribute to early labor, including premature rupture of the membranes, which can place mother and baby at increased risk of infection; prolonged labor; uncontrolled delivery; or an abnormal presentation.

### **Immediate Postbirth Physical Concerns**

High-risk preterm infants can experience a higher rate of respiratory, neurological, and gastrointestinal problems that affect general developmental problems. A number of physical functions affect each other, and when one goes wrong, other linked physical problems may follow. Immediate postbirth concerns include the monitoring of immature lungs that are likely to suffer from respiratory distress syndrome and periods of apnea. Respiratory distress syndrome arises when the

infant's lungs are too immature to successfully guide the exchange of oxygen and carbon dioxide. Unfortunately, mechanical ventilation, which essentially blows air under pressure into the lungs, can, in turn, cause irritation and long-term lung damage.

Poor fetal circulation may occur, bringing on hypoxia. At times of hypoxia, the infants' body directs blood to the brain and away from the lower part of the body. As a result, the poor supply of blood to the intestines may lead to necrotizing enterocolitis (gangrene of the intestines), which must be treated surgically. Brain damage as a result of brain bleeds can be related to the difficulties in breathing and in blood circulation. Finally, premature high-risk newborns are also likely to have dangerously high bilirubin, which can be treated with medication and with phototherapy using ultraviolet light.

In summary, high-risk infants may spend many weeks in the NICU, where they are necessarily subjected to many invasive procedures; they must often be fed by tube through the nose or mouth, have their breathing artificially assisted, and receive medications or fluids intravenously. Technology has become so advanced that most infants could be kept alive indefinitely with assistance in breathing, artificial feeding, and even kidney dialysis. This calls into consideration difficult questions of whether life alone is the highest priority, or whether quality of life is a greater concern.

In addition to these aspects, there may be complications that some prematurely born children experience in the NICU. Continued short- and long-term health problems for premature infants can include feeding and growth problems because of an immature digestive system, anemia, infections, and general failure to thrive.

For any infant, it is impossible to predict the likelihood of a significant handicap (moderate or severe mental retardation, inability to walk without assistance, blindness or deafness). However, some factors increase the risk for these handicaps: extreme prematurity, identifiable brain abnormalities, and lengthy periods of illness. It is necessary to understand the limitations of trying to use information available during infancy and early childhood to predict later development. Some aspects of development are affected by experience; other aspects of development will unfold at the rate they would have if the child had been born at term.

### **Continued Childhood Disabilities**

Children who are born prematurely have an increased risk for early brain injury that is often associated

with developmental difficulties. Motor symptoms are usually the earliest manifestation of early neurological injury. These symptoms may resolve as the child recovers, or they may eventually be diagnosed as cerebral palsy. Although early identification is necessary for early intervention, it can be very difficult to establish clear diagnoses of neurodevelopmental problems in developing infants.

During childhood, health difficulties can continue in the form of frequent illnesses. Minor disabilities during school age may result, which include short attention span; specific learning problems in school, such as difficulty with math or reading; language delays; low intelligence test scores; deficits in motor coordination and school learning; and poor emotional adjustment. Generally, children with these relatively minor disabilities lead normal lives.

### **SOCIAL COMPONENTS: FAMILY ISSUES**

During this stressful time of infant diagnosis, parents may unknowingly worsen the situation. Separate from the physical elements are the social elements of high risk. From the very beginning, there are many reasons to be concerned about the high-risk infant's early social environment. In most physical high-risk situations, parents are unable to be with their babies in the same way, particularly if life-supporting technology is involved. Hospital isolettes provide the baby support, but the necessary physical separation can interfere with parent-infant bonding. Hospital procedures can delay opportunities to hold and interact with the baby in semiprivate settings.

Parents may have their own personal concerns around past experiences that can affect bonding with the high-risk baby. Even the baby's characteristics can affect bonding, such as the baby's health, physical defects, alertness, and responsiveness. Each of these has potential to interfere with eye contact or with facial expression, which are key to developing a bond between infant and parent.

Concerns about parental competence certainly overwhelm parents. These areas include providing physical care, physical protection, and psychological support; controlling, motivating, and regulating children's behavior; and teaching and providing knowledge and skills in a loving environment. These, in addition to the stress of having a high-risk infant, along with financial concerns, can add to these overwhelming feelings.

### **Psychosocial Concerns for Families**

In addition to bonding and social stressors, there may be psychosocial issues on the part of family members that can affect the high-risk infant. First, high-risk pregnancies and low birth weight are most common among low-income women, especially women of color. These mothers are more likely to be undernourished and live in conditions that expose them to harmful environmental influences such as pollution, unsafe housing, and chemical exposures. Further, they may have less access and experience more barriers that keep them from receiving the prenatal care necessary to protect them and their babies. Maternal psychological status during pregnancy can also be a risk concern, which may include unwanted pregnancy, lack of support, and psychiatric disorders. These psychological issues may manifest themselves in drug or alcohol use, mental illness, or depression. Other psychosocial concerns, including parental issues about attachment and loss, adolescent-aged parents, and extreme situations involving violence, can affect the social environment of an infant, whether high risk or not.

Second, a difficult infant may be so frustrating to the caregivers that they spend less time interacting with him or her. The infant's poor social competence may also put him or her at risk, particularly if the infant is incapable of expressing needs to adults. Risks are greater when the infant shows low readability, low predictability, and low responsiveness to adults.

Finally, experiences that occur by chance may also affect the family or infant alone. Sudden and too-frequent changes from familiar to unfamiliar situations can be stressful for the infant. Other extreme experiences, such as the death of a parent or separation after attachment has taken place, can negatively affect the infant. Risk is more evident when the separation is abrupt and prolonged, and can be seen in the infant in the forms of protest, despair, and then detachment.

### **Psychosocial Coping With Stress**

Caring for a premature infant can be a great challenge, which can naturally bring on anxiety about the baby's health and feelings of anger, guilt, or depression. Postpartum depression and physical recovery from birth, in addition to caregiving stresses, can lead

to overwhelming fatigue. Some suggestions for parents may help during this difficult time:

- Learn everything you can about your baby's condition. In addition to talking to your doctor and your baby's caregivers, read books on premature birth and look for information on the Internet.
- Take care of yourself, providing yourself with rest and good nutrition to feel stronger and better able to care for your baby.
- Seek good listeners for support, including partners, friends, family members, or premature baby support groups.
- Accept help from friends and family to help save your energy for your baby.
- Keep a journal. Record the details of your baby's progress as well as your own thoughts and feelings. Include pictures of your baby, so that you can see how much he or she is changing.

### STRATEGIES TO DECREASE RISK: INTERVENTIONS

Most high-risk premature infants eventually develop beyond any negative consequences associated with prematurity. Close attention to developmental needs can help lessen any long-term impact of the temporary developmental problems many premature infants experience. For children who develop long-term conditions as a result of early medical complications, immediate interventions can reduce the eventual level of *disability*.

#### Perinatal Services

Perinatal services must be provided as quickly as possible to minimize disability by identifying possible conditions requiring further evaluations, diagnosis, and treatment. Early intervention programs often take place in the neonatal nursery, at home, and at special centers. In addition to early screening assessments (reviewed earlier), special attention may be given to the handling of the newborn. A form of holding encouraged in many NICUs is known as *kangaroo care*, the skin-to-skin contact between infant and caregiver. This form of holding was adopted from countries where isolettes to keep preterm infants warm are scarce. Studies show that the mother's body temperature adjusts to keep the baby's temperature at the right level. The baby's breathing also becomes more even, and heart rate and blood oxygen levels stay steady. Also, giving the stable infant

gentle massage for short periods daily has been shown to help babies gain weight faster.

Perinatal services also may provide parents training in infant caregiving skills: when effective stimulation helps preterm babies develop, parents are likely to feel encouraged and interact with the baby more effectively. For example, home visit programs include multiple visits, during which physical exams and developmental screenings are administered by nurses. Evaluations of homes for infant safety, providing health and parent education, and reinforcing hospital discharge treatment instructions are also part of these programs. Nurses also provide referrals to other public health and community social services that can assist the family. At each visit, the infant's physical, developmental, psychosocial, cognitive, and emotional growth is assessed so that any need for further services can be identified quickly. Studies have found that those receiving home visits had fewer life-threatening illnesses, fewer hospital admissions, fewer intensive care admissions, and fewer days in the intensive care unit than those not receiving the program.

#### Developmental Care for the Newborn

Another widely used strategy for working with high-risk newborns is developmental care. Developmental care is designed to prevent the brain from being injured by intense or painful stimulation, and to provide the kinds of everyday experiences that will help the baby to develop normally. A major goal of developmental care is to protect the high-risk infant's brain and central nervous system, which control the five areas of development (physiological, motor, sleep/wakefulness, attention, and self-regulation) that are the base for the baby's motor, mental, and social development.

Studies of developmental care have shown that by making the NICU world more "baby friendly," some of these problems can be prevented. The physical environment can be changed to reduce the amount of sound and light, provide some support for the baby's position because he or she cannot get into a comfortable position alone, make treatments less stressful and frequent, and provide gentle handling by pacing the care according to how the baby reacts.

Through the developmental care approach, parents are taught to become attentive to the many ways an infant interacts with those around him or her: by looking,

listening, and touching and feeling. When the baby attends, he or she focuses on and follows things and makes eye contact. This approach can easily be incorporated into discharge planning from the NICU. Important aspects include the parents' involvement in their infant's care, plans for special needs such as oxygen and apnea monitoring, and teaching the parents special skills such as cardiopulmonary resuscitation.

With the realization that the parents are undergoing transitional stress that may interfere with their ability to learn, parental education is often reinforced after the infant's discharge. This educational programming includes developing parenting skills, helping parents build close affectionate ties to their infants so that they will be attuned to their babies' special needs, and encouraging the family to work together, particularly during crises and decision making.

### Continued Care for Toddlers

As the high-risk infants develop into toddlers, specific skill areas such as vision, speech, and hearing will continue to be examined as well as overall developmental performance. During this developmental period, preschoolers develop, modify, and master skills in the areas of motor performance, cognitive development, social awareness, and language functioning. Toddler intervention programs have the following general characteristics: (1) orientation to prevention of developmental delay; (2) orientation to changes in the infant's behavior, development, or relations with caregivers; and (3) focus on change within the family system to foster positive changes in the child.

### Prenatal Prevention

Perhaps the best treatment for preterm and low-birth-weight infants is before the actual birth. Prevention in the form of focused self-care, regularly scheduled prenatal care visits, proper nutrition, avoiding any exposure to tobacco smoke, avoiding alcohol and illegal substances, and control of chronic medical problems are all ways that women can help maintain a healthy pregnancy to the full term.

In summary, high-risk infants face many developmental challenges that are caused by multiple factors. Given the high numbers of high-risk infants in the United States, many public health strategies have focused on prevention and early intervention with hopes of encouraging and funding multidisciplinary

approaches to risk reduction during pregnancy and education of the general population about modifiable risk factors for and consequences of low birth weight.

## HIGHER EDUCATION

---

At the beginning of the 21st century, colleges and universities in the United States are among the most visible and highly regarded in the world—providing individuals from all walks of life the opportunity to pursue higher education. From the founding of Harvard College in 1636 to the present, the twin pillars of change and innovation have shaped and continue to inform the character, quality, diversity, and access to higher learning offered in this nation.

### CHANGE AND INNOVATION IN THE LATE 18TH AND 19TH CENTURIES

#### Establishment of New Institutions

##### *Public Institutions*

The first institutions of higher learning in the United States—anchored in the classical liberal arts curriculum offered solely at the undergraduate level—served the elite and were founded as secular institutions that prepared men for leadership in the American colonies as well as for careers in the ministry. This changed, however, in the late 18th and early 19th centuries as many states began establishing state institutions and, in 1819, the U.S. Supreme Court in the famous Dartmouth

College case drew a distinction between public and private institutions. As society became less agrarian and more industrial, public pressure grew on universities to meet the utilitarian needs of the expanding society throughout the 19th century. The new state universities gradually became increasingly responsive to society, especially through establishing so-called modern fields of study and conducting research that contributed to the “public good.” They were aided in these efforts by the passage of the Morrill Federal Land Grant Act of 1862, which provided grants to each state for support of at least one college to teach subjects related to agriculture and engineering.

### ***Women’s Colleges***

As state universities were flourishing during the second half of the 1800s, certain groups were being denied their benefits. Women were one such group. Although Oberlin College, a liberal arts school in Ohio, first admitted women in 1837, most eastern colleges refused to admit them. Thus began the women’s college movement, with the founding of Vassar (1865), Wellesley (1875), and a host of other all-female schools. Women in these schools were taught subjects—such as grammar, geography, and household arts—aimed at preparing them to be housewives, mothers, and school teachers, and their proponents argued that these schools met the demand for higher education without sacrificing a woman’s femininity. There were 119 women’s colleges by 1900.

### ***Historically Black Colleges and Universities***

In the years following the Civil War, most institutions closed their doors to blacks, just as they did to women. New educational opportunities were created, however, with the passage of the Second Morrill Federal Land Grant Act of 1890. This law specifically prohibited payments of federal funds to states that discriminated against blacks in admission to their tax-supported colleges; states using federal funds had to either make their schools open to both blacks and whites or make money available for segregated black colleges to serve as an alternative to white schools. This led Southern states to establish dual systems of higher education, and to the founding of 17 land-grant colleges that had the principle mission of educating black Americans. These schools came to be referred to as

*historically black colleges and universities (HBCUs)*, and today there are 103 of them in the United States.

## **Change and Innovation Within Institutions**

### ***Faculty***

The mid-19th century saw not only a transformation in the types of institutions that were educating our citizens, but also a change in who was teaching them in the classroom. Especially beginning during the late 1870s, faculty began to be trained in specific disciplines and took on new careers as full-time instructors; they were no longer preparing for the ministry or for leadership. By the late 1870s, only 15% of faculty engaged in clerical activities, whereas more than half were engaged in their fields of specialization.

## **Vertical Expansion: Growth of Graduate Education**

Just as faculty were becoming specialists in selected fields, students began to further their education by obtaining master’s and doctoral degrees. The University of Michigan awarded the first master’s degree in 1851, Yale awarded the first PhD in 1861, and graduate education began to grow rapidly after the Civil War. Especially during the latter part of the 19th century, many colleges would become “universities”; many state colleges were transformed into universities, and some liberal arts colleges were reorganized into universities—institutions that offered advanced study leading to master’s or doctoral degrees.

### ***Horizontal Expansion in the Curriculum***

As more institutions served an increasing number—and diversity—of students in the mid-1800s, new fields of study developed beyond the traditional fields. Modern subjects like mathematics, sciences (physics and chemistry), and fine arts were introduced, as was the elective system; students could now choose almost all of their courses and specialize in their choice of fields of study. The study of the liberal arts and sciences and professional fields was encouraged as the universities increasingly committed to advanced study and the advancement of knowledge through research.

## CHANGE AND INNOVATION IN THE 20TH CENTURY

### Establishment of New Institutions

#### *Two-Year Colleges*

Although the 19th century had seen a growth in state institutions and women's colleges, before the 20th century, no more than 4% of the college-aged population attended college. This did not mean that there was not a need for mass higher learning. The beginning of the 20th century saw a dramatic increase in the need for trained workers, growing public concern about advancing equality of opportunity, and concern about the inaccessibility of many 4-year colleges. These factors, combined with the desire of small and medium-sized cities without major institutions to bring mass higher education to their areas, led to the proliferation of 2-year, or "junior," colleges. Students needed training, but many were unable to attend state universities or private colleges, and 2-year colleges gave them another option when it came to access to higher education. By 1948, there were 650 junior colleges, and today there are more than 1,200. These schools focused on offering their students a collegiate education and "academic transfer" programs for the first half of the century, but since the 1950s, they have increasingly emphasized programs such as vocational and career education, continuing education, and remedial education.

#### *On-Line Colleges*

Today, the most accessible means of mass higher learning is on-line, or "virtual," higher education. On-line courses are often composed of students from all over the country—or the world—communicating via e-mail or video conference without ever setting foot on a physical college campus. Students in a mathematics class can, for example, simply dial in from a computer, watch a video of the lecture, and do their homework on-line. Initially, on-line education was often viewed as a preferred mode for meeting the needs of nontraditional, adult learners who needed to update their technological knowledge quickly, or who simply wanted intellectual enrichment. Increasingly, however, colleges and universities are incorporating on-line programs in their distance education and "traditional" programs, thereby allowing many more students access to higher education.

The University of Phoenix is the most well-known and oldest of the on-line institutions. It was founded in 1978 to provide educational programs for working adults and enrolled about 40,000 at that time. It has granted more than 370,000 degrees, most of which are in the fields of business and education.

### Change and Innovation Within Institutions

Whereas 2-year colleges increasingly emphasized vocational and career education after World War II, a growing interest in the professions led most universities to offer a much greater range of undergraduate professional programs, from the arts to journalism to pharmacy and communications. And although most professional study took place at the undergraduate level through the first half of the 20th century, many universities began establishing graduate professional programs in such fields as architecture, business, and education. In addition, university presses and scholarly journals were founded to provide outlets for the results of investigations, and professional associations were created to disseminate research and scholarship in the various fields of study.

### Contemporary Portrait: Diversity in Higher Learning

According to the *Almanac of the Chronicle of Higher Education*, more than 15 million students are enrolled in America's institutions of higher learning. In 2001, more than 1,200,000 undergraduate degrees were conferred, 57% of which went to women. At the beginning of the 20th century, there were almost 591,000 full-time faculty members spread across 4,197 institutions of higher learning. Women account for about 56% of college students, and about 28% of all students are minorities.

As these statistics show, institutions of higher education in the United States are thriving. Two-year colleges have become increasingly important in recent years as an increased need for vocational training, for both adults and traditional students, has resurfaced in the marketplace. On-line and distance education continue to grow at a very fast pace: in 2001, more than 127,000 distance education courses were offered at more than 2,320 institutions—with traditional institutions adapting their programs to match what schools such as the University of Phoenix already provide its

students, not least for fear that they will lose potential students to programs that are more convenient and accessible. Finally, today's university has become a multipurpose "multiversity" that serves diverse purposes and peoples and has a close connection to society. There are more than 460 such diverse "universities," virtually all of which offer their students a wide variety of programs of study and activities.

## CONCLUSION

Anchored in the legacy of change and innovation, our system of higher education has greatly enhanced the quality of opportunity for many diverse students while concurrently advancing both high-quality curriculum and diversity through higher education. At the same time, there continue to be many external and internal pressures as higher education moves further into the 21st century. Among them is a growing public consensus that the private benefits of higher education are greater than the public benefits, and, in turn, many states and institutions are witnessing significant losses of public funding. Among many others, the challenge of maintaining quality and a commitment to equality of opportunity will clearly advance change and innovation across the higher learning environment. As it has in the past, higher education will need to build on its legacy and embrace change and innovation throughout the 21st century.

## HISPANIC AMERICANS

---

Americans of Hispanic descent include people of any Mexican, Central and South American, and Caribbean nationality. Hispanics in the United States are a diverse population with great within-group and between-group differences. Many are relatively acculturated to mainstream American values, whereas others are more oriented toward their own traditional culture. Most (60%) of Hispanics in the United States were born in the United States, speak English, and aspire to achieve many of the same goals as others in the United States, such as earning a decent wage, providing a comfortable home to their children, and having their children excel educationally. In general, Hispanic Americans have a strong work ethic, are passionate about life, and are highly committed to their families and children. Their ethnic culture is rich in both tradition and customs, and their growing presence in the United States is reflected by their increasing influence in popular culture and in contemporary political discourse.

The term *Hispanic* stems from the word *Hispania*, which originally referred to the Iberian Peninsula that is now Spain. The U.S. government first used the term for the 1980 census count in reference to individuals with Latin American ancestry residing within the United States. Individuals of Spanish descent in the United States also may be included under the term. The ethnic label, *Hispanic*, however, is not universally accepted by all, and individuals rarely refer to themselves in that manner in their countries of origin. Different groups, and even individuals within the groups, have varying opinions regarding their preferred term for self-identification. Some individuals, particularly in the West, prefer "Latino/a" and view Latino/a as a more progressive ethnic label. Yet, Latino/a is opposed by some because they believe the term reflects the Roman empire that had conquered Spain, or because the term Latin generally refers to various southwestern European countries. Moreover, both terms (Hispanic and Latino/a) are polemic because neither term conveys the heterogeneity among people of Latin America. Nevertheless,

ethnic nomenclature is arbitrary and constantly changes across time and geography.

During the past 20 years, the Hispanic American population has grown tremendously in the United States. The U.S. Census of 2002 reported that there were 37.4 million Hispanics living in the United States, in comparison with 22.4 million in 1990, and 17 million in 1985. In fact, Hispanics have surpassed African Americans in number and are now the second largest ethnic group in the United States. As of 2002, about 66.9% of Hispanics living in the United States were of Mexican heritage, 8.6% of Puerto Rican descent, and 3.7% Cuban; the remaining 20.8% were mostly from various countries in Latin America. Some areas in the United States, such as Central Florida, for example, recently have experienced a large influx of South Americans, which is altering the Hispanic landscape of Florida. Not reflected in the national figures are the illegal or undocumented migrants who were not adequately counted. Although accurate figures are hard to obtain, it is estimated that about 7 million illegal Mexican immigrants currently live in the United States. Because of their illegal status, they often are taken advantage of and occupy low-paying jobs, working in agricultural settings, factories, and as domestic workers.

Collectively, the Hispanic American population is exceedingly young. The average age of Hispanics is close to 9 years younger than that of non-Hispanic whites. The median age, however, of the subpopulations of Hispanics ranges from 43.6 years (Cuban Americans) to 24.6 years (Mexican Americans). Hispanics' relatively strong religious background with an emphasis on large families also contributes to twice as many Hispanic households composed of four or more people (54%), compared with non-Hispanics (28%). About 40% of the Hispanic population was born outside the United States, and about 28% report speaking English "not well" or "not at all," suggesting that most Hispanics in this country do acculturate and master English in various degrees.

Metropolitan areas are home to the majority of Hispanic Americans, but they reside in every state, including Alaska and Hawaii. Additionally, several states have substantial percentages of their populations made up of Hispanics, such as New Mexico (42%), Texas (32%), California (32%), and Arizona (25%). Certain cities also have high percentages of Hispanic Americans, such as San Antonio (54.5%), Los Angeles (43.5%), Miami (34.1%), Houston (31.6%), New York City (19.9%), Denver (19.5%), and Chicago (17.3%).

The largest Hispanic subgroup—Mexican Americans—primarily populate the southern (34%) and western (55%) regions of the country in addition to many metropolitan areas. Cuban Americans reside primarily in the south (75%), whereas large northeastern cities are the principal residences of Puerto Ricans (58%).

## CHALLENGES FOR HISPANIC AMERICANS

The Hispanic population in the United States, along with their Latin American and Caribbean counterparts, has experienced a series of conquest, oppression, and struggle for freedom, which has led to pervasive social oppression. Spanish and Portuguese conquistadors destroyed much of the indigenous cultures and religions while subjugating, killing, and enslaving the people (it bears noting that intertribal warfare and slavery were common among indigenous Americans before the arrival of Europeans to the New World). The European immigrants quickly claimed ownership of territories in the New World, thereby holding the power and being able to oppress the indigenous people. Ironically, the ancestors of Hispanics have been, and continue to be, the oppressors as well as the oppressed. Because of the continued socioeconomic and political oppression in many Latin American countries, many people from all over Latin America hope for a better life in the United States.

Upon arrival in the United States, some Hispanics are disheartened to find that they still encounter societal oppression. Facing a society with a different set of values is difficult for many ethnic minority groups, including Hispanics. As an attempt to inoculate themselves from real or perceived discrimination, some Hispanics resist acculturating and strive to hold onto their language and cultural traditions. Most, however, acculturate in various degrees and gradually relinquish old ways in favor of mainstream culture. A modest amount of research suggests that having a bicultural orientation is most optimal for Hispanics because biculturalism seems to provide individuals with opportunities to selectively conserve preferred aspects of their native culture while incorporating practices and values of the host culture.

Although the various Hispanic groups may face similar challenges here in the United States, competition among Hispanic subgroups is not uncommon. This is believed, in part, to relate to the history of conflicts between and within their countries of origin. Intra-Hispanic

relationships, for example, are affected by racism and classism. Throughout Latin America, those with darker skin or having indigenous or African ancestry are considered to have lower social status than those with lighter skin. Also, Latin America is plagued by deeply entrenched notions of classism. Those of the lower social classes experience discrimination in practically all spheres within their respective communities. Many Hispanics transport their prejudices with them from their countries of origin and sometimes discriminate against each other in the United States, especially when they fear that individuals from other groups may obtain more of the scarce jobs and resources. To non-Hispanics, these prejudices often are inconspicuous because the groups may share communities together and appear outwardly to coexist amicably.

### HISPANIC DIVERSITY AND SIMILARITIES

Even though there is great diversity among Hispanics as a function of their country of origin, cultural ancestry, and social class, there also are some similarities across many individuals belonging to this broad ethnic group. For example, the primary language of most people from Latin America is Spanish, although, even on this characteristic, there is wide variation. For example, the most common language spoken in South America is Portuguese because Brazil is the most populous country on that continent. The primary language of citizens of Belize, including among those of African ancestry living in Costa Rica, is English. Moreover, numerous dialects of both indigenous people and descendants of Africa are spoken throughout Mexico, Central America, and South America. Roman Catholicism is the most common religion. *Personalismo*, placing a high value on individuals' dignity and self-worth and preferring close, intimate friendships, is theorized to be another common value for many Hispanic people. The emphasis placed on family unity, connectedness, and loyalty arguably is the most common value among Hispanics. The family is valued above the individual, and cooperation generally is valued above competition among family members. Many Hispanics feel that they can always count on their families to provide them with various forms of support throughout their lives; they in turn feel responsible to reciprocate in this regard to their childhood, extended, and procreational family members.

Hispanic families vary and are in a state of flux because of a confluence of factors. The traditional

Hispanic family commonly is hierarchical in nature, with the elderly, parents, and males having special authority. Children typically are socialized to be *bien educados*, which refers to behaving well and complying with adults' requests. After children reach adolescence, many are expected to contribute to the family finances, especially among those from the working classes. The parents, in turn, often assist their children financially, morally, and with child care of their grandchildren throughout their children's lives. Sex roles tend to be rigidly defined in some Hispanic families. Consistent with traditional Hispanic culture, men are expected to be strong, dominant, and the family provider, whereas women are expected to be nurturing, submissive, and self-sacrificing. The father is considered to be the head of the family.

Although some Hispanics may exhibit similar physical characteristics, they also may vary tremendously, resembling blacks, Native Americans, Asians, or Europeans as a result of the mixing of races that has taken place in their countries of origin. Mexican Americans are primarily of mixed (*mestizo*) indigenous and Spanish background (in Mexico, about 50% of the population is *mestizo*, 30% is indigenous, and 20% is of European heritage). Cuban Americans and Puerto Ricans often are of Spanish heritage, but also may be of African or mixed ancestry.

Although it might be assumed that the significant increase of Hispanics in the U.S. population would lead to an increase in political or economic power, this has not been the case thus far. Many Hispanics struggle economically and are disproportionately represented among the unemployed and underemployed. Many hold semiskilled, blue-collar jobs. It also is common for Hispanics to live in substandard housing. Although this situation may be related to discrimination, it also is due to Hispanics' relative lack of education or vocational skills. Generally, Hispanics do not fare well in the educational sphere. More than one third drop out of school before obtaining a high school diploma, which is about twice the rate of African American students and almost four times the rate of non-Hispanic whites. Some parents of Hispanic children have difficulty advocating their children's educational needs because of their own low education levels or lack of English proficiency. Surveys reveal that most Hispanic parents have high hopes for their children's educational attainment, but struggle knowing how to appropriately support their children's academic endeavors.

## A CLOSER LOOK AT THREE HISPANIC SUBGROUPS

### Mexican Americans

The Mexican-American war, which began in 1846 and resulted in the signing of the Treaty of Guadalupe Hidalgo in 1848, resulted in Mexico's forfeiture of lands now constituting Texas, California, New Mexico, and parts of Colorado, Arizona, and Utah. The Mexicans inhabiting those areas were primarily *mestizos*—of mixed indigenous and Spanish ancestry. In essence, with the stroke of a pen, more than 100,000 Mexicans instantly became Mexican Americans.

Historically, Americans' attitudes toward Mexicans and Mexican Americans have been less than favorable or ambiguous at best. Many Mexican American landowners lost their lands to white Americans shortly after the Treaty of Guadalupe Hidalgo as a result of duplicitous U.S. legal maneuvers. Also, during various periods over the past 150 years, the United States has vacillated between encouraging Mexican migrants to the United States to satisfy cheap labor demands and discouraging them by conducting deportation sweeps and denying social benefits and educational opportunities for their children. Today, although completely irrelevant to some Mexican Americans, issues related to immigration still affect many Mexican Americans given that they or extended family members must contend with immigration issues at some point in their lives. Further, because Mexican Americans generally have darker skin than whites, they have endured ongoing social discrimination in various degrees.

Contemporary Mexican Americans are quite diverse. Descriptors commonly applied to Mexican Americans have included loyal, hardworking, humble, family oriented, and Catholic. Although some values and traditions are shared across vast segments of the Mexican American population, Mexican Americans vary in personalities, acculturation, socioeconomic status, educational attainment, and occupation. Mexican Americans also vary in their preferred ethnic label, often as a function of interactions between sociodemographic variables, language proficiency, and experiences with discrimination and oppression. Some self-identify as Mexican, Spanish, Mexican American, Americans of Mexican descent, Latin, Chicano, Hispanic, and Latino. Also, intermarriage increasingly is leaving its imprints on Mexican American identity, attitudes, and behaviors. Marriages in which one partner is Mexican American and the other is non-Hispanic

white represent the most common interethnic marriage in the United States.

For some Mexican Americans, the pressure to adapt or acculturate toward mainstream customs and values is stressful as they struggle to negotiate a myriad of personal, family, and cultural changes. In contrast, some Mexican Americans comfortably gravitate toward behaviors and attitudes consistent with non-Hispanic white American culture. Still, other Mexican Americans selectively acculturate, electing to maintain specific Mexican beliefs and values while adopting specific mainstream ideas or customs. Despite the inevitability of acculturation, the unity and cohesion of Mexican American families sometimes can be compromised as family members—particularly during the first few generations—learn to balance their adherence to traditional family values with their adoption of egalitarian and individualistic values of mainstream American culture.

Mexican Americans' loyalty to their families is a prominent cultural characteristic. Mexican Americans' concept of "family" extends beyond the nuclear family and includes uncles and aunts, cousins, and grandparents. An acceptable situation among many Mexican Americans is living with their parents until they marry. Even then, it is not uncommon for newlyweds to live with either the bride's or groom's parents indefinitely following the wedding. Among most Mexican Americans, no social stigma is attached to adults who live in their parents' homes. Another custom among many Mexican American families is socializing children to value their relationships with siblings over friendships. The end result is that Mexican Americans often maintain very close, lifelong ties to their siblings. Close sibling ties into adulthood perpetuate the family bonds because their own children will have extensive contact with uncles, aunts, and cousins. Also, many Mexican Americans abhor the practice of placing aging or sick parents into elderly institutions. Aging parents expect to live with one or more of their children up until their death.

Mexican culture has historically provided well-defined hierarchal roles for husbands and wives whereby males enjoyed power, privilege, and status. However, changes over the past several decades have modified those perceptions and expected behaviors. Contemporary Mexican American women generally have more freedom to pursue their own occupational or professional interests. Moreover, various social, acculturative, and political changes have created a

wide range of lifestyles that have characterized family life for Mexican Americans anywhere from patriarchal to egalitarian, and every style in between.

## Puerto Ricans

In 1898, following the Spanish-American war, Puerto Rico became a territory of the United States. Since 1917, when U.S. citizenship was granted to all Puerto Ricans, they have been migrating to the United States in search of improved economic opportunities. During the first half of the 20th century, Puerto Ricans settled primarily in New York City and performed mostly manual labor in various industrial and agricultural types of employment. The largest Puerto Rican migration occurred between 1946 and 1965, when an average of 34,000 Puerto Ricans per year relocated mostly to New York City, but also to some areas of New Jersey, Connecticut, and Chicago. As economic conditions improved dramatically on the island of Puerto Rico during the 1970s, the number of Puerto Ricans immigrating to the United States declined considerably and even influenced many U.S. Puerto Ricans to return to the island. Nonetheless, today, almost as many Puerto Ricans live in the United States (3,406,178) as on the island (3,623,392). The Puerto Rican migration has been described as a “revolving door” because since 1965, many Puerto Ricans have moved to and from the United States, sometimes multiple times.

Puerto Ricans’ experiences in the United States are similar to other immigrant groups because they have different sociocultural traditions and speak a language other than English. Even after several generations in the United States, Puerto Ricans tend to maintain a strong ethnic identity and retain the ability to speak Spanish. Puerto Ricans living on the island have most of the rights and obligations of U.S. citizens, such as paying social security taxes, receiving some federal welfare, electing to serve in the U.S. military, and holding U.S. passports. Only Puerto Ricans living in the United States must pay federal taxes and have the right to vote in the presidential elections.

Puerto Ricans, both in the United States and on the island, often call themselves *Boricuas* and refer to the island as *Borinquen* in verses, songs, and conversation. Puerto Ricans, as a group, are ethnically and racially mixed. They are the descendants of Taino (the original indigenous people on the island when it was discovered by Spaniards), Spanish settlers, and African slaves

(Puerto Rico actively participated in the slave trade until 1870). Taino and African cultural beliefs and traditions blended with the dominant Spaniard culture to give rise to Puerto Rican musical, literary, and cultural tradition and to their contemporary national identity. Puerto Ricans have a fluid concept of race that considers shade of skin color, facial features, and hair texture in determining a person’s race. Racial categories in Puerto Rico include black and white as the two ends of the continuum, with other categories in between that describe specific combinations of features such as *trigueño* (light brown skin), *moreno* (dark brown skin), *indio* or *canela* (light brown skin with Caucasian features), or *jabao* (light skin color with Negroid facial features or hair texture).

In the United States, Puerto Ricans are one of the most economically disadvantaged ethnic groups. They have a lower rate of labor force participation, a higher rate of unemployment, and a higher poverty rate than non-Hispanic whites as well as other Hispanic groups. According to the Census Bureau in 1999, the unemployment rate among Puerto Ricans in the mainland aged 16 or older was 8.1%, compared with 3.4% for whites, 7% for Mexicans, and 5.8% for Cubans. Moreover, close to 26% of Puerto Ricans lived below the poverty level, compared with less than 8% of whites, 24% of Mexicans, and 17% for Cubans. In addition to social discrimination, it is believed that their relative lack of educational attainment and difficulty with the English language significantly contribute to their economic problems. They also have been affected disproportionately by the industrial restructuring of the northeast United States in the past decade.

Many Puerto Ricans long to return to their island, where they think they will feel “at home.” However, once back on the island, they often experience language and adjustment difficulties, including occasional rejection by island Puerto Ricans. From the perspective of those on the island, U.S. Puerto Ricans have excessively liberal gender attitudes, inadequate fluency in Spanish, low achievement levels, and somewhat of an aggressive demeanor. On the island, Puerto Ricans born or raised in the United States are referred to as *Nuyoricans*, a term referring to Puerto Ricans from New York. That label implies a separate identity from island Puerto Ricans.

Puerto Ricans generally place a high value on maintaining harmonious and interdependent relations with family and friends and place less emphasis on individual autonomy. Puerto Rican culture is relatively

sociocentric. The needs and interests of the group (usually the family) take precedence over individuals' needs. There is a tendency to avoid dealing with conflict directly. For example, they prefer to say a "white" lie rather than openly refuse information to someone. They also expect their children to be respectful, quiet, and obedient. Regarding religion, Puerto Ricans are overwhelmingly Catholic, although Puerto Rican men tend to be Catholic "in name only." Elements of Taino mysticism, African Santería, and European spiritism have infiltrated Puerto Rican Catholicism. Evidence of their influence is apparent by some Puerto Ricans' willingness to consult with traditional folk healers for social support or assistance with emotional or family problems.

### Cuban Americans

Among Hispanics in the United States, Cuban Americans make up roughly 3.7%, with 65% of them residing in Florida alone. There also are significant Cuban American populations in New Jersey, New York, and California. The mean age for Cuban Americans is 40.7 years (for comparison, the mean ages for other U.S. Hispanics and for the entire U.S. population are 25.9 and 35.3 years, respectively). Moreover, in comparison to other Hispanic groups in the United States, Cuban Americans have the highest education and income levels, the lowest birthrates, the highest percentage of married households with both spouses present, and ironically, the highest rate of divorce.

People from Cuba have been immigrating to the United States since the 19th century, and Cuban influence in the history of the United States often is overlooked. The U.S. government has a history of intervening in Cuban affairs dating back to the Spanish-American war. When Fidel Castro assumed control of Cuba in 1959, his government implemented drastic social, economic, and political changes to the country, consequently instigating the first significant wave of Cuban immigrants to the United States. This first wave of immigrants was primarily upper-class and upper-middle-class professionals whose ethnic background was mostly Spanish (white Europeans). They generally were welcomed to the United States, and many benefited from federal resettlement programs. Shortly thereafter, this cohort of Cuban Americans came to be viewed as "model minorities" in terms of their ability to integrate into U.S. society

and establish themselves as a viable economic and political social group.

Subsequent waves of Cuban immigrants increasingly resembled the Cuban population as a whole in terms of race and socioeconomic class. In the early 1980s, the *Marielito* wave of Cuban immigrants was largely unemployed and had a larger percentage of Afro-Cubans. Many of these immigrants were interned upon entry to the United States and were frequently stereotyped as criminal, homosexual, or socioeconomic outcasts of Cuba. Their plight in the United States was further complicated by the social rejection they encountered by many Cuban Americans who, having come to the United States during the first wave, had already established themselves in their respective communities. Cuban immigration once again peaked after the collapse of the Soviet Union with the *balseiro* (rafters) wave of immigration in 1994. Although there has not been a subsequent wave of immigrants, some Cubans still attempt to navigate the treacherous waters between Cuba and Florida with the hopes of reaching the United States. Cubans—unlike any other national group—are the recipients of a favorable U.S. immigration policy that grants permanent residency to any Cuban who physically reaches U.S. soil.

Despite the fact that compared with other minority groups, Cuban Americans generally have excelled along various economic and political indexes, many continue to contend with an array of problems associated with their status as ethnic minorities, including racial discrimination. For example, they still lag behind non-Hispanic whites in terms of annual income and educational attainment. Also, Cuban American professionals may encounter a "glass ceiling" restricting their promotion and upward mobility. A common problem among Cuban American families is related to differential rates of acculturation, causing intergenerational conflict. More specifically, younger family members typically adopt mainstream U.S. social values more quickly than their parents and grandparents. This form of strife between parents and children is a common presenting problem at counseling centers where some Cuban American families seek professional assistance for intrafamilial distress.

Moreover, for many Cuban American elderly people, life in the United States has been a mixed blessing. Many of the first wave of Cuban immigrants had believed they were coming to the United States on a temporary basis while they awaited the demise of

the Castro government. Many members of that generation have died or are quite elderly and have witnessed, to their own surprise, the tenacity of the Castro government despite a U.S. military invasion, the collapse of the Soviet Union, and an ongoing economic embargo. Consequently, despite relative success in the United States, many elderly Cuban Americans have considerable anger and resentment over the lives and property they have lost in Cuba. Although they may have pride in the success of their children and grandchildren, they also may resent younger generations' inability to sustain, or lack of interest in sustaining, traditional Cuban culture.

## CURRENT TRENDS

Because of relatively high birthrates and legal and illegal immigration, Hispanics are the fastest growing ethnic group in the United States. Projections indicate that the percentage of Hispanics in the United States will be comparable to that of non-Hispanic whites or possibly larger within the next 30 to 50 years. Because of the United States' close proximity to Mexico, Hispanics of Mexican ancestry likely will continue forming the largest Hispanic subgroup in the United States. However, the national origins of U.S. Hispanics will continue diversifying given the new and steady flow of South Americans immigrating to this country. Whether Hispanic Americans collectively attain more economic and political power remains to be seen and will depend in large part on the degree to which they attain higher levels of education. Nonetheless, their presence and influence are already felt in areas such as music and art, foods, political discourse, and scholarship, and they will continue to have a significant impact on contemporary U.S. culture.

## HOLOCAUST

---

Holocaust is the term used to refer to the attempted annihilation of European Jewry and the brutal persecution of an extended “mosaic of victims” by German Nazis.

### WHEN DID THE HOLOCAUST OCCUR AND HOW DID IT UNFOLD?

The persecution of Jews began soon after Adolph Hitler was appointed Chancellor of Germany on January 30, 1933. Between that date and November 9, 1938 (the date of *Kristallnacht* or “night of broken glass” during which there were state-sanctioned assaults on Jewish persons and property throughout Germany), the rights of Jews were continuously defrayed. Social, political, and psychological separation from German society was succeeded by physical attacks and incarceration in German concentration camps. During these years, many Jews tried to emigrate from Germany, but most countries of the world refused to accept them.

By the outbreak of World War II, Nazi rule extended to Austria and Czechoslovakia, and by 1941, most of Europe fell under Nazi domination, including the millions of Jews who resided in these countries. At this point, Jewish emigration to nonoccupied areas of the world—which was difficult before—became virtually impossible. Fueled by an “ideology of death,” Nazi leadership began to generate a series of “solutions to the Jewish problem” (the excess number of Jews living in areas that the Nazis wished to clear for repopulation by their own citizens). An early plan was to deport and concentrate all Jews on the French island of Madagascar, off the coast of southwest Africa. However, this plan became technically impossible once the

Germans lost the Battle of Britain. The Nazis next confined Jews in ghettos and forced labor and concentration camps. In 1941, as Germany prepared to invade the Soviet Union, Nazi policies toward the Jews changed once again. It became clear that efforts to rid Nazi-occupied lands of Jews required more extreme measures. Thus “the final solution to the Jewish question” was set in motion: complete and total annihilation of the Jewish people, whereby every Jewish man, woman, and child was to be killed. Several strategies were implemented to achieve this end: massacres were perpetrated by killing squads (the *Einsatzgruppen*); and systematic murder by asphyxiation was conducted first in mobile gas vans and then in stationary “death factories,” the extermination camps.

By the end of World War II, approximately 6 million Jews (one third of the Jewish population in Europe before the war) had perished. An additional 5 million people, representing different victim groups, also succumbed to the Nazi onslaught: “victims by birth” (Gypsies, the mentally and physically handicapped), “victims by belief” (Jehovah’s Witnesses, Catholic priests), and “victims by behavior” (Communists, political dissidents, homosexuals). However, the Jews were the main focus of the German “ideology of death.” For this reason, the Hebrew word *Shoah* (whirlwind) is often used to distinguish the Jewish experience from the experience of other victim groups.

## HOLOCAUST VERSUS GENOCIDE AND ETHNIC CLEANSING

The word *genocide* had not yet been invented when the Holocaust began. Indeed, it was coined in 1944 by Raphael Lemkin, a Polish Jew who managed to find refuge in the United States in 1941. Derived from the Greek word *geno* (race or tribe) and the Latin word *cide* from *caedere* (killing), Lemkin defined genocide as “a coordinated plan of different actions aiming at the destruction of essential foundations of the life of national groups, with the aim of annihilating the groups themselves.” He further identified two patterns of genocide: (1) destruction of the oppressed group, and (2) imposition of “the national pattern of the oppressor” onto the oppressed population. Implied in this second pattern is that members of the oppressed group might be allowed to remain, but their leadership, language, culture, and religion would all be subsumed into the “colonizing culture.” The distinction between these two patterns of genocide makes it possible to differentiate the Holocaust (exemplar of Lemkin’s first definition) from other incidents

of genocide. Indeed, for many, the word Holocaust itself has evolved into the generic name for an ideologically motivated, planned total murder of a whole people.

Ethnic cleansing, in contrast, was defined by the United Nations in 1993 as “rendering an area wholly homogeneous by using force or intimidation to remove persons of given groups” manifested “by means of murder, torture, arbitrary arrest and detention, extrajudicial military attacks or threats of attacks on civilians and civilian areas, and wanton destruction of property.” Thus, while ethnic cleansing can occur through murder, it is not necessarily the total murder of a whole people.

## PSYCHOLOGICAL EFFECTS OF THE HOLOCAUST

The Holocaust experience was one of extreme stress: there were pervasive hostile forces; death was imminent. In addition, the concentration camps and ghettos were closed systems where inmates could exercise only limited control over their environment, were frequently separated from their loved ones, and were often forced to violate their belief systems in the process of surviving or to helplessly watch while others were murdered. Understandably, after the war, many survivors manifested a variety of seemingly “abnormal” behavioral and psychological symptoms. Collectively, these symptoms have come to be identified as the “survivor syndrome”: chronic anxiety, fear of renewed persecution, depression, recurring nightmares, psychosomatic disorders, social withdrawal, fatigue, hypochondria, distractibility, irritability, a hostile attitude toward the world, and—in the extreme—hallucinations and depersonalization. Identification of this syndrome was based on work with those survivors who sought psychiatric assistance and was initially generalized to all survivors, despite the fact that most Holocaust survivors never sought professional psychiatric or psychological help. This early “skewed picture” of survivors then most likely was an artifact of the fact that in order to receive reparations from the West German government, survivors had to “prove” that they were sufficiently psychologically disabled to warrant assistance *and* that these disabilities were a product of their treatment during the war. Thus, the most negative symptoms were emphasized within the early psychological literature.

An often highlighted symptom in this literature is “survivor guilt,” or the expression of self-recrimination because one survived and others did not. This was identified primarily among those who were the sole

surviving member of their family, were unable to protect their children or other loved ones from harm (they survived but their children/parents/siblings did not), and felt that they were less worthy than those who had perished. This guilt often kept survivors “locked in the past,” but it has also served as motivation to bear witness to the Holocaust and to keep alive the memory of those who perished.

More recent research has focused on the resiliency of Holocaust survivors—their ability to move on, to create new families, and to make significant contributions to society. The heterogeneity of the survivor community has also come to be emphasized. Not all survivors are alike. Their postwar adaptation may be seen as a function of their age at the time of the Holocaust, sex, country of origin (how long they lived under persecution), placement during the war (ghetto, forced labor camp, extermination camp, in hiding, engaged in active resistance), familial circumstances of survival (e.g., lone surviving member of their family or community), and pre-Holocaust family life and personality.

Another aspect of behavior that has received new focus is the kinds of resistance victims used to maintain their sense of self in a situation designed to render them “life unworthy of life.” Circumstances delimited the degree of armed resistance that could occur, although there are some notable examples (e.g., the Warsaw ghetto uprising). More frequently used were spiritual resistance where Jews continued to observe holidays, say prayers, and maintain religious practices even in the most dire circumstances; artistic resistance, which has left a legacy of visual art pieces, musical compositions, and written poems, stories, and essays; interpersonal resistance, whereby victims helped each other survive in whatever ways they could; and psychological resistance, whereby victims refused to be reduced to sub-humans. The use of “gallows humor” by adults enabled many to put themselves in a psychologically superior place; play served the same function for children.

Although the Holocaust ended 60 years ago, the effects of the Holocaust continue to live on within individual survivors as well as their children. Survivors continue to feel vulnerable and may communicate this sense of vulnerability to their children. Survivors and their children often experience role reversal, whereby the children take on the caretaking role. Conversely, and sometimes at the same time, parent survivors try to compensate for their inability to protect loved ones during the war by overprotecting their children. Again, the early literature on the second generation focused on the pathological aspects of the relationships with

their survivor parents. More recent research, however, has shifted to explore the special strengths of children of survivors, most notably their capacity for empathy.

## SUMMARY

The Holocaust was a unique event in human history, the thrust of which was to annihilate the Jewish people. About one third of the Jewish population of Europe did indeed perish. Of those who survived, many have incurred deep psychological scars. They also demonstrate the amazing resilience people are able to muster in the face of extreme traumatic experiences.

---

## HOME BIRTH

---

Giving birth at home is a tradition in many parts of the world because of limited access to health care facilities. In parts of Europe, the United Kingdom, Australia, and North America, women may choose to

give birth at home instead of in the hospital. The choice to give birth at home is undertaken for a variety of reasons: to enjoy the comfort of familiar surroundings; to have family and friends in attendance; to minimize separation from young children; to avoid contact with a “technological” environment; to have one-on-one care as opposed to care in a multidisciplinary, teaching environment; and to access the care that midwives qualified and experienced in attending healthy women are trained to provide. The term *home birth* implies that the birth is planned to take place at home. Unplanned home births are births that were intended to take place in hospital but happened at home or en route to the hospital because the labor was uncommonly fast, the mother couldn’t get access to transportation, or the mother didn’t know how far advanced she was in labor. Unplanned home births sometimes occur without professional attendants, and rates of adverse outcomes among unplanned home births versus planned home births are known to be higher. In North America, New Zealand, Australia, and some countries in Europe, for example, Switzerland, planned home births account for between 1% and 2% of births. In contrast, in the Netherlands, 30% of births are planned home births.

## PLANNING FOR HOME BIRTH

Birth at home requires advanced preparation. There is a requirement to purchase needed supplies for a cost of about \$20.00 (U.S.) and to have available adequate linen, a protective cover and pads for the bed, baby supplies, and maternity supplies for the mother. Access to a telephone and transportation must be assured on a 24-hour basis. The midwife should have formal arrangements in place to transfer care to a physician consultant if necessary, or to transport the mother or baby to hospital. Impending changes in weather and road conditions that could delay or eliminate the possibility of transport may influence the midwife or pregnant woman to initiate transport early in labor.

## WHO PROVIDES CARE FOR HOME BIRTHS?

Birth at home is most often attended by midwives. Physicians are generally not covered by malpractice insurance to attend home births. Practicing midwives vary in their training and experience, and it is important to know the qualifications of the midwife under

consideration for attending a home birth. Some countries (e.g., the United States (Washington State) and Canada) license direct-entry midwives. These midwives have completed an accredited course of training but are not necessarily nurses. In other countries (e.g., England and Australia), all midwives are nurses and are referred to as *registered* or *certified nurse-midwives*. In contrast, some midwives practice without formal training and are known as lay midwives. The practice of lay midwives is not monitored or regulated by a professional practice organization, unlike licensed or registered midwives. Families who wish to have a home birth may contact the professional practice association for midwives in their region or country and find out how to obtain the services of a credentialed midwife.

## WHO IS ELIGIBLE TO HAVE A HOME BIRTH?

Consideration of a home birth requires an assessment of a woman’s health status. Most professional organizations governing the practice of midwifery issue strict guidelines about who should plan birth at home. These usually include a singleton fetus (not twins or triplets), baby in the cephalic presentation (head coming first instead of the buttocks), full term (37–41 completed weeks of pregnancy), and no more than one previous caesarean section. Exclusion criteria include preexisting serious medical conditions, for example cardiac (heart) or renal (kidney) disease, insulin-dependent diabetes, or health problems arising in pregnancy such as preeclampsia (elevated blood pressure with protein in the urine), placental abruption (placenta is detaching from the uterine wall), placenta previa (placenta is covering the opening to the cervix), or active genital herpes.

## SAFETY OF HOME BIRTH

A number of studies around the world have examined the safety of planned home birth among healthy women with a qualified midwife in attendance. These large studies from Canada, the United Kingdom, the United States, Switzerland, and New Zealand have not reported an increase in rates of adverse outcomes for mothers or babies compared with those among healthy women planning birth in hospital. In addition, planning birth at home is associated with reduced interventions during labor and delivery. About 15% of women initiating birth at home are transferred to the hospital at

some point during their labor. Even including these women, planned birth at home is associated with reduced rates of use of narcotic drugs and epidural anesthetics for pain relief, amniotomy (rupturing the membranous sac around the baby), and administration of drugs such as oxytocin and prostaglandins to accelerate labor. Women who initiate labor at home are more likely to have a vaginal than a caesarean delivery, electronic monitoring of the fetal heart rate, and episiotomy (an incision to widen the vaginal opening to hasten the birth of the baby). In addition to transfer during labor, a small percentage (1–2%) of mothers and babies require transport to hospital during the period immediately after birth. Whether reductions in interventions are attributable to the setting, home versus hospital, the practice of the attending midwife, or some aspect of the woman herself who has chosen home birth is not entirely clear because few studies have randomly assigned women to home or hospital birth. Certainly, women who chose birth at home are generally strongly motivated to have a natural or “physiological birth” because most midwifery professional organizations do not permit administration of drugs for pain relief in the home setting.

### PAYMENT FOR HOME BIRTH

Midwifery care is paid for by the government in most countries with public health care systems. Private insurers cover home birth in some cases, but policies vary and should be examined in detail before making the decision to give birth at home.

### WOMEN'S SATISFACTION WITH HOME BIRTH

Women who have completed birth at home, in comparison to women planning and completing birth in the hospital, report increased satisfaction with the birth experience, particularly in regard to having a feeling of control over the process of birth. Women giving birth at home are able to have whoever they want in attendance, to eat and drink nourishment of their choosing, and to engage in a variety of methods of pain management, including sitting in a hot tub, going for extended walks, and experiencing the comfort of familiar surroundings. Women also have reported a sense of accomplishment and readiness for mothering. Midwives attending a home birth stay at least 4 hours after the birth and visit daily thereafter for a number of days. This intensive

contact with both the new mother and her family may allow for enhanced opportunities for teaching related to care and feeding of the baby and care of the new mother. Women giving birth in a hospital are discharged within 24 to 48 hours after an uncomplicated vaginal delivery and 72 hours after a caesarean birth. Home visits after the birth are rarely provided by physicians but often are by midwives. In most communities, public health nurses visit new mothers, but are often mandated to provide only one visit if the mother and infant are healthy.

### SUMMARY

In summary, healthy women experiencing normal pregnancies may choose to plan a home birth with a qualified midwife. Although no birth is risk free, home birth overall is not associated with increased risk for adverse outcomes for the mother or baby. Women planning birth at home are less likely to experience obstetrical interventions during labor and delivery.

—Patricia A. Janssen

---

## HOMICIDE

---

For a person to take the life of another person is in most, if not all, religions and cultures seen as one of the most serious crimes someone can commit. This holds true historically as well because killing has

always been looked on as a serious offence, resulting in diligent investigation and severe punishment.

*Homicide* is a term used by criminologists—those who study crime and criminals—and sociologists—those who study society and its members—to describe the act of an unlawful killing of another person. The term is used to enable them to discuss and study the whole category of killing as such, without having to take into account that the definition of legal categories such as murder and manslaughter vary with time and place. The term homicide consequently covers the legal categories of murder and manslaughter, whereby murder generally refers to premeditated or intended killings, whereas manslaughter involves less culpability of the offender and thus indicates the killing was not intended or premeditated or was caused in self-defense. In some studies, infanticide (the murder of a newborn child by its mother; see Infanticide entry) is also included in the homicide category, and some researchers argue other forms of unlawful killing, such as corporate manslaughter (when the death of an employee or customer is caused by the company's neglect, carelessness, or noncompliance with regulations), should be recognized in the category. The label of homicide is consequently used to focus on people who die as the result of unlawful acts of other people, and it is the outcome, the fatal result of death, and not the legal requirements (e.g., premeditation, provocation, and temporary insanity) that classify an act as homicide.

As an act, homicide is not as prevalent as might commonly be believed. The actual number of homicides is comparatively low, especially when compared with other crimes like assault or property crimes such as theft, shoplifting, and burglary. What is apparent, however, is that homicide is a crime that is firmly rooted in our everyday lives and experiences. Despite the fact that most of us run a very low risk of ever becoming a victim of homicide, or an offender committing homicide, or even of knowing someone who is a homicide victim or offender, this is a crime that is much feared and much debated. One contributing factor to this awareness and fear of homicide is that murder is a regular feature in news reporting and is a major topic of interest in crime fiction. If the murder rate as experienced in crime fiction series, films, and books would have been the real one, there would not be many people left in the end! There are different reasons that homicide features in media to such an extent. One is that homicide, especially when perpetrated by sex murderers, violent pedophiles, serial

killers, and the like, has many titillating and interest provoking qualities. Heinous crimes have an ability to awaken our curiosity. Some of these qualities may be emphasized by the finality of the crime—the fact that the victim dies.

One way of enabling comparisons between different countries with different sizes of population and varying numbers of homicide is to give the rate of homicides per 100,000 inhabitants. This way, countries and regions can be compared with each other. The rate per 100,000 in Western Europe is on an internationally low level, with a rate of 1.6 in the countries in the European Union. The level in Eastern Europe is considerably higher. In the Baltic countries, the rate is about 10 per 100,000, and in Russia, the rate is 22.1. The United States, with a rate of 5.6 homicides per 100,000, falls between Western and Eastern Europe. Higher still is the homicide rate in South Africa, 55.86. Generally, the homicide rate is higher if a country suffers from unrest or conflict, either internally from civil war or externally by being in conflict with other countries. For example, in Northern Ireland, the homicide rate is 2.65. From other countries, like Zimbabwe, Palestine, and Iraq, it is much more difficult to get reliable figures because of turmoil and instability. Studying homicide rates also shows that the homicide rate is usually higher in big cities than in smaller ones and rural areas.

Even if the prevalence of homicide is quite low, however, when someone is murdered, the consequences reach far more people than the victim and perpetrator. The impact on other people—family, friends of victim and offender, witnesses, sometimes the general public—also needs to be taken into account when discussing homicide. Those close to the victim suffer the trauma of loss and sudden death, whereas the surrounding community may suffer from the general feeling of being unsafe, and fear of crime can increase as a result.

Despite homicide being a relatively rare phenomenon, it is far from a homogeneous one. Homicide can be classified in a range of ways, typically sorted by offender–victim relationship (intimate, family, acquaintance, stranger), number of offenders (gang killings) or number of victims (serial, multiple, and mass murders), and motive or scene of crime (home, public space). Generalizations have been attempted; for example, Katz divided homicide into righteous slaughter and cold-blooded murder. The problem with trying to categorize homicide is that there are always types of

homicide that do not fit into general divisions, and there are other situations in which too many different types of homicide fit in one category, diluting the explanatory power of the label.

Usually, categorizations are more detailed and reflect the relationship of the victim and offender. The two most common types of homicide are then domestic and confrontational homicide. Domestic homicide includes spousal homicide, child homicide, parental homicide, and crimes of passion, whereby the death can be the result of years of abuse or related to a more sudden crisis, like a separation or the discovery of infidelity. Confrontational homicide typically denotes male-on-male drunken brawls and honor contests in public places. Other, smaller groups include crime-related homicide (e.g., assassination, armed robbery with fatalities), sexually motivated murder, serial murder, mass murder, and multiple killings.

To connect to what was said previously about the media's portrayal of homicide, the general trend is that the less frequent the homicide type, the more publicity it gets in media. Even when it comes to the rarity and horror of any homicide, it is still not as interesting to write about domestic violence with deadly outcomes, fatal brawls among drug takers, or the pub brawl among young men that leads to someone's death, as it is to follow the killings of a Ted Bundy or the Columbine High School shootings.

How can we explain homicide? Wolfgang (1958) pointed out the personalized trait of homicide and claimed it was the most personalized of crimes. This is because in most homicide cases, victim and offender know each other, if not closely, at least by name. This is why the police always carefully check a victim's friends and family members because the offender is usually found there.

No one has managed to put forward a general theory of homicide, but there is a range of theories that go toward explaining homicide, taking into account childhood, biology, and psychological and sociological factors. The wide range of homicide types means that different kinds of homicide need different kinds of explanations because offender and victim characteristics, motives, crime scenes, and the like all vary depending on homicide type. It might seem obvious that the husband who kills his wife after years of abuse does so for other reasons (frustration, power, and control) than a serial sex murderer (sadistic and perverted sexual drive) or a bank robber prepared to use a gun to get the money he or she wants.

## SUMMARY

To summarize, homicide is a rare crime, but it is one that we all are very well aware of and frequently fear as well. Despite its rarity, the impact of homicide extends far beyond the victim and offender—it can have an impact on the whole society. Also despite its rarity, homicide is still far from a homogeneous phenomenon. There are a number of different types of homicide and therefore a number of different explanations, usually varying from individual to individual in what has been called the most personalized of all crimes.

## HOMOSEXUALITY

---

The construct of homosexuality can be conceptualized from two major perspectives: essentialist and constructivist. Essentialist assumptions have informed the thinking of many theorists and researchers traditionally associated with human sexuality, such as Sigmund Freud. The essentialist perspective views homosexuality as a core attribute of individual identity. From this perspective, homosexuality is held to be temporally and culturally stable, biologically driven, and internal. As such, its development is said to follow a predictable and predetermined course.

A second perspective, the constructivist perspective, posits that individuals, cultural groups, and social institutions actively define the meanings attached to sexuality, sexual identities, and sexual behavior. In rejecting the primacy of biological determinism and essentialist assumptions, the constructivist perspective holds that theories about sexualities must incorporate a social-psychological focus. Looking to the past and considering how sexuality has been conceived and

lived out during different eras and in different places lends support to the contention that its construction is both culturally and temporally variable. It is really only in recent times that sexuality has been framed as an essential part of the individual, as an identity in and of itself. In fact, the term *homosexuality* was first coined in the late 19th century.

## HISTORICAL CONTEXT

Before the 19th century, religion was largely responsible for the social and political organization of sexuality. However, in the past century and a half, the social and political organization of sexuality has taken place in more secular venues. During the late 19th century, interest in sexuality emanated from the medical tradition, wherein the concern was in examining pathology. The emergence of the homosexual in contrast to the heterosexual can be seen in the work of Richard von Krafft-Ebing. Krafft-Ebing's *Psychopathia Sexualis*, published in the late 19th century, became one of the most influential texts on pathological sexuality. In this, Krafft-Ebing's use of the terms *hetero-sexual* and *homo-sexual* introduced the idea of two sex-differentiated eroticisms, one deemed to be normal and healthy and the other abnormal and unhealthy. Krafft-Ebing's main focus was on distinguishing between congenital sexual perversion and acquired sexual perversity. In this context, the notion of a physiologically based sexual orientation (healthy or unhealthy, normal or abnormal) emerged.

In the early part of the 20th century, Freud suggested that individuals were born bisexual and, as life progressed, moved toward either a homosexual or heterosexual orientation. Freud postulated that a restriction in object choice was necessary for the development of normal sexuality. Restriction in object choice occurred through the resolution of the Oedipus complex. In so doing, the individual became exclusively monosexual. Freud suggested that fixed sexual identity was established by the onset of adolescence. He further maintained that homosexuality and heterosexuality could not coexist, and so the basis for exclusivity in orientation was established.

In the United States in the 1940s and 1950s, the work of Kinsey and colleagues was pivotal in influencing ideas about sexuality. Kinsey and his team used a taxonomic method to capture the range of human sexual behavior. They allowed for the complex nature of sexuality by introducing the use of a continuous

scale to understand sexual orientation. This scale ranged from 0 to 6, with 0 indicating exclusively heterosexual and 6 indicating exclusively homosexual. They suggested that individuals may fall in any position on that continuum, thus allowing for a range in terms of sexual attraction and behavior. Despite the introduction of the continuum concept in the 1950s, categorical definitions that constructed homosexuals and heterosexuals as opposites continue to be used when talking about sexuality.

## IDENTITY DEVELOPMENT MODELS

In the past 35 years, models of sexuality that have been proposed have generally focused on the development of homosexual identity. These development models have primarily focused on gay men, with lesbians most often being subsumed under this group, and with minimal attention accorded to bisexual identity development. Most homosexual identity development models have come from an essentialist position and share a number of common features. Most hold that development of homosexual identity involves a series of stages (e.g., predisclosure, disclosure, exploration, identity development, identity prizing, and identity integration). Other models have adopted more of a sociological approach. These latter models particularly seek to chart the process by which women or men come to construct their identities as gay, lesbian, or bisexual and allied to this are said to exhibit particular attitudes, behaviors, and lifestyles.

## CRITICISMS OF CATEGORICAL MODELS

Using categorical definitions of sexuality (i.e., homosexual, bisexual, heterosexual) is clearly part of the dominant cultural script in North America. However, the categorical model of sexuality has been subject to considerable criticism. Often this term has been used to reference sexual identity (usually fixed), sexual behavior, and sexual fantasies simultaneously and simplistically. Many have claimed that these phenomena may not be congruent. Increasingly, sexual orientation, sexual identity, and sexual partner choice are being recognized as independent variables. For example, the National Health and Social Life Survey reported low intercorrelations among dimensions traditionally associated with sexuality and sexual orientation. Specifically, they reported that 4.3% of women and 9.1% of men in the study (N = 2,000) had

experienced some form of sexual activity with a same gender partner since age 18. Additionally, 5.6% of women and 4.5% of men found same-gender sex appealing, with 6.2% of men versus 4.4% of women reporting attractions to someone of the same gender. More than 95% of the respondents identified themselves as heterosexual.

Seeking to capture more of the dimensional experience of sexuality and sexual orientation, Klein and colleagues suggested that sexual orientation is best defined as consisting of seven components: (1) sexual behavior; (2) emotional preference; (3) sexual fantasies; (4) sexual attraction; (5) social preference; (6) lifestyle, social world, and community; and (7) self-identification. These seven components together resulted in the Klein Sexual Orientation Grid. Each dimension can be rated on the Kinsey scale (0—exclusively heterosexual to 6—exclusively homosexual). It is suggested that there may be low or high congruence in ratings among the differing dimensions. Individuals can also rate the grid for past, present, and future sense of self.

When thinking about homosexuality, we are challenged to move beyond categorical, simplistic definitions that confound separate dimensions in an effort to be descriptive. In simplifying this construct, the complexity is lost, and moreover, we fail to allow for the dynamic and fluid nature of sexuality and sexual identity construction. More and more researchers and theorists are advocating examining these constructs more complexly using both traditional and nontraditional methods, thus allowing for the examination of variability in construction and description at the individual and group level.

## HOPE

---

References to a concept of hope can be found throughout historical writings and across many different disciplines. Despite the frequency of discussions about hope, there is not one unified description or definition for the concept. Christian scholars frequently characterize hope as a virtue from God in which individuals are confident in receiving an eternal reward. Philosophers provide a range of viewpoints, from hope as a misleading influence, like a mirage that motivates but is unattainable, to hope as an understanding of realistic desires. Hope has most recently been a focus of study for social scientists, who, through research, have defined hope as the mental motivation and plans that a

person has for his or her goals. This latter understanding of hope will be explored in more detail.

## COMPONENTS OF HOPE

Hope can be broken down into three basic components: goals, pathway thinking, and agency.

### Goals

Any desired outcome, object, or experience that individuals can imagine is considered a goal. A goal can be something tangible, such as wanting to buy a new car, or intangible, such as the desire to win a soccer game. Goals also range from the concrete, as in wanting the car, to the vague, as in the aspiration for success. Likewise, there is variation in the magnitude of goals. At times, they reflect more immediate desires (I will read this article today), and at others, distant wishes (I will complete a doctoral degree in literature).

People set goals constantly, often without realizing it. By reading these words right now you are engaging in behavior that reflects a goal (such as to read this sentence or to gather information about the concept of hope). By this definition, humans engage in goal setting almost constantly. But hope is not concerned with those goals that are assured successes or failures. For literate, educated adults, the goal of reading this sentence is virtually certain to be reached. Hope is an active process. Therefore, the reading goal would not be considered in relation to a person's level of hope because it is not open to change.

All goals are not created equal. One way that individuals can enhance their level of hope is by making their goals more specific. An undefined goal like wanting to be happy may be harder to picture than defined goals such as wanting to make a new friend or finding an enjoyable hobby. Specific goals also facilitate agency and pathway thinking.

### Pathway Thinking

For many goals, there are multiple viable routes to reaching them. Pathway thinking is used to identify possible ways to achieve a goal. Pathway thinking can be aided by focusing on specific important goals. Starting with a clear goal will increase one's ability to identify targeted pathways. Similarly, pathway thinking is more active when the goal is important to the individual.

### Agency

Agency is the motivation that moves people toward their goals. It is made up of thoughts that relate to individuals' beliefs that they can start working on a goal and continue progressing until the goal is reached. Agency thoughts can include a person's thoughts about his or her competence (I can do it), abilities (I know how to do this), and readiness for action (I'm ready to try). These can be applied to a variety of goals, but certain characteristics of goals make it easier to activate agency. When one imagines an important goal, motivation is more available. For example, an athlete is much more likely to play hard to win a state championship basketball game than a friendly family game of basketball. Furthermore, those goals that are specifically defined are more likely to spark mental energy.

### HIGH HOPE EXAMPLE

A high level of hope reflects strong agency and pathway thinking. It is possible for someone to be high in agency but low in pathways (and vice versa), but neither of these alone is sufficient to create high levels of hope. Consider the example of Andrea, a college student who has the goal of earning an "A" in biology class. When Andrea thinks about how to achieve this goal, she is able to generate numerous pathways, including turning all assignments in on time, studying an extra 20 minutes per day, getting a tutor, and organizing a study group before each test. Because she has multiple routes to her goal, Andrea's progress towards an "A" will not be stopped if one of her routes becomes blocked.

Andrea also exhibits high agency. Although the goal may be challenging, she focuses on her desire for a good grade, her willingness to work hard, and her past success as a student. These agency thoughts push Andrea to initiate her pathway behaviors and will motivate her to keep trying when she does encounter obstacles.

### BENEFITS OF HOPE

The positive effects of high hope have been demonstrated in many areas of performance. In the area of academics, level of hope at the beginning of the college semester has consistently predicted students' final grades, even when the influence of high school academic performance is removed. What makes this even

more striking is that hope is not correlated with IQ; therefore, the superior performance of high-hope individuals cannot be explained by simple achievement or intelligence. Research with athletes has also found that hope predicts athletic performance, even after controlling for natural physical ability.

Because of their level of agency and ability to identify pathways, high-hope people are more likely to reach their goals. This alone is important knowledge. But people with high hope also tend to do other specific things that help them to cope with life's problems. When they encounter stressful events, people with higher hope do not perceive the events as negatively as do people with lower hope. Presented with a challenge, high-hope individuals concentrate on how to deal with the situation, whereas low-hope individuals begin to worry and focus on themselves. Social support is also stronger among higher-hope people.

Studies of hope and health, both mental and physical, find that higher-hope people have better outcomes. Although hope does not immunize people against illness, it is correlated with lower rates of anxiety and depression, quicker recovery from surgery, and better adjustment to injury and chronic disease.

## CHANGING HOPE

Without intervention, a person's level of hope tends to remain stable. But it is possible to strengthen one's goal setting, agency, and way-power thinking. By practicing goal setting with a focus on creating positive and specific goals that represent a moderate challenge, people can create a solid basis for hopeful thinking. For specific activities to measure and improve hope, see the Further Readings and References section.

## SUMMARY

Hope is a way of thinking about goals. A person's level of hope reflects the amount of agency and pathways he or she has. Agency refers to the motivation to reach a goal, whereas pathways are workable routes to reach the goal. By increasing one's level of hope, one may experience improved performance in academics, at work, or in athletic pursuits. Higher levels of hope have also been correlated with more positive health outcomes.

## HORMONE REPLACEMENT THERAPY

---

Hormone-replacement therapy (HRT) is a physician-prescribed program of treatment for women who are experiencing hormonal imbalances, during or after the occurrence of menopause. It usually refers to supplementing the body with the hormones estrogen and progesterone, which naturally decline during menopause, to treat the symptoms that follow.

Estrogen is produced by the ovaries along with progesterone. Together, these two hormones regulate menstruation and ovulation. Menopause occurs as part of a woman's natural aging process when production of these hormones becomes erratic and eventually stops. This may happen over several years. At the beginning, a woman experiences irregular menstrual periods, often accompanied by hot flashes, night sweats, and a lack of energy. Eventually, her menstrual periods stop completely. Long-term postmenopausal symptoms include pelvic organ atrophy, bone changes that range from joint aches to osteoporosis, and circulatory changes such as varicose veins or even high blood pressure. Sometimes, circulatory changes lead to heart disease or stroke.

HRT works by supplementing the body with estrogen or with a combination of estrogen and progesterone, relieving some of the menopausal symptoms. Other beneficial effects of HRT include promoting the amount of HDL ("good") cholesterol and decreasing the amount of LDL ("bad") cholesterol in the blood. HRT slows or stops the loss of bone mass and density (osteoporosis), and may even increase bone density.

HRT may be given in the form of either naturally derived or synthetically produced estrogen. Less potent forms of natural estrogen, termed *phytoestrogens*, are derived from plants and can also be used in HRT. The two most common regimens are cyclic HRT and continuous HRT. The cyclical regimen is designed to mimic the natural menstrual cycle, in which estrogen is taken every day and, for 2 weeks of the month, progesterone is taken also. In continuous HRT, estrogen is taken in conjunction with a lower dose of progesterone every day. Transdermal estrogen patches, which are applied only one to two times per week, can also be used.

The risks associated with HRT include an increase in blood clots, heart attack, and abnormal mammograms when taken short-term. Risks of long-term HRT include an increased risk for breast cancer, heart disease, gallstones, pulmonary embolism, deep vein thrombosis, stroke, Alzheimer's disease, and other dementias. Many of these findings were discovered as a result of the Women's Health Initiative (WHI) study. The WHI is a major research program established by the National Institutes of Health (NIH) to address the most common causes of death, disability, and poor quality of life in postmenopausal women. The study included the assessment of the effects of treatment with estrogen plus progesterone, or estrogen alone, in healthy postmenopausal women. The estrogen-plus-progesterone study was prematurely halted in July 2002 when it was found that the risks (increased breast cancer, coronary heart disease, strokes, and pulmonary embolism) outweighed the benefits (fewer hip fractures and colon cancers). In March 2004, the estrogen-alone trial was also prematurely halted. The NIH reported that this therapy did not appear to affect the risk for heart disease, but increased the risk for stroke in postmenopausal women. This therapy also significantly increased the risk for deep vein thrombosis, had no significant effect on the risk for breast or colorectal cancer, and reduced the risk for hip and other fractures. Because the WHI studies focused on the risks of long-term use of HRT rather than shorter-term use, the NIH recommends that the information obtained should be used by women considering use of HRT for longer than 3 or 4 years. The decision to use HRT should be made after weighing risks and benefits and on the basis of the individual woman's health history and specific needs.

## HORMONES

---

Hormones are chemical substances that are produced, stored, and released into the bloodstream by secretory structures (glands) of the endocrine system. The endocrine system, in turn, is designed to modulate various body functions, including digestion, metabolism, growth and development, reproduction, and response to stress and injury. Hormones are released by specific glands, move through the bloodstream to target locations, and act there upon cellular "receptors" designed specifically to receive and be activated by particular hormones. Hormones are capable of altering the structure and function of many organs, including the brain. There are more than 50 distinct hormones that play diverse and pivotal roles in development and homeostasis and that may also affect behavior. Among the most well-known are the sex or steroid hormones, including androgen (e.g., testosterone, produced in the testes, ovaries, and adrenals) and estrogen (produced in the ovaries, testes, and adrenals). Alone, these two groups of substances exert widespread effects on the developmental process, as well as throughout life, and will be the primary exemplars of hormones in the following discussion.

### HOW DO STEROID HORMONES DETERMINE SEX?

All mammals secrete sex hormones. Beginning in the prenatal period, the process of sexual differentiation begins with genotypic sex (as determined by the presence of sex-specific chromosomes, e.g., XX for female and XY for male), which in turn codes for the development of either testes or ovaries. At this early prenatal stage, both genotypic males and females possess dual sets of duct systems—the müllerian ducts and wolffian ducts. Hence, early in development, the fetus is considered "bipotential" with regard to sex. As the testes or ovaries develop, however, and begin to secrete

hormones, further sexual differentiation of the body occurs. Specifically, the production of testosterone and other male-specific hormones leads to the regression of the müllerian duct system and the formation of the primal male internal reproductive system (epididymis, vas deferens, and seminal vesicle). Conversely, the absence of these male substances coupled with later ovarian output results in a female phenotype (including the development of fallopian tubes, the uterus, and the inner part of the vagina). Thus, structural or “physical” sexual characteristics define phenotypic sex. In most all cases, genotypic sex and phenotypic sex are identical, but occasional hormone anomalies may lead to an outward sexual appearance and behavioral pattern that is inconsistent with genotypic sex.

Hormones also lead to sexual differentiation of the external genitalia and modulate the emergence of sex-specific behaviors. Thus, testosterone directs the masculinization of external genitalia and the organization of male-specific behavior, whereas a lack of testosterone coupled with the later presence of ovarian activity results in female external genitalia (and the accompanying establishment of female-typical behaviors). Following the development of internal reproductive organs, external genitalia, and the organizational effects of hormones on brain and behavior, secretion of sex steroid hormones drops to quiescent levels until the approach of puberty. However, steroid hormones go on to play an important role in the activation of sex-specific behaviors in puberty and adulthood.

## HORMONES IN ADULTHOOD

Puberty is marked by the beginning of gametogenesis (the development of an egg or sperm by the gonads), a rise in secretion of sex hormones by the gonads, the accompanying development of secondary sexual characteristics, and the activation of reproductive functions that have been “organized” by early gonadal hormone secretions. These behaviors may reflect permanent alterations to brain structure and function, which nevertheless require the presence of circulating hormones to trigger their activation. This explains why reproductive behaviors are not seen (or occur at much lower levels) in prepubertal mammals, even though the groundwork for the display of these behaviors appears to be laid down in the brain early in development, during the process of sexual differentiation.

Mammalian females, for example, are characterized by an ovarian cycle. After puberty, females show cyclic

production and release of ovarian hormones that are in turn responsible for activating female-typical sexual behaviors. Such behaviors have been studied extensively in nonhuman mammals, particularly rodents (i.e., sexual receptivity and mating behaviors). Moreover, these sex-typical female behaviors have been shown to be conditional on the presence of estrogen and another ovarian hormone, progesterone.

Sexual behaviors in male mammals are also dependent on the presence of hormones. Testosterone is secreted by the testes and activates sexual behaviors such as penile erection and mating behavior. In the absence of testosterone, sexual behavior is severely compromised. However, testosterone is converted into two different metabolites, dihydrotestosterone (DHT) and estrogen, and these two by-products appear to have different effects on behavior. For example, it has been shown in rodents that one behavior (penile erection) is induced by the conversion of testosterone into DHT, whereas other behaviors (mating behaviors) are activated when testosterone is converted intracellularly into estrogen. Moreover, these androgen metabolites act in different areas of the brain (estrogen) and body (DHT) to mediate these different sexual functions.

One obvious question arises as to how estrogen can exert both feminizing effects in females and simultaneous masculinizing effects in males. One possibility that could account for these differing effects of estrogen involves differences in the relative amounts of estrogen between the sexes. Specifically, in males, estrogen appears mainly within the cell, where it has been actively converted from circulating testosterone into estrogen, and intracellular levels of estrogen derived through this metabolic pathway are much higher in males than intracellular levels of estrogen in females. In addition, estrogen may act on different structures and at different time points in male and female development.

## HORMONES AND COGNITION

Hormones also play a role in behaviors other than sexual behavior. For example, men generally have been shown to outperform women on tests of visuospatial ability, whereas women perform better on tests of verbal fluency and perceptual speed. It should be noted that these differences are typically small, particularly as compared with population and individual variability, and are largely irrelevant to issues of gender, ability, and career choice. Nevertheless, studies have shown

that performance on some cognitive tasks may be influenced by circulating levels of hormones (in fact, hormone levels may be as important as gender in mediating some of the observed sex differences in cognition).

In support of this view, animal research shows that neonatal testosterone affects a number of measures of cognitive performance, shifting it in a male-like direction. However, female hormones also influence aspects of nonsexual behavior. As one example of the complexity of sex differences in nonreproductive behavior, spatial navigation behavior has been shown to differ in male and female rats. Moreover, it has been shown that males and females utilize different strategies to complete the same task. Finally, some aspects of cognitive performance, which involve the use of differing strategies, appear to change over the ovarian cycle, specifically changing with fluctuating hormonal levels. Thus, it appears that “sex” differences on cognitive tasks may be not just a function of gender but also of circulating hormones.

## HORMONAL MANIPULATIONS

Throughout life, humans also manipulate their hormonal levels to achieve different outcomes. For example, anabolic steroids (which represent synthetic forms of testosterone) are used by athletes for their effects on the musculoskeletal system (i.e., increased lean body mass and increased muscle strength). Oral contraceptives also represent hormonal manipulation, in this case used to prevent pregnancy in females by altering estrogen and progesterone. These two hormones, which direct many of the processes surrounding the menstrual cycle, work by preventing an egg from being released from the ovaries most of the time and also make the uterus a hostile environment for an embryo by causing a thinning of the uterine lining. Evidence suggests that both anabolic steroids and oral contraceptives may exert some effects on cognition and emotions, although the specific nature and pattern of these effects remains unclear.

## HORMONES AND AGING

As we age, our hormonal levels also decrease. In females, ovulation ceases after middle age, and in males, testosterone levels decrease with age. In postmenopausal women, there is a decline in the ovarian production of estrogen that results in estrogen deficiency. This deficiency is associated with a number of

health problems as well as cognitive and behavioral changes. A way to compensate for these changes involves the use of hormone replacement therapy (HRT). This therapy supplements the age-related decline in naturally produced estrogen and progesterone with an external source, although controversy indicates that the negative side effects of HRT may outweigh benefits for some women. In males, testosterone levels decrease with age, and they experience similar cognitive and mood changes, as well as a loss of sexual drive. One way to deal with the latter problem is with drugs designed to combat the decline in testosterone and its effect on sexual performance. For example, certain drugs can be used to exert a direct influence on male erectile mechanism, specifically by working on the brain and spinal cord pathways that control penile erection. The male counterpart to dealing with declining estrogen and progesterone levels in women is to take testosterone. However, there are few studies to date addressing the effects of HRT in men, and preliminary evidence suggests both beneficial and detrimental effects on health and cognition. Some studies addressing the influence of HRT on cognition in aging males show that testosterone enhances spatial memory and possibly verbal and working memory, whereas other studies show no influence on cognition. A similar discrepancy exists for aging women and HRT. Although some studies have shown that HRT has a positive effect on verbal memory and mood, others have not found significant differences between users and nonusers of HRT on any cognitive measure.

## SUMMARY

The data discussed here represent only a small portion of the many effects that hormones exert on human physiology. In this entry, sex steroids are addressed as an exemplar, given the highly significant effects these substances exert across the human life span. However, many other hormonal systems affect metabolism, sleep, stress, and other systems, and the reader is referred to one of the excellent resources below for more information on these diverse effects.

## HOSPICE

---

Hospice is a philosophy of care for people who have terminal illnesses and their families through the use of an interdisciplinary team that develops a coordinated, individualized plan of care. The focus of such care is on pain management and symptom control, within the context of maintaining quality of life for the dying patient and his or her family. In this respect, death in the hospital (or nursing home for that matter) is “hidden,” in contrast to the death of a person in hospice, which is real, human, and meaningful. Rather than view death as the end of life, death in hospice is better thought of as “spiritual transformation” from this life to the next. This redefined notion of death in hospice is predicated on the basis of the fact that death need not be accompanied by suffering; that is, that such care is palliative, and that the patient’s and family’s wishes will be identified and honored. In effect, death and dying in hospice are a natural event, in contrast to dying in an institution, the many problems of which have begun to be addressed by societal and professional efforts to humanize dying by defining the rights of dying persons and by making recommendations about how end-of-life care might be improved. Such efforts were stimulated by the failure of project SUPPORT, which attempted to enhance the quality of life for dying patients by improving the communication skills of health care professionals (i.e., physicians). Although hospital care has been characterized as *event oriented* (focused on the prevention of the event of death), hospice care is *process oriented*—dying is its focus.

In North America, five models of hospice care exist: (a) home-based care, often provided by community-based professionals and volunteers (90% of Hospice care is provided in the patient’s home); (b) home-based care provided by home health care agencies, or Visiting Nurse Associations (VNAs); (c) free-standing, full service, autonomous hospice

facilities; (d) separate hospital-based palliative (pain-reducing) care units; and (e) hospital-based subacute units, emphasizing continuum of care. In addition, some hospices have begun to explore the concept of adult hospice day care. Pediatric hospice programs are also becoming more common. About half of all hospices are hospital based, and the remainder are operated by home health care agencies. Most (nearly 75%) are nonprofit in nature, whereas 15% are for-profit. One third are free-standing facilities. It is also becoming more common to see nursing homes and assisted-living communities provide hospice care. Although most hospice patients have cancer, people being cared for by hospice also die of acquired immune deficiency syndrome (AIDS), end-stage renal disease, dementia, and cardiovascular illness.

Regardless of one’s model of hospice care, all hospices share certain characteristics that set them apart from other forms of health care: (1) the dying person and family are the unit of care; (2) the interdisciplinary team serves both the dying person and the family; (3) care focuses on both the physical and psychosocial aspects of dying; (4) services are available on a 24-hour per day, 7 days per week basis; (5) inpatient and home care services are available; and (6) bereavement counseling and support (both before and after the individual’s death) are available to both the dying person and the family. Many, if not all, of these issues are reflected in the dying person’s perception of what is important at the end of life.

These characteristics reflect some very basic ideas about life and death: (1) that dying is a natural experience, with life and death being equally important and meaningful aspects of our existence; (2) that dying people and their families are important in themselves, with the dying person’s welfare coming first; (3) that dying people should be able to continue to make decisions for themselves until they are unable or unwilling to do so; and (4) that dependence on others and being cared for by them are not demeaning.

The essential one-on-oneness of the hospice care philosophy has historically stood in contrast to the cure orientation of conventional hospital oncological care or the maintenance mentality of the nursing home. In this light, hospice patients are less likely to receive intensive medical interventions such as chemotherapy or surgery as well as diagnostic tests (e.g., blood tests, X-rays) in the weeks before death than are those in conventional hospital oncology units. Moreover, although analgesics are also more likely to

be regularly prescribed for pain on a fixed schedule in conventional health care, pain medication is prescribed on an as-needed basis in hospice.

## HISTORY AND ORIGINS OF HOSPICE CARE

The primary stimulus for hospice in America came from the St. Christopher's hospice in London, founded by Dr. Cecily Saunders in 1967, although hospices clearly had existed for many years in Europe. Since then, initiated by the opening of a home-based care hospice, Hospice, Inc. in New Haven, Connecticut, in 1974, nearly 3,300 hospices have been founded in North America. Changes in attitudes toward death, legal decisions and legislation affirming the right of the individual to refuse life-sustaining treatment, and the development of the Medicare Hospice Benefit have also encouraged the expansion of hospice in the United States. Other events important to the development of hospice are the founding of the first hospital-based hospice in North America—the palliative (pain-reducing) care unit at the Royal Victoria Hospital in Montreal, and the formation of the National Hospice Organization (NHO) in 1977 (now known as the National Hospice and Palliative Care Organization [NHPCO]). In 1992, the principal fund-raising arm of the NHPCO, the National Hospice Foundation (NHF), was founded. NHPCO has been important in educating the public about hospice and in formulating standards for quality hospice care critical to their accreditation, which makes hospice a viable alternative to institutional care for terminally ill persons and their families.

Hospice care became a recognized benefit under Medicare in 1983. Studies have shown that although dying persons represented only a small percentage of all Medicare beneficiaries at any given time, such persons were consuming a disproportionate share of all Medicare expenditures. Three years later, legislation was passed permitting state Medicaid programs the option of covering hospice. The hospice benefit under Medicare requires that core professional services—physician, nursing, counseling, and medical social work services—be directly provided by the hospice. However, it does not require that hospices directly operate home care or inpatient care facilities. Rather, Medicare simply requires that the hospice staff maintain responsibility for all services regardless of their location and that they guarantee access to such services on a 24-hour basis. The same concerns regarding the

costs of acute care for dying persons that convinced Congress to establish a Medicare benefit have moved private health insurance companies toward hospice coverage. Even when covered by Medicare, hospice costs are sometimes unnecessarily paid by patients and families because questions about private health insurance coverage were not asked.

## HEALTH CARE DELIVERY IN HOSPICE

Case management ensures that quality care is available to, and continuous for, each patient and family. This is especially important because patients and families often know little about caregiving and may have difficulty in dealing with other agencies. The coordination of care within the interdisciplinary team, as well as with other professionals outside of hospice, is an essential component of the case management mold in hospice. Case management matches each unique patient-family unit with whatever services they may need, as well as monitoring changes in their needs for such services. Case management also helps patients and families arrange for insurance coverage, plan for emergencies, and if necessary, arrange for services from other agencies. In hospice, case management is often carried out by the primary care nurse or the social worker.

The care plan for the patient and family is implemented with the patient's and family's needs in mind. It is likened to a process—something that patient and family actively participate in. Information about the patient's needs is often gathered by interactions with patient and family, and such information is assessed by the interdisciplinary team in formulating a care plan. The team also arranges to coordinate and deliver hospice services, monitors the effectiveness of these services, and if necessary, reevaluates the care plan if the patient's physical or emotional status changes. Numerous decisions regarding everyday changes in the dying person's energy level, emotional state, functional (decision-making, self-care) skills, and needs for pain medication must be made by the team, yet balanced against the quality of the dying person's life as well as against the demands of work, school, raising children, house cleaning, cooking, and bill paying. Additionally, changes in the family's needs for support and information are likely. For example, the patient and family may initially ask about insurance coverage, the nature of the illness, its progression and treatment, or what the family can do to help to care for a dying loved one. They may also want to know about the side effects of

pain-relieving medications. As the patient's condition worsens, needs for reassurance and support may surface, and concerns about planning a funeral, writing a will, or living without a loved one may be shared. Near death, the family may be less verbal about their needs, and emotional support from a staff member or volunteer may be all that they require. Rather than "doing" something, hospice personnel may meet this need by simply "being there."

### LEGAL AND ETHICAL ASPECTS OF HOSPICE CARE

NHCPO does not support either suicide or euthanasia in hospice, and indeed, they are infrequent among hospice patients. However, there is the occasional individual for whom "rational" suicide or euthanasia may be perceived as an alternative to living in pain or dying an undignified death. Although such statements may mean that the patient's needs are not being met by the hospice, they may also reflect family difficulties, resulting in the dying person's feeling rejected and unloved. Suicidal thoughts may be shared openly, or they may remain unexpressed. Such patients may have a hard time sleeping or eating, refuse medications or visitors, or suddenly change a will. A wish to commit suicide may reflect an individual's particular moral values about the quality versus quantity of life. If such concerns do surface, one should explore whether they are shared by family members, and if they are not, or if family members are unaware of them, the caregiver must make a choice regarding whether to discuss them with the family. In most cases, it is preferable that the patient's wishes to discuss suicide or euthanasia with his or her family be respected. Many hospices have adopted a policy against active euthanasia and against the acceptability of suicide. What death and dying mean to each person should be explored, so that the dying patients can understand and clarify their feelings as to why suicide or euthanasia might be preferable to living, and so the caregiver can more fully understand the dying person. Not discussing such topics or making them seem unimportant suggests communication difficulties that must be remedied quickly.

### INTERDISCIPLINARY TEAM

Hospice uses the interdisciplinary team in tending to the well-being of dying patients and their families, and has been demonstrated to be effective in this respect.

The term *interdisciplinary* reflects the variety of skills that professionals, paraprofessionals, and volunteers contribute in meeting the complex and changing physical, psychosocial, and spiritual needs of the patient and family. In this regard, the team functions to ensure that the dying patient and family function as well as possible given the burden of having a terminal illness and the realities of daily life, including maintaining a household, holding a job, and raising children. Not only are the patient's medical needs given priority, but also the patient's and family's needs for intimacy, privacy, and support from relatives, friends, or neighbors must be met. As the essential component of hospice, the team functions to evaluate and meet the special requirements of each patient-family unit. Within the plan of care that has been developed for the patient and family, the patient care coordinator, who is often the social worker or nurse, brings together each member of the team to assure continuity of care. Not only is this vitally important during the period of time the patient is actually receiving hospice services, but it is also essential to providing effective bereavement support. Such support is especially critical if the staff sense that the family wishes to disengage from them after the death.

Ideally, the team is composed of people with a mix of professional expertise and background: nurses, social workers, clergy, physicians, counselors or psychologists, dietitians, physical therapists, pharmacists, and volunteers. For the most part, direct patient hospice care is managed and carried out by nurses in either inpatient or outpatient settings, under the direction of the hospice medical director in concert with the patient's physician. Important roles are also played by clergy, social workers, and especially volunteers. In most cases, teams meet on a weekly or semi-weekly basis to review each case and to discuss problems encountered in carrying out the plan of care, as well as to discuss problems within the patient-family unit itself. As noted earlier, the care plan may need to be modified for any number of reasons.

Physicians have direct input into the delivery of care and are primarily responsible for the direction of the medical care that includes both ongoing, daily, and emergency care. Physicians formulate a medical regimen of pain and symptom control using an array of narcotic and nonnarcotic analgesics (pain-relieving drugs). In hospice, however, the physician's role is best defined in the context of the entire team and most likely varies a great deal from hospice to hospice. In rare cases, the role of the physician may be minimal, and the physician

may not actively function as the medical director or as a participating member of the team. Relative to the more traditional physician, hospice physicians are more likely to play a less authoritarian role in the delivery of care. They are more patient and family oriented and emphasize more strongly clear, effective, and empathic communication with both patient and family as well as with other hospice staff. Perhaps the physician's most important role, other than in prescribing pain medication, is to serve as a liaison between the hospice and physicians in the community as well as with the patient's personal physician, from whom referrals often originate, and whose attitudes about hospice are critical in this respect.

Nurses in hospice often make an initial assessment visit with the family, and because they see the dying person most often, frequently oversee the coordination of direct patient care among the team. In an initial visit, the nurse learns about the history of the illness from both the dying person's and the family's point of view, and assesses their needs to help the hospice care team to design a care plan. The nurse is equally attentive to the emotional needs and physical well-being of the patient and family. Relieving pain promptly, wherein pain often but not always accompanies a terminal illness, and keeping the patient as pain free as possible, are vitally important. Listening and "normalizing" everyday life are also very important aspects of the role that the hospice nurse plays.

Although nurses often provide most of the direct, hands-on skilled care, the social worker may also serve as a case manager. The social worker often conducts the initial psychosocial assessment of the patient-family unit, dealing with such issues as insurance coverage, pensions, wills, and funeral planning. Although medical social workers may function similarly to the nurse regarding the family's well-being, they usually assume primary responsibility for tending to the financial and legal aspects of terminal care with the family, and in helping the family obtain outside assistance with home care, meal planning, or meeting transportation needs. The social worker also often oversees the follow-up bereavement care of the family.

The volunteer assists the patient and family in a variety of ways on a continuing as-needed basis. Volunteers can, by simply listening and observing, monitor the family's physical and emotional status so that a crisis of caregiving can be avoided. Volunteers can also help in the provision of care itself: turning patients in bed, personal grooming and hygiene, helping with

household chores, picking up children from school, and most important, simply being present. Volunteers have been and are viewed as an absolutely essential component of the hospice team and should function as such. In most hospices, a volunteer coordinator helps match and assign volunteers to patients and families and may assist in coordinating and delivering volunteer training. By accompanying the nurse or social worker on an initial visit, the volunteer coordinator can learn about each family's background, interests, and unique needs that influence hospice care, as well as form an impression of each family member as a person.

The role of the clergy is usually more subtle and often only on a demand basis in hospice, although it is difficult to generalize about the extent of their involvement. Clergy are involved in the team to shed light on the spiritual needs of the patient, and if the patient has no religious affiliation, to minister to the patient and family. Rather than promoting a particular religious philosophy, the chaplain sees to the patient's spiritual well-being by being a link to the religious community. The chaplain often assists in bereavement follow-up, as well as in the training of volunteers. The chaplain can also function as counselor, listener, problem solver, mediator, or friend, as can the hospice administrator, depending on his or her training, over and above the overseeing of personnel and reimbursement issues within the hospice.

Few hospices actually have a psychologist as a paid staff member or a volunteer, although this is changing as the patient-family unit's emotional well-being is being recognized as an even more important influence on the health of the dying person and his or her family. Moreover, hospice staff members offer more counseling than any other activity other than providing nursing care. The psychologist or counselor, for the most part, plays a supportive role in consulting with the team regarding the psychosocial functioning of the patient or family. Counselors' or psychologists' expertise is sought regarding family conflicts associated with the stress of terminal care, or long-standing difficulties that are brought to the surface by the dying of a family member. Such conflicts often interfere with either the delivery of care or the patient's or caregiver's well-being.

## **BURNOUT AND ATTRITION IN HOSPICE**

Stress among hospice workers is unique in that uncertainty about whether one's efforts are effective,

the duration of time spent with patients, and the importance attached to one's work are all high. Although individuals vary in their ability to appraise and respond to stress, the unique commitment hospice staff have to their work and the demanding nature of working with dying people make them especially prone to stress and burnout. Most hospices now recognize that some form of regular, timely staff support is crucial to lessening stress and minimizing staff turnover, although this has not always been so. Staff with little family support, who work in home care-based hospice situations, appear to be at greater risk for job stress and burnout. Younger and less mature caregivers also seem to be more prone to dysfunctional stress reactions owing to a lack of emotional preparation, as do people who are more death anxious or who are trying to cope with the loss of a loved one by immersing themselves in hospice. Given that burnout predicts the long-term attrition of hospice staff, perhaps most important to minimizing burnout is the selection of hospice staff. Excluding people who have experienced recent personal losses as well as those with a great deal of anxiety or concern about their own deaths or about being around dying people is important. Over and above the selection of team members, the team itself must have time to be alone with one another to discuss technical and creative issues, as well as to express their feelings and provide emotional support to one another regarding their work. Taking care of oneself is central to lessening hospice team stress and burnout. Moreover, opportunities for continued training and cross-disciplinary sharing outside of hospice are essential to minimizing attrition.

### **PATIENT-FAMILY DYNAMICS IN HOSPICE**

Although the needs of the dying person are an important focus of hospice, that person is nevertheless embedded in the matrix of relationships and interactions with other family members. Death may disrupt patterns of communication, role responsibilities, decision making, and assertions of power or dominance within the family. The very identity of the family and of the individuals in that family may be threatened by death. Each family's reaction to the diagnosis of a terminal illness, its management of a loved one's dying, and its post-death functioning are determined by previous family styles and patterns of coping. The impact of death also varies by whether a parent or a child dies, interacting with what stage of the family life cycle the family is in.

When hospice care is provided by the family at home, caring for a dying loved one can present an additional burden the family may see as impossible to cope with. The family must believe that home care is both possible and desirable, and they must have access to professional assistance as well as specialized equipment often essential to quality terminal care. The family must also have the nursing skills to make physical care possible. Moreover, knowing when death is imminent, what to do at the moment of death and what to do immediately after death are important skills and knowledge that are important in choosing home care. Families report that changes in the dying person's mental status (inability to communicate, confusion, seizures), and such changes in his or her inability to care for oneself are the most troublesome, as are administering medications and dealing with the loss of bladder or bowel control. Putting personal and career goals on hold, having little "alone time," being isolated from others, feeling guilty, and neglecting one's own health are also sources of stress among caregiving families. Recent findings suggest that families who have a loved one dying of AIDS face even greater difficulties. Such families express more difficulty in sharing their feelings, report more stress, are less trusting, and have more illness anxiety than families with other terminal illnesses. Hospice staff can help in the performance of many of these needed tasks through education of the family and through the provision of psychological and spiritual support to them. In most cases, details that seem unmanageable, horrid, or repulsive become less so with a bit of hands-on teaching and knowledge. As hospice care extends beyond the death of the patient, it is also important to observe how both the patient and family deal with their grief because it influences the postdeath adjustment of survivors. Opening up lines of communication may help families face the reality of a loved one's death, particularly if they have had little recent contact with the dying person or when there are long-standing family difficulties.

In evaluating the patient-family unit, the focus is likely to be on the woman's well-being, health, and extent of social support from others because female spouses tend to experience more family caregiver burden than do both men and children. Indeed, psychosocial and emotional support to primary caregivers by family is crucial. It is also helpful to explore the extent to which family caregivers are depressed, whether they have used social services in the past, and their explanations for the dying person's behavior because these

factors have also been found to predict caregiver burden and may constitute adjustment difficulties in themselves. Such insight may require several visits to achieve and may necessitate an assessment by more than one hospice staff member. An evaluation of the family's support system is also crucial to understanding how they will cope with the illness—do they have extended family, friends, neighbors, or coworkers available? What area support agencies have they contacted (e.g., nursing home, home health care services)? Do they have savings or private insurance? How much of the cost of care is Medicare likely to cover? Has a will been written? Have funeral arrangements been made? Do they attend or are they members of a church? Would a visit from the hospice clergy be helpful? Through all of this, the family should sense this active support and interest in their welfare and functioning by hospice staff. In cases in which significant family dysfunctional patterns are interfering with care, more formal family therapeutic interventions may be necessary.

## GRIEF AND BEREAVEMENT IN HOSPICE CARE

Bereavement follow-up is a primary characteristic of hospice, and it sets hospice apart from other types of health care for dying persons and their families. In many respects, the job of the formal caregiver has just begun when the patient dies. The family must be sustained and cared for well beyond the death of a loved one, and bereavement care facilitates the expression of grief before death and thereby lessens its severity after death. Because the same personnel are encouraged to stay in contact with the family, this ensures continuity of care. Different staff, however, may be involved to encourage the family to develop new relationships.

The major objectives of hospice bereavement care are (1) accepting the reality of the loss of a loved one, (2) experiencing the pain of grief, (3) adjusting to an environment without a deceased family member, and (4) reinvesting energy into other relationships. At present, research growing out of the National Hospice Study suggests that although hospice bereavement programs can be very beneficial, objective evidence supporting their efficacy is sparse; however, the odds of a surviving spouse dying in the 18 months of his or her spouse's death are greater if hospice is not used. In addition, better postdeath adjustment has been found among spousal survivors who used hospice.

Bereavement care is often carried out by social workers, nurses, or volunteers. Bereavement care often focuses on those whose grief is pathological, or on the identification of persons who might have later difficulties in coping. A variety of very diverse bereavement services are offered by hospices. These include attending the funeral, providing individual or group counseling, sending postcards, making telephone calls, and holding memorial services and other social events. The intensity of involvement by individual hospice staff or by the interdisciplinary team varies, as does the formality of objective bereavement follow-up. Counseling, companionship, and assessment are the prime reasons reported by staff for bereavement visits, and persons in home-based hospices typically receive more bereavement support and counseling than do those in hospital-based hospices. Related to such bereavement support is the fact that people in home-based hospices are more emotionally distressed and experience more caregiver burden before death than those in hospital-based hospices. Because hospice care places a special burden on those family members caring for a loved one at home, individuals who have suffered more because of the demands of caregiving may fare more poorly after death.

## A FINAL WORD

Perhaps the greatest lesson that hospice teaches us is that people can grow spiritually and emotionally by being with a loved one at a very sad and emotionally difficult time of life. This lesson is vividly expressed in the words of the wife of a hospice patient who died of cancer:

Knowing that your spouse has a terminal illness is not all bad. It gives you time. Time for all the things you might otherwise not do. Time to talk, mend bridges, get to know each other better, and even time to fight through the things that you need to fight through. This great thing we call time allows us to let go of that loved one without regrets. We can say goodbye and mean goodbye with all our hearts. The time spent preparing for my husband's death is probably the most valuable time of our 17-year marriage. Perhaps in your mind that casts a shadow over our marriage. I think not. I believe that we were very typical of the great percentage of couples. We got caught up in the work of life and often lost contact with each other. We were fortunate to be extremely close and in tune to one another, but we still got caught up in our own

personal strives for survival. Had Ray suddenly dropped dead one day we would not have had 6 months to bond and prepare. I am fortunate to be able to say that I have no regrets after Ray's death.

## HOT FLASHES

---

The hot flash is a sudden sensation of heat typically experienced by women during their menopausal years, although they have been reported among young women during various phases of the menstrual cycle. Flashes (also called flushes) are the most common complaint of women in the menopause transition. The heat sensation generally begins in the chest and radiates to the face, head, and arms. Women may also report feeling palpitations or anxiety with hot flashes. Other sensations reported include feeling nauseated, pressure in the head or chest, and a feeling of suffocation. Some women who experience hot flashes also complain of a reduced ability to concentrate; however, the relationship between hot flashes and memory is not well understood. At times, women report having night sweats and not hot flashes, although the two terms refer to the same physiological phenomenon.

For researchers, clinicians, and even the casual observer, hot flashes can be identified by the visible changes that accompany them, including skin flushing,

increased skin temperature, and sweating. These characteristics provide the basis for assessment of hot flashes through measurement of skin and central body temperature, measurement of skin moisture, and analysis of skin conductance for clinical or research purposes.

In the United States, 75% to 80% of women undergoing the natural course of menopause and 95% to 100% of women whose ovaries are surgically removed experience hot flashes. Generally, hot flashes occur in women 40 to 60 years of age, with 87% experiencing them daily and about 30% reporting more than 10 flashes per day. Hot flashes are usually experienced over a period of 1 to 5 years but may last for more than a decade. Some women experience only one flash per month, whereas others have one per hour; alternatively, some 15% to 20% of postmenopausal women do not experience any hot flashes during the menopausal transition. Distress associated with having hot flashes varies among women from those that are barely noticeable to severe episodes of flushing, sweating, and feeling hot. Severe hot flashes can significantly disrupt activities of daily living, including work and sleep. In addition to being disruptive, hot flashes may be embarrassing in social situations.

Although prevalent during the menopausal transition, the cause of hot flashes is still not well understood. The hot flash is known to be related to estrogen decline as the number of follicles diminishes in the aging ovary. However, estrogen does not directly cause hot flashes. It appears that estrogen decline alters basic processes in the brain, which leads to the hot flash. These relationships are currently under investigation.

Various factors that can trigger hot flashes have been identified. These include consumption of hot drinks, spicy foods, alcohol, or caffeine as well as smoking cigarettes. Such identifiable triggers can be controlled to reduce hot flashes.

There are currently two effective treatments available for women experiencing hot flashes. Hormone replacement therapy (HRT) is the gold standard in treatment of menopausal hot flashes; HRT has been the cornerstone of therapy since the 1950s. It is the only therapy for hot flashes approved by the U.S. Food and Drug Administration (FDA). HRT generally reduces the frequency and intensity of hot flashes but may eliminate them completely for the duration of hormone use. Black cohosh, an herbal supplement, has also been demonstrated to be effective in treating hot flashes. Eight clinical trials have shown both the

safety and effectiveness of black cohosh. Other treatments reported to reduce hot flashes are acupuncture, vitamin E supplements, exercise, and biofeedback. However, scientific evidence to support use of these therapies is lacking.

## HUMAN GENOME PROJECT

---

Determining the sequence of the human genome has been compared in significance to Neil Armstrong's first steps on the moon and to revealing the "book of life." At the White House announcement of completion of a draft sequence, the achievement was described by President Clinton in 2000 as "Without a doubt . . . the most important, most wondrous map ever produced by humankind."

The word *genome* is used to describe the entire DNA sequence of an organism. The cells of all plants and animals contain two copies of the genome—one inherited from each parent—except of course for the germ cells (eggs and sperm), which contain a single copy. The DNA (deoxyribonucleic acid) is tightly coiled on chromosomes, of which there are 23 pairs in humans. If all of the DNA in a single human cell was stretched out, it would be about 2 meters in length. DNA consists of two antiparallel strands coiled into a double helix. The strands are held together by hydrogen bonds between molecular structures known as *bases*. The bases on each strand are held together by a sugar-phosphate backbone. The length of DNA is measured in base pairs (bp), with the entire human genome being about 3,000,000,000 bp in length.

The DNA contains all of the information required to synthesize each of the proteins present in every cell and

the manner in which each is expressed. For example, although there is a subset of proteins that every cell requires to survive, there are others that are specific to liver cells, kidney cells, or nerve cells. The information (or code) for each must, however, be in every cell because all plants and animals develop from a single fertilized egg. The portions of the genome that code for proteins are referred to as *genes*. The DNA around each gene contains information controlling gene expression—so that liver proteins are made in liver, kidney proteins in the kidney, and so forth. Alterations in the DNA sequence encoding proteins may result in corresponding changes to the protein sequence as well. These changes (mutations) are the direct cause of inherited diseases such as cystic fibrosis, muscular dystrophy, and sickle cell anemia. Other diseases such as heart disease and hypertension are believed to result from different mutations in different genes. Some sequence differences do not cause diseases at all, but are necessary for there to be variation in a population—otherwise, everyone would look the same. Furthermore, if there are no changes in DNA sequence, animals and plants would be unable to adapt to changing environments, and species would not evolve.

The possibility of identifying each and every gene was first discussed in the mid-1980s after a few viral genomes had been sequenced and the construction of the first human gene maps had been accomplished. The U.S. National Research Council (NRC) endorsed the notion in a report in 1988. The Human Genome Project (HGP) officially started on October 1, 1990 under the oversight of the U.S. National Institutes of Health (NIH) and Department of Energy (DoE) in conjunction with United Kingdom's Wellcome Trust and Medical Research Council, and subsequently involved scientists from France, Germany, China, and Japan. The 15-year, \$3 billion project envisioned the determination of the complete human genome sequence after the generation of detailed genetic and physical maps and the development of high-throughput, efficient sequencing technologies while determining the genome sequences of model organisms such as *Escherichia coli*, yeast, a worm, fruit fly, and mouse.

Eventually, two parallel approaches were taken to sequence the genome. In the first, the HGP cloned human genomic DNA into fragments of about 100 to 200 kilobase pairs (kb) in bacterial artificial chromosomes (BACs), organized these clones into overlapping series, sequenced each BAC, and then assembled the sequence using the order of BACs to make sure the sequence was in the proper order. In the alternative

approach, employed by Celera Genomics, the genome was broken into fragments of 2, 10, and 50 kb, sequenced from either end, and reassembled. Every base was sequenced 5 to 10 times from different clones, and the ends of each clone were a known distance apart (mate pairs). This latter approach (“shotgun sequencing”) only became feasible with the development of high-throughput automated sequencers (by Applied Biosystems) and the design of the necessary assembly algorithms. Both approaches had to handle the substantial repeat content of the human genome that affects both the mapping of BACs and the assembly of sequence. Independent drafts of the genome sequence were completed in 2000, and an essentially complete sequence was finished in 2003. The efficiency of the shotgun approach allowed the rapid determination of the genome sequences of mouse, rat, mosquito, chicken, and many other species from 2001 to 2004. The finished human sequence has been shown to be 99.99% accurate (i.e., no more than one mistake in 10,000 bp).

An important result of the HGP has been the delineation of the genes encoding all of the proteins that make up the human body and those that regulate its development. These proteins are encoded by about 20,000 genes. Because humans usually regard themselves as more complex beings than flies or worms, it was surprising to find that, in comparison, the fruit fly genome has about 13,000 genes and the nematode genome about 19,000. Comparison of genes between species indicates that mammals have more regulatory genes than invertebrates, perhaps allowing for more complex developmental processes. Another surprising observation is that the protein coding sequences account for only 1.2% of the entire genome and that nearly half of the genome is composed of repeated sequence elements. However, by comparison with the mouse genome, about 5% of the human genome can be seen to be under active selection. It is believed that most of this conserved sequence is made up of elements that regulate the expression of nearby genes. Now that the genome sequences of different mammals (mouse, rat, dog, chimpanzee), as well chicken, frog, and fish, have been determined, it is possible to compare the human sequence to each of these species to identify parts of the sequence that have been conserved over hundreds of millions of years of evolution and that are presumably important in regulating the developmental processes that animals have in common. On the other hand, the differences between closely related species should help identify the cause of specific

characteristics. For example: Why is a rat bigger than a mouse? Why are humans taller than chimpanzees?

Another important observation is that the genome sequences of any two unrelated people are 99.9% identical. The 0.1% difference is the variation that makes each of us different—taller, shorter, brown hair, blond, and so forth. There is actually more difference within a large geographically defined population than between two populations (e.g., between the population of northern Europe and China). Thus, the grouping of individuals by skin color has no more biological relevance than grouping by height or shoe size. Scientists are now using this variation between individuals to identify the genes that predispose people to heart disease, diabetes, hypertension, asthma, and other disorders.

Rapid technological advances are expediting these studies. Over the course of the HGP, the cost of DNA sequencing was reduced by more than 100-fold from about \$10 per base to less than \$0.10 per base. Scientists are now working to lower the cost to \$1,000 per *genome*, so that personalized medicine becomes feasible for everyone. It should be possible to accurately predict the chances of an individual developing cancer or heart disease by examining their DNA sequence, rather than their family history and diet. It will also be possible to identify the best drug to treat individual patients, knowing how different drugs will act in people with variation at specific genes.

—Iain McIntosh

## HUMAN IMMUNODEFICIENCY VIRUS (HIV)

---

The human immunodeficiency virus (HIV) is a retrovirus. A retrovirus is a type of virus that has viral

RNA in its nucleus instead of DNA. The primary targets of HIV in the human body are T4 or T-helper cells. T4 cells help to organize the immune system's response against a foreign invader (e.g., virus, bacteria, fungus). HIV attaches itself to T4 cells then inserts its genetic material into the cell. Through various chemically initiated changes, the viral RNA becomes viral DNA and makes its way into the nucleus of the T4 cell. The T4 cell becomes an HIV-producing factory. Eventually, the infected T4 cells die, and their numbers decrease, which leads to a weakening of the immune system. When a person's T4 cell count drops below 200, which is roughly 70% immune damage, they are diagnosed with acquired immune deficiency syndrome (AIDS).

There are two types of HIV: HIV-1 and HIV-2. HIV-1 is the more common of the two types and is more easily transmitted. HIV is found in all body fluids. However, the quantity of HIV in bodily fluids varies, with blood, semen, and vaginal fluids having the highest concentration of viral particles. Unsafe sexual practices, injection drug use, and transfusions are the main causes of infection. Most people exposed to HIV test positive 2 weeks to 6 months after exposure. Some people changing from HIV negative to HIV positive (called *seroconversion*) experience viremia or severe flu-like symptoms.

HIV was first identified in 1981. It is believed to be related to simian immunodeficiency virus (SIV). Researchers discovered that chimpanzees were exposed to SIV by eating monkeys. Over a long period of time, chimpanzees became resistant to the disease. Humans are believed to have been exposed to SIV through hunting chimpanzees for bush meat. Because of the 98% comparability of genetic material between humans and chimpanzees, the virus began to infect human beings, a process called *zoonosis*.

HIV is unique in world history as being one of very few pandemics or worldwide epidemics. It is estimated that up to 46 million people worldwide are infected with HIV. Most infected individuals are adults; however, up to 2.9 million children are estimated to be infected with HIV worldwide. In 2003, 3 million adults and children died from AIDS.

Drugs have been developed that can keep levels of HIV in the blood very low. Persons infected with HIV must take combinations of two or more antiretroviral drugs, also called *highly affective antiretroviral treatment* (HAART). There are three broad classes of antiretroviral drugs, which attack HIV at various stages in

its life cycle. Currently, 22 drugs are approved to treat HIV, with many more being researched. However, there is no cure for HIV. In people with AIDS and those who have sustained damage to their immune system, antiretroviral drugs keep viral levels low, but researchers continue to search for ways to rebuild the immune system.

Researchers are hopeful that a vaccine for HIV will be found. Until a successful vaccine is developed, behavior change remains the key method of preventing new HIV infections. Despite prevention efforts, 5 million new cases of HIV were reported in 2003. Also of concern are the millions of orphaned children in Africa from AIDS, and the growing number of people infected with HIV in Asia and other parts of the world. Finally, many countries cannot afford the drugs to treat HIV. Therefore, getting antiretroviral medications to developing nations will be a key focus for the world.

## HUMOR

---

Humor is closely related to play; indeed, it can be viewed as a form of “mental play.” When we engage in humor, we are playing with words and ideas. Compared with other forms of play, however, humor involves a more deliberate distortion of reality. For example, a child engaging in “serious” make-believe play might dress up in her mother’s high-heeled shoes and evening gown and apply lipstick in a way that closely imitates adult behavior. On the other hand, in

humorous play, the child might put the dress on backward, wear the shoes on her hands, or use the lipstick to give herself a clown face, in order to create a surprising effect and elicit laughter in others. This distortion of reality is an aspect of incongruity, which is a defining characteristic of humor. In general, *incongruity* refers to a discrepancy between what is normally expected and what is actually experienced.

To recognize and enjoy humorous incongruity, children must first have an understanding of what is “normal” or expected. The development of humor through childhood therefore parallels the increasing complexity of cognitive structures and reflects an increasing sophistication in the detection of incongruity. Laughter first appears in infants about 4 months of age. During the first 2 years of life, much of children’s humor focuses on observing and performing various forms of visual and behavioral incongruity, such as peek-a-boo, tickling, and chasing games. Children at this age also laugh at incongruous actions of people, animals, or objects, such as exaggerated facial or vocal expressions or seeing a dog wearing a hat. Later, as children begin to develop language skills, they start to laugh at incongruous uses of language, such as sound play (e.g., repeating nonsense rhyming sounds) and word play (e.g., deliberately calling a person or object by the wrong name).

By the age of 4, children typically begin to enjoy semantic incongruity, which is often expressed in the form of riddles. As they reach elementary school age, their humor involves conceptual incongruity, such as telling jokes that incorporate multiple meanings. In adolescence, their increased capacities for abstract thinking and formal logic are reflected in even more sophisticated forms of humor such as satire and irony. Many researchers believe that, like play in general, humor serves an important function of enhancing cognitive and linguistic development by enabling the child to practice and consolidate newly acquired skills.

Humor also has important social functions. It is a beneficial way of sharing fun and forming bonds among friends. However, it can also be used in aggressive ways (e.g., through teasing and “put-down” humor). Humor is often a way of defining and reinforcing group norms by communicating what is acceptable and what is unacceptable, and making fun of those who are different. Children with a strong sense of humor often tend to be more aggressive and dominant than their less humorous peers. At the same time, they also tend to be more creative, verbally fluent, self-confident,

extraverted, and socially competent. Thus, a sense of humor can be channeled toward either socially facilitative or aggressive ends.

Humor is also an important way of coping with anxiety and stress. By laughing and joking about something that is potentially threatening, one gains a sense of mastery over it. Young children's enjoyment of "bathroom" humor and adolescents' sexual jokes may be seen as ways of coping with anxieties and insecurities relating to bodily functions and sexual development. Throughout our lives, humor continues to be an important mechanism for coping with stress and adversity. Thus, despite its "frivolous" appearance, humor plays an important role in our cognitive, social, and emotional functioning.

## HUNTINGTON'S CHOREA

---

Huntington's disease (HD) is an inherited brain disorder named for Dr. George Huntington, who first described this disorder in 1872. HD is now recognized as one of the more common genetic disorders. HD currently affects 30,000 Americans, and nearly 250,000 more are at risk for this disease. At present, there is no known cure.

This disorder was traditionally known as *Huntington's chorea* (after the Greek word for dance) because of the involuntary movements associated with HD. The gene that causes HD is known to code for a specific protein called *huntingtin*. Mutant huntingtin is thought to be more resistant to destruction than normal huntingtin, which leads to toxic buildup and cell

death. The HD gene is located on the tip of the short arm of chromosome 4 and was isolated in 1993 by the Huntington's Disease Collaborative Research Group. The discovery of this gene led to the development of a genetic test that can accurately determine whether a person will develop HD. However, there is as yet no test that can predict when symptoms will begin.

The gene causing HD is dominant, meaning that only one copy of the Huntington's gene is necessary to develop the disease. Each parent who possesses one HD gene has a 50% risk for passing on the gene to each of their children. Everyone who carries the gene will develop the disease eventually, and it appears most frequently after age 30. These symptoms rarely appear in infants, but children who do develop the juvenile form of the disease rarely live to adulthood. Death usually occurs 15 to 20 years after onset of the disease.

Early symptoms appear as slight physical, cognitive, and emotional changes. Physical changes can include nervous behavior, clumsiness, alterations of handwriting, and difficulty with normal skills such as driving. Cognitive changes can involve problems with organization and dealing with novel situations, short-term memory loss, and impairments in decision making and attention to detail. Emotional changes can include periods of depression, apathy, irritability, and impulsiveness and changes in personality. In some cases, a person may become delusional or paranoid. At-risk individuals should not worry about the occasional appearance of some of these symptoms because these incidents happen to everyone and do not necessarily indicate the onset of the disease. The person dies, not from the disease itself, but from complications such as pneumonia, heart failure, choking, or infections developing from the weakened condition of the body.

The symptoms of HD are associated with atrophy of the caudate nucleus, particularly the head of the caudate. Reduced metabolism and blood flow have been observed in the caudate nuclei of HD patients using positron-emission tomography (PET) and functional magnetic resonance imaging (fMRI) as well as other methods. This reduction has been found to precede caudate nucleus atrophy. There is no known cure for HD, but a number of treatments have been proposed. Drugs antagonistic to dopamine D2 receptors reduce the chorea of early HD, and some experimental treatments may help to decrease the aggregation of the huntingtin protein.

In summary, HD is a fatal genetic disorder due to mutation of a specific gene and currently has no cure.

Research is progressing to identify the exact mechanism of cell death and methods to stop it, with the hope that one day this disease may be conquered.

## HYDROCEPHALUS

---

The Mayo Clinic reports that about 4,000 infants in the United States are born with hydrocephalus, and an estimated 6,000 children develop hydrocephalus during the first 2 years of life. The mechanics of hydrocephalus are interesting. The spinal cord and the brain

are cushioned or protected from jarring injury by the systemic flow of cerebrospinal (CSF) fluid. If there is a blockage in some portion of any cerebral pathway, fluid can build up. This blockage can be acquired or can be congenital. The obstruction of the channel and buildup of CSF fluid are the dominant characteristics of hydrocephalus.

The word *hydrocephalus* originates from two Greek words: *hydro* means “water” and *cephalus* means “head.” Hydrocephalus is then a condition in which excess fluid (CSF fluid—not water) accumulates in the brain due to (1) oversecretion of CSF, (2) obstruction of CSF passages, or (3) impaired absorption of CSF. The signs and symptoms of this condition vary depending on the age when the symptoms initiate. Because the skull bones of an infant are not yet fused, continued pressure causes the expansion of the head in all directions; it expands to accumulate the buildup of the CSF fluid, which can result in an increasing head size. There are numerous common signs in infants, in addition to an unusually large head. These symptoms might include vomiting, developmental delay, and depending on the amount of fluid buildup, seizures. In older children, there may be a slowing of development or loss of already achieved development; physical symptoms including nausea, vomiting, and headaches; and problems with motor skills, like balance and coordination.

Hydrocephalus is a serious condition because as CSF accumulates, it displaces and kills neighboring neurons, the building blocks of the central nervous system. The condition is very treatable; however, some children have developmental delays, muscle tone and movement issues, eye movement and speech impairments, and feeding problems. Once the condition is diagnosed, the most imperative goals are to reestablish the flow—absorption and production—of CSF between the brain and spinal cord and reduce the pressure in the child's head. There are two typical treatment options. The most common course of treatment is the placement of a shunt (a tube) inside the head to regulate the flow of CSF. This tube runs under the skin into the stomach or abdomen. The shunt track can irritate surrounding brain tissue and increase the potential for seizures. The second, less common (although gaining in acceptability) treatment is endoscopic third ventriculostomy (ETV). This procedure allows for creating an alternative pathway around the blockage that allows the CSF to flow unimpeded.

Hydrocephalus can also occur as a secondary effect to some other pathological event or process. This

could be either prenatal or postnatal in origin. For instance, some prenatal disorders, such as spina bifida, Dandy-Walker malformation, Arnold-Chiari malformation, and stenosis of the aqueduct of Sylvius, often result in the buildup of excess CSF fluid in the brain. Other causes of hydrocephalus, both prenatal and postnatal, include infections (meningitis, encephalitis), vascular abnormalities, tumors, cysts, and other disease processes.

## HYPOTHESIS

---

In scientific research, a hypothesis is a statement about a predicted relationship between variables. A good research hypothesis can be formulated as an “if-then” statement:

- *If a child is exposed to the music of Mozart, then that child’s intelligence will increase.*
- *If students learn a math lesson by interacting with a computer, then they will solve math problems more accurately than students who learn the same lesson by listening to a lecture.*

Notice that a hypothesis is not a question. It is a statement, a prediction that requires the researcher to go out on a limb and say what he or she thinks will happen in a given situation. When stating a hypothesis, the researcher *must* run the risk of being wrong—a scientific hypothesis must be falsifiable.

Hypotheses come from many sources. Researchers are not all wildly creative people, but they do tend to be careful observers of the world around them. One’s own everyday observations can lead to the formulation of a hypothesis, as when a babysitter observes that “children who eat ice cream before bedtime have a

harder time falling asleep.” That simple observation can lead to a formal hypothesis about the relationship between sugar consumption and sleep onset. A famous hypothesis in social psychology was generated from a news story, when a woman in New York City was murdered in full view of dozens of onlookers. Instead of simply shaking their heads in sadness, psychologists John Darley and Bibb Latané developed a hypothesis about the relationship between helping behavior and the number of bystanders present, and that hypothesis was subsequently supported by research. This type of reasoning from a specific case to a more general principle is called *inductive logic*.

Reading existing research and theory can also lead to the generation of hypotheses. Through the process of *deductive logic*, a general theory leads to the prediction of a specific effect or conclusion. For example, someone who is familiar with Piaget’s theories of human development might predict that “if a child is younger than the age of 12, then that child will be unable to solve an abstract reasoning problem.” Such a hypothesis could then be put to the test in systematic research.

Hypotheses can be either *directional* or *nondirectional*. A directional hypothesis states a specific prediction about the precise type of effect that a variable is expected to have on another variable—for example, “If the number of bystanders increases, then the probability of any given bystander rendering help decreases.” A nondirectional hypothesis states that a relationship will exist between two variables, but it is not specific about the nature of that relationship: “If the number of bystanders increases, then the probability of any given bystander rendering help will change.” This type of hypothesis can be confirmed if the probability of help increases *or if it decreases*. Nondirectional hypotheses are useful in the early stages of research in a given area, when the researcher may not have enough information to make a more specific prediction. A nondirectional hypothesis is still falsifiable, however, if the data suggest that there is no systematic relationship between the variables after all.

Whether directional or nondirectional, a good research hypothesis must ultimately be objectively testable. Before actually turning a hypothesis into a study, the researcher must develop operational definitions of the variables stated in the hypothesis. If the hypothesis postulates that “If a child is exposed to the music of Mozart, then that child’s intelligence will increase,” then the researcher must define what specifically is

meant by “child” (a person under the age of ?), by “intelligence” (a score on a particular standardized test, perhaps), and what it means to be “exposed” to the music of Mozart (Which compositions by Mozart? For how long? Played how loudly?). Thus, the development of the hypothesis is only the beginning of the process of psychological research.

## **IQ Tests**

*An intelligence test sometimes shows a man how smart he would have been not to have taken it.*

—Laurence J. Peter

---

## **ID**

---

The id (Latin for “that thing”) is present at birth and developmentally is the oldest of the three psychological structures proposed by Sigmund Freud as part of the mind. According to Freud, neither the ego nor the superego is active or even formed so early in the individual’s development, when the id serves as the storehouse for all the instincts. Initially, all the psychic energy available in the system is invested in the id, which uses this energy to satisfy basic needs through reflexive or reflexive-like behaviors. These needs must first be satisfied if (1) the organism is to survive (again, self-preservation), and (2) the organism is to move on to higher, less biologically and more socially based needs (again, species preservation).

In its most basic form, the id is an inborn biological structure that has as its purpose immediate gratification and reduction of tension. As the initial reservoir of psychic energy, it accomplishes this primary goal of tension reduction through the pleasure principle (also referred to as the principle of lust, the pleasure-pain principle, or the lust-unlust principle). The pleasure principle states that the primary goal in mental operations is the achievement of pleasure through gratification.

Controlled entirely by the pleasure principle, id energy is under no constraints and makes no distinction between fantasy and reality. Thought that does not distinguish what is real from what is not real is called primary process thinking. For example, in the older child or adult, a need can become temporarily satisfied by means of remote representation of the drive object (or that which satisfies a need), perhaps in the form of an image. Daydreaming is thought to exemplify this type of thinking. For example, thinking about a favorite food when one is hungry may relieve hunger pangs for a short period of time. Although daydreaming or primary process thinking satisfies only temporarily, it is an effective way of discharging stored energy and reducing tension so that the tension does not dominate one’s thinking.

The psychic energy associated with the id is unconscious in that the individual is unaware of it and cannot talk or think about it. All of the psychic energy associated with the id is unlabeled, or without any verbal associations. It is not available to higher mental processes, and the emotions and feelings associated with it cannot be considered on a rational basis. For this reason some Freudian psychologists believe that events that occur when the child is preverbal cannot be remembered.

The unconscious urges of the id remain active throughout life, but, as healthy development proceeds, a smaller and smaller proportion of psychic energy becomes associated with the id, and more and more psychic energy becomes associated with the more socially adaptive ego and superego.

## IDENTICAL TWINS

---

When two fetuses are carried simultaneously and delivered by a woman, it is termed a *twin birth*. Most multiple births are twins. In 1997, 94% of multiple births reported were twins. However, most of these twin births were *fraternal* or *nonidentical twins*.

Twins referred to as *identical* or *paternal twins* (also known as monozygotic or uniovular) are much less common than nonidentical twins. They are derived from a single fertilized egg. During fertilization, only one ovum (or egg) is impregnated by only one sperm. Afterwards, the egg divides into two separate embryos. Each embryo has the same chromosomes, they are mostly identical in appearance, and are always the same sex. In rare cases, the division is not complete and results in conjoined twins. The degree of union may be great or slight, and the twins may be conjoined at any part of their bodies. The majority (70%) of conjoined twins are females. Most conjoined twins do not survive long after birth, although there are some who have lived as long as 63 years.

The term *identical twins* is somewhat of a misnomer and is not generally used in professional medical language; monozygotic is more often the term used. The main difficulty is that identical twins are not necessarily identical. Frequently one twin has a physical feature (i.e., mole) that the other does not, for example. More dramatically, some identical twins are “mirror images” of each other, even though they have the same DNA. In such rare cases, one twin’s heart is on the left side (normal) and one twin’s heart is on the right side (mirror image). The parents of twins can

usually tell them apart by subtle visual cues. While their fingerprints are generally similar, they are not identical. Because physical appearance is influenced by environmental factors and not just genetics, identical twins can actually look very different. The only true means of determining whether or not same-sex twins are fraternal or paternal is through DNA testing.

The rate for identical, or monozygotic, multiples is random and universal; it is the same in all populations regardless of race, heredity, or other factors, and it has remained constant over time. The chance of having identical twins is about 1 in 285. Improvements in the early detection of twin gestations through the use of ultrasound techniques, improved prenatal care, and medical advances in the care of neonates have increased the survival rate of twins.

All multiple pregnancies are automatically considered “high risk.” Twins are eight times more likely than singletons to be born at a weight of less than 1,500 grams or **very** low birthweight (VLBW). More than one half of all twins are born with low birthweight (LBW) (less than 2,500 grams). This compares with only 6% of singletons born with LBW. Additional risks for the infants include prematurity, underdeveloped lungs that can lead to respiratory distress syndrome (RDS), cerebral palsy, hearing or vision problems, developmental delays, or learning disabilities. Risks for the mother include preeclampsia (a rapid rise in blood pressure, protein in urine, and fluid retention), anemia (low red blood count), preterm bleeding, preterm labor, gestational diabetes, blood clots, and miscarriage. There are thought to be many more twin conceptions than births, as often one or both fetuses are lost during the first trimester to miscarriage or vanishing twin syndrome. As would be expected, families of twins face increases in financial burdens, marital stress, childcare issues, and a multitude of other adjustments.

Some identical twins have been known to switch places with each other in school to have their twin take tests for them, or to play tricks on others. An interesting part of many identical twins development is the emergence of idioglossia, or “twin language.” Identical twins also are thought to be able to read each other’s minds, and to develop a special bond unlike any other interpersonal relationship. There is great interest in researching the unique and intriguing aspects of identical twins.

## IDENTITY

---

The problem of identity is where psychology merges with culture. Human beings are biological creatures, to be sure. But among the myriad species on our planet, we are strongly given to the absorption of story into our being, so that we are self-consciously biographical creatures, needing reminders from time to time that we are animals as well. We are animals who inherit and create history; we take seriously our religions, our nationalities, our kinships, our racial markers, and our occupational and professional achievements and failures. We are identified by these and other markers—some transient, some permanent.

We are bathed in culture from birth. A name is given—in Western culture, a first name to provide distinction, a surname to provide connection. Words are spoken to the mewling infant, a preposterous exercise, it would seem—but one that lays down the fundamentals of social identity. Given the medium of language, children can learn who they are—can come to see themselves, more or less, as others see them—as having a particular name and connection to others via family, as having a gender and a race and a nationality, and perhaps even a religious identity. As children grow, they acquire more social connections—in schools, on playgrounds, in the streets, in the fields, and by coming to participate, selectively to be sure, in such

opportunities for human affiliation as are afforded by the host society. Identity is both given and acquired.

Identity is so pervasive in human experience that the meaning of the term itself can be slippery. Indeed, the term is used in a variety of senses in contemporary psychology. Social psychologists refer to identity as congeries of social roles and perceptions of those roles. Piaget thought of identity as a cognitive achievement, so that a young child is at some point able to see that objects, including human objects, retain their essential identities even though they are reshaped or transformed. Conservation of identity is demonstrated by an exercise described by Michael Lewis, wherein a child of 3 years of age touches his or her own rouged nose while looking in a mirror, as opposed to the behavior of a younger child, who reaches out to touch the rouged nose of the “person” in the mirror. The identity problem is implicit in Freudian psychology, with the parents serving as the major vehicles for connecting the child to the civilization in which, all unknowing, it came to be born. Identification is the major mechanism for socialization, in the Freudian view. The ego psychology that is the intellectual product of many of Freud’s followers can be seen centering about the problem of human identity.

### ERIK ERIKSON'S THEORY OF IDENTITY DEVELOPMENT

Erik Erikson is the first psychologist to give identity a central position in his psychology. In his seminal work, *Childhood and Society*, Erikson extends, develops, and reshapes the basic psychoanalytic position on the development of human identity. For Erikson, human development proceeds through eight distinct stages, each succeeding stage building on the accomplishments of the previous stage, as an architectural construction is laid together from its foundation upward.

Erikson’s eight stages of social and emotional development are not described as conditional upon the particularities of culture or historical epoch. Rather, they are meant to stand as a universal progression, given in the nature of things, like the Freudian stages of psychosexual development of which they are an extension. Of course, the way in which an individual traverses these stages is not posited as uniform, but is subject to the vagaries of external influences. Each stage, in fact, is thought to be accompanied by a “psychosocial crisis,” which demands resolution of some kind before the next stage be confronted.

The stages are as follows:

1. *Basic Trust vs. Mistrust*. First 2 years of life. The child is either loved and nurtured into being trustful, or neglected or mistreated, producing insecurity.

2. *Autonomy vs. Shame*. Ages 2 to 4 years. Success at this stage produces a child with self-assurance, pride, and self-control. Tantrums and displays of stubbornness are part of the work toward autonomy. Failure to overcome the crisis at this stage produces a lasting sense of shame.

3. *Initiative vs. Guilt*. From about 4 to 6 years of age. Healthy children learn to play with others, including the initiation of play activities. Failure to achieve this broadening of social life produces a child who is overcome with shyness and guilt, hanging back from social engagement.

4. *Industry vs. Inferiority*. From about 6 years of age until about 12. At this stage, the child learns mastery of major social conventions, including how to relate to peers, as well as mastering basic intellectual skills, such as reading and writing and quantitative skills. Children who have negotiated the previous stages successfully are likely to be successful at this stage as well. Insecure, shamed, and guilt-ridden children are likely to fail at primary school tasks.

5. *Identity vs. Diffusion of Identity*. This period is that of adolescence—ages 13 to 20. The primary task of this stage of development is to develop a solid answer to the question, “Who am I?” This will entail experimentation with the borders of propriety, of legality, of acceptable social conventions. Successful resolution of this stage results in a young person with a strong and stable sense of who they are, success in their sexual identity, male or female, and a sense of potential achievement in life. Failure produces delinquency, withdrawal, and an unclear sense of identity, including confused gender identity.

6. *Intimacy vs. Isolation*. The young adult can experience the sort of intimacy that produces successful marriages and enduring friendships. Once again, failure in the previous stages of development leads to failure in this later stage—producing isolation.

7. *Generativity vs. Self-absorption*. The successful outcome of adulthood is the generation of children and creative personal achievements. The self-absorbed individual is seen by Erikson as incapable of achieving this kind of extension.

8. *Integrity vs. Despair*. The person who has negotiated all of the previous crises successfully is now ready to assume a position as a wise elder in society, showing acceptance rather than fear, pride rather than despair.

It seems evident now that the progression Erikson described with such confidence in the era just after World War II is a vision of identity development shot through with the ideals and values of the times. Critics have noted that the model here seems distinctively masculine and decidedly unsympathetic to forms of identity that depart from the standards of heterosexual marriage and the production of children. It has been noted as well that Erikson developed this progression “out of his head”—that is, it is not the product of systematic or documented observations about the ways in which development occurs. Even so, Erikson must be credited with having established identity as a central term in human development and with having argued persuasively that human development must be regarded as a lifelong process, not something that is finished with childhood.

## RECENT DEVELOPMENTS

Contemporary conceptions of human identity are sensitive to differences in cultural norms. It is generally conceded that there is no universally correct progression of identity development. This is clearly illustrated by cases in which identity conflict becomes manifest by the conjunction of differing cultural norms.

Benson provides an excellent illustration of such a conflict. In 2002, a woman of Kurdish origin was murdered in Sweden by her father, an immigrant to Sweden, because of her announced intention to marry a Swedish man. Her father had grown up in Turkey, immersed in Turkish/Kurdish culture, wherein the father bears responsibility for upholding the honor of his family. The young woman grew up in Sweden, where individuals are supposed to have the right to make their own choices about intended mates, not adhering to the preferences of parents. As Benson notes, her “hierarchy of feelings with respect to identity-relevant decision-making did not synchronize with that of her father.” Her death resulted not from a conflict between good and evil, or the failure of the socialization of identity, but rather from a conflict between two quite divergent versions of what is good.

Henri Tajfel has developed a theory of social identity based on the premise that social affiliations are formed rapidly and have great power as determinants of

social action. His “minimal group” group experiments have shown that random assignment of individuals to groups immediately produces a loyalty to the group and barriers with respect to outgroups. In actual practice, social identities are highly complex and layered, as the illustration of the conflict between Swedish and Turkish/Kurdish culture demonstrates. As William James pointed out in his seminal chapter on “The Consciousness of Self,” we have as many identities as there are groups about whose opinions we care. Since our world is now characterized by an unprecedented freedom of access, directly and symbolically, to other groups and cultures, it is increasingly clear that the problem of identity is of absolutely central importance to the understanding of the relation of the individual to the social order, and in turn, of the psychological health and well-being of the individual as such.

### ILG, FRANCES (1902–1981)

---

Frances Lillian Ilg, MD, was born in Oak Park, Illinois. A pediatrician and professor at Yale, Ilg was a pioneering scholar in infant and child development and cofounder and first director (1950) of the Gesell Institute of Child Development (now the Gesell Institute of Human Development) and recipient of the Snow award for Distinguished Service to Humanity.

Ilg came from a large family. It was remarked by Gesell that she may have learned to value collaboration

and question the predominant behavioral paradigm due to her large natal families. She graduated from Wellesley in 1925 and Cornell Medical School as a pediatrician in 1929. She interned at Saint Mary's Hospital for Children in New York. Her position at the New England Hospital for Women and Children impressed her with the need for preventive pediatrics and initiated her passion to capture and write about “the natural history of the child.” Ilg also worked at Bellevue Hospital in New York City and was a child health worker in Stockholm. She adopted her daughter, Tordis Kristen, as a single parent, unusual in 1936. She wrote that her years of looking at child behavior closely mirrored her daughter's developmental stages.

Ilg started her work and collaboration with Dr. Arnold Gesell at the Yale Clinic for Child Development. Together, using the guidance nursery, clinical examination suite, and photographic processes, Ilg and Gesell coauthored *Feeding Behavior of Infants*. This was the first of more than 30 collaborative works to be authored and coauthored through the work of the Yale University initiated school of child development, the first in the United States. The study of maturation, showing a pattern of similar growth and benchmarks for youngsters, ran counter to the prevailing paradigm. Her work not only targeted the physical aspects of children, but also the social, emotional, and intellectual growth patterns. As thousands of children were seen at the clinic, careful scientific databases were collected, including rich cinematic records and meticulous observations of children to validate the findings. Parents and records of family interactions were also included. The collaborative nature of her work continued with Dr. Louise Ames and Dr. Janet Rodell as Ilg and the team recognized, investigated, and expounded on the biological timetable functioning in conjunction with the surrounding social milieu. As a maturationist, Ilg also authored the *Gesell Developmental Assessment Manual* in 1965. She wrote the widely syndicated daily column, “Child Behavior” for many years.

In collaboration with Gesell, the world-renowned trilogy exploring youth and development was written, including *Gesell Institute's Child from One to Six*, *The Child from Five to Ten*, and *The Years from Ten to Sixteen*. This material is still available at local bookstores and referenced in child development literature as well as popular writing.

## IMAGINARY AUDIENCE

---

Originally used to represent the false belief that one is being watched and evaluated by others, David Elkind proposed that construction of an imaginary audience during early adolescence was a form of “adolescent egocentrism,” which he saw as a natural outgrowth of the transition to Piaget’s formal-operational stage of cognitive development. Adolescent egocentrism is reduced as adolescents’ cognitive capabilities become more refined and as more social experience is acquired.

Research has not supported the theoretical connection between the acquisition of formal-operational abilities and the imaginary audiences. Other developmental theoretical models of the imaginary audience involving identity exploration and the development of social perspective-taking skills have been tested, but have received little empirical support. Nevertheless, the imaginary audience construct has remained of interest to developmental and clinical psychologists for its presumed connection to what appear to be common facets of adolescents’ experiences, such as feelings of self-consciousness and susceptibility to peer pressure.

Currently, the best-supported theoretical approach to the imaginary audience construct is the “New Look” model, which states that adolescents experience a heightened tendency to think about themselves and others in social scenarios to cope with concerns resulting from the process of separation-individuation. During this process, adolescents must balance their competing needs to pull away from and stay connected to parents. Multiple studies have shown a positive relation between imaginary audience ideation and separation-individuation concerns, particularly those reflecting concern regarding interpersonal connection. The New Look model has relocated the imaginary audience construct within a new developmental framework,

and has redefined its basic nature. The belief that others are attending to and evaluating one’s every move would be just one possible example or variety of imaginary audience thinking under this newest model.

In fact, how to measure the imaginary audience has been a major obstacle in its study. The two most commonly used survey measures do not assess the original crux of the construct—that is, that adolescents incorrectly believe others attend to and evaluate them. The two classic operational definitions—feelings of self-consciousness and the belief that it is important to anticipate how others will react to oneself—do not require the misperception of others’ attention and evaluation. Both could result from the correct perception of others’ attention and evaluation; their relative absence could reflect a false belief that others attend to oneself in an admiring fashion.

Recently, alternative methods have been used: When asked to rate the attentiveness, criticalness, and admiration of hypothetical peer group conversations in which another peer was mentioned in a critical, admiring, or nonevaluative manner, adolescents’ and early adults’ ratings were not significantly different. Performance on memory tests for conversation content did not support the classic notion of the imaginary audience as indicative of an adolescent tendency toward distorted social cognition. When given an ambiguous peer group conversation, in which the evaluative tone and target of the group’s comments were unclear, roughly one out of five participants across four age groups (children, early, middle, and late adolescents/early adults) said the group was talking about them. The best predictor of perception of self-as-target was the interpretation of the group’s comments as admiring in nature.

While references to the imaginary audience continue to appear in textbooks discussing early adolescence, the use of newer methodological approaches continues to challenge the information typically presented. Much about the imaginary audience remains to be discovered. In particular, what is the normative developmental trajectory for the imaginary audience, and what role does it play in adolescent development? Are there cultural differences in imaginary audience ideation? Longitudinal and cross-cultural studies would provide answers to these as-of-yet unanswered questions.

---

## IMAGINARY FRIEND

---

Imaginary friends are a charming part of early childhood and beyond. Between one half and two thirds of children create such friends, and they come in all shapes and sizes. Some children create imaginary companions that are ordinary playmates with common names. Other companions have unusual qualities, like the ability to fly or magical eyes that can see around corners and over long distances. Imaginary companions are also sometimes animals, such as a friendly monster who comes out at bedtime or a group of cows that need bottles and diapers. These fantastical friends may stay long enough to play for an afternoon, or become part of the family for months or years.

Imaginary friends are usually classified into two types: invisible companions and personified objects. Invisible companions may have no basis in reality, but some are based on real people, or on story, movie, or television characters. Personified objects are usually stuffed animals or dolls that children animate and treat as people, much like Christopher Robin thought of Winnie the Pooh in A. A. Milne’s children’s stories. Most imaginary companions are regarded as friends or playmates, although children with personified objects sometimes nurture them the way a parent nurtures a child.

Many imaginary friends appear when children are in preschool. However, children in elementary school also have pretend friends, although they may talk about them with others less frequently than younger children do. Moreover, adolescents who keep journals sometimes

address them to imaginary friends, suggesting that this type of fantasy is not limited to one age group.

In general, children with imaginary friends are similar to children without them. The two groups tend not to differ in intelligence, creativity, or shyness. Preschool children with imaginary friends have just as many real friends as do their peers, so the idea that children create pretend friends because they have no real friends is unfounded. Children with and without imaginary friends differ most often in birth order and sociability. Specifically, firstborn or only children are more likely to have imaginary friends than children who are later-born. As for sociability, although the differences are modest, children with imaginary companions appear to be highly sociable, cooperating willingly with adults and peers and participating in social activities within the family. These children may also have a predisposition toward fantasy play, preferring pretense over other activities. Lastly, some studies find that more girls than boys create imaginary companions, although boys engage in other types of imaginative play.

Children who create imaginary friends know that these companions are not real. These children are just as good at distinguishing between fantasy and reality as children without imaginary friends. In fact, having an imaginary friend appears to facilitate the development of social cognition, or thinking about other people. For example, the creation of an imaginary companion has been positively related to the development of theory of mind, or the ability to explain and predict other peoples’ behavior in terms of their beliefs, thoughts, and desires. Pretending to have an imaginary friend may give children practice in thinking about other minds and may help them to appreciate the fact that what a person thinks and what is actually true may not be the same.

Although children with imaginary companions are often portrayed by the media as suffering from psychopathology, almost all children with imaginary companions create them for fun and in the course of play. The orientation toward fantasy and social interaction shown by these children appears to manifest in their creation of imaginary friends when other people, especially siblings and peers, are not available to play with them.

## IMAGINARY THINKING

---

Imaginary thinking occurs when the contents of our thoughts escape the boundaries of the here and now, such as when we reflect on the past or imagine the future. Sometimes the content of imaginary thinking is accurate or realistic, but frequently our thoughts go beyond what is true or likely as we contemplate fictional worlds and nonactual possibilities. Although prototypes of imaginary thinking might include a child's imagined conversation with an invisible friend or an adult's creation of a fictional narrative, imaginary thinking is also involved in mundane everyday activities (e.g., planning for the weekend). Thus, imaginary thinking or imagination should not be equated with special creativity or "imaginativeness." Imagination is an essential component of creativity, but theorists such as Paul Harris have conceived it more broadly as a basic capacity of human thought that is connected with memory, problem solving, counterfactual reasoning, and other fundamental aspects of cognition.

Imaginary thinking begins early. In fact, some of the most compelling examples are found in pretend play, a widespread activity in human children that is almost entirely absent in other species. Children start to pretend in the second year of life, about the same time that they begin to talk. The first acts of pretense

are simple; the toddler raises an empty cup to the lips, makes drinking noises, and smiles at the caregiver. By the time children are 5 or 6 years old, they are capable of engaging in elaborate social games of pretending, stepping in and out of their roles to give stage directions to the other players and to deal with the interruptions of everyday life. They also use their developing imaginations to entertain themselves when they are alone. For example, it is common for preschool children to invent imaginary companions who serve as a combination of friend, confidant, and scapegoat.

In the past, children's pretend play has not always been viewed in a positive light. In particular, Piaget described early pretending as evidence of immature thought that was not adapted to reality, an activity that would be outgrown with the cognitive advances of middle childhood. More recently, theorists such as Dorothy and Jerome Singer, Inge Bretherton, and Paul Harris have proposed a more positive view linking pretend play with children's understanding of reality, emotional mastery, and adult imagination. In pretend play, children explore emotions in games that are under their control. They learn to make sense of the world by considering alternatives to reality. According to Harris, the capacity to consider what *might* have happened is crucial to causal and moral reasoning.

The findings of correlational research are consistent with this positive view of pretending. Children who participate in elaborate and frequent pretending tend to score higher on tests of language ability, self-control, divergent thinking, perspective taking, and a range of other measures of social and emotional development. When children show significant deficits in pretending, there is cause for concern. For example, a deficit in pretend play is one of the primary symptoms associated with autism. Children with autism might be fascinated with blocks or other toys and spend hours lining them up, but they do not use them as props in games of make-believe in the way that is so common in normally developing children.

Children continue to pretend beyond the preschool years, although these activities tend to be more private (e.g., a teenager who writes to an imaginary companion in her diary or spends hours in role play games on the Internet). More broadly, imaginary thinking continues with an increasing ability to conceptualize nonactual, fictional, and metaphysical possibilities. It is a

uniquely human capacity that develops early and is crucial in everyday thinking throughout life.

## IMITATION

---

Anthropological evidence has shown that, in many cultures, observational learning and imitation are the major ways by which behaviors unique to that culture are transmitted from one generation to the next. It has been argued that imitation is more efficient than either trial-and-error learning or individual problem solving. Learning by imitation is much more rapid, particularly when the environment of the demonstrator and the observer are similar, the cost of individual learning is high, and in situations when it is not readily apparent how the demonstrator is solving the problem.

Perspective taking and intentionality may develop as a result of imitation, and imitation deficits may lead to impaired social cognitive development. Children with autism, for example, have imitative deficits and imitate much less frequently than typically developing children. It has been argued that such deficits in imitation production are also linked to subsequent deficits in the development of theory of mind.

Before language, imitation is an important way that adults show and teach the child about how objects work, how to solve problems, and a critical way to communicate with other children. Imitation tasks have, therefore, been used extensively in developmental studies with preverbal infants and young children. Simply put, imitation tasks involve a “monkey see, monkey do” procedure in which an experimenter

models a behavior, and the subject is then given the opportunity to reproduce it afterward. Gesture imitation and deferred object imitation have been the focus of most developmental studies.

### GESTURE IMITATION

Piaget proposed that facial gesture imitation does not emerge until 8 to 12 months of age because while infants teach themselves vocal gestures and manual gestures through listening to their own voices or by watching their own hand movements, this intramodal matching process is logistically impossible for facial gestures.

Meltzoff and Moore, however, challenged the traditional Piagetian notion and found that significantly more newborn, 1-month-old, and 3-month-old infants than would be expected by chance responded with a gesture matching the adult display as judged by observers blind to the experimental condition. Furthermore, infants were able to imitate a range of behaviors including mouth opening, tongue protrusion, and head movement displays. Even infants less than 72 hours old were able to imitate facial gestures. More recently, it has been shown that 6-week-old infants remember the specific facial gestures modeled by the experimenter after a 24-hour delay.

The neonate is capable of storing representations of absent objects and events at birth, and can recognize the equivalence between their behavior and the behavior of other humans. Such a “starting state nativism” allows that infant to come into the world with the ability to imitate, and this early ability also allows for intermodal mapping and, from there, inference to others or detection of “like me.” To extend this notion, neonatal imitation of facial gestures is an early form of perspective taking, and mutual imitation games give infants practice in social interaction and communication. Adults respond to this early imitation by imitating their infants’ behaviors, including object and vocal play and facial gestures. Infants also recognize when they are being imitated.

Neuroscience’s recent discovery of the mirror neuron system adds support to the argument that the imitation system is playing a fundamental role in the emergence of social cognition. Mirror neurons map visual information of actions by others onto motor representations in primates including humans. That is, mirror neurons allow imitation to occur by building the motor plan for action at the time of the demonstration.

## DEFERRED IMITATION

The ability to reproduce an action that was previously modeled by another individual after a delay is called *deferred imitation*. Deferred imitation was originally described by Piaget from observations of his own children. He described how his daughter (Jacqueline) precisely imitated a peer's temper tantrum that she had seen 24 hours earlier. According to Piaget, Jacqueline watched as a peer tried to get out of his playpen. The boy screamed, moved the playpen backwards, and stamped his feet. The following day when Jacqueline was placed in her playpen, she imitated the same series of actions even though the boy was not there. Deferred imitation has important implications for memory development and learning.

In deferred imitation experiments, target actions involving single or multiple steps are demonstrated by an adult experimenter with an unfamiliar object. Control groups do not see target actions but are often exposed to adult manipulation of the stimuli. Deferred imitation is reported if the imitation score of the demonstration group significantly exceeds that of the control groups.

The age at which deferred imitation emerges has long been debated. Originally, Piaget claimed that deferred imitation did not emerge until infants were 18 to 24 months of age. This finding was challenged when it was demonstrated that 9-month-olds could exhibit deferred imitation. Then neuropsychologists argued that before 9 months of age deferred imitation may not be possible because of the immaturity of the prefrontal cortex or limbic system. Recently, however, studies have demonstrated that even infants as young as 6 months of age exhibit deferred imitation.

Serial learning has also been studied using an imitation procedure in which an experimenter models a specific sequence of actions with a set of props and then children are allowed to imitate the sequence. With increasing age, infants correctly reproduce increasingly longer ordered sequences. Thus, they can correctly reproduce familiar and novel sequences that contain two steps at 11 months, three steps at 13½ months, and eight steps at 30 months of age.

Recall of sequences is consistently influenced by the structure of the target event. Without exception, infants' recall of a series of actions that can only be performed in a specific temporal order ("enabling" or "causal" events such as making a rattle by placing a ball in a container, putting a lid on it, and shaking it)

is superior to their recall of actions that can be performed in any order ("arbitrary" events such as dressing a teddy bear by putting on trousers, a scarf, and a cap). The finding occurs even when the enabling and arbitrary events have been matched on the basis of target actions and event goals, and is identical to findings with older children and adults.

Further evidence that toddlers understand the causal nature of the enabling event has been found when irrelevant components have been added to event sequences. The irrelevant components are reliably omitted or displaced to the end of the sequence during reenactment by children between the ages of 19 months and 7 years. That is, imitation is flexible and adaptive; when the sequence requires a specific order, that order is imitated but when the actions are arbitrary order is not imitated.

A somewhat related issue is how an imitation mechanism may interact with other learning mechanisms. If an imitation task, typically remembered for 1 day by 6-month-olds, is associated with an operant task that is remembered for 2 weeks, the imitation task can also be remembered for 2 weeks, and once both tasks are forgotten both equally serve as reminders for the other task. This finding suggests that imitation may be combined with other learning mechanisms to increase retention of otherwise rapidly forgotten information.

Deferred imitation is particularly appealing to study because it is so commonplace in real-world settings. A particularly rich source of imitation is television. Overall, infants imitate fewer behaviors from television than from live demonstrations. When televised demonstrations are repeated, however, even 6-month-olds can imitate simple actions from television. This finding has important applied implications for television programmers. Siblings are another rich source of information for infants and toddlers. Diary studies have shown that infants with older siblings imitated more behaviors without explicit instruction than did infants without siblings, and imitation was characterized by a higher level of pretense and rough and tumble play. Taken together, these studies indicate that imitation is a powerful mechanism by which infants acquire new behaviors in the course of their everyday lives.

## CONCLUSION

The range of behaviors that infants imitate after a delay expands with age from facial and body

movements, to actions on and generalization across objects, to intended actions and social goals. By 12 months of age, infants imitate new actions frequently and generalize imitation across different environmental contexts. Cognitive flexibility in imitation continues to increase between 12 and 18 months. Infants can generalize across different objects as well as different environmental contexts. Furthermore, imitation of pretend play emerges between 12 and 18 months. This gradual developmental progression is thought to reflect developmental increases in infants' motor competence and cognitive abilities as well as age changes in their social niche. Cognitive neuroscience is providing exciting insights into the underlying neural correlates that govern imitation production. Studies of deficits in imitation in children with autism indicate the important developmental role that imitation has in social cognition. It is, however, not possible to consider the development of imitation in isolation without considering cognitive development as a whole. The development of imitation is also undoubtedly linked to the development of an increasingly flexible representational system.

## IMMIGRANTS

---

Long-term relocation across national borders represents one of the major ways in which the structure of populations in various countries changes. As a result, immigration remains one of the most important and highly charged sociopolitical issues today. Although everyone is a native of one particular nation, people may sometimes find it necessary to move from their native country to reside permanently in another nation. Thus, entailed in the concept of migration are emigration, moving out of a particular nation, and immigration, settling into the receiving nation.

A 1998 UN report indicates that international migration has risen sharply in recent years. For example, in 2000 alone, the United States accepted

more than 650,000 immigrants. This number does not include individuals who come to the United States illegally. U.S. law defines immigrants as persons lawfully admitted for permanent residence in the United States. Australia also accepted 76,000 immigrants in 2000, while Canada admitted about 196,800 in the same year. The recent increase in international migration could partly be attributed to the ease with which people can now travel from one end of the globe to the other. This is not to suggest that international migration is a recent phenomenon; immigration has been part of human existence since early ages. For example, in the late 1800s and early 1900s, Italian immigrants arrived in the United States to look for work, while Russian immigrants came to the United States to escape political persecution. This period also saw the arrival of Jewish immigrants who came to the United States because of the religious freedom the United States offered.

Given the inconvenience involved in relocating to a new country, and the uncertainties people face when they leave their familiar environment, such decisions are not reached casually. Reasons that underlie immigration could broadly be categorized into “push” and “pull” factors. The push factors range from extenuating circumstances, such as being displaced by wars and other natural disasters, and the motivation to escape political or religious persecution, to simple dissatisfaction with one’s economic and social life. For instance, the civil wars in Liberia and Rwanda led many people to flee their countries to seek refuge elsewhere. While some of these people might return to their home countries, many others would remain permanently in the nations that granted them asylum. Similarly, lack of jobs and declining economic conditions might make a country less attractive, motivating individuals to emigrate to escape such economic and social hardships.

While these push factors may explain the inclination to move out of one particular country or region of the world, they cannot fully account for the choice of nations in which individuals and their families ultimately settle. Immigration is jointly determined by the push factors, as well as certain pull factors, such as the belief that a particular country offers religious and political freedom, better chances for social and economic advancement, and greater opportunities for fulfillment in all aspects of life. For instance, individuals may be motivated to migrate to a particular country where they believe their skills would be put to maximum

use. This is particularly germane to unintended immigration, where some individuals who travel abroad temporarily to study end up staying longer to pursue their careers.

The statutes that govern whom to admit, and on what basis, are typically created at the national level by the individual countries. The process of creating these immigration policies are guided by the interplay of a country’s actual experiences with immigrants and the dominant perception among the leaders and citizenry of a nation regarding the desirability and value of immigration. For instance, right after the Canadian confederation, the Canadian government pursued policies aimed at stimulating development in the vast territory of the Canadian West. Immigration was used deliberately as an instrument of industrial development and nation building, and Immigration Acts, such as the Free Grants and Homestead Act of 1868 and the 1925 Railway Agreement Act, were passed to encourage recruitment of workers for the agricultural, railway, mining, and the lumber industries. Although the Canadian government was committed to encouraging immigration, based on public perception, not all prospective immigrants were considered suitable for Canada. Specific immigration policies, such as the Chinese Immigration Act in 1885, were therefore established in an attempt to restrict immigration based on national origin. Immigration was strongly encouraged during periods of economic growth, particularly 1896 to 1913 and in the 1920s, and strongly restricted in the 1930s. In particular, British and other Europeans immigrants were encouraged, while non-white arrivals were strongly restricted out of concern for maintaining a particular national identity.

Traditionally, immigration policies of many countries have been guided by four broad objectives: fulfillment of international obligations and humanitarian traditions with respect to refugees, reunification of families that have been separated through migration, fostering of strong and viable economies, and promotion of greater diversity. These objectives are reflected in the designated categories under which people are admitted into many countries as permanent residents. While these broad goals underlie many immigration policies, not all goals are emphasized to the same extent by every country. For example, although the United States admits immigrants in accordance with all four objectives, it particularly emphasizes family reunification. Indeed, 71% of immigrants admitted to the United States in 2000 were family sponsored,

while 21% were economic based. In contrast, Canada puts a high premium on admitting independent immigrants. This class of immigrants is selected, primarily through a point system, on the basis of their potential to contribute to the enrichment of the labor market and stimulate overall economic development of the country. Points are awarded based on personal factors, such as age, education, and language proficiency, and a cut-off point determines eligibility for migration under the independent category. Australia maintains a similar point system for determining admissibility of independent immigrants, and 53% of immigrants admitted in 2000 fell under that category. Countries such as the United Kingdom, Germany, and Sweden also encourage economic immigrants or immigration of individuals who possess special skills.

Migration could potentially facilitate positive change in the social and economic climates of many regions, and, in many instances, is beneficial to the immigrants and members of the giving and receiving nations alike. For many people, migrating to countries such as the United States and other industrialized countries provides economic opportunities, political security, and religious freedom that far exceed those they could possibly experience in their home countries. Immigrants can also enrich the cultures of the host nations by creating diversity of nationalities, traditions, and languages. Indeed, one of the reasons why the United States opens its borders to immigrants from all corners of the universe is to ensure greater diversity of its population than it currently enjoys. To this end, a sizable number of immigrants are admitted into the United States under a diversity lottery system that is aimed at attracting citizens of countries that are underrepresented in the United States. A potential benefit of this cultural diversity is possible elimination of dominant groups, which ultimately could ensure that different racial, religious, and ethnic groups relate to one another on an equal basis. Apart from these sociocultural benefits, immigration can also prove economically beneficial to the host nation and the given nation alike. In fact, many immigrants maintain ties with their families at home, and regular remittances to them have proven to be an important contribution to the gross domestic incomes of some countries, especially among developing nations. Immigrants can also provide special skills that are in short supply in the host nation, such as the current efforts by Germany to attract immigrants with expertise in information technology (IT). This goal of

attracting economic and specially trained immigrants underlies the immigration policies of countries such as Canada, Australia, and the United Kingdom.

In spite of the potential benefits of immigration, attitudes toward immigrants and immigration have not always been uniformly positive. In many European countries, for instance, a sizeable number of the citizenry express some concerns about admitting immigrants into their countries. Even members of countries that are historically regarded as nations of immigrants such as Canada and the United States also express misgivings about the continued influx of immigrants. Some survey studies have found, for instance, that only 6% of Americans are favorably disposed toward increasing the current level of immigration in the United States, whereas over 75% would like to see immigration kept below the current levels. The citizenry of Canada, the United Kingdom, and other European and Asian countries would also like to restrict immigration in some way.

Part of the discomfort with immigrants stems from people's perceptions that immigrants threaten their national identities. This threat entails real or perceived differences between members of the host nations and immigrants in terms of values, norms, standards, beliefs, and attitudes. Thus, greater assumed mismatch between the values of members of the host nation and those of immigrants leads to greater perceptions of threat, and, consequently, to less favorable immigration attitudes. Immigrants may also be perceived as posing a realistic threat to members of the host nation. Realistic threat involves perceptions of encroachment upon a group's existence, its political and economic power, and the physical or material well-being of its members. Thus, the perception that immigrants compete for limited resources, such as jobs, education, and housing, has been implicated in unfavorable attitudes toward immigrants and immigration. Perhaps fostering perceptions that immigrants are part of the new home they have found would help improve immigration attitudes, as has been suggested by some research findings.

The challenges involved in international migration notwithstanding, various census data indicate substantial increases in international migration. The pattern of international migration reflects the tendency for the most advanced countries to receive the greatest net change in immigration. The United States has been the largest recipient of immigrants, and this trend is expected to continue into the immediate future,

especially in light of the current U.S. immigration policies that promote family reunification. Many immigrants in the United States would, predictably, sponsor the immigration of their family members, leading to further hikes in the number of immigrants in the United States. A majority of immigrants to the United States since the 1970s have come from the Latin American and Asian countries, especially from Mexico, and this trend is expected to continue. Other countries such as Canada and Australia are also expected to receive immigrants, as are most of the European nations, especially in the advent of the European Union.

## IMMUNE SYSTEM

---

The immune system is a defense system that protects invertebrate and vertebrate animals from microorganisms and substances recognized as foreign and potentially harmful. It evolved through a gradual process of increasing diversification that led to the

enormous complexity of recognition and elimination mechanisms present in higher vertebrates.

These recognition and elimination mechanisms operate and cooperate within the two components of the immune system—that is, the innate immune system and the adaptive immune system, thus leading to immune responses that protect the body from infectious diseases and cancer. Recognition mechanisms allow the detection of foreign organisms and molecules as well as cancer cells through binding by receptors expressed on the cell surface of certain cells of the immune system.

The specific portion of the foreign invader that is detected by the recognition mechanisms is called antigen. Elimination mechanisms are responsible for the destruction of foreign invaders and cancer through the action of specialized cell types. The complement system, a set of plasma proteins, is also involved in destroying foreign invaders. Innate and adaptive immune responses rely on the activity of white blood cells, or leukocytes. Innate immune responses represent the first line of defenses, exist prior to exposure to a pathogen, are nonspecific, occur in a few hours or days, and involve the participation of two major types of leukocytes—neutrophils and macrophages—which are phagocytic cells able to take up and destroy foreign invaders.

Adaptive immune responses develop several days after encounter with the pathogen, are specific, include the development of immunological memory, and require the participation of two types of lymphocytes: B and T lymphocytes. B lymphocytes produce antibodies, which activate the complement system, neutralize pathogens, or prepare them for uptake and degradation by the phagocytic cells of the innate immune system. T lymphocytes exist in two subsets, helper T lymphocytes and cytotoxic T lymphocytes. Helper T lymphocytes help B lymphocytes and cytotoxic T lymphocytes to become activated for their respective functions.

Cytotoxic T lymphocytes kill cancer cells and infected cells by opening up pores in the surface of these cells and inserting molecules that cause cell death. Adaptive immune responses also require the participation of antigen-presenting cells, which prepare and present the antigen in a form recognizable by T lymphocytes. All cells of the immune system originate in the bone marrow. B and T lymphocytes undergo a maturation process that includes the assembly of their antigen receptors. B lymphocytes mature in the bone marrow, whereas T lymphocytes develop in the

thymus. All cells then migrate to the bloodstream, circulating in the blood and in the lymphatic system, a specialized system of vessels that collects extracellular fluid from the tissues and returns it to the blood.

Adaptive immune responses develop in lymph nodes, which are located at the points of convergence of vessels of the lymphatic system. Although the immune system is generally capable of protecting us from foreign invaders, there are several instances in which it may fail. Immune responses are sometime elicited by antigens not associated with infectious agents and, in conjunction with genetic and environmental factors, may result in serious autoimmune diseases such as multiple sclerosis and systemic lupus erythematosus. Responses to environmental antigens cause allergic diseases and other hypersensitivity reactions. In immunodeficiency diseases, a defective gene causes the elimination of one or more components of the immune system leading, in the most severe cases, to overwhelming infection. The acquired immune deficiency syndrome, or AIDS, is a form of immunodeficiency. It is caused by a virus, the human immunodeficiency virus or HIV, and is characterized by the destruction of several cell types of the immune system, especially helper T lymphocytes.

---

## IMMUNIZATIONS

---

Immunization is a procedure routinely used to improve the body's ability to overcome infection and protect against diseases caused by infectious agents. It works against a specific disease by training the immune system to rapidly recognize and eliminate the

infectious agent that causes that disease, thus resulting in immunity. Protection can be acquired either by passive or by active immunization.

Passive immunization involves transfer of antibodies obtained from an immune donor to a nonimmune individual and results in temporary immunity. Currently, antibody-based therapies represent a form of treatment for disorders induced by venoms or toxins and for viral infections. Injections of antibody preparations derived from immunized human donors are used for the prophylaxis and treatment of tetanus, rabies, and pneumonia caused by respiratory syncytial virus (RSV), as well as infections caused by hepatitis A virus, hepatitis B virus, and varicella-zoster virus. Monoclonal antibodies are expected to replace preparations derived from human donors. However, at this time, only one monoclonal antibody has been licensed for an infectious disease (RSV infection).

Active immunization induces an adaptive, long-lasting immune response to a pathogen by introducing the killed or attenuated pathogens or antigens derived from the pathogens into the body. These nonpathogenic forms of the pathogen are the major component of a vaccine. Therefore, active immunization is routinely achieved by administering different types of vaccines. In the past 100 years, the use of vaccines (along with sanitation practices) has dramatically reduced the number of deaths caused by infectious diseases. Administration of vaccines results in the induction of a vigorous immune response, similar to the one that would be induced by natural infection. Vaccine administration may result in antibody responses, cellular responses, or both. A major feature of effective vaccines is the ability to induce memory immunity, which allows the immune system to respond quickly and strongly to infections even several years after immunization. However, in order to maintain sustained, long-term responses, it is necessary to give multiple doses of a vaccine.

Due to the dangers associated with administering a live, infectious agent, attenuated or killed pathogens are routinely used as vaccines. Attenuated pathogens lose their ability to cause disease while maintaining their capacity to transiently grow within the immunized individual. Killed or inactivated vaccines are produced by killing pathogens with chemical or heat treatments. Certain other types of vaccines dispense with the whole organism and use just the important parts that will stimulate an immune response. Such

vaccines are called subunit vaccines and consist of inactivated toxins (toxoids), capsular polysaccharides, or recombinant protein antigens.

In 1798, Edward Jenner developed the first live vaccine for smallpox from the cowpox virus. Jenner observed that a person who contracted cowpox, a much milder disease, would not get smallpox. He inoculated a farm boy with fluid from cowpox lesions of a milkmaid. Six weeks later, Jenner injected the boy with fluid from a smallpox sore. As expected, the boy did not develop the infection. Jenner's discovery established the general principles of safe and effective vaccination and resulted in a sharp decline in the death rate from smallpox in Europe and North America. The use of improved smallpox vaccines eventually led to the eradication of this disease in 1980. However, doses of smallpox vaccine are once again being stockpiled around the world because of concerns related to bioterrorism. Jenner's success with the smallpox vaccine set the foundation for future vaccine development. In 1881, Louis Pasteur developed the first heat-killed anthrax bacilli vaccine. He also proposed that attenuated forms of a virus could be used for immunizations against more virulent forms and developed the rabies vaccine in 1885. Jonas Salk introduced an inactivated vaccine for polio in 1955, which was composed of killed poliovirus. In 1959, Albert Sabin developed an oral polio vaccine from live, weakened strains of the poliovirus. In 1988, the World Health Assembly resolved to eradicate polio by the year 2005. The Global Polio Eradication Initiative is now the largest public health initiative in history. Global immunization rates for the oral polio vaccine peaked in 1990 at 83%. The number of polio cases worldwide has decreased from 350,000 in 1988 to fewer than 800 cases in 2003. Three quarters of all cases globally are now linked to only a few polio "hot spots." Before the measles vaccine was approved in 1963, measles was common in childhood, with more than 90% of infants and children infected by 12 years of age. Since 1997, there have been fewer than 150 measles cases reported annually in the United States. Measles is the only other infectious disease currently targeted for eradication.

Immunization programs in recent decades have achieved genuine success around the world. However, every year, nearly 3 million individuals, including 2 million children, die from diseases that could have been prevented by immunizations. Therefore, increasing attention is paid to childhood immunizations, a series of immunizations given to children to prevent

diseases that pose a threat to them. Immunity provided to the newborn by maternal antibodies transferred through the placenta protects against many diseases. However, this immunity generally declines during the first year of life. In addition, the majority of children do not have maternal antibodies against whooping cough, polio, hepatitis B, or infections due to *Hemophilus influenzae* type B, all diseases that can be prevented by currently available vaccines. Thus, immunization programs are started early, with many vaccines given during the first months of life. The recommended immunizations for children and adolescents in the United States currently include the following vaccines: HepB (hepatitis B), DTaP (diphtheria, tetanus, pertussis), Hib (*Haemophilus Influenzae* type b), IPV (inactivated poliovirus), MMR (measles, mumps, rubella), varicella, PCV (pneumococcal), influenza (for children with certain risk factors) and, in selected populations, hepatitis A.

Despite the successes of immunization programs in most parts of the world, immunization coverage rates haven't reached their potential in some areas. Coverage rates are constantly used as an indicator of the health of a population and refer to the percentage of a defined population protected by immunizations against specific vaccine-preventable diseases. In areas where low coverage rates exist, not enough people get vaccinated, and subsequently the nonimmunized population remains susceptible to disease. Only when sufficient numbers of people are vaccinated is adequate protection of that population achieved. Indeed, when the number of individuals susceptible to a specific infectious disease in a population decreases because of immunization, the natural reservoir of infected individuals present in that population falls, thereby reducing the probability of transmission of infection. This phenomenon, which is called herd immunity, explains why even nonimmunized members in a population can be protected from that specific infectious disease if the majority is immunized.

The coverage rates of the DTP vaccine is a useful indicator of the performance of immunization programs in a country because it is administered on a routine basis as compared to other vaccines. In 1999, the Americas and the Caribbean, the Middle East and North Africa, and East Asia and the Pacific had coverage rates close to 90%, with some regional variations. However, even though global coverage of 72% for routine DTP vaccination was achieved, regions of

sub-Saharan Africa and South Asia fell well below the average. Globally, among vaccine-preventable diseases, measles is responsible for most deaths in children under 5 years of age. While western and central Europe, the Americas, and the Caribbean have achieved coverage of above 90% with the measles vaccine, other regions lag far behind with coverage levels at about 50%.

Political, economic, and social instability have undermined immunization programs in different parts of the world, as seen with declining coverage rates in sub-Saharan Africa and in central and east Europe. Poor health service delivery systems, lack of cold chain equipment, and improper administration have compromised the quality and safety of vaccines in some developing countries. Budgetary constraints, low political commitment, and lack of effective disease surveillance have also limited the effectiveness of immunizations in these areas.

To reduce barriers and increase immunization rates, federally funded public health centers in the United States are required to conduct regular assessment and feedback of vaccination rates. To maintain high vaccine coverage, the Centers for Disease Control and Prevention have developed the Clinic Assessment Software Application (CASA) to assist in measuring vaccination rates. CASA also assists in improving vaccination practices, encouraging parents to initiate the vaccination series on time, and contacting parents when children are due for or have missed vaccinations. The Advisory Committee on Immunization Practices, which periodically reviews the U.S. childhood and immunization schedule, recommends regular feedback about vaccine-delivery practices in order to motivate providers and staff in personal health care services. Around the world, Global Alliance in Vaccines and Immunization is involved in efforts to improve overall public health infrastructures that can monitor disease patterns. These organizations also explore strategies to increase overall financing for immunizations and raise the visibility of immunizations, especially among vulnerable populations. Mass immunization campaigns have historically played an important role in starting new immunization programs in developing countries and in areas with political instability, wars, and epidemics. Therefore, several approaches are being undertaken in the United States and around the world to maintain the remarkable progress of the various immunization programs, which, in general, continue to represent an impressive

public health success with benefits extending to future generations.

## IMPRINTING

---

In contrast to altricial animals, precocial species must be able to walk within a short time after birth. However, this ability may result in wandering away from the safety of the mother. Newly hatched domestic fowl, ducks, geese, quail, ungulates, and guinea pigs are precocial. These young animals are dependent on the mother for food, guidance, and protection. Therefore, they must develop an attachment to the mother to ensure they stay with her to increase the probability of survival. Konrad Lorenz, in the 1930s, coined this attachment behavior as *imprinting*.

Imprinting must occur within a specified time period following birth or hatching. This time period is called the sensitive, or critical, period. In most cases, if the animal does not become imprinted to an object during this critical period, it is highly unlikely that it will develop later. Additionally, Lorenz found that the imprinting affects the future sexual preferences of the animal.

Lorenz examined the imprinting process of young goslings. He found that they imprinted to the first moving object they saw within the first few days of hatching. The moving object could be a ball, a toy soldier, or a person. Lorenz himself became the imprinted object of many Graylag goslings. Other researchers

have found that the imprinted figure could also be the one who provides the first feeding, living figures and individuals, female caregivers, and moving objects, whether living or inanimate. Imprinting, therefore, is the mechanism that evolved to produce following behavior. The adaptive function of imprinting is to allow the young animal to distinguish its own mother from other mothers of the same or different species and to remain near her.

Imprinting facilitates future adult social behavior in addition to feeding, guidance, and protection in infancy. Lorenz suggested that the imprinting provides a model for the individual to compare all members of its species against other species. Japanese quail, for example, have been observed to choose sexual mates that are similar to those individuals they were exposed to during the imprinting stage. Although the mates were similar to the imprinted figure, they were not exactly like them. Lorenz and others speculated that this is a mechanism that evolved to reduce the probability of inbreeding. Specifically, in their natural environment, young animals imprint on immediate relatives, typically their mothers. By choosing mates that are somewhat similar to the imprinted figure, the animal is increasing the chance that the mate is unrelated.

Lorenz also believed that imprinting was enhanced by its consequences. When a young chick, duckling, or gosling imprints to its mother, she will provide positive rewards for this behavior. Specifically, she will scratch the dirt for food, guide the young to appropriate shelter, and provide protection from predators. Additionally, laboratory studies have shown that rewarding young birds with food enhances their imprinting behavior. However, food is not the only reward that influences imprinting behavior. Studies have shown that young animals tend to avoid novel objects and exhibit fear responses when around them. Imprinting provides the young animals with a familiar object to approach. The familiar object symbolizes safety and comforting thus reducing anxiety. This reduction of anxiety may be an additional reinforcement for imprinting behavior.

Finally, Lorenz suggested that imprinting is an innate behavior that is genetically programmed to occur when activated by a releaser mechanism. Nikolaas Tinbergen, a colleague who worked closely with Lorenz, suggested that sign stimuli are environmental cues that elicit certain behaviors. In the instance of imprinting, the sign stimuli serve as the releaser mechanism that promotes parental

proximity-seeking behavior by newly hatched or born animals.

## INBORN ERRORS OF METABOLISM

---

Inborn errors of metabolism (IEMs) are single-gene disorders that block a normal metabolic process and produce a nonmetabolized substance that often has serious, in some cases fatal, consequences. Each of the over 300 known IEMs is of low prevalence in the population at large, ranging from 1/10,000 to perhaps 1/350,000 births, but in combination affect about 1 in every 2,500 to 5,000 births. Additionally, a few are far more prevalent in some groups than others. Tay-Sachs, for example, although generally rare, occurs in about 1/3,500 Ashkenazi Jews. In most cases, effects do not begin until some time after birth when the newborn begins to eat and metabolize its own food.

Most IEMs are autosomal recessive, and are manifested equally in males and females who have inherited a mutant recessive gene from each parent. A few, Lesch-Nyhan for example, are X-linked and manifested largely or solely in males.

### ONSET AND DEVELOPMENTAL PROGRESSION

IEMs may present at any time during life with a variety of symptoms and rate of progression, making

some diagnoses difficult. Most affected individuals appear normal at birth, although some disorders have facial and other physical characteristics. Batshaw and Tuchman describe three types in terms of their first appearance: (1) Silent disorders (e.g., phenylketonuria and congenital hypothyroidism) are not apparent until severe developmental delay and mental retardation occur in infancy or childhood unless they have been identified in newborn testing. (2) Disorders (e.g., urea cycle disorder and organic acidemias) presenting, at about 3 days of age, acute metabolic crisis and severe symptoms, including vomiting, respiratory distress, abnormal odor, and lethargy followed by coma. These symptoms also characterize other newborn disorders, complicating diagnosis. Death generally follows in the absence of accurate diagnosis and acute medical intervention. (3) Disorders with progressive neurological deterioration (e.g., lysosomal storage disorders, including Tay-Sachs, Hurler, and metachromatic leukodystrophy) show apparently normal development for some period followed by loss of motor and cognitive skills, general nonresponsiveness, and death in infancy or early childhood.

## CATEGORIES

Categorical systems are based on the type of metabolic error, but no one system has been adopted. The following is taken from Weiner with examples from various sources.

1. Disorders of protein metabolism (e.g., amino acidopathies, including PKU and maple syrup urine syndrome)
2. Disorders of carbohydrate metabolism (e.g., galactosemia)
3. Lysosomal storage disorders (e.g., mucopolysaccharidoses [MPS], Tay-Sachs)
4. Fatty acid oxidation defects (e.g., medium chain acyl-CoA dehydrogenase deficiency [MCAD])
5. Mitochondrial disorders (e.g., mtDNA depletion syndromes)
6. Peroxisomal disorders (e.g., Zellweger syndrome)

## DIAGNOSIS

As Kelley suggests, pediatricians routinely see infants and young children with developmental delay or mental retardation, but no clear sign of an IEM.

Specific IEM diagnosis is generally through blood or urine test, but many can be identified prenatally through specific amniocentesis or chorionic villus sampling assay. Some signs in the newborn period, as indicated above, are highly suggestive of an IEM. According to Weiner, the following are potential signs of an IEM: any severe illness in a newborn; unexplained death of a sibling; otherwise undiagnosed developmental delay or motor and/or cognitive deterioration; onset of symptoms in reaction to change in diet or unusual dietary preferences; apparent toxic reactions to certain foods, particularly proteins or carbohydrates; and exaggerated symptoms from routine infections.

Several IEMs can be identified through routine neonatal screening. Although virtually all hospitals now screen for PKU, screening for other IEMs varies widely.

## TREATMENT AND OUTCOME

Several forms of treatment are effective in at least partially reducing the impact of a variety of IEMs, particularly those that can be identified in neonatal screening. Batshaw and Tuchman describe the following approaches: (1) limit intake of toxic substance through its elimination from the diet or a specially designed diet; (2) provide deficient enzyme to enable normal metabolism; (3) stimulate a detour around the metabolic block through medication; (4) provide a vitamin co-factor to increase deficient enzyme action; (5) provide synthetic enzyme replacement; (6) transplant a normal organ to supply needed enzyme; (7) employ gene therapy.

Outcome of treatment varies widely from prevention of most adverse effects of some IEMs (e.g., PKU and galactosemia) to those where no treatment is available and the disease's progression is unavoidable. Overall, treatment for about half of known IEMs increases affected individuals' longevity, growth, cognitive functioning, and other functions. In many cases, treatment will be lifelong.

—Robert T. Brown

---

## INCEST

---

The legal definition of incest varies from state to state, but most often includes a prohibition of sexual contact between persons who are related by blood and/or social ties. Most states consider that minor children cannot give consent before a defined age and therefore child/adult incest is a criminal act, whether or not there is coercion or violence involved. Some theorists and researchers have broadened the term to include any sexual betrayal of a relationship of trust between a child and an adult. This definition emphasizes the psychological trauma that occurs with childhood sexual abuse.

Accurate prevalence statistics are difficult to obtain. Most researchers agree that between 20% and 25% of girls and about 2% to 16% of boys will be sexually abused by the age of 18. Men account for 90% to 95% of perpetration for both girls and boys, most often in the father role, although perpetration by women is most likely underreported. Incest typically begins when a child is between the ages of 8 and 12, lasts an average of 4 years, and averages 20 incidents over that time frame. Although stereotypes abound, incest crosses all ethnic groups, socioeconomic statuses, and is no more likely in rural areas than in urban ones.

Generally, greater psychological trauma is associated with a younger age of onset, a closer relationship between the child and the perpetrator, and a longer duration or greater frequency of incidences. Psychological effects on the victim are often tied to the developmental age of the child when the incest occurred. The idiosyncratic meaning of experience greatly influences the amount and type of trauma experienced. Initially, the reaction to the outcry is influential regarding recovery: if the child is believed by the adults they tell, blame is placed with the perpetrator, and support is given, there is a good prognosis for healing. If the child is not believed, or is blamed

for the abuse, more psychological distress is usually encountered.

Adults who, as children, experienced no intervention or poor intervention often experience a range of psychological problems due to the incest. The most common psychological effect for victim/survivors is pervasive self-blame. Posttraumatic stress disorder, characterized by hypervigilance and anxiety, avoidance of cues that remind them of the abuse, and intrusive thoughts about the abuse, is often observed with victims of incest. Adult survivors of childhood sexual abuse can also experience depression, suicidal ideation/attempts, and substance abuse. Sexual functioning can be disturbed, from lack of sexual desire to indiscriminate sexual behaviors. Relationships are affected, as many victim/survivors note that they have difficulties with trusting. Victims often use dissociation to cope with difficulties throughout their lives, because it was a likely adaptive skill during the actual abuse. Somatization is a common occurrence, with stress-related medical problems such as TMJ and reproductive illnesses. Incest victims often report repeated revictimization throughout their lives, including other forms of interpersonal violence, such as battering and rape in adulthood, as well as increased frequency of victimization in other violent crimes. Importantly, the above psychological reactions should be regarded as ways to cope as a child with a very intrusive and overwhelming experience that may or may not be adaptive into adulthood.

Few criminal charges are filed when the incest occurs. As adults, victims are winning increasing numbers of civil cases, and the statute of limitations is being extended in many states from time of first outcry. Unfortunately, for more perpetrators there is little chance of being caught or prosecuted. Most will abuse several children during their lifetimes.

## INCLUSION/MAINSTREAMING

---

### INCLUSION OF CHILDREN WITH DISABILITIES IN REGULAR CLASSROOM SETTINGS

Over the last 30 years, there has been a steady shift toward greater inclusion of children with disabilities in regular classroom settings. Inclusive education means that children with and without disabilities are educated together in integrated classrooms. In inclusive settings, all children and their parents have an equal opportunity to interact with the larger school community. Inclusion is not the same as mainstreaming. Mainstreaming includes children with disabilities in the general classroom only part-time. Where mainstreaming occurs, children with disabilities receive the majority of their education in segregated classrooms with other children who have disabilities. The opportunity to interact with typically achieving peers is limited, and children who are mainstreamed are less likely to feel like they belong to the larger school community and are less likely to be accepted by their peers.

Children with special needs who are educated in inclusive schools are provided with individually tailored support and instruction so that their specific psychoeducational needs are met. Many children with disabilities require accommodations to profit from the general education curriculum. In inclusive schools, accommodations and adaptations are provided within the setting of the regular education classroom. Accommodations may be made with respect to methods and materials (e.g., hard copies of notes and breaking lessons into smaller segments), assignments and assessments (e.g., modified assignments and extra time to complete work), or the learning environment (e.g., preferential seating and small group instruction).

Classrooms around the country have become more inclusive over the years. According to the U.S. Department of Education, from 1998 to 1999, 47% of students with disabilities in the United States spent over 80% of the day in a regular education classroom. Increasingly, general education teachers have had to learn how to address the different educational needs of students with and without disabilities who are included in their classrooms. Indeed, approximately 96% of general education teachers have at some point taught a student with a disability. There are approximately

5.8 million children with disabilities in the United States. Widespread efforts to promote positive attitudes toward disability and to train school personnel are necessary to break down some of the educational barriers to inclusion. Knowledge about the characteristics of various disabilities and the ability to adapt one's teaching to meet the needs of children with disabilities in the general education classroom are now essential responsibilities of general education teachers. Unfortunately, most teachers report that their preservice training did not adequately prepare them to meet the educational needs of students with various disabilities.

Children with disabilities and their parents have been given equal and fair access to education ever since the inception of the Individuals with Disabilities Education Act (IDEA). IDEA became law in 1975 and was updated in 1997 and again most recently in 2004. The Amendments of 1997 gave children with disabilities and their parents unprecedented rights. Under the law, children with disabilities and their parents are actively encouraged to participate in their education. And, although schools are not required by law to practice inclusion, schools are required to make every effort to include all children in general education programs and settings. Indeed, the language in the IDEA Amendments underscored that all children and youth with disabilities shall have access to a free, appropriate public education with nondisabled peers to the maximum extent appropriate and may be included in any state or district-wide accountability programs. Accordingly, U.S. schools have been increasingly educating students with disabilities in regular classrooms.

Prior to the IDEA, children with disabilities were segregated and taught in separate classrooms. Unfortunately, research suggests that children with disabilities frequently experience isolation, peer rejection, and loneliness, and also tend to suffer chronic depression and anxiety more often than children who do not have disabilities. Negative and prejudiced attitudes toward peers with disabilities are evident as early as the preschool years and may persist through high school. Indeed, school segregation of children with disabilities contributed to their poor experiences in school and to the negative attitudes held by other children and adults. In the 1980s, mainstreaming—pulling children with disabilities out of their regular classrooms for special help with resource teachers—was

especially commonplace. While mainstreaming was an effort at eliminating school segregation of children with disabilities, it was not enough. Today, children who are educated in inclusive settings are not in isolated classrooms and they are not pulled out of the general classroom for special assistance; instead, they receive all the help they need in their general education classroom. Today, even children with the most severe disabilities (e.g., Down syndrome, autism) are included in general education classrooms for at least some portion of the school day.

Nevertheless, critics of full inclusion argue that placing children with disabilities in the general classroom taxes the already overworked general education teacher. Some general education teachers echo this criticism, believing that inclusion results in a heavier and more challenging workload. Other critics worry that the inclusion of children with disabilities in the general classroom results in a lowering of curriculum standards for the typically achieving children. In contrast, proponents of inclusion argue that segregating children with disabilities is a violation of their human rights. They further contend that all people regardless of whether they have a disability have a role to play in society. Advocates of inclusion argue that integrated schools prepare children for an integrated life beyond school. Indeed, recent scientific studies are encouraging and point to positive social and academic outcomes for children who are educated with typically achieving peers in inclusive settings. Without a doubt, with appropriate support and continuing intervention efforts, all children can experience success in school and beyond.

---

## INCONTINENCE

---

Urinary incontinence is a condition that occurs when there is involuntary loss of urine from the bladder. It is estimated that more than 17 million Americans are affected, women more commonly than men (38% versus 19%). Costs related to medical care, sanitary products, and pharmaceutical agents top \$28 billion per year.

Urinary incontinence occurs across the life span; it encompasses bedwetting in older children, urine loss after childbirth, postmenopausal leakage, middle-aged prostate complications, and a variety of situations in the elderly.

There has been considerable medical research relating to the management of urinary incontinence. Newly developed medications (with few side effects), behavioral interventions (such as muscle training, electrical stimulation, and biofeedback exercises), vaginal pessary use, and surgery to lift and reposition the bladder can successfully help 8 out of 10 people suffering with urinary incontinence.

Urinary incontinence occurs when the lower urinary tract, composed of the bladder, prostate gland in men, urethra, internal and external sphincters, and

urethral meatus malfunction. Normally the bladder, a hollow organ that expands to store urine from the kidneys, receives sensory signals that direct its detrusor muscle to fill and empty. Although the usual capacity of the bladder is about the size of a large orange, when the bladder is half full the first sensation to urinate should occur. The desire to void is voluntary. This allows the bladder to contract while the urethral sphincters relax, so that urine passes freely. When standing, men voluntarily contract abdominal muscles to aid in emptying. Women sit or squat to empty, thus compressing their abdomens by positioning.

Urinary incontinence can be acute or chronic. Different causes create these conditions. Acute (transient) urinary incontinence is usually associated with illness or a specific medical problem. Dehydration, restricted mobility, vaginitis, bladder infection, severe constipation, and side effects of high blood pressure medications are common examples. For those people taking multiple medications on a daily basis, urinary incontinence can occur because of drug interactions. Urinary incontinence is usually transient in those with high fever or delirium.

Chronic conditions affect the majority of people experiencing urinary incontinence. Dysfunction in the bladder can cause overactivity and hypersensitivity or distention. Obstruction from an enlarged prostate or narrowing and poor urethral tone can lead to urethral or sphincter dysfunction, resulting in incontinence.

Stress urinary incontinence commonly occurs when the urethra or sphincter are weakened. Activities that change the interabdominal pressure, such as coughing, sneezing, laughing, lifting heavy objects, performing aerobic exercise, and changing positions from supine to upright, are associated with urine leakage when the urethra and/or sphincter are weakened. Amounts of leakage can range from a few drops to complete soaking of clothing. Obesity, recent child-bearing, birth trauma, having multiple pregnancies, and experiencing menopause can increase urinary incontinence in women. In men, prostate surgery and radiation to the bladder or prostate can contribute to stress urinary incontinence. Pelvic muscle strengthening exercises, called Kegels, have been shown to be 75% effective in reducing symptoms by half for mild to moderate cases. Vaginal weights and pessaries (a mechanical device to hold muscles in place) can be used for mild to severe cases. If fitted correctly, pessaries can be 100% successful in maintaining

continence. In women, estrogen supplementation by mouth, patch, or direct application has demonstrated improvement in. In men, Kegel exercises (75%), biofeedback techniques (66%), and electric muscle stimulators (62%) can offer relief. For moderate to severe leakage, gynecologic surgery to resuspend the bladder is successful in most cases.

Urge urinary incontinence (also called overactive bladder) is caused by confused neurological pathway signals. Urge incontinence occurs while the bladder is filling when the detrusor muscle involuntarily contracts and pushes the urine out the urethra. Once the bladder starts emptying, it cannot be voluntarily stopped. Often large amounts of urine are leaked. Symptoms of urge incontinence include sudden urge to void, greater than eight voids per day, and three to four nocturnal voidings. People report common triggers such as running water, dish washing, cold exposure, anxiety, caffeine consumption, and immersion of an extremity in water. Conditions that commonly occur with urge incontinence are stroke, spinal problems, multiple sclerosis, diabetes, and bladder tumors. Most elderly people suffering from incontinence have this type. People with urge incontinence frequently perform "toilet mapping." "Toilet mapping" involves identifying areas with toilets at malls, or locations with toilets when traveling. Behavioral therapies to assist with urge incontinence focus on timed bladder emptying. Toileting training has been successful with 25% to 40% of elderly people with incontinence. Anticholinergic medications (Detrol and Ditropan are most commonly prescribed) are very effective in decreasing urgency and frequency and stabilizing signals to the bladder. Studies have shown that 43% to 67% of people taking anticholinergic medications became continent and another 50% had reduced symptoms in 61% to 86% of cases. These medications can be used long-term. Electrical stimulation can improve symptoms in 50% to 60% of cases. Penile clamps, placed half way down the shaft of the penis, can be 100% effective in controlling urge incontinence following cancer surgery in men. Care must be used to avoid injury to the penis. Combination anticholinergic medications with behavioral treatments have demonstrated an 88% continence rate. Surgery cannot help remedy this type of incontinence.

expanded, and the idea that one could have a severe disability and still live independently in the community was promoted by Ed Roberts, also known as the “father of independent living.” Roberts’ story is a heralded one in the brief history of independent living. As a child, he developed polio at age 14, leaving him a quadriplegic, reliant on a large piece of equipment called an “iron lung” to breathe. He lived in a nursing home for many years. Roberts fought many battles with vocational rehabilitation and the University of California, Berkeley, to gain their support in his quest for higher education (Levy, 1988). Upon acceptance to UC Berkeley, Roberts needed a place to live on campus. He was able to secure part of a university hospital unit and gain the assistance of others to get him up in the morning, ready for classes, and put him to bed again in the evening. The need for these and other services by many people with severe disabilities eventually led to the development of the first Center for Independent Living (CIL) in Berkeley around 1974. The mission of the CIL was not just to provide services to people with disabilities, but also to stress the importance of civil rights to ensure their full participation in the community like nondisabled peers.

In the early 1980s, the U.S. Rehabilitation Services Administration initiated a grant competition to establish funding for 10 CILs. These nonprofit organizations were to serve as community disability resource centers to provide independence-promoting services based on a peer support model and raise awareness of disability issues in the community. As of 2005, this consumer-directed network of resource centers has expanded to include 390 CILs, each with its own board of directors. These centers sponsor more than 300 branches and satellite offices in communities across the nation (Enders, n.d.).

---

## INDEPENDENT LIVING

---

The independent living movement was born in the mid- to late 1960s along with several other civil rights groups, such as African Americans and women, who became activists for equality in American society. Before this time, many people with disabilities lived either with their parents or sadly, in nursing homes or other institutions, because they did not have access to community-based services to facilitate their independence. These limited options were eventually

## PHILOSOPHY

What makes CILs unique from other nonprofit human or medical service organizations? The composition of CILs differs as funding regulations require that over 51% of staff and governing board members must be people with disabilities. In contrast to other disability-specific organizations such as the Association for Retarded Citizens (ARC) or the National Federation of the Blind (NFB), CILs serve people *across all disabilities*. CILs refer to their constituency as “consumers.” In contrast, vocational rehabilitation

**Table 1** Comparison of the Rehabilitation and Independent Living Paradigms

<i>Issue</i>	<i>Rehabilitation Paradigm (Abling Model)</i>	<i>Independent Living Paradigm (Enabling Model)</i>
The problem defined	Disability or impairment Lack of vocational skills	Lack of autonomy Dependence on professionals
Problem focus	On the individual	In the environment In the rehab process
Problem solution	Intervention by professionals	Peer counseling Advocacy Self-help Consumer control Barriers removal
Social role	Seen as patient or client	Seen as consumer
Who is in control?	Professionals	Consumer
Desired outcomes	Restore maximum function Obtain gainful employment	Living independently in the least restricted environment

agencies use the term “client.” The term “consumer” was selected to emphasize the importance of choice for people with disabilities in deciding what services best fit their unique needs as individuals, in contrast to a “one size fits all” service model. DeJong (1979) contrasts the paradigms of the medical model and the independent living model of service provision. For a more detailed comparison, see Table 1. The IL model stresses that consumers are experts on their needs, rather than being viewed as having a problem that needs to be fixed or rehabilitated. It also emphasizes that any problem typically resides in the environment, and that when modified can allow consumers to more fully participate. Thus, rehabilitating a person without giving consideration to how the environment could accommodate the person’s functional limitations would be short-sighted. The latter approach demedicalizes the disability and focuses on environmental change to accommodate the person’s needs. It underscores the importance of the Americans with Disabilities Act (ADA), which prohibits discriminatory programs,

practices, and policies against people with disabilities.

## INDEPENDENT LIVING CORE SERVICES

Federally funded CILs are required to deliver four core services. These include: information and referral, advocacy, independent living skills training, and peer counseling. Currently, there is consideration of a fifth core service—assisting people with disabilities living in institutions to relocate to community settings. These core services are supplemented by other services such as housing assistance, transportation, and advocacy, which is considered the most important service to facilitate independent living.

## THE FUTURE OF INDEPENDENT LIVING

Currently, CILs are fighting for restoration of parts of the ADA that have been weakened by the federal courts. Centers are also mobilizing for passage of Medicaid Community-Based Attendant Services and Supports Act of 2003 (MiCASSA) (S 971 and HR 2032) to move people with disabilities living in institutions to community-based settings.

## INDIVIDUAL DIFFERENCES

Human variation in psychological, physical, and behavioral characteristics is both an obvious and

inescapable reality. Recognition of this universal phenomenon likely arose in step with the rise of human civilization. Formal philosophical treatment of individual differences in intellect, integrity, and motivation, for example, can easily be traced back at least to Plato, and evidence indicates that testing for such differences was practiced by the Ming dynasty in ancient China. The scientific study of *how* and *why* people differ in systematic ways is known as the psychology of individual differences. The psychology of individual differences seeks to understand how inter- and intra-individual differences in psychological characteristics interact with environmental affordances and demands to produce differences in a variety of personal, work, educational, and social outcomes. The theories and psychometric methods developed by individual difference researchers are used by social scientists to understand, critique, and address practical problems in a variety of contexts such as education, selection, evaluation, and guidance.

### CORE DOMAINS: INTELLECTUAL, PERSONALITY, AND CONATIVE

Individual differences have traditionally been studied as three broad domains: intellectual, personality, and conative. It is important to note that, although these are often treated as separate aspects for the purpose of investigation, they are intertwined to some degree.

#### Intellectual Differences

Arguably, no area of psychological study has been more closely scrutinized than the science of mental abilities. Since its beginnings in the late 19th century, the scientific study of intellectual differences has amassed a wealth of empirical data that unarguably supports two conclusions. First, what people typically think of as “intelligence” is best described by a hierarchical model with numerous specific abilities occupying the lower levels, a small number of group factors at an intermediate level, and a single general cognitive ability factor, referred to as “*g*,” at the top. That is, although specific mental abilities (e.g., verbal ability, quantitative ability, visual-spatial ability, short-term memory) can be identified, people who are high (or low) on any individual specific ability tend to be relatively high (or low) on the others. Second, although the assessment of intra-individual differences in specific abilities may be especially useful in personnel classification, and academic and career

counseling, it is the *g* factor that accounts for most of the variance in important academic, occupational, and social outcomes attributable to mental abilities. The *g* factor is formally defined as the “education of relations and correlations,” that is, the ability to infer or deduce meaningful principles and concepts from abstractness and novel situations.

Unfortunately, a number of misconceptions continue to plague the interpretation of this research. For example, although the popular media (and an occasional scientist) use the term “IQ” as a synonym for intelligence or cognitive ability, it is important to recognize that IQ is a score from a specific test, not a characteristic of a person. Just as the number associated with a given temperature will change if one switches from a Celsius thermometer to a Fahrenheit thermometer, a person’s IQ score may change if assessed with two different IQ tests. Nothing has changed about the person, but rather the scale used to generate the number has changed. IQ scores do tend to be very useful, though, because they tend to reflect *g* to a large extent, as well as other factors. A similar misunderstanding arises from how IQ tests are scored. Individual differences in IQ tend to be stable across a person’s development because IQ tests are age-normed (i.e., scored relative to the typical level of development for that age group). Obviously, a person’s actual intellectual capabilities change over time; however, IQ tests are usually not designed to show this *within-person* development, but rather to assess the relative level of developed cognitive characteristics for a given stage of development. This is why IQ scores tend to appear stable despite notable changes in the population mean level of actual capacities across time. Another misconception is that, because the nature of human mental abilities is known and can be reliably measured, the source of individual differences in them is well-understood. This is not the case. Rather, an enormous amount remains to be understood about the nature of mental abilities, their development across the life span, and the specific genetic, biological, and environmental factors that either hinder or spur their development.

#### Personality Differences

Personality is of interest to numerous disciplines, including the science of individual differences, which has given rise to a variety of theories. Despite their dissimilarities, most theories typically view personality

as dispositional tendencies, or “a preparedness,” to exhibit certain behavioral reactions to certain environmental affordances and demands. Within the individual difference tradition, most research has followed the “lexical approach” suggested by Galton. This approach assumes that important dimensions of human behavioral tendencies will be encoded in natural language. Using this approach to identify personality characteristics has led to a model of personality commonly referred to as the Big Five. The exact labels used to describe the dimensions have varied, but generally include (1) extraversion (includes surgency and positive emotionality factors), (2) neuroticism (includes anxiety and negative emotionality factors); (3) agreeableness, (4) conscientiousness, and (5) openness to experience. Though there is not a consensus regarding the appropriateness of this model, it is arguably the dominant model in individual difference research, and alternative models tend to be variations with two or more of the factors combined into broader factors or, alternatively, split into more narrow factors.

The use of personality tests for applied practices such as employee selection has had a long and rather tumultuous history. After a period of widespread use beginning in the early 1900s, industrial psychology placed a virtual moratorium on personality testing in the mid-1960s, primarily as a result of a failure to identify a clear pattern of criterion-related validity evidence. Applied personality testing was given new life in the mid-1980s, fueled by the emergence of the Big Five model and subsequent meta-analytic findings of meaningful, though moderate, criterion-related validities for some of these personality dimensions.

### Conative Differences

The importance of conative factors (or volition; e.g., interests and motives) is found in virtually all theories of the determinants of purposeful behavior. For example, John Campbell noted that one of the three major determinants of work performance, in addition to declarative knowledge and procedural skills, was motivation. Similarly, Richard Snow has long held that conative (as well as affective) factors are a critical component in the development of aptitudes, a contention supported by substantial research showing that interests, for example, are related to the acquisition of domain-specific knowledge and academic achievement. Likewise, vocational psychologists

have long studied differences in interests to forecast vocational adjustment. For example, a widely used model of interest types developed by John Holland, known as the RIASEC model (which is an acronym based on names of the six interest types), has proven an effective framework for studying the impact of person-environment fit on developmental, educational, and occupational outcomes.

Some individual difference scholars have begun using the term “affcon” to refer to this third domain, making salient the potential importance of affect (e.g., emotion, mood, and temperament) in conation. However, some researchers argue that so-called “affcon” factors, or at least the affective component, are actually part of personality. For example, some temperament theorists are emphasizing the role of early appearing differences in temperament as the basis for the development of the Big Five traits. Likewise, some personality researchers have shown evidence for trait-based motivational differences. Although such debate may initially seem to reflect confusion, it also appears to demonstrate the increasing effort to study the development of individual differences as constellations, rather than independent domains.

### THE DEVELOPMENT OF INDIVIDUAL DIFFERENCES: NATURE OR NURTURE?

Discussions of individual and group differences too often embrace a false dichotomy. The infamous “nature versus nurture” debate, though once central to the discourse of individual differences, is no longer a credible question asked by informed scientists. Differences in human characteristics are the result of a longitudinal interaction between genetic, biological, and environmental factors. To take a nonhuman example, the color of the hydrangea blossom will vary depending on the acidity of the soil during a certain period in its growth. Thus, the color of its blossom cannot be attributed solely to genetic or environmental factors; the color of the blossom is due to both genetic and environmental factors and the interaction between them. Likewise, to understand how human differences develop, it is necessary to understand (a) how differences in “nature” (i.e., genotypic differences) nurture environmental differences, and (b) how environmental differences (e.g., social, cultural, biological) nurture the expression of genotypic differences.

In addition to genetic–environment (g–e) interactions (e.g., differential reactivity to a given environment), that genetic and environmental factors have a symbiotic relationship is also made salient by the observation of three types of genotype–environment covariance. First, *passive* g–e covariance is reflected by circumstances where biological parents provide both the genetic code and the environment for a child. For example, parents who have high verbal abilities and like to read pass on both a genotype conducive to the development of verbal abilities and interest in reading, and a home environment filled with books and role models who read and express joy in reading. Second, *evocative* g–e covariance occurs because individual differences evoke different responses from the environment, and thus differences in experiences. For example, cooperative, bright students are more likely to receive positive responses from instructors than students who are argumentative and slow. Although a group of students is exposed to the same objective environment, differences in the experienced environment are evoked by manifest trait differences. Third, g–e covariance occurs because people *actively* select, attend to, and seek out specific opportunities and information from the myriad choices provided (often referred to as “niche-picking” or “niche-building”). To the degree that full and unimpeded access to a wide range of environments is available to all members of a group, genotypic and environmental differences are likely to become increasingly correlated as individuals seek out experiences that afford pleasantness (such as success and excitement) and withdraw from or avoid experiences that result in frustration, confusion, boredom, or consistent failure.

## SUMMARY

The Declaration of Independence proclaims, “We hold these truths to be self-evident, that all men are created equal, that they are endowed by their creator with certain unalienable rights, that among these are life, liberty, and the pursuit of happiness.” When Jefferson penned this phrase, he was neither denying nor ignorant of the omnipresent impact of human variability. Rather, his intent was to suggest the opposite; that is, despite undeniable individual differences, all humans should have equal rights and opportunities. “Created equal” means equality before the law, a concept that has found expression in parts of the U.S. Constitution, and has been given operational force in

both legislation and judicial opinion. The study of individual differences embraces this philosophy by seeking to understand how and why humans differ from each other so that we can ensure each individual has an *equal opportunity* for optimal development.

## INDIVIDUALIZED EDUCATION PROGRAMS (IEP)

---

Special education has been through many stages of reform. By the 1970s, the need for safeguarding students with disabilities from erroneous or permanent special education placements gave way to the development of service contracts—individualized education programs. These documents, or IEPs, gave families protection from schools and made educators accountable for the services they offer children with disabilities. Today, IEPs continue to serve this purpose

and guide special education services aiming to meet students' individual needs.

## WHAT ARE INDIVIDUALIZED EDUCATION PROGRAMS?

Special education services are offered to qualifying children with disabilities ranging from ages birth to 21. When a child turns 3 years old, an IEP is developed as specified in Part B of the Individuals with Disabilities Education Act (IDEA). The IEP is a written plan that details the special education and related services the child receives and the supplementary aids provided for the child. The key to IEP development is individualization.

### The IEP Team

The IEP is developed collaboratively by the student's parents, the student (when appropriate), a regular and a special education teacher, a local education agency representative (usually the principal), an interpreter of evaluation results, and other persons invited by the school or family.

### Elements of the IEP

IDEA specifies several key requirements for IEPs. First, the IEP contains information regarding the student's present levels of educational performance, including how the student's disability affects involvement and progress in the general curriculum. Next, measurable annual goals and short-term objectives are developed to meet the child's unique needs for participating in the general curriculum. Although children with disabilities do not always participate in the general curriculum, it is viewed as the ultimate goal.

Another element incorporated in the IEP is the services including special education and related services, supplementary aids, and program modifications or supports. Importantly noted, school personnel are provided the program modifications or supports, which enable them to assist the student in attaining goals, participating and progressing in the general curriculum, and learning with children without disabilities. A statement of the extent to which the student *will not* participate with students without disabilities in general education classes must also be incorporated within the IEP. Of further issue, the IEP must address the student's participation or lack of

participation in state- or district-wide assessments and identify the modifications the student will need for such assessments.

For adolescents, there is an additional element to the IEP—a transition plan. Beginning at age 14, a statement detailing the student's needs related to transition services is included. Beginning at age 16, the IEP describes all needed transition services that the student will receive, including interagency responsibilities and linkages as needed. Transition services are those services that promote the student's movement to postschool activities, such as employment, post-secondary education or training, independent living, and community integration. In addition, as the student reaches the age of majority, all rights transfer from the parents to the student. Parents and the student must be notified of these upcoming changes at least a year prior to this shift.

For services identified in the IEP, a timeline should be defined that includes the anticipated frequency, location, and duration of each. A statement of how students progress toward annual goals will be measured and how parents are informed of such progress should be included. The parents should be informed at least as often as parents of students without disabilities are informed of their children's progress.

IEPs are to be periodically reviewed. This review, which occurs not less than annually, takes place to determine if the annual goals for the student are being achieved. The IEP may also be revised based on several issues: (1) lack of progress toward goals and in the general curriculum; (2) reevaluation results; (3) information presented to or by the parents; (4) student's anticipated needs; and (5) other matters related to the student's education.

## SUMMARY

IEPs provide the blueprint for educational planning for students with disabilities. Their development should aim to create the best possible special educational programming for these students.

## INDIVIDUALS WITH DISABILITIES EDUCATION ACT (IDEA)

---

The Individuals with Disabilities Education Act (IDEA) of 1997 is the latest reauthorization of the Education for All Handicapped Children Act of 1975. This federal legislation provides the structure and funding for the provision of special education and related services to over 6.2 million children with identified educational disabilities between the ages of 3 and 21 years. Educational disabilities include autism, behavior disorder, deaf-blindness, developmental delay, hearing impairment, mental retardation, multiple disabilities, orthopedic impairment, other health impairment, specific learning disability, speech/language impairment, traumatic brain injury, and visual impairment.

The provision of special education services begins with the prereferral process by which any child suspected of having a disability is assisted through interventions in the regular classroom in order to be successful in that setting. If such classroom-based interventions are unsuccessful or insufficient, the child is individually and comprehensively evaluated, using nondiscriminatory and language-appropriate assessment measures. At the completion of the evaluation, the child's teacher(s), parent(s), school administrator, special education teacher, school psychologist, and other relevant service providers meet to discuss the evaluation results and determine if the child has an educational disability. If the child has a disability, this group becomes the child's individualized educational program (IEP) team.

The IEP team members write an IEP that ensures that the child is provided with a free appropriate

public education. The team members make decisions about educational and related services needed by the child in an environment that is most like that of nondisabled peers, also known as the *least restrictive environment*. A range of options exists for the placement of students with disabilities, including the regular classroom with special education support, a special education classroom with small teacher-to-student ratios, and homebound services for children who are unable to be successful in the school setting. Some of the related services available to children with disabilities include occupational therapy, physical therapy, social work, medical assistance, and counseling.

IEP teams meet at least once annually to determine the appropriateness of the child's written IEP. Every 3 years, the team decides if the child is in need of further assessment for planning purposes. In addition, this team meets anytime a child exhibits behavioral and/or emotional problems that negatively influence academic performance. The team members are required to conduct a functional behavioral assessment (FBA) to examine any patterns in the antecedents and consequences of the child's behaviors. A *manifestation determination* may be held at this time to determine whether the child's inappropriate behavior is a manifestation of his or her disability. Following this assessment, the team will create a behavior intervention plan (BIP) that includes positive behavior supports (PBS) in an effort to assist the child in behaving appropriately. Once a child turns 14 years old, the IEP team must also annually discuss plans for that student to transition from secondary school to higher education or employment settings.

Children and their parents have numerous documented rights related the IDEA. For example, no child can be denied services if he or she has a diagnosed educational disability. Written permission must be obtained from parents prior to conducting an individual evaluation. Parents also have the right to ask for an independent individual evaluation or a mediator if they don't agree with the evaluation results or any part of the IEP process for their child. It is encouraged and expected that parents are involved as much as possible in the educational planning for their child.

A number of major issues related to IDEA are currently under review. For example, some educators are concerned that children with disabilities cannot be disciplined adequately when they continue to violate school policies. Another issue is related to the criteria by which a specific learning disability

is identified. The reauthorization was completed by the fall of 2004.

## INDUCTIVE REASONING

---

Inductive reasoning is the ubiquitous mental activity of using existing knowledge to generate new knowledge that is likely, though not guaranteed, to be true. Inductive reasoning is required whenever people need to fill in gaps in their knowledge with “best guesses” about the state of the world. Generalizing that all snakes are black after encountering three black snakes, predicting rain in the afternoon upon seeing dark clouds in the morning, and using the analogy that an atom is like the solar system to infer new properties of atoms are all examples of inductive reasoning.

In the mid-1900s, psychologist Jean Piaget developed a highly influential developmental model of human thought that posited that inductive reasoning capabilities—and other kinds of reasoning capabilities as well—develop slowly from infancy until about 11 years old. Infants and toddlers were believed to be unable to reason but rather to be bound to their perceptions of their immediate environment. Children aged 7 to 11 years were thought to be able to do some simple reasoning but only with very concrete problems. Finally, after about the age of 11, children were thought to have fully developed abstract reasoning systems that could be used in any situation.

Today, in contrast, it is widely believed that inductive reasoning shows remarkable continuity across the

life span. It is subject to similar strategies, influences, and biases in both children and adults. Limitations that were previously identified as resulting from an underdeveloped reasoning system are now more often attributed to a lack of content knowledge among children. For example, it would be difficult for a child—or an adult for that matter—to learn to diagnose diseases without first having a more general understanding of how symptoms and diseases are related. In other words, content learning and use of reasoning skills are now believed to go hand in hand.

Perhaps not surprisingly, people are most inclined to draw inferences between things that are highly similar to one another. For example, when reasoning about animal categories, people are more inclined to infer that “cheetahs have spleens” after finding out that “tigers have spleens” than after finding out that “mice have spleens.” People also prefer to use typical things, rather than atypical ones, as the basis for their inferences. For instance, it is more compelling to transfer knowledge from robins to canaries than from ostriches to canaries because a robin is a more typical example of a bird. Influences of similarity and typicality are seen both in adults and in children as young as 2 years old.

People are also influenced by the perceived transferability of the property under consideration. For example, people are willing to transfer the eating of alfalfa from one rabbit to another, but they are not willing to transfer a scratched surface from one television to another. Interestingly, the property under consideration can also influence the perceived similarity of two situations. Adults, for example, perceive whales and fish to be highly similar when reasoning about whale behaviors, but perceive whales and bears as more similar when reasoning about whale biological properties. Such property influences have been seen both in adults and in children as young as 4 years old.

Inductive reasoning is very often contrasted with another kind of reasoning known as deductive reasoning. Deductive reasoning refers to the use of formal rules of logic to produce new knowledge that is guaranteed to be true to the extent that the available knowledge on which it is based is also true. For example, using the knowledge that “All living animals breathe” and “Fido is a living animal” to determine that “Fido breathes” is an example of deductive reasoning. Deductive reasoning can be applied only in situations that conform to certain logical structures. Inductive reasoning differs in that because it is not based on

formal rules, it cannot guarantee a true conclusion, but it can offer highly likely conclusions in a much wider range of situations.

## INFANCY

---

Infancy ranges in age from the moment of birth to about 2 years of age when the young child begins to use words to make sentences. In fact, the word “infant” means literally “one who is unable to speak.” Infancy is unique in that it is the earliest stage of life outside of the womb and is viewed as the most important formative period of development. During this early stage of life, infants are remarkably dependent on their caregivers for all their needs. Prior to the emergence of single words, which occurs as the first year of life comes to an end, infants convey their needs to their caregivers nonverbally through facial and body expressions and verbally such as crying and cooing.

Very young infants spend a great deal of their time sleeping and when awake are occupied with bodily sensations and sensory experiences. As they get older, infants become more interested in exploring the objects in their environment and establishing relationships with the significant people in their world.

The single most significant aspect of human development is the impressive brain growth and plasticity

that takes place during the first 2 years of life. The neural pathways of the human brain undergo major changes in response to environmental stimulation during infancy. Importantly, these changes in brain maturation along with environmental events contribute to the development of the ability to use and understand single words, which signals the emergence of language in the second year of an infant’s life. As infants develop the ability to use language to communicate, it also enables them to think and conceptualize in the ways that we commonly identify as characteristic of only human beings. Play becomes central to an infant’s exploration of his or her world. Infancy is also a period of marked changes in body size and motor skills. As the infant comes to the end of the second year of life, independent locomotion becomes firmly established and further characterizes the demarcation of infancy from later childhood stages. In spite of the uniqueness and importance of the infancy stage in human development, only recently are infants being considered worthy of systematic, scientific pursuit.

### HISTORICAL PERSPECTIVES ON THE STUDY OF THE INFANT

Over the last few decades, the scientific study of the infant world has had a tremendous growth spurt likely due to innovative investigative techniques applied to study a broad range of infant abilities. We currently have more information on early perceptual, sensory, cognitive, language, motor, sensorimotor, social, emotional, and self-regulatory abilities than had been imagined 50 years earlier. However, regardless of the fact that new information on infant abilities has been amassing exponentially for the past 50 years, the contributions of the early theorists remain among the most influential in the field of infancy. By deeming children, including infants, worthy of systematic study, John Locke (1632–1704) and Jean Jacques Rousseau (1712–1778) laid the groundwork for modern developmental psychology even though they expressed different outlooks on what goes on in the mind of the infant.

Locke stressed the role of the environment as the main determinant of infant behavior, a precursor of modern behaviorism. This empiricist view has frequently been interpreted as support for “controlling” children, which many, including Rousseau, disagreed with. Rousseau who represented the romanticist view, recommended “understanding” infants rather than

seeking control of them. Infants, as depicted by Rousseau, are born with a natural ability to learn, although, in his view, they are born as “idiots automaton,” knowing nothing.

As the 19th century began, the ideas of Charles Darwin (1809–1888) fueled the romanticist viewpoint. In particular, Darwin’s assertion that human development was duplicating human evolution although at an accelerated pace furthered the viewing of infants as objects to be studied. Interestingly, Darwin was also considered a pioneer infancy researcher in that he kept a detailed diary of his sons’ first 2 years of development, one of the first known “baby biographies.” The early romanticism versus empiricism controversy was replaced in the 19th century by one of the most widely debated topics in the field of developmental psychology: Which contributes more to development, environment or nature?

An early proponent of the nature theory, Arnold Gesell (1880–1961) claimed the primacy of genetics in determining development. To capture what he considered the genetically determined unfolding of development, Gesell created scales to assess behavioral change in infants and young children. Contrary to Gesell, John B. Watson (1878–1958) believed that children could be taught just about anything, given the right kind of nurturing environment. To highlight the impact of environmental contribution, Watson emphasized parental responsibility for infant outcome; if the outcome was negative, it was the parents’ fault. Both Gesell and Watson made a lasting imprint on how infants are viewed. In fact, heated discussion of the nature-nurture viewpoints continued throughout the 1800s, 1900s, and still is being debated today. While many researchers have sought to provide evidence that only one of these viewpoints is correct, the most up-to-date interpretation from years of systematic study by many developmental psychologists is that environment and genetics together contribute to infant development.

Sigmund Freud (1856–1939) believed that the value of understanding infant development lay in what it might reveal about the adult mind. While psychoanalytic theory stresses the importance of biologically determined aspects of psychological functioning, the importance of the environment, particularly as it encouraged the child’s nature to unfold, was acknowledged as well. Freud’s theories countered the extremist views of nature or nurture. Freud never used direct infant observation to understand the mind of the infant.

Rather, he used reconstructive techniques. Like Freud, Jean Piaget (1896–1980) was ultimately interested in the working of the human mind throughout the life span, but in contrast to Freud, Piaget directly observed and experimented on infants to understand the progression of cognitive ability. Piaget’s detailed descriptions of his own children led to his conceptualization of infant skills as inherited capabilities emerging as substages in an invariant order with each subsequent stage representing a stable reorganization of the infant in relation to his or her environment.

Throughout the last century, the focus of infant development has been to document the emergence and extent of a wide range of infant abilities. Theorists of the earlier centuries, such as Rousseau, claimed that infants were capable of very little. However, current scientific findings support the idea that infants have a myriad of capabilities evident from birth and even before. Contemporary infancy researchers have created innovative experimental paradigms that tap into the behavioral repertoire of infants in order to discover what goes on in the mind of infants. Dramatic findings from the past 50 years of systematic, scientific inquiry not only determined that infants are capable of learning more and learning earlier than previously believed, but also were dispensed readily to consumers because of the rise of mass media and electronic communication. Once in the public domain, research findings quickly became topics of major interest for parents, shaping the way babies were being raised. Producing intellectually precocious infants became somewhat of an obsession for many parents, resulting in less emphasis on rearing mentally healthy infants. The emphasis of infancy research has shifted somewhat in the past few years, however, to include the identification of factors associated with producing optimal psychological outcomes for infants and their families. In addition to this recent interest in infant social, emotional, and behavioral development, contemporary infancy researchers continue to investigate a broad range of infant abilities.

## THE SCIENTIFIC STUDY OF INFANT DEVELOPMENT

### Overview of Infant Abilities Studied

Using the scientific approach, researchers have investigated various areas of infant development. To describe infancy, psychologists traditionally divide

development into separate domains of perception and sensation, motor skills, cognition and language, social behavior, and emotional and behavioral development. However, despite the depiction of infant development as discrete areas, research on infant development would suggest that there is much interdependence of all of the domains.

Perception and sensation involves the development and use of the infant's senses, specifically vision, touch, hearing, smell, vestibular-proprioceptive movement, and taste. Although not fully developed at birth, perception and sensation are critical experiences for the infant; in fact, until infants can engage in active exploration of the environment, which occurs toward the latter part of the first year of life, they spend most of their time looking at, listening to, touching, smelling, and tasting their environment. The development of motor skills enables infants to become independent explorers of their environment. Investigating the development of perception and sensation in infants includes not only the study of the emergence of gross motor skills such as crawling but also fine motor skills such as hand-eye coordination. Motor development progresses from simple acts, such as turning over, to more complex motor skills, such as walking, to fine motor coordination of objects, such as little pieces of food, crayons, or toys.

Cognitive development refers to the study of mental processing skills used by infants to understand their world, with the development of representational and symbolic thinking critical markers for later optimal development. Although findings from scientific investigations prove that even newborns are not in a state of "blooming, buzzing confusion," as characterized by William James in the 1800s, it is more toward the end of the second year that infants behave in a way that indicates they are actually reasoning and planning actions mentally. Prior to that, infants do show the ability to form conceptual categories but do not have the cognitive skills to mentally represent a plan of action in thoughts or words in order to choose appropriate plans of action and eliminate less worthy plans. Processing of information becomes more sophisticated with the emergence of symbolic thinking, and social relationships are enriched as infants develop shared meaning with others through language.

Infants process and express social cues long before they ever use language to form relationships. Descriptions of mother-infant relationships by Daniel Stern in the 1980s depicted the nonverbal and verbal

"dances" between caretakers and infants, which Stern described in terms of eye gaze, touch, and positive verbalizations such as cooing. Tiffany Field studied how mothers and infants develop shared experiences by analyzing face-to-face interactions during which infants were seen matching their own experiences with that of their caretakers. The interchange between social and emotional development becomes clear when considering the studies by Mary Ainsworth that showed that infants who are secure in their relations with their caretakers show good self-regulation of emotions upon separations and reunions.

Investigators studying emotional development during infancy focused on the emergence of feeling states, how emotions are expressed, and how infants interpret the emotions of others. Michael Lewis and colleagues evaluated infants' facial expressions and found that the emergence of basic primary emotions, such as joy, interest, sadness, and anger, is apparent from birth but secondary emotions such as shame and guilt emerge in the second year of life. Studying behavioral skills of infants involves the measure of inherited temperament and later learned patterns of behavior. A number of researchers have paid particular attention to the emergence of self-regulatory skills and how infants use these skills to cope with everyday stresses, such as separation and frustration, sleeping through the night, adjusting to new food tastes, and inhibiting one's impulses when told "no." Jerome Kagan and colleagues engaged in extensive longitudinal studies and determined that infant's feelings, affects, and emotions are moderated by individual, inherited temperament traits, such as behavioral inhibition, and that these temperament traits persist in one form or another into later childhood, adolescence, and adulthood.

## **Recent Scientific Advancements**

The dramatic increase in our understanding of infant development over the past 50 years can likely be attributed to the growth of scientific approaches utilized to study infants as indicated earlier. It is generally agreed that the best way to investigate the world of infants is to observe them directly in a controlled environment using systematic experimentation. Use of a scientific approach yields better validity and reliability and can control for the effects of experimenter bias and subjectivity. Much of the research prior to the second half of the 20th century used less scientific

means to study individual infants. For example, Piaget, among others, documented qualitative case studies from baby biographies. While many researchers agreed that Piaget ushered in a direct, rather than retrospective, approach to studying infant development, his investigative style was not scientifically rigorous, which may account for some of the discrepancies found by later researchers regarding the emergence of early cognitive skills. It is well acknowledged, however, that infants are not as easy to study as older children or adults.

The mode of communication relied on most frequently by researchers in the field of psychology to collect information is language expression, typically verbal and sometimes written. To systematically study infants, researchers had to determine how to develop methods that compensated for the infants' lack of mature expressive ability. Infants cannot describe their feelings, fill out self-report measures, complete standardized written tests, or respond to interview questions. Because it is so difficult to utilize typical methodology with infants, infancy researchers have deduced what is going on in an infant's mind by developing creative procedures for systematically measuring responses using behaviors within an infant's repertoire, such as crying, sucking, tracking objects visually, kicking, or orienting the head.

### *Habituation/Dishabituation*

The habituation paradigm measures infant response to repeated exposure of the same visual or auditory stimulus. This paradigm is based on the premise that infants, like older humans and animals, will show reductions in attention as they encounter the same stimulus repeatedly, which is determined by assessing length of visual gaze to the familiar stimulus. Eventually infants will fail to attend when they have "habituated" to the stimulus as if they were bored. The gradual decline in looking time over repeated presentations or trials due to increasing familiarity with the same stimulus is known as habituation. Researchers also assess how quickly infants recover or "dishabituate" when changes are made to the original stimulus and infer from changes in looking behavior whether infants can detect differences. Typically, a criterion for initial looking time duration is determined and habituation occurs when subsequent presentations consistently yield durations shorter than the habituation criterion. Following habituation, the

stimulus is changed. If the infant's looking time increases from the habituation criterion, signaling dishabituation, or recovery, it is inferred that the infant can tell the difference between the two stimuli. If the infant cannot detect a difference, looking time will be shorter than the habituation criterion.

Using this paradigm, Bennett Bertenthal and colleagues found that 5-month-old infants when presented with point lights of a person can discriminate when that person is moving from a random, disorderly pattern of the same person's point lights. Bertenthal interpreted this as suggesting that young infants have stored knowledge of the human form and its movements. Tiffany Field and colleagues used the habituation/dishabituation technique and found that even newborns could differentiate between happy, sad, and surprised facial expressions. This paradigm has also been used to investigate many other aspects of infant development including recognition of the mother's face, object categorization, and the detection of emotions and speech sounds.

### *Preferential Looking and Violation of Expectancies*

Another creative approach to understanding infant behavior relies on head turning to determine preferences and is called the paired-preference approach. For example, in a number of preferential looking studies, infants are required to show preference between two visual stimuli presented side by side or two sounds presented to one or the other ear. Investigators try to determine which of the two stimuli is most preferred by the infant by judging where the infant is looking. In the 1960s when infancy researchers first began to use innovative experimental techniques, Robert Fantz and his colleagues used the preferential looking paradigm to document that infants could distinguish visual patterns and, in fact, demonstrated marked visual preferences by infants when presented with two different patterns side by side. To do this infants were introduced to competing patterns while in an infant seat or on their mother's lap and in a darkened room. Patterns were mounted as a display of flashing lights on a screen directly in front of the infant. In earlier studies, observers gazed through a small peephole in a screen to allow them to look directly at the infant's face and judge where the infant was looking.

As the preferential looking methodology became more sophisticated, researchers such as Marshall

Haith detected the precise position of the infant's gaze by using an electronic sensor to measure the angle of reflection of an invisible infrared light reflected off the infant's cornea. By using the preferential looking method, researchers have found that young infants prefer the sound of their mother's voice and the odor of their mother's breast milk compared to that of another woman. Recently researchers have used variations on preferential looking to cleverly detect cognitive abilities in infants not documented or even believed to exist earlier because of limits in the methodology of prior time periods. For example, in the 1990s Karen Wynn used preferential looking as part of a violation of expectancy paradigm to show infants could detect the outcome of the addition or subtraction of one discrete object from a small collection of two or three objects. Wynn interpreted this as evidence of precocious number concept and concluded that 5-month-olds discriminated between quantitative outcomes when their expectancy of addition or subtraction solutions was violated.

### *Classical and Operant Conditioning*

The interest in behaviorism during the 20th century led a number of infancy researchers to try conditioning young infants to determine aspects of conditioned learning. Hans Papousek, for example, demonstrated classical conditioning in newborns by pairing a neutral stimulus (a sound) with an unconditioned response (head turning). The sound eventually became the conditioned stimulus triggering the head turning, which became the conditioned response. Specifically, Papousek paired a sound with the turning of an infant's head by touching the corner of the infant's mouth with a bottle. After repeated exposure, as soon as the sound was heard the newborns turned their heads in anticipation of contact with the bottle. Thus, the neutral stimulus, the sound, became a conditioned stimulus and the head turn became the conditioned response.

While the classical conditioning of an infant demonstrated that infants have the potential to learn, infancy researchers sought to go further and investigate whether infants can be instrumental in changing their own behavior to secure reinforcement, a technique referred to as operant or instrumental conditioning. Operant conditioning has been used by many infant researchers to assess whether infants can learn that their own behavior controls environmental stimuli,

thus actively engaging in the learning process. In the 1970s, James B. Watson, one of the first infancy researchers to utilize this approach, conditioned infants to turn their heads to produce movement in an overhead crib mobile. In the 1980s Anthony DeCasper and William Fifer used newborn infants' nonnutritive sucking responses to activate a tape recording of either the mother's or an unfamiliar female's voice reading from a book. DeCasper and Fifer found that the newborns learned that different pause lengths between bursts of sucking would differentiate which recording would be turned on and as a function of what was learned infants consistently sucked in such a way that would turn on the mother's voice.

A series of studies by Carolyn Rovee-Collier and colleagues investigated infant learning and memory utilizing a paradigm termed mobile conjugate reinforcement, a variant of operant conditioning. Infants learned to produce movement in a crib mobile when placed supine in their cribs with a ribbon extending from one ankle to the bar of a mobile stand. Movement in a mobile attached to the mobile stand was contingent on the kicking of the infant's ankle. Infants readily learned to increase their ankle movements over an initial baseline and if presented with the same mobile at later increments of time demonstrated good short- and long-term retention. Rovee-Collier and colleagues used mobile conjugate reinforcement to demonstrate memory for color, number of components, and even contextual determinants of memory, such as odor and music. Investigation of infant response to changes in the mobile suggested that infants differ in how they react to violations of the expected type of stimulation with some infants demonstrating extreme negative reactivity and others learning to compensate for the change.

### *Physiological Responses*

Infancy researchers have also used physiological indices to expand on or substantiate behavioral measures of infant ability and from this infer what is going on inside the infant's mind. Two common ways that have been used to assess levels of physiological arousal under a variety of circumstances are by using instruments that measure heart rate and galvanic skin response. Recent technological advances have also made possible physiological measurements of electrical brain activities recorded by surface electrodes or brain scans. Using physiological measures has been particularly

useful in providing researchers with a way to investigate infant abilities prior to the infant's capability of expressing the ability behaviorally. For example, depth perception was assessed in infancy using a visual cliff paradigm that required crawling. Based on this research by James and Eleanor Gibson and colleagues, it was concluded that at 6 months of age infants are capable of perceiving the drop-off between themselves and their mother. However, does depth perception emerge at 6 months of age or was research on the emergence of depth perception limited because the visual cliff paradigm could not be used with young infants who were not yet crawling? To study depth perception in younger infants, researchers cleverly attached heart monitors to the infants and looked at changes when young infants were merely placed next to the visual cliff. Moderate arousal signified by changes in heart rate was found in infants as young as 2 months, suggesting depth perception occurs earlier than previously determined.

A number of infancy researchers have studied emotional development using physiological measures to corroborate findings originally yielded by behavioral measures. Jerome Kagan and colleagues initially used behavioral responses to investigate how infants respond to unexpected or novel situations. They found that infants who respond with crying and high motor activity, a response dyad he termed "inhibited temperament," tend to develop into children who avoid people, objects, and situations that are novel or unfamiliar, whereas uninhibited infants tend to develop into children who spontaneously approach novel persons, objects, and situations. As he continued investigating inhibited temperament longitudinally, Kagan developed an interest in determining if physiological differences could further distinguish between inhibited and uninhibited temperament types. His next step was to utilize the latest developed technology and he measured functional MRI signal response within the amygdala, finding, as he suspected, variations in amygdalar responses to novelty. Adults who as infants were categorized as inhibited showed greater functional MRI signal response within the amygdala to novel versus familiar faces compared with those adults categorized as uninhibited during infancy. Kagan interpreted these findings as evidence of early appearing manifestations of brain functions relating to temperament that are preserved into early adulthood.

Physiological findings also broadened our understanding of how self-control of emotion develops

during infancy. Stephen Porges developed a procedure called vagal tone to measure heart rate variability that occurs at the frequency of breathing. Suppression of vagal tone has been found to be associated with the activation of coping strategies in children. Susan Calkins used this measure to investigate relations between mother-infant interactions during which the mother's face remained still and infants' physiological responses. Infants showed suppression of vagal tone during the still-face interaction indicating the need for physiological regulation of distress. Infants who did not suppress vagal tone (did not activate coping strategies) during the still-face interaction showed less positive affect and higher reactivity and lower mother-infant synchrony in normal play.

## INFANCY IN PERSPECTIVE

Learning about infant development is becoming so sophisticated that the questions that can be answered about infant ability seem limitless. Infants are clearly not "idiots automaton" as proposed by Rousseau centuries earlier, and new scientific inquiry confirms that Piaget, among others, underestimated the emergence of infant skills abilities. Researchers have even found novel ways to document perceptual and sensory abilities in the developing fetus. It has become clear that many recent research findings have had a dramatic impact on how parents regard their infants. Our recent history has shown that many parents influenced by findings of early skill development became determined to produce "smarter" babies as early in life as possible. To produce "superbabies," many parents enrolled their infants in programs of structured education before the age of 3 years. This also led to the phenomenon of the "supermom," the woman who raises superbabies while holding down a job and performing as a "perfect" wife. Perhaps as a reaction to the overemphasis on achievement for both infant and mother, the early 21st century has seen a rise in concern for the psychological outcomes of infants and parents. The current research trend focuses on topics such as emotional intelligence and the goodness of relationships between parents and children. From an applied standpoint there is also growing emphasis on early detection of developmental problems and interventions that may alleviate or even prevent delays. Knowing when certain skills emerge during infancy can help clinicians determine mature or immature developmental status of infants and identify those

infants at risk for future difficulty. In spite of centuries of study about infant development, it seems like our knowledge about this first stage of life outside the womb is still in its infancy, but it is clear that continued scientific research is valuable for our society.

## INFANT MORTALITY

---

Infant mortality is defined as the death of an infant prior to its first birthday. This definition clearly excludes death *in utero*, or stillborn infants. Although there has been a gradual reduction in the worldwide rate of infant mortality over the last 20 years, this remains a significant public health concern, as infant death continues to remain a concern throughout the world. The overall rate of infant mortality is around 36 deaths per 100 live births, which worldwide translates

into roughly 5 million deaths per year. The largest declines in rates of infant mortality have been evident in more highly developed countries such as the United States. Interestingly, these rates declined steadily through the 1990s but have recently turned upward again for reasons that will be discussed later. For example, in the United States for the year 2000, the rate of infant mortality reached an all-time low of 6.9 deaths per 1,000 live births. Much of this reduction during the last decade was attributed to an increase in maternal education about the prevention of infant death and illness, the development of new medical strategies for supporting infants born at high risk of infant mortality, and a record number of mothers getting early prenatal care. The rate of infant mortality in the United States remains relatively high compared to that of other industrialized countries. For example, despite the improvements cited above, the nation still ranked 27th in infant mortality among industrialized countries in an analysis of 1997 data. Recent data indicate that Sweden is among the countries with the lowest recorded rates of infant mortality in history, with a rate of 3.6 deaths per 1,000 live births. Importantly, disparities remain among racial and ethnic groups in many measures of maternal and child health, both in the United States and elsewhere. For example, the infant mortality rate among black children in the United States is more than double that for white children. Recent data show that whereas the infant mortality rate for Caucasians and Hispanics averages 3.3%, for African Americans it was over 8%.

### RECENT PROGRESS

An ongoing emphasis on the importance of health behaviors during pregnancy including stress reduction, avoidance of drugs and alcohol, abstinence from smoking cigarettes, and the importance of maternal nutritional status have also contributed to this positive change. Public service campaigns supporting the placement of infants on their backs to sleep have also helped reduce this rate by reducing the occurrences of sudden infant death syndrome (SIDS). Moreover, although significant ethnic disparities remain in the rates of infant mortality in the United States and elsewhere, in recent years rates of infant mortality in all ethnic groups as well as in other high-risk populations such as adolescent mothers were also lower during the 1990s than in previous recording years. Very recently, however, the rate of infant mortality in the United States increased after a long period of decline. This

change has been attributed not to reversal of the abovementioned positive trends, but rather to an increase in the average age of childbearing in the United States. More and more women are choosing to delay pregnancy and childrearing until later in life, a time at which the risk of infant mortality as well as that of pregnancy complications and developmental challenges increases significantly.

An additional, related challenge to that of SIDS is the potential for the practice of sharing a bed with a young infant to increase the likelihood of infant mortality, via SIDS or suffocation. This is a complex issue, and the role of bedsharing in infant mortality remains under debate. Some have suggested that bedsharing might reduce the risk of SIDS as a parent would be present to rouse the infant in the event that the infant stopped breathing, but the American Academy of Pediatrics (AAP) has stated that there are no conclusive scientific studies showing clearly that bedsharing reduces the incidence of SIDS and points out that several studies do strongly suggest that under certain circumstances, bedsharing may, in fact, increase the risk of SIDS. The practice of bedsharing is tied to a variety of infant care issues, including breastfeeding and cultural traditions, and thus, there has been no blanket statement condemning the practice as endangering infants.

Educational campaigns, however, have been effective in educating parents about the potential risks of bedsharing along with guidelines for other safe infant sleeping practices including the “back to sleep” campaign, and other aspects of appropriate choices for infant bedding. One important aspect of this educational campaign has been to describe situations to parents in which bedsharing may be especially problematic, including cases in which the parent is obese and is thus more likely to suffocate the infant or the parent has a drug- or alcohol-use problem, and may again be more likely to suffocate the infant and less likely to rouse if the infant is distressed. An additional caution to parents considering bedsharing is that some studies suggest that SIDS, both in bedsharing situations and in crib sleeping situations, is more common among infants whose mothers smoke in the postpartum period. The connection between smoking and bedsharing is not easily separated from that of smoking and SIDS, however, but it has been suggested that smokers who bedshare with an infant may put the infant at additional risk merely by virtue of additional smoke exposure from a parent smoking in bed.

## ONGOING CHALLENGES

As mentioned above, two additional factors that may contribute to infant mortality is the occurrence of premature labor and delivery and infants born with low birthweight. Premature labor is defined as labor that commences prior to 37 weeks of gestation, and low birthweight (LBW) is defined as an infant born weighing less than 5 pounds. Recently, maternal stress has been identified as a potential contributing factor to these poor outcomes; factor in early development, and there is growing evidence that prenatal psychological and environmental stresses are detrimental to pregnancy outcome. Importantly, there are significant disparities among ethnic groups in poor pregnancy outcomes including LBW and prematurity, and these may be contributing factors to the disparities in infant mortality seen in these groups. Maternal stress experiences during and after pregnancy can range from severe (e.g., trauma) to moderate (e.g., life event changes) to low (e.g., experience of daily hassles). Although some studies have shown minimal effects of prenatal stress on pregnancy, the majority of studies show that stress experienced throughout pregnancy can negatively affect pregnancy and infant outcomes. For example, significant stress around conception (e.g., death of a loved one, divorce) resulted in greater chances of delivering an infant with conotruncal heart defects, neural tube defects, and isolated cleft lip, and trauma from an earthquake had a greater negative effect on gestational length if experienced earlier in the pregnancy. Stress experiences later in pregnancy are related to lower birth weights, reduced gestational length, preterm labor and delivery, and infant mortality; infants of stressed pregnancies have higher rates of childhood allergies and asthma, and perinatal stress appears to contribute to respiratory illness in infancy. The implications of these studies are important: 70% of infant perinatal deaths in the United States are related to LBW, preterm delivery, and restricted fetal growth. Those infants who survive the perinatal period are at greater risk for physical and cognitive developmental delays in later years.

## ETHNIC DISPARITIES

Especially distressing when examining the frequency of poor pregnancy outcomes in the United States is the fact that the rate of occurrence of these events is significantly higher in non-white minority

women than in Caucasian women. For example, the rate of infant mortality and LBW is nearly 2.5 times higher among African American women than among Caucasians. Although Hispanic women as a whole have been reported to have rates of LBW similar to those of whites, women of Puerto Rican descent and highly acculturated Hispanic women have significantly higher rates of LBW, pregnancy complications, and poor infant outcomes than their Caucasian counterparts. A significant component of considering poor pregnancy outcome in Hispanics is the "Hispanic Paradox" that has been described by several researchers, which states that although Latinas suffer similar socioeconomic challenges as other minority groups, they have lower rates of LBW and infant mortality than other minorities and white women. Recently, however, several published reports have called this paradox into question. These studies show, among other things, that although relatively few LBW infants are documented in Hispanics compared to other minority groups, errors in data recording and interpretation often mistakenly represent the rates of LBW in this population. For example, the reported lower rates of LBW in Hispanic infants in their sample reflected more preterm delivery and lower mean birth weights, and thus fewer infants who were small for their gestational ages, in Hispanic women compared to whites. This apparent paradox has also been attributed to other types of recording, sampling, and data-driven errors, such as not uniformly considering country of origin of those being sampled, and inappropriate selection of data. For example, when examining the Hispanic Paradox of infant mortality, removing infant deaths by SIDS or defining infant mortality as exogenous mortality increases the rate of infant mortality in Hispanics to 26% higher than that reported for whites. Thus, although the Hispanic Paradox of LBW and infant mortality is often cited, it may be, at some level, an artifact of data recording, selection, and interpretation, and should not be used to discount the importance of addressing poor birth outcomes in Latinas.

There are several other aspects of pregnancy success that are compromised in Hispanic women that emphasize the need for considering ethnic differences in addition to racial differences in pregnancy outcomes in minority women. For example, American-born Latinas have twice the rate of LBW, preterm delivery, and pregnancy complications as Latinas born in Mexico, and Mexican-born Latinas living in

America have higher rates of adverse pregnancy outcomes compared to Caucasians. Moreover, inadequate weight gain during pregnancy associated with poor infant outcome is a significant problem in Hispanic women compared to whites, and rates of pregnancy-related mortality are significantly higher in Hispanic and African American women. Taken together, these studies show a disproportionate frequency of poor pregnancy outcomes including complications, LBW, and preterm labor and delivery among minority women, both based on race and ethnicity, and underscore the need for understanding the complex biological, social, psychological, and cultural factors that contribute to these disparities.

## STRESS

Several investigators have suggested that stress, social structure and support, and other psychosocial factors are critical in the disparities in pregnancy outcome and infant mortality observed between minority and nonminority women. For example, although stress exposure during pregnancy is generally related to poorer outcomes regardless of racial or ethnic group, the negative effects of stress appear to be more severe for African American women than for Caucasians. For example, in a study of LBW in urban populations, Orr and colleagues found that although many prenatal behaviors such as smoking and hypertension in pregnancy were risk factors for LBW for both Caucasian and African American women, exposure to stressors was only predictive of LBW for African American women. Other investigators have shown that non-white women experience more adverse birth outcomes associated with prenatal stress, poor social support, and low self-esteem than white women, further suggesting that the combination of being a member of a minority group and psychosocial challenges may be especially perilous for pregnancy success. Interestingly, several investigators have noted ethnic differences in stress experiences and in the effects of coping with psychosocial stress. In a study of the factors contributing to clinical depression in adult women, Myers and colleagues found not only higher rates of stress-associated depression among African American women compared to whites, but also that the combination of being Latina and high levels of perceived stress were predictive of more severe depression. Moreover, a significant stressor for non-American born Hispanic

women is the challenge of assimilating and adjusting to American culture. This type of acculturation stress has been associated with generally poorer health in Latinas, more unhealthy behaviors such as smoking and drinking, and, importantly, with poor birth outcomes including LBW and prematurity. Thus, although women of all backgrounds are affected by stress in meaningful ways, women who are members of minority groups may experience more severe effects of stress on their mental and physical health, and on their unborn children.

An important aspect of considering the role of prenatal stress in pregnancy outcome and infant mortality is determining the biological mechanisms through which the external experience of stress exposure might translate into challenges to pregnancy. Stress is often defined as events, situations, emotions, and interactions that are perceived as negatively affecting the well-being of the individual or that cause responses perceived as harmful. The concept of a psychosocial stressor encompasses life experiences, including changes in personal life, job status, housing, domestic violence, and family makeup, which require adaptive coping behavior on the part of the affected individual. Stressor exposure activates a cascade of physiological events that help the individual to cope with stress-inducing stimuli and affects numerous physiological processes and systems. Perception of a stressor activates the sympathetic nervous system (SNS), a process known as the “fight or flight” response, and increases release of catecholamines including norepinephrine (NE). Activation of the hypothalamic-pituitary-adrenal (HPA) axis is a component of this response, beginning with the release of corticotrophin-releasing hormone (CRH) in the hypothalamus. CRH stimulates the anterior pituitary gland to release adrenocorticotrophin hormone (ACTH), which, in turn, stimulates cortisol release from the adrenal cortex. These neurochemical changes temporarily direct energy toward dealing with the stressful situation and away from other bodily functions. At the conclusion of short-term stress, the body quickly returns to homeostasis. In contrast, chronic stress prolongs activation of these systems and has detrimental effects on health and immunity. Existing evidence shows that stress experienced by mothers can have deleterious effects on pregnancy and infant development, and can adversely affect immunity and health. Further, there is evidence that there may be differences in stress responsiveness among racial and ethnic

groups, suggesting that psychosocial stress may affect minority women differently. For example, African Americans have more extreme vasoconstrictive responses to laboratory stress and more pronounced neuroendocrine responses to work stress than Caucasians. Moreover, the actual experience of stress is likely to differ across ethnic groups, as minority groups in this country may experience more chronic stress as a result of deeper poverty, acculturation, decreased access to health care, and experience of institutional racism in the workplace.

Activation of the stress response affects human pregnancy, and women experiencing preterm labor and delivery have significantly higher levels of plasma cortisol and CRH prior to onset of labor than women who deliver normally. Considerable interest has focused on the role of stress-related CRH production in modulation of labor and delivery because CRH may act as a signal for normal labor, and stress-related elevations of CRH may induce preterm labor. Others suggest that stress-related changes in immune function may contribute to these effects. A large body of work shows that psychological stress modulates physiology independently of pregnancy. Although these connections have an adaptive role in channeling energy to deal with the immediate stress, this relationship may result in changes in endocrine and immune function that put pregnancies at risk when the stress is of long duration as many psychological or social stressors may be. For example, when maternal CRH levels increase, they engage adrenal functioning in the fetus, producing higher fetal cortisol levels. Recently, animal and human studies support the role of maternal-fetal-placental CRH in modulating infant development and behavior, and suggest that prenatal stress may exert its effect on infant development by altering not only infant stress responsiveness, but also infant neural development. If, as some have suggested, infants with high basal cortisol levels are more prone to stress and distress, then a potential connection exists between high stress during pregnancy, infant neuroendocrine function, and neurobehavioral development. These studies show that prenatal stress has negative consequences for pregnancies and infants, suggest that factors such as ethnic background and stress responsivity may mediate these interactions, and underscore the importance of understanding both the significance and mechanism of these effects to improve maternal and child health. Thus, not only may prenatal stress increase the risk of pregnancy

complications and infant mortality, but it may potentially alter the course of infant development.

## PREVENTION

An important aspect of managing infant mortality and its root causes is developing public information programs to assist mothers and prenatal care providers in doing what is possible to prevent suboptimal pregnancy outcomes and ultimately, infant mortality. In the United States a variety of programs have been designed to both understand and prevent infant mortality. These efforts include programs to improve access to prenatal and newborn care, including Healthy Start, Medicaid, and the State Children's Health Insurance Program (SCHIP). In addition, public health campaigns to promote healthy habits among parents expecting a child or caring for an infant to prevent child malnutrition as well as medical research to better understand and prevent birth defects, premature birth, and sudden infant death syndrome (SIDS) and to promote healthy infant development are focused on preventing and understanding infant mortality.

Improving maternal physical and mental health during pregnancy continues to be a priority for reducing infant mortality. Clear connections exist between some types of maternal illnesses during pregnancy and infant mortality, and there is compelling support for the hypothesis that stress may exacerbate the occurrence of these effects by reducing maternal immune function. Ongoing work in several laboratories is addressing this connection in the hope of further supporting healthy pregnancies. Importantly, infant mortality is not the only negative by-product of prenatal maternal stress. Maternal physical and mental stress is also associated with a variety of developmental problems and delays including chronic illnesses. Perinatal stress has already been linked to the development of childhood illnesses including asthma, allergy, and respiratory syncytial virus, and addressing the role of prenatal stress and maternal health and immunity in pregnancy and in infant immune system development will provide new data for the treatment and prevention of these effects.

The need for thorough, biopsychosocial approaches to supporting maternal prenatal experiences and outcome issues is clear. As already noted, the fact that a range of stressors from low to severe can alter developmental experiences of the embryo and fetus, and thus of the developing infant and child, has major

relevance for child health and welfare. Low birth weight, one of the greatest predictors of at-risk status for infants in the first year of life, is an outcome implicated in a number of studies of psychosocial stress during pregnancy. Existing data clearly show that maternal stressors of various types need to be taken seriously during pregnancy, and thorough screening and intervention measures need to be investigated.

The development of prenatal support strategies groups to assist in buffering women and their infants against the impact of prenatal stress is critical, but interventions also must continue through the first years of childhood, as social-emotional development of infants with less optimal emotion regulation has been linked to maladjustment in children between ages 2 and 12, and across variables of social class and ethnicity. Infant-mother relationships can be enhanced through intervention, in situations of at-risk infants and even in those families with not-at-risk status. For example, research has shown that children and parents who were part of a counseling group, regardless of risk status, were able to improve goodness of fit between infant/child temperament and parent interaction, and had fewer psychiatric problems than controls at ages 5, 10, and 14 years. Provision of programs such as these for women with at-risk pregnancies may help to support not only healthy infants, but also family and child development by providing comprehensive biopsychosocial support at critical points in development.

Finally, early and continuous prenatal care helps identify conditions and behavior that can result in low birthweight babies, such as smoking, drug and alcohol abuse, inadequate weight gain during pregnancy, and repeat pregnancy in 6 months or less. Additional preventive strategies include public education about folic acid consumption during pregnancy, placing infants on their backs to sleep to prevent SIDS, reducing teen pregnancy, and reducing transmission of HIV from mothers to infants. All these measures, combined with ongoing research, will support further understanding and prevention of infant mortality.

## INFANTICIDE

---

Infanticide is the killing of an infant or young child(ren) by a parent or stepparent; however, specific terminology varies with the age of the victim. Murders occurring within 24 hours of birth are referred to as neonaticides. Those committed after the first 24 hours but prior to 1 year of life are labeled as infanticide. And, the murder of a child more than 1 year of age is referred to as filicide.

In the United States, mothers commit the majority of filicidal acts. Fathers are more likely to kill older children, and as a result of physical abuse. Homicide is the leading cause of death resulting from injury for infants less than a year old. Slightly more males under the age of 1 are killed than females. In 2000, 10.3 and

7.8 per 100,000 males and females were killed, respectively. According to FBI Supplementary Homicide Reports, from 1976 to 1991, deaths of children less than 1 year of age increased while the number of older children (i.e., ages 1 through 4) remained relatively constant. The number of deaths of children less than 1 year of age became stable between 1991 and 2000.

Although alternative labels have been offered, the act of infanticide is not a new phenomenon. Documents of cases of parental child murders can be traced throughout history due to superstitious beliefs, poverty, and overpopulation. In ancient Greece, children with birth defects were destroyed in fear of the cost they would incur the state. Conversely, during the Middle Ages, Christian doctrines and Protestant churches strongly enforced laws against killing a child. More recently, for hundreds of years, female infanticides were prominent and socially accepted in India and China. Impoverished Indian families feared they would be unable to fulfill their daughter's responsibility of a marriage dowry. In China, food and medicine were sparsely available, and it was better thought to invest time and money in raising a productive male than a consuming female.

Child murder is relatively uncommon; however, the majority of child deaths are at the hands of parents (or stepparents). The unthinkable act of infanticide has received a growing amount of media attention. Highly publicized cases have led to a growing interest by the public and law enforcement agencies alike. In an attempt to determine causality, many researchers have categorized different types of infanticidal acts: accidental, acutely psychotic, altruistic, spouse revenge, and unwanted child(ren).

Accidental deaths are typically those that result from physical punishment gone too far. Acutely psychotic cases, the most common, usually result from mental illness. Parental psychosis can range from severe depression to delusions. Altruistic cases are those where the parent believes killing the child is the merciful way to protect them from current hardships (e.g., economic struggles, abusive spouse). Spouse revenge cases are attributed to the desire to hurt the husband or wife by inflicting death on the child. Unwanted children deaths typically result from teenage pregnancies and low socioeconomic families. Neonaticides are most frequently the result of an unwanted pregnancy. Young (or teenaged), single, uneducated women offer the highest risk in this category. Because the majority of neonaticide victims are born outside of a hospital, the prevalence is probably underrepresented.

Such births can lead to obstetric complications and accidental death. Inadequate social support, and possible embarrassment by the church and family, might contribute to the prevalence of neonaticides.

Circumstances vary for each parent, child, and case; however, the most common methods of killing an infant include battering, maltreatment, suffocation, strangulation, drowning, and death by firearm. Stabbing, mutilation, and death by fire are the least common. Infanticide is most often viewed as a crime of desperation or result of mental illness rather than a premeditated, malicious act. The legal systems employed in England and Canada offer statutes that address infanticide as a result of postpartum depression, thus leading to lessened sentencing. Conversely, in the United States, mental disease or defect is not in itself cause for a just defense. A better understanding of the pathology and criminal nature of perpetrators is necessary to provoke early prevention and provide help to those who need it.

## INFECTIOUS DISEASES

Infection refers to the successful transmission of a microorganism (bacterium, virus, fungus, or parasite) to the host, with subsequent multiplication of the microorganism (infectious agent). The host response to infections is highly variable and depends on the

relationship between host and infectious agent. An infection may be subclinical (unapparent) or may result in disease. The disease is the clinical expression of the infection and indicates that the microorganisms not only are present and replicating, but that they are also disrupting the host to the extent that signs and symptoms are being produced. A sign (e.g., fever, rash, or vomiting) is the objective evidence of damage to the host, whereas a symptom (e.g., headache) is subjective evidence of damage to the host. A subclinical infection is marked by absence of visible symptoms, but there is a measurable host immune response, either through the appearance of specific antibodies or through cell-mediated reactions, such as positive tuberculin test results.

An individual who harbors a microorganism without evidence of disease and, in some cases, without evidence of a host immune response is called a carrier. The carrier status may take place during the latent phase of the incubation period as a part of asymptomatic disease, or may be chronic and persist following recovery from illness. Carriers may shed organisms into the environment intermittently or continuously, and this shedding may lead to transmission of the infectious agent. Shedding and potential transmission may be increased by other factors affecting the host, including infection by another agent.

An infection is the product of three interrelated factors: (1) the agent, (2) the host, and (3) the environment.

### AGENT

The infectious agent is the first link in the chain of infection. Factors that are important in the characterization of the agent are as follows: (a) *Infectiousness* is the easiness with which a pathogen can spread in a population. (b) *Pathogenicity* is the ability of an agent to cause disease. An example of an organism with high pathogenicity is the smallpox virus. There is no known human carrier state for this agent; once infected with the virus, the host will develop disease. (c) *Virulence* is the pathogen's power to cause severe disease and therefore is a measure of the severity of the disease. The virulence of organisms ranges from slightly to highly virulent. (d) *Invasiveness* is the ability of a microorganism to invade tissues. For example, *Vibrio cholerae* is not invasive, remains localized to the intestinal mucosa, and produces a toxin that is responsible for signs and symptoms. In contrast, *Shigella* is highly invasive and, by invading the submucosal tissue, becomes established

and causes disease. (e) *Infective dose* is the quantity of the agent necessary to cause infection; it varies from microorganism to microorganism and from host to host and is influenced by the mode of transmission. In a study of typhoid fever, it has been demonstrated that with an inoculum of  $10^3$  *Salmonella typhosa*, no clinical disease develops in normal volunteers. When the dose of the inoculum is increased to  $10^7$  or to  $10^9$  bacteria, there is a 50% and 90% attack rate, respectively. The attack rate is the ratio of the number of new infections divided by the number of exposed, susceptible individuals in a given period. (f) *Specificity* refers to how microorganisms may be specific with respect to their range of hosts. Some salmonella species, such as *S. typhimurium*, are common to both animals and humans, but others have a narrow range of specificity; for example, *S. dublin* primarily infects bovines, while *S. typhosa* is known to infect only humans. (g) *Antigenicity* refers to the ability of the agent to induce immune responses in the host. Agents may or may not induce long-term immunity against infection. For example, reinfection with the measles virus is thought to be rare, whereas repeated reinfection with gonococci bacteria is common.

## HOST

In order to cause disease, pathogens must be able to enter the body, adhere to specific host cells, invade and colonize host tissues, and inflict damage on those tissues. Entrance into the host typically occurs through mucosal membranes or through wounds. Although some pathogens can grow at the initial entry site, most invade areas of the body where they are not typically found. The human body is capable of immune responses that reduce the likelihood that an agent will penetrate and cause disease. The host immune responses may be divided into specific and nonspecific. Specific immune mechanisms include humoral (antibodies) and cell-mediated immunity. Nonspecific host defenses require the presence of intact skin and mucous membranes, which provide barrier protection. The high pH of our gastric juices is lethal to many agents that manage to enter the body via ingestion. Tears and saliva can be thought as means to wash away would-be infectious agents. Several other factors influence the susceptibility and host response to an infectious agent. As we age, the ability of our nonspecific defense mechanisms to fend off agents may decrease. Immunocompromised individuals are more at risk to develop infectious disease than normal individuals. Genetic traits may result in reduced or

enhanced susceptibility to infection and subsequent disease. For example, individuals who lack both Duffy blood group antigens are resistant to malaria caused by *Plasmodium vivax*, as these antigens are required for attachment of the agent. Individuals who have a homozygous 32 base pair deletion in the CCR5 gene have been found to resist HIV-1 infection, as CCR5 is a co-receptor used by HIV-1 for attachment and entry to the cell. The nutritional status and dietary habit of the host are also important. Malnutrition contributes significantly to infectious disease-related morbidity in developing countries.

## ENVIRONMENT

The environment refers to the domain in which the disease-causing agent may originate, survive, or exit. This milieu has been categorized into three areas: physical, describing the geography and the climate; biologic, made up of plants, animals, and other life forms; and socioeconomic, which is the totality of the behavioral and attitudinal characteristics of a group of individuals. All these environmental categories have an impact on both microorganisms and potential hosts, as the environment may either enhance or diminish the survival of infectious agents and plays a major role in bringing microorganism and host into contact with each other. The environment may act as a reservoir or niche that fosters the survival of the infectious agent.

## TRANSMISSION

Is the method by which an infectious agent passes from a source to the host. There are two general modes of disease transmission: direct and indirect. *Direct transmission* occurs through direct physical contact or direct person-to-person contact, such as touching with contaminated hands, kissing, or sexual intercourse. *Vertical transmission*—that is, the passage of the microorganism from mother to child—is considered a form of direct transmission.

*Indirect transmission* occurs when agents are transferred or carried by an intermediate source: vehicles, fomites, or vectors. Indirect transmission may be airborne (via droplets or dust particles), waterborne, vehicleborne, foodborne, or vectorborne. *Airborne transmission* occurs when a person sneezes, coughs, or talks, spraying microscopic pathogen-carrying droplets into the air that can be breathed in by nearby susceptible hosts (as occurs for the transmission of the influenza virus). Airborne transmission also occurs when droplets are carried through a building by heating

or air-conditioning ducts, or are spread by fans throughout a building or complex of buildings (as occurred for Legionnaire's disease). *Waterborne transmission* occurs when a pathogen is present in drinking water, swimming pools, streams, or lakes used for swimming (as in the examples of cholera and shigellosis). *Vehicleborne transmission* relates to fomites, such as eating utensils, clothing, washing items, combs, shared drinking bottles, and so on. *Foodborne* illness is transmitted by ingestion of contaminated food or drink. This type of transmission may be active if the organisms replicate while in the vehicle (such as salmonellae in food), or passive if the organisms are passively carried by the vehicle, as in the example of the hepatitis A virus in food. Some *vectorborne* disease transmission processes are simple mechanical processes, as when the pathogen uses a host (e.g., fly, flea, or rat) as a mechanism for a ride, for nourishment, or as a physical transfer process in order to spread. This is called *mechanical transmission*. When the pathogen undergoes changes as part of its life cycle within the host/vector and before being transmitted to the new host, it is called *biologic transmission*. An example of biologic transmission is that of the *Plasmodium* protozoan that completes its sexual development cycle in the female *Anopheles* mosquito.

## PREVENTION AND CONTROL

Infectious diseases can be prevented or controlled at a variety of points, depending on the infectious cycle for the particular disease. Direct person-to-person transmission may be inhibited by proper hygiene and sanitary conditions as well as education. Vectorborne diseases may be prevented by control measures that either kill the vector or prevent its contact with humans. Infection by a pathogen or development of a pathogen within a host may be prevented by vaccination. Finally, drugs may be used to prevent infection or suppress the disease process.

## INFERTILITY

---

The majority of couples worldwide expect to have children, and few ever contemplate the possibility that they will be unable to do so. Yet at least 1 in 10 couples experiences difficulty in becoming pregnant, a stressor that can rank among the most emotionally taxing crises of adulthood.

### WHAT IS INFERTILITY?

About one fourth of couples will conceive after 1 month of regular, unprotected sexual intercourse, and 80% are likely to conceive within 12 months. Couples are considered infertile if they are unable to conceive after 1 full year of unprotected sex. Couples who have never conceived are considered to have *primary infertility*, whereas couples who cannot conceive despite prior successful conception are defined as having *secondary infertility*.

The prevalence of infertility varies considerably across countries. In the United States, 10% to 14% of couples experience infertility, a rate that has been stable since 1965. Rates of infertility in developing countries tend to be higher, due in part to a greater prevalence of contributing infectious diseases. In some regions of sub-Saharan Africa, for example, rates of infertility have been reported to be as high as 30%.

### WHAT CAUSES INFERTILITY?

The World Health Organization has estimated that less than half of infertility is attributable to inherent genetic and biological factors (e.g., anatomical or endocrinological abnormalities). More often, infertility is due to preventable factors, which include sexually transmitted and other infectious diseases, inadequate or unsafe health care, and harmful environmental substances.

Maternal age is an important determinant of fertility, and the tendency in Western countries for women to delay childbearing has likely contributed to the misperception that infertility is on the rise. Unlike men, whose decline in fertility is not thought to occur until age 50, and even then may be slight, women's fertility begins to decrease in the late 20s or early 30s, with a steeper drop after age 35. By age 40, approximately 1 in 3 women is likely to be infertile, and by age 45, only 1 in 10 women is likely to conceive.

Physiologically, this decline is explained by a gradually diminishing supply, and weakening quality, of oocytes (unfertilized eggs).

Although infertility has historically been perceived as a “women’s problem,” male factors are the specific cause of at least 20% of infertility cases and a contributing factor in another 30%. (Many cases of infertility are the result of multiple factors, and some, of course, are unexplained.) The most frequent basis for male infertility is an abnormality of sperm, in particular, oligospermia (low numbers of sperm), problems with sperm motility (movement), or irregular sperm morphology (shape). The precise reason for impairments in sperm production and function is often unclear, but genetic disorders, diseases, infections, environmental factors, and even nutrition are thought to play a role.

The most common physiological female factor contributing to infertility is infrequent or absent ovulation, implicated in up to one third of infertility cases. A primary cause of ovulatory dysfunction is polycystic ovarian syndrome, an endocrine disorder affecting at least 5% of U.S. women. Blocked or damaged fallopian tubes, often due to pelvic inflammatory disease or endometriosis, are another frequent cause of female infertility.

## HOW IS INFERTILITY TREATED?

Infertility is often treated by reproductive endocrinologists, physicians with a specialization in obstetrics and gynecology who have completed advanced training and research in infertility. Treatment begins by testing both partners in order to determine the most likely cause or causes of infertility. Women with ovulatory problems are typically treated with *ovulation-inducing medication*, sometimes referred to as “fertility drugs.” Two different classes of drugs may be used: clomiphene citrate, which is taken orally, or gonadotropins, which must be injected subcutaneously or intramuscularly. Clomiphene successfully induces ovulation in the majority of women for whom it is prescribed (estimates range from 60 to 90%); however, less than half will conceive within 6 months, the recommended maximum treatment period. When clomiphene is ineffective, the more expensive gonadotropins are used. Although gonadotropin injections are more likely than clomiphene to result in pregnancy, they also have more significant side effects, including a greater increase in the likelihood of multiple births.

*Surgery* is a second treatment approach. Women with fallopian tube blockages may benefit from surgical attempts to reopen or repair the tubes. Likewise, some male factor causes of infertility can be corrected by surgery. Finally, microsurgical procedures can be performed to reverse prior tubal ligation surgery in women as well as vasectomies in men.

*Intrauterine insemination (IUI)*, in combination with fertility medications, is often the first intervention in cases of infertility caused by sperm abnormalities or infertility that is unexplained. This procedure involves collecting a semen sample from the male partner, removing and preparing the sperm, and then, by way of a thin catheter, placing the sperm directly in the woman’s uterus. IUI must be carefully timed with ovulation to maximize effectiveness. Scientific studies of IUI success rates report pregnancy rates per cycle ranging from 4% to 15%. (In interpreting success rate statistics, keep in mind that a small percentage of technically “infertile” couples will conceive without any intervention—as many as 3% per cycle.) Because most couples attempt IUI up to six times, the overall pregnancy rate, across all attempts, is higher, with estimates ranging up to 25%. Several factors influence effectiveness, for example, maternal age, the number of ovarian follicles (sacs that contain the eggs) at the time of the IUI, and sperm motility.

*Assisted reproductive technologies (ART)* are defined by the Centers for Disease Control (CDC) as a group of therapies that involve the “handling” of both eggs and sperms. Although ART has received considerable attention from the media, less than 5% of infertile couples in the United States undergo ART, typically only after all other treatment options have been exhausted. It is also still a relatively new treatment, introduced in 1978. In general, ART involves stimulating a woman’s ovaries, surgically removing her eggs, combining the eggs with a man’s sperm, and then transferring any resulting fertilized eggs, or embryos, back to the woman’s body.

By far the most commonly practiced type of ART is *in vitro fertilization (IVF)*. “In vitro” comes from the Latin “in glass,” referring to the laboratory dish in which the eggs and sperm are combined to facilitate fertilization; the embryos are then placed directly into the woman’s uterus. *Gamete intrafallopian transfer (GIFT)* is similar to IVF except that the woman’s eggs are transferred to her fallopian tubes and fertilized there, rather than outside her body. A third type of ART is *zygote intrafallopian transfer (ZIFT)*, which

combines laboratory fertilization of a woman's eggs with embryo transfer to the fallopian tubes. ART procedures tend to be expensive, and, in the United States, the cost is only rarely covered by health insurance.

The CDC collects data from fertility clinics in the United States each year in order to track the effectiveness of ART. Among 384 clinics that provided data in 2001, 33% of ART cycles that used fresh, nondonor eggs resulted in a pregnancy. Success rates decline as maternal age increases; the likelihood of pregnancy in women over 40 was 23%. The success of ART has gradually increased over time, helped in part by the introduction of intracytoplasmic sperm injection (ICSI) in 1992, a technique that allows a single sperm to be directly injected into an egg, thereby increasing the chance that fertilization will occur.

*Third party reproductive techniques* refer to the donation of eggs, sperm, or embryos to infertile couples. Donors may be acquainted with the couple or anonymous. Surrogacy, the carrying of an embryo throughout pregnancy by another woman, is also considered a third party reproductive technique. As noted by the American Society for Reproductive Medicine, third party techniques present significant psychological, ethical, and legal issues and, with the exception of sperm donation, are still quite new approaches to the treatment of infertility.

## HOW DOES INFERTILITY AFFECT MENTAL HEALTH?

The experience of infertility, as well as its treatment, can be profoundly distressing. For nearly one half of women who undergo IVF, infertility is seen as the worst experience of their lives. Studies based on descriptive interviews with infertile couples reveal many emotional consequences, including feelings of loss of control, a lowered sense of personal competence, perceptions of alienation and hopelessness, and a sense of social stigma. For some couples, infertility is viewed as a strain on their relationship, although other couples report that the jointly experienced stressor of infertility serves to bring them closer. In addition, couples, and particularly women, find themselves immersed in the treatment process, and the invasive nature of infertility therapy exerts additional stress.

Empirical investigations of the impact of infertility have demonstrated that infertile couples tend to experience greater anxiety, depression, and self-esteem

than their peers, and a subset of couples are at risk of developing clinically significant mental health problems. Women tend to struggle more than men and consequently are more apt to avoid day-to-day reminders such as contact with babies and pregnant women. Women are also more likely than men to seek out information about infertility, initiate treatment, and desire to continue treatment.

Although psychological studies in this area are far from perfect, experiences of infertile individuals who have opted to undergo medical treatment clearly indicate that, overall, infertility is a highly disruptive life crisis. Consequently, many infertility practices employ mental health professionals who can address emotional aspects of infertility with clients. In addition, many infertility patients have found comfort in support groups, national infertility organizations, and Internet chatrooms and newsgroups.

## INFORMATION PROCESSING THEORY

---

Information processing theories explain how people work with or perform mental operations on information they have received. These operations include all mental activities that involve noticing, taking in, manipulating, storing, combining, or retrieving information. This approach to human development emphasizes the fundamental mental processes involved in attention, perception, memory, decision making, and reasoning. Basically, information processing theory attempts to explain how humans think. Prior to the evolution of information processing theory, the field of psychology was dominated by behaviorism, a school of thought in which emphasis was placed solely on externally observable behaviors. Because mental processes were not directly observable, they were not a concern among behaviorists. Cognitivists representing a contrasting theoretical school based on cognition, on the other hand, postulated that internal cognitive processes serve as the basis for understanding many human behaviors and that these cognitive processes could be understood by analyzing the ways in which people think. Consequently, in the late 1950s, cognitivists suggested that behaviorists' explanations of behavior were inadequate because they did not account for human thought processes. As a result, an upsurge in theories resulted that detailed models of human thinking and problem solving. Cognitivist models typically placed an emphasis on serial, or step-by-step, processing of information and adopted the computer as a model of human cognitive activity.

### THEORIES OF INFORMATION PROCESSING

In 1956 George A. Miller was among the first to apply a step-by-step theory to information processing by relating it to the way that high-speed computers processed information. He proposed that, similar to a computer, the human mind takes in information, performs operations on it to change its form and content,

stores and locates the information, and then generates output of some type. According to Miller's theory, information processing in humans involves gathering and representing information (encoding), holding information (retention), and getting at the information when necessary (retrieval). In addition to comparing information processing of humans to that of computers, Miller made a significant contribution to the understanding of information processing with his concept of chunking as related to short-term memory. He proposed that individuals could only store five to nine chunks, or meaningful units, of information in their short-term memory. Anything from digits to words to people's faces were considered to be chunks of information. The concept of chunking was one of Miller's major contributions, because it became a basic element of later theories of memory.

A later development, the *three-stage information processing model*, is now perhaps the most accepted model among information processing theorists. This model was first developed by Atkinson and Shiffrin in 1968 (referred to as the Atkinson-Shiffrin model). This model was then modified by others, including Loftus and Loftus, producing various versions. Generally, this model proposes that there are three stages involved in memory: input or sensory registry, short-term memory, and long-term memory. Sensory registry involves input from sight and sound and processing at this level occurs in 3 to 5 seconds. During the short-term memory stage, information is transferred to short-term memory, where it can remain for 15 to 20 seconds. Typically, five to nine chunks of information can be recalled from short-term memory. Short-term memory capacity can be increased by chunking information into manageable units or by rehearsing information until it is committed to memory. During the third and final stage, information for future reference is stored in long-term memory, which is thought to have an unlimited capacity.

In addition to the three stage information processing model, there are three more models that have been widely adopted. The first, *levels of processing theory*, is based on the work of Craik and Lockhart in 1972. The major premise behind this theory is that people use different levels of elaboration as they process information during the learning process. Elaboration involves taking simple information and applying meaning to it in a way that increases the chance of remembering that information. Different levels of processing or elaboration can make it easier for an

individual to retrieve a piece of information that is stored in memory.

The two remaining models have been labeled the *parallel-distributed processing model* and the *connectionistic model*. These models were proposed as alternatives to the three stage model. According to the parallel-distributed processing model, information is processed by several distinct parts of the memory system in a simultaneous fashion. This is different from the three stage model because it proposes a simultaneous process, as opposed to the step-by-step process proposed by Atkinson and Shiffrin.

The connectionistic model was proposed in 1986 by Rumelhart and McClelland. This model assumes that bits of information are stored in numerous locations throughout the brain in the form of networks or connections. According to this model, the more connections there are to a single concept or bit of information, the more likely that concept is to be remembered. For example, according to this theory and its supporting research, trying to find your keys after misplacing them can be difficult if you cannot remember where you were the last time you saw them. If you *can* remember where you were the last time you saw them *and* you can also remember at least three places you went after you last saw them, you may be more likely to find your keys.

## DEVELOPMENTAL ISSUES

Some information processing theorists suggest that children differ from adults primarily because they have had less experience. These theorists believe that, with proper training or education, children can learn to succeed at various cognitive tasks. Thus, exposure to the environment affects cognitive development. Other theorists believe that children's natural maturation processes influence the complexity of their thinking. Therefore, as children grow older and naturally mature, they are able to perform cognitive tasks of increasing difficulty and complexity. Information processing theorists assume that development involves qualitative and quantitative changes. Examples of these changes have been seen in children's performance in several domains. These include perception, memory, verbal comprehension, mathematical skills, problem solving, and reasoning.

With regard to perception, studies have shown that young children have trouble distinguishing between appearance and reality. That is, when asked to describe something, young children will describe the

way it appears to them, rather than what is really in front of them. Memory has been found to be better in older children than in younger children. When learning new material, young children are likely to use very simple strategies, while older children employ more elaborative strategies to aid in memorizing information.

Verbal comprehension is the ability to comprehend words, sentences, paragraphs, and other forms of spoken information. Children's verbal comprehension appears to increase with age. The ability of children to generate useful strategies that improve verbal comprehension also increases with age.

These findings indicate that, as humans get older, there is a trend for us to develop more sophisticated ways of acquiring, processing, and retaining information. Thus, information processing skills become more developed with age. This aspect of change implies that, when teaching children new things, it is important to consider where they are in the developmental process and to adjust teaching techniques so that they are compatible with children's information processing capabilities.

## INFORMATION PROCESSING RESEARCH METHODS

In the late 1980s, David Klahr characterized information processing research as falling along a continuum ranging from "soft-core" to "hard-core" approaches. Soft-core research involves describing a child's processing of information as a flow diagram or in some way that is not as complex or formal as a computer program. Hard-core approaches, on the other end of the spectrum, involve writing computer programs that imitate a child's output as that child processes information. A program that successfully matches the child's output is considered to be a theory of how the child's mind operates.

The first computer simulation program used to understand information processing was developed by Allen Newell and Herbert Simon in the late 1960s and early 1970s. This program, originally called the *Logic Theorist* and later termed the *General Problem Solver*, was essentially a theory of human problem solving stated in the form of a simulation program. This theory was tested by comparing the results of the computer simulation with human behavior in a given task.

The information processing approach has gained considerable popularity in recent years. Nevertheless, weaknesses in this approach have been noted. A primary weakness is that there is no guarantee that flow

diagrams or computer programs that predict behavior actually represent the way human cognitive processes really work. There may be reason to believe that the differences between computers and the human mind far outweigh the similarities. Furthermore, because information processing studies are conducted in highly controlled laboratory settings, such findings may be unequal to results that would result from studying children in their natural environments.

## INHIBITORY CONTROL

---

Broadly speaking, inhibitory control is the ability to suppress the activation, processing, or expression of information that would otherwise interfere with the efficient attainment of a cognitive or behavioral goal. Everyday examples of inhibitory control include a student who must ignore the conversations of her siblings while she is trying to study for an exam, a baseball player who starts to swing at a pitched ball but then attempts to stop his swing, and a small child who must ignore all of the extra visual information when he is searching for Waldo in his *Where's Waldo* book. Given the countless sources of interference encountered on a moment-by-moment basis, intact inhibitory control is essential for navigating and effectively interacting with the environment.

Although inhibitory control involves many regions of the brain, past research suggests that one particular region, the prefrontal cortex (PFC), plays an essential role in the mediation of inhibitory control. Evidence from studies such as the one conducted by D. Guitton and colleagues supports this notion. The researchers administered a task designed to measure inhibitory control to three groups of individuals: people who had previously experienced injury to the PFC, people who had previously experienced injury to parts of their brain other than the PFC, and people who had no history of brain injury. The researchers found that people with PFC damage performed more poorly on the inhibitory task than the other two groups. This finding supports the notion that the PFC is very important for efficient inhibitory control.

Additional support for the role of the PFC in inhibitory control is evident in the early development literature. Specifically, the emergence of proficient inhibitory control during childhood parallels the maturation of the PFC. The PFC and its connections with other brain regions are the last brain structures to reach maturity. Whereas most other regions of the brain reach adult-like levels of development by 12 years of age, the PFC continues to mature for several additional years. A similar pattern of improvement is observed on tasks requiring inhibitory control well into young adulthood.

The importance of the PFC in the development of inhibitory control is further underscored by the fact that inhibitory deficits have been observed in a range of childhood disorders, including attention deficit/hyperactivity disorder, Tourette's syndrome, obsessive-compulsive disorder, and childhood-onset schizophrenia. Although the specific etiology of each of these disorders is unclear, in each instance it is believed that damage occurs during PFC development, and abnormal neural activity in the PFC and/or structural PFC abnormalities have been observed for individuals with each disorder.

Present research efforts are focused on several topics related to inhibitory control. For example, work is currently underway investigating the relationship between inhibitory control and other cognitive abilities such as working memory and processing speed (how fast your brain can process information). Understanding the interplay between abilities like these and learning how each of these abilities develops can provide invaluable insight into the overall intellectual development of humans throughout childhood. Other researchers are exploring the possibility that several different subtypes of inhibitory control may

exist. Using a combination of behavioral and neuroimaging studies, researcher B. J. Casey has taken a lead in this area of study. She has recently proposed that five different subtypes of inhibitory control may exist, with each type being supported by a different brain pathway. While Casey's model remains speculative at this time, it provides a nice starting point for future research in the area of inhibitory control.

## INJURIES

Injuries have a significant impact on development beginning in infancy, reaching a peak during the adolescent and young adult years, but persisting in importance throughout the life span. Most experts no longer use the term “accidents,” when referring to these events. Based on its Latin roots, accident refers to an event that happens unexpectedly or by chance. As scientists and others have studied this problem over the past 50 years, it has become clear that many of these events do not occur by chance, but are predictable, based on the individual and environmental circumstances.

William Haddon, a physician/scientist, built upon the wealth of injury research stemming from World War II to describe a framework that has become central to understanding the causes and consequences of injuries. Haddon recognized that a phenomenon common to most injuries is the transfer of energy—thermal, radiant, chemical, electrical, and mechanical—in amounts that are too great or at rates that are too

high for the body to absorb, hence an injury results. For example, when a motor vehicle collides with a tree or a streetlamp, the mechanical/kinetic energy of the vehicle is transferred to the driver or passengers, causing an injury such as a fractured arm or head trauma. The faster a car is going, the more energy it transfers in a collision. A safety belt or airbag absorbs much of that energy, decreasing the severity of injury. Another example would be a burn. When a child exploring a sink or tub turns on the hot water, the temperature setting may be so high that the transfer of that heat energy to the child's hand or face results in a scald. Interestingly, the absence or lack of energy can also result in an injury. Many poisons, for example, act by disrupting the normal biochemical processes in the body.

In order to understand these transfers of energy with a view toward preventing injuries, Haddon created a two-dimensional matrix (Table 1). One dimension consists of the characteristics of individuals, their environments, and the particular type of energy or agent in question. Individual characteristics include age, developmental stage, physical or mental disabilities, and gender. One individual characteristic that has been the source of much debate is “injury proneness.” Although studies have examined aggressiveness, hyperactivity, and other behavioral characteristics with a view toward defining “proneness,” conclusions are inconsistent. Environments consist of the physical and social circumstances in which individuals find themselves. For example, an elderly woman, already at risk of hip fracture by virtue of her age, would have a much higher risk in an icy, wintry climate compared to a warmer climate. The energy or agent is specific to a particular injury. For example, roadways, sites of motor vehicle crashes, could have well-designed shoulders, improved lighting, proper grading and curves and many other environmental alterations to decrease injuries, even if the driver of a motor vehicle loses control for some reason. The second dimension reflects three stages in the timing of the transfer of energy—pre-event, event, and postevent. For example, the speed of a motor vehicle, combined with its size or mass, generates energy as it cruises along a road, prior to a crash (the pre-event phase). When a crash occurs, the energy is transferred to the driver and passengers (event phase). In the postevent phase, the effects of the transfer of energy can be lessened by appropriate emergency care and rehabilitation.

Understanding the interaction among the agent, host, and environments is key to injury prevention.

**Table 1** Haddon Matrix to Consider Ways to Decrease the Risk of Motor Vehicle Injuries for Teenage Drivers

	<i>Host</i>	<i>Agent/Vehicle</i>	<i>Physical Environment</i>	<i>Social Environment</i>
Pre-event	Provide training about safe driving behaviors through programs such as Graduated Driver Licensing	Assure that safety belts and airbags are in working order	Improve the quality of safety devices such as road lighting and road grading	Help teens understand the role of risk-taking and the impact of peers on their behavior
Event	Provide training for situations such as unexpectedly driving on a shoulder, necessitating a careful return to the road	Encourage the use of heavier and safer motor vehicles that are better able to absorb the energy transferred in a crash	Improve the design of highways so that when a crash occurs, a secondary or rebound crash is avoided	Create strong norms against the use of alcohol while driving, because alcohol increases the risk of injury, controlling for crash severity
Post-event	Provide training about access to emergency services	Design cars with sturdy fuel tanks to decrease the risk of fire when involved in a crash	Facilitate physical access for emergency vehicles	Support community emergency medical services

From a developmental perspective, strategies that minimize the need for individual actions are more effective in preventing injuries than strategies that expect individuals to act repeatedly. For example, passive restraints such as automatic safety belts and airbags are more effective than restraints that depend on individual behavior each time one enters a motor vehicle. Installing energy-absorbing materials on playgrounds is more effective than expecting parents to maintain constant vigilance as their children explore climbing equipment and develop new skills.

Within the overall problem of injuries, there are two major categories—unintentional and intentional. Intentional injuries refer to willful, deliberate actions that result in harm. Homicides represent intentional injuries in which one individual willfully attempts to kill or harm another individual. Suicides represent intentional injuries in which an individual attempts or succeeds in harming himself or herself. Unintentional injuries refer to those events that occur without a willful goal to do injury or harm. Most of what have commonly been referred to as “accidents” are unintentional injuries. The focus of this entry is unintentional injuries. Homicide and suicide are covered in other entries.

## OVERVIEW OF INJURIES ACROSS THE LIFE SPAN

There are many indicators to describe the outcomes of injuries. Because deaths are a basic component of public systems of vital statistics (i.e., deaths, births, marriages, divorces), deaths due to injuries are a commonly used indicator of the injury problem. Each year, there are approximately 100,000 deaths due to unintentional injuries in the United States—overall, a relatively small fraction of the more than 2.4 million deaths that occur. Looked at in alternative ways, however, injuries represent a significant health event for many ages. For example, about 27 million individuals visit an emergency department for an injury each year, representing just less than 10% of the entire population. Further, as shown in Table 2, after the first year of life, unintentional injuries are the leading cause of death through the young adult years. While injuries decline in rank after the age of 35, more than 36,000 adults between the ages of 35 and 64 die of injuries each year. It is only after the age of 45 that unintentional injuries begin to decline in importance as a cause of death compared to heart disease, cancer, and other chronic diseases. Other

indicators of injuries include rates of hospitalization, visits to emergency departments, visits to physicians/clinics, and reports from individuals in community surveys about injuries that did not require contact with the health system. Table 3 shows that, of

all injuries, falls are the leading cause of visits to hospital emergency departments across the age spectrum, except for adolescents and young adults. In general, deaths due to injuries represent just a small piece of the picture, with 40 to 50 hospitalizations

and more than 1,000 emergency department visits for every death.

Although Tables 2 and 3 provide an overall picture of injuries, it is important to point out that males are at greater risk of injury for virtually every type of injury, throughout the course of life. Physical, psychological, and cultural factors all may play a role in this increased risk for males.

## ALCOHOL

Any review of the issue of injuries must consider the role of alcohol. Alcohol has profound and subtle effects on the physical, cognitive, and social characteristics of individuals, so it is not surprising that use of alcohol is one of the most important injury risk factors. In 2000, the per capita consumption of alcohol was estimated at nearly 290 cans of beer, 60 glasses of wine, and 133 shots of spirits. Although consumption of alcohol is widespread, it is calculated that about 10% of the population is responsible for 50% of alcohol use. Decreasing the use of alcohol would be one of the most effective strategies to decrease the toll that injuries take on health. Alcohol is associated with over 30% of fatal motor vehicle crashes, accounting for nearly 13,000 of the 42,000 traffic-related fatalities in 2000. Adults between the ages of 25 and 44 are at greatest risk for alcohol-related motor vehicle deaths, with 44% of traffic fatalities involving alcohol. For 16- to 24-year-olds, alcohol is involved in 30% of fatalities in contrast to only 4.7% for those older than age 65. It is noteworthy that many motor vehicle deaths for teens involve alcohol, even though every state prohibits alcohol consumption younger than age 21. Even for children, alcohol represents a substantial risk for motor vehicle-related deaths. Annually, of the approximately 2,800 children under the age of 16 who die in motor vehicle-related events, 20% involve drinking drivers. About 60% of the deaths involve children as passengers in cars and the other 40% involve them as pedestrians or bicyclists. For the children who die as passengers in alcohol-related crashes, more than two thirds are in cars in which their own driver had been drinking alcohol. Alcohol has also been associated with other injuries. For example, burns and smoke-related injuries and deaths from fires, especially in homes, often involve alcohol. Similarly, the risk of falls, the leading cause of hospitalization for injuries, is understandably increased by alcohol consumption. Alcohol is associated with a significant proportion of drownings. Given the important

role that alcohol consumption plays in injury-related deaths and disabilities, policy efforts to control alcohol are key to reducing injuries.

## INFANTS AND TODDLERS

The interaction among host and environmental characteristics of infants is unique and complicated. Infants begin their lives entirely dependent on the behaviors and actions of their parents or other caretakers with regard to the relationship to their environments. As they develop during the first year, however, two changes take place. First, as their brains and neuromuscular systems develop, infants are able to exert more control over their behavior. Second, parents must learn to become more attentive to these newly emerging capabilities. The interaction between these two phenomena explains why unintentional falls are the leading cause of nonfatal injuries for this age group. Falls from changing tables, for example, may result from the newly emerging and perhaps first expression of the ability to roll over combined with a momentary distraction by a parent as they reach for a diaper. Agran and colleagues actually looked more precisely at the relationship between development and injury hospitalization by examining rates in 3-month intervals, rather than the usual 1-year or several-year age categories. They found, for example, that indeed the risk for injury rises markedly between 9 and 11 months. Rapid and complex developmental processes are associated with a variety of injuries beyond the first year of age. Agran reported that for children under 4, injury rates peaked at 15 to 17 months. The types of falls varied greatly, again reflecting the different exposures that are associated with increasing physical and developmental capacities. Falls from stairs were prominent for the youngest children, giving way to falls from playground equipment as they moved into this new environment. Poisoning due to medications was the greatest risk at 21 to 23 months before declining in importance.

Even for infants and toddlers the overall risk of injury differs markedly between boys and girls.

## YOUNG CHILDREN

The beginning of school represents a developmental milestone that is accompanied by its share of injury risks. Motor vehicle injuries are the leading injury, but especially between the ages of 5 and 14, pedestrian injuries represent a significant risk. Recent data show that the pedestrian death rate for 5- to 9-year-olds was

1.36 compared to 1.85 for motor vehicle occupants. For 10- to 14-year-olds the rates were 1.23 and 2.80, respectively. Children of this age are only beginning to develop the ability to judge the distance and speed of a moving vehicle. In addition, these children are likely to dart into the traffic, even if they happen to be at an appropriate safety crossing.

Several prevention strategies have had remarkable impacts on injury deaths and disabilities for children. Each of these strategies is designed around an understanding of the physical and developmental characteristics of this age group. For example, the design of child safety seats recognizes the need to restrain children in ways that are both secure, comfortable, and, for parents, convenient. When used correctly, safety seats reduce the risk of death and serious injury by 70%. Since the implementation of the first child safety seat law in Tennessee in 1978, hundreds of children have been spared death or serious injury in motor vehicle crashes. Recently, many states have passed laws requiring booster seats for children up to 80 pounds out of recognition that adult safety belts do not adequately correspond to the anatomic characteristics of children. The Poison Prevention Packing Act of 1970 regulates access to containers and other features of hazardous substances, building upon an understanding of the exploring behaviors of toddlers and young children coupled with the difficulty that parents and other caretakers have in vigilantly monitoring these youngsters. Fencing for swimming pools, requirements that children wear bike helmets, regulation of hot water heater temperatures, and other interventions are most effective when they take into account the developmental stages of those children most at risk.

## ADOLESCENTS

The collision of the developmental tasks of adolescents with their physical and social environments makes it possible to understand the high rates of injury death and disability in this age group. Establishing autonomy, becoming comfortable with pubertal changes, building relationships outside the family, and developing abstract reasoning abilities all combine to increase the risk of injuries. In contrast to school age and early adolescence, where the injury-related death rate is about 8.9 per 100,000 population, the rate markedly increases to nearly 40 per 100,000 for 15- to 24-year-olds, and then begins to decline.

Driving is perhaps the most important symbol of adolescence. The use of a motor vehicle gives

expression to growing feelings of independence and facilitates interactions with new friends and groups. Motor vehicles, with their capacity to generate and thus transfer huge amounts of energy, create a challenge in view of the rapid and sometimes intense physiological and psychological developments for adolescents.

The National Youth Risk Behavior Survey (YRBS) is a school-based, nationally representative survey of over 15,200 students in grades 9 through 12. The YRBS identifies many behaviors that reflect how adolescent development increases the risks of injury. Nationally, over 18% of students had rarely or never worn seat belts when riding in a car. During the 30 days preceding the survey, 30% of students had ridden with a driver who had consumed alcohol and 12% had themselves driven after drinking alcohol.

Given the complex interaction between the driver, the motor vehicle, and the external environment, adolescents, and particularly new drivers, are especially at risk. Safe driving requires a level of maturity that is heavily dependent on time as well as experience with the multiple and frequently changing circumstances that drivers encounter. Motor vehicle crashes account for nearly 40% of all deaths for 15- to 19-year-olds, over 2,600 deaths per year. Sixteen-year-old drivers are involved in 42 crashes per million miles driven compared to 30 and 15 for 17- and 18-year-olds, respectively. Approximately 25% of 16-year-olds are involved in a crash in any given year.

In order to address the risk of death and injury for new drivers, over 40 states have adopted graduated driver license (GDL) programs, interventions that reflect the developmental needs of adolescents. Basically, GDL places restrictions on new young drivers and gradually removes those restrictions as they gain maturity and experience. For example, in North Carolina, individuals obtain a Level 1 permit at the age of 15 that allows them to drive as long as there is an adult supervisor in the front seat with them. For the first 6 months, the new driver is restricted to the hours of 5 a.m. to 9 p.m., to gain important experience during the more forgiving driving conditions of daylight, before being exposed to driving during the nighttime hours. After 1 year of supervised driving, new young drivers are permitted to drive by themselves, but only until 9 p.m. for 6 months. In addition, during this 6-month period of newly unsupervised driving, only one passenger is permitted, because for 16-year-olds, two passengers more than double the risk of a crash, and three passengers increase the risk by nearly fivefold. GDL programs, incorporating an understanding of adolescent

development, have had remarkable effects, such as a 25% reduction in deaths for 16-year-old drivers.

## ADULTS

During adulthood, the death rate due to unintentional injuries remains relatively stable at around 30 to 32 per 100,000 population, with motor vehicle injuries accounting for at least half of these deaths. After the age of 35 years, injuries fall to second behind cancer as a cause of death.

The workplace is obviously an important environment to consider in describing injuries during the productive adult years. For younger adults (20–34 years), workplace fatalities average 1,760 per year (3.9 per 100,000 population), while for adults 35 through 54, the rate increases to 4.5. Approximately 18% to 19% of these deaths are associated with assaults (intentional injuries). Reflecting the contribution of motor vehicle injuries to overall mortality, transportation incidents account for 40% of occupational deaths. Untoward encounters with equipment or other objects is responsible for the next most frequent cause of occupational death at 16%, with falls and exposures to harmful substances accounting for 9 to 12% of fatalities. Not surprisingly, the risks vary greatly by industry. Agriculture, forestry, and fishing have reported about 800 deaths per year in recent years for a rate of about 23.8 per 100,000, followed by mining with 150 deaths per year with a rate that has varied between 21.7 and 27.0 over the past several years. At the other end of the spectrum, finance, insurance, and real estate has experienced around 100 deaths per year at a rate of 1.2 per 100,000 population.

## AGE 65 AND BEYOND

The interaction between host and environmental characteristics results in particular risks for injuries among this age group. Physical characteristics include changes in vision, losses in strength, coordination and response times, and changes in bone density with increasing fragility. In addition to these developmental changes, many medications for hypertension, heart disease, and other chronic diseases may impede normal strength and reflexes. Complementing these changes in the elderly individual as the host are environmental characteristics. The problem is not changes in environments per se, but rather the failure to attend to safety hazards in the home or other locations. Climbing into a tub poses a minimal risk for a 40-year-old, but may create a sizable hazard for a 70-year-old. At night, the same darkened hallway that for years was second nature

becomes a hazard as physical skills diminish. The ability to negotiate the complicated environmental interactions of driving is dependent on physical and cognitive skills that are in decline.

Injuries constitute only a fraction of deaths for seniors. For those between the ages of 65 and 74, the death rate is only 47 per 100,000 compared to 860 and 776 for cancer and heart disease, respectively. Beyond the age of 75, the differences in rates are even more dramatic. The mortality rate for injuries does increase to 146 per 100,000 population, but the rates for heart disease (3,100 per 100,000) and cancer (1,462 per 100,000) overshadow that rate.

In spite of the relative decline in importance of injuries in the later years, recognition of the physical and cognitive needs of elderly individuals can decrease the risks of disability and death. Regular health visits allow assessment of the capacities of elderly patients. Such visits should evaluate vision, balance, strength, and use of pharmaceuticals for other chronic diseases. Weight-training and other exercises, for example, may improve strength and gait. Screening for osteoporosis may identify those in need of attention to weakening bones, a risk factor for falls and fractures. Health care providers or indeed anyone who interacts regularly with the elderly should inquire about their physical environments as well, as a way to address injuries. Improvements in lighting, attention to potential obstacles, creation of nonslip surfaces, handles in tubs and showers, and many other interventions may decrease the risk of injury for individuals with physical impairments. Transportation, in particular, is a challenge. Safe driver programs for the elderly are an important approach. Development of alternatives for elderly individuals who drive themselves is a growing need as the overall population ages.

## SUMMARY

Injuries are a prominent health and behavioral outcome throughout the life span, becoming the leading cause of death after the first year and remaining the leading cause until well into adulthood. Even when injuries decline in rank, they are the source of death and disability for a large segment of the population. Perhaps the most significant aspect of injuries is that most of them are preventable with attention to the characteristics of individuals and their interactions with their physical and social environments. Deaths due to motor vehicle injuries, the leading cause, have declined by 38% during the past 50 years. This decline has resulted from interventions that are based on an

understanding of the mechanisms of injuries as informed by the Haddon matrix combined with the political will and resources to effect environmental changes. In addition, interventions have enabled individuals to become more aware of the important role that they play in their interaction with environments. Across all causes of injuries, amelioration of individual and environmental risk factors has been associated with thousands of averted deaths and hundreds of thousands of cases of averted disability and distress. Given the ability to understand the factors associated with injuries, further substantial progress in reducing this cause of distress is desirable and feasible.

## INTELLECTUAL DECLINE

Many adults believe that their thinking and memory skills are getting poorer, or will become so, as they grow older. Older adults frequently report that their memory is “not as good as it used to be,” and some may avoid participating in adult education or workplace training because they believe that “you can’t teach an old dog new tricks.” While scientific evidence shows that some intellectual skills may decline in old age, these declines are neither inevitable or universal and not as profound as popular beliefs suggest.

For many years, cognitive psychologists studying intellectual functioning believed that cognitive skills begin to deteriorate by middle adulthood and decline markedly in old age. During World War I, the U.S. Army began testing inductees’ intellectual abilities to determine the kinds of military work for which they would be suited. Intellectual abilities were shown to peak in early adulthood and then decline systematically with age and type of skill measured. Verbal abilities showed the least decline, and numerical and reasoning skills suffered the greatest losses.

Results from early intellectual aging studies were based on cross-sectional samples of individuals of different ages, such as 20- versus 40- versus 60-year-old adults. Such studies do not show how intelligence changes *within* individuals over time: Age changes are confounded with age differences, giving a misleading picture of intellectual decline. Because older adults typically have had less education, and are not well practiced in test-taking compared to younger adults, they tend to look less intelligent.

When longitudinal data became available, a different picture of intellectual changes began to emerge. Longitudinal studies follow individuals over a lengthy period of time—several years or decades—and measure their intellectual abilities every few years. For example, one study retested 50-year-old men who had taken the Army Alpha Test during WWI. These men were found to have higher IQ scores, on average, than when they were 19 years old. A second follow-up showed that they had maintained these abilities into their 60s. But, like cross-sectional designs, longitudinal studies have limitations. The primary problem is that individual changes are confounded with time of measurement differences. Time passes from one measurement to the next, and events that occur during the interim could have an impact on individuals’ performances.

To confront the problems with these two approaches to studying intellectual aging, K. Warner Schaie, at Penn State University, has conducted an ambitious study. His *Seattle Longitudinal Study* has taken place over five decades. He obtains intelligence test scores, using the Primary Mental Abilities Test, on a cross-section of adults in a given year (beginning in 1956), and these persons are retested every 7 years. At each time of testing, a new sample of participants is selected, tested, and followed over time. Thus, Schaie's research combines cross-sectional and longitudinal methods. Schaie has found that most intellectual abilities remain stable or even grow well into the 50s and 60s. Declines in some abilities begin in the 60s, and by the 70s significant losses are evident for most intellectual skills. Even so, there is little impact on everyday cognitive functioning.

Thus, intellectual aging is more complex than originally believed. Some gender differences in intelligence test performance have been observed. Women's test scores decline earlier for biologically determined intellectual domains, while men's scores decline earlier for culturally determined domains. Also, persons with cardiovascular disease and other health problems are most likely to suffer cognitive losses. Studies have shown that older adults can benefit from training designed to improve intellectual functioning. Remaining active and healthy is the key to intellectual vitality in old age, according to many experts.

## INTELLIGENCE

---

One of Karl Spearman's (an important figure in the early work on intelligence) major works was titled *The Nature of Intelligence and the Principles of Cognition* (1923). Galton, Binet and Henri, Thurstone, and Guilford also published works regarding the concept of intelligence. Nonetheless, cognitive psychology was not identified as a part of psychology until the 1960s according to Kessel and Bevan. The authors of *Plans and the Structure of Behavior* (Miller, Galanter, and Pribram) and *Cognitive Psychology* (Neisser) wrote about mental events such as plans, sets, thoughts, imagery, memory rehearsal, stimulus codings, short- and long-term memory storage, and executive processing. An information processing perspective (Newell and Simon) was later developed in which cognitive problem-solving tasks were described as an integration of programs to process information and the senses. Williams' Aptitude Test Taker program devised its own rules for solving inductive reasoning problems after being given examples. Pellegrino and Glaser stated two approaches of the research: (1) the cognitive correlates approach where relationships between tasks and intelligence test results are investigated, and (2) the cognitive components approach which focuses on revealing parts of cognitive tasks found in cognitive ability tests. The cognitive components approach was described in Sternberg's work in that he analyzed task performances into components. Carroll attempted to link cognitive ability with psychometrics and factor analysis. He performed subjective analyses of 24 factors of cognitive ability, which were described by Hunt in a distributive memory model. Carroll also referred to Newell's statements about mental production systems.

After 1980, groups conducted similar studies. Vernon and Jensen performed studies demonstrating that intelligence tests have significant relationships with performance on reaction-time tasks. Their studies also showed intelligence test correlations with speed of performance on tasks that incorporated retrieving information from long-term memory. After working with Cronbach in studying aptitude-treatment interactions (ATIs), Snow worked on the study of aptitude processes. He worked on developing a theory for how aptitudes may interact with learning processes. Learners with different aptitude profiles may use different learning strategies, or need different

types of instruction for learning success. Snow and Lohman published a summary of this work. Factorial reanalysis in studies of the more important types of abilities demonstrated known cognitive abilities and the kinds of tests and tasks that can be utilized to measure them. Future research should attempt to continue to interpret cognitive ability findings in terms of cognitive psychology concepts.

Gardner, Sternberg, and Das, Naglieri, and Kirby additionally developed cognitively oriented intelligence theories. For example, the triarchic theory of intelligence (Sternberg) and the theory of multiple intelligences (Gardner) described the external worlds of people and the creation of products that are valued by cultures. Both theories could be important to develop assessment more relevant to multicultural populations than traditional assessment. In addition, tasks measuring cognitive processes identified in Das and Naglieri's Planning, Attention, Simultaneous, and Successive (PASS) theory could be important to help people with poor planning skills.

### **INTELLIGENCE TESTING: A HISTORICAL PERSPECTIVE**

Definite trends do exist in test interpretation practice and are outlined by Kamphaus, Petoskey, and Morgan. In the early 1900s, psychologists emphasized assessment of a general intelligence level. After World War II and the development of the first of the Wechsler scales for children, interpretation was based predominantly on profile analysis. Specific profiles and subtest results often were associated with diagnosis. Profile analysis changed in the 1970s because of widespread use of factor analysis. Factor analyses yielded the familiar Wechsler Intelligence Scale for Children—Revised (WISC-R), which was an alternative to interpreting subtest profiles or general intelligence levels. This psychometric approach to intelligence test interpretation included an emphasis on utilizing calculations to reveal significant profiles and factors.

If the purpose of cognitive ability assessment is to sample a behavior that represents a construct in order to make inferences about the construct, recommended by Anastasi, the process of interpretation has been limited by the lack of clarity of the definition of the construct being measured. Kaufman suggested that a problem results from a lack of theory being utilized in

the test development process, and developed his Kaufman Assessment Battery for Children (K-ABC) as a solution. In the late 1980s, Woodcock further advanced the effort to increase the meaning of intelligence test results by applying the fluid/crystallized theory in the development of the Woodcock-Johnson Tests of Cognitive Ability—Revised (WJ-R). The K-ABC and the WJ-R used factor-analytic means to form a set of subtests related to their theories, with two or more subtests used to measure a particular trait. Cronbach advocated such a process more than three decades ago, indicating that whether the operations that make up a test relate to a specific universe defines content validity.

Present test interpretation emphasizes theory as central to interpretation. John Horn (Gf-Gc theory) and John Carroll (three-stratum theory) are examples of researchers using theory as approaches to deriving score meaning. These theories will be expanded on in subsequent sections. Kamphaus developed an interpretative approach that utilizes both theory and research findings.

### **CONTEMPORARY INTELLIGENCE THEORY: CATTELL/HORN GF-GC THEORY**

Horn and Noll state that common factors in cognitive ability tests are known as primary mental abilities (PMAs). PMAs include nine broad abilities, several of which appear to represent what has traditionally been called intelligence. This evidence of common factors, in addition to evidence demonstrating different patterns of change for the factors and evidence from neurological functioning and heritability, indicates that a single, unified concept of intelligence does not fully or properly represent human cognitive ability.

Horn and Noll propose that several intelligences, including reasoning intelligence (Gf), the intelligence of knowledge stemming from acculturation (Gc), visual intelligence (Gv), auditory intelligence (Ga), the intelligence of short-term apprehension and retention (SAR), the intelligence of fluency and retrieval from long-term storage (TSR), and quantitative intelligence (Gq) better represent human cognitive ability. In addition, the process of intellectual speed (Gs) and speed of decision making (QDS) may be other forms of intelligence.

Horn and Noll also report evidence from different studies suggesting that the structural organization of

intelligence relates to organization in the central nervous system, genetic and environmental influences, and age differences. No broad intelligence is fully predicted by a combination of the others. They are combinations of different genetic and environmental influences, and are affected by different factors, such as injuries, childrearing, and education. Different patterns of practice in individuals vary in intensity, length, and quality. Broad intelligences increase with learning, practice, and use, and without practice they decrease in strength, as well as with decreasing neurological base. During childhood, all broad intelligences increase. During adulthood, increases in Gc and long-term storage (TSR) are demonstrated, while Gf, short-term apprehension and retention (SAR), and Gs abilities decrease with age.

### CONTEMPORARY INTELLIGENCE THEORY: CARROLL'S THREE-STRATUM THEORY OF INTELLIGENCE

In the three-stratum theory of intelligence, abilities are categorized at three different levels or strata, including narrow (stratum I), broad (stratum II), and general (stratum III), which is represented by the psychometric "g" for general intelligence. The three strata that are part of the theory are not strictly defined. Instead, abilities are placed in general categories. The three-stratum theory follows a hierarchical model and should be thought of as an expansion of models developed by researchers such as Spearman, Holzinger, Thurstone, P. E. Vernon, R. B. Cattell, and Horn. Factors, at all strata, appear to relate to individuals' real experiences that make up cognitive performances. Three-stratum theory is a theory of cognitive abilities that attempts to account for total range of cognitive performances. Three-stratum theory also presents an organization in which relationships between different variables can be interpreted.

Carroll reports that genetic influences are present from the research that correspond to a general (stratum III) intellectual factor and to other cognitive factors, such as the stratum II factors proposed in the three-stratum theory. The organization of cognitive abilities does appear to have important relationships with the organization of the brain and the central nervous system according to neuropsychological research.

## INTERGENERATIONAL RELATIONSHIPS

---

Intergenerational relationships refer to ties between individuals or groups of different ages. Sweeping changes in American family structure, especially since World War II, have dramatically altered ties between generations for older and younger generations alike. Many intergenerational ties now last longer than at any time in the past. As social networks contract due to loss of spouse through widowhood or, increasingly, divorce, intergenerational relationships are more likely to be the first place that older adults turn for help.

Bengston's theory of intergenerational solidarity points to the multifaceted ways in which generations relate to one another in terms of living arrangements (structural), shared values (normative), norms (consensual), contact (associational) and closeness (affectual), and instrumental support (functional). Older generations are generally perceived to invest in younger generations (generational stake) because resources are often seen to flow down generations. More recent explanations using the contingent exchange perspective have focused on differences in

needs and resources of each generation. In other words, more assistance will be given to the child or the parent with the greatest need. Likewise, available resources may constrain the limits of what is given, and individuals with the greatest resources may be more likely to provide assistance. There is also mounting evidence that patterns of intergenerational exchanges can have important psychological consequences for both parents and children. The circumstances under which this is the case are only beginning to be identified.

Early work on the predictors of intergenerational support have focused on variables such as frequency of contact between parents and offspring, but most current approaches consider the content of, and satisfaction with, exchanges, including instrumental assistance, such as with household tasks or transportation, financial assistance, emotional support and advice, and sharing information. Despite growing consensus on *what* to measure, *how* it is measured often complicates comparisons of findings from studies using different methods for measuring exchange.

Human development scholars have long regarded individuals as being embedded within a latent matrix of support. Unfortunately, most previous research on the characteristics of this matrix has been largely ahistorical and ignored the family as a system of inter-related relationships. We suggest that a shift from considering *families in context* to one of studying *families as contexts* will provide ample theoretical purchase on the antecedents of intergenerational support, and point the way to innovations of measurement, design, and analysis of ties between generations, by considering sources of variability within and between families simultaneously. This can be achieved by capturing the characteristics of multiple relationships at the family, individual (parent and child characteristics), and dyadic level. At the family level, researchers could consider characteristics such as race, ethnicity, and family size. At the individual level, one could measure parent characteristics such as age, gender, marital history, health and functioning, income, education, and labor force participation. Similarly, characteristics of the adult children such as age, gender, marital history, the child's own parental status, biological versus step relationships, and income could be included. While parent characteristics are common among all children, child characteristics may vary across relationships in the same family. A number of indicators

of the dyadic relationship between the parent and the adult child could therefore be included. These include residential propinquity and contact, coresidence, relationship quality, and past support between parents and offspring. These variables can be considered as most proximal to exchange and because they are unique to each relationship, they can be expected to account for intrafamilial variability in exchange patterns.

This is an exciting juncture in the study of intergenerational relationships, with plenty of new and emerging family structures, methodological advances, and opportunities for key theoretical advances. It also represents some of the most salient and enduring family relationships individuals will ever experience.

## INTERNET

---

Internet use is widespread and growing. Current studies indicate that 149 million people are online worldwide, and that the number is increasing at a rate of 12% per month. According to the U.S. Census Bureau, 22.2% of the 76 million American computer users aged 3 and older use the Internet, and one fifth of children with home computers were using them to access the Internet as of 1997. Today, that number is undoubtedly higher. The Internet affects family life, politics, business, education, and social life in a variety of ways, both potentially beneficial and harmful.

## EDUCATION

Technology-driven school reform is still relatively new, and yet it is already present in all aspects of education. Supporters claim that the Internet will help propel students into the future and increase their understanding of the world. According to Gillan, the impact of technology is limitless to society, and society now demands that students develop the ability to operate in a technological environment. So much of the planet is becoming connected through the Internet that online protocol has become an important part of technology-based education. Donald J. Leu, Jr., Rachel A. Karchmer, and Deborah Leu of Syracuse University have written that access to the Internet allows all teachers to benefit from learning what occurs in other classrooms around the globe. They point to the example of teachers and children at the Fahan School in Tasmania, who developed online resources that led to connections with schools in Malang, East Java, the International School in the Netherlands, and many others. The Internet offers central sites for Internet project descriptions, central sites for stories of teachers' experiences, and mailing lists or listservs.

Some teachers and researchers, however, question the benefit of Internet use among children and young adults. A national survey conducted by the Annenberg Public Policy Center in Washington found that most parents in computer households fear the Internet's influence on their children, because the Internet exposes them to so much information and so many other Internet users. At a large university in New York, the dropout rate among freshman newcomers rose dramatically as the school's investment in computers and Internet access increased. Administrators learned that 43% of the dropouts were staying up all night on the Internet. No one has proved definitively that the Internet is either "good" or "bad" for children and young people. A recent study conducted at Carnegie Mellon University, called HomeNet, suggests that if parents limit and monitor their children's Internet use, and if educators carefully incorporate Internet technology into their lesson plans, most children will benefit from the technology.

## POWER

In all of the spheres mentioned above, the Internet alters the balance of power. The members of society

who are traditionally powerful—celebrities, professional criminals, the wealthy, and so on—are given that power through their titles. They are much less powerful on the Internet. Rather, skilled computer users have much more power on the Internet because of their knowledge of its mechanics, not because of a position they have been granted. People whose authority comes from their position do not necessarily lose power, but now, anyone can achieve a powerful position through knowledge of computers. Certain traits that determine social standing in the "real world"—physical appearance, style, confidence and charm in social situations—do not matter on the Internet. The traditional "cool" people may be mocked on the Internet, but they can also be the targets of more serious injury, such as net crime and pranks.

## GOVERNMENT AND ECONOMICS

The Internet has affected the business world in many ways. More employees can now avoid the increasingly stressful workplace, the commute to and from work, and the polluted air of big cities by working at home. Some businesses are starting to allow their employees to work at home for 2 to 4 days per week and send their work via e-mail or through direct connection to their company's intranet. Employees can take breaks when they wish, save money on child-care and gas, and set their own hours. This system primarily works for computer-oriented jobs, however, and it can discourage productivity. It may also increase stress for a worker who has many responsibilities at home in addition to his or her job.

The relationship between businesses and consumers is also changing. By selling items over the Internet, companies save money by employing fewer people, eliminating the cost of land and real estate, and reducing administrative costs. Consumers benefit from lower prices and the convenience of shopping at home. Still, because less staff is needed to run Internet sites, the workforce suffers as a result of online shopping. People who shop online do not leave their homes to socialize, get necessary exercise, or help their local economy. The Internet has become a vital tool for businesses like the real estate industry, according to a California Association of Realtors survey. Online information about real estate helps consumers educate themselves better and save money.

Government agencies have also been able to save money by making more information available to citizens online. Developing countries have not been able to take advantage of the Internet as extensively as developed countries, however. In a study published in 2003, the World Library and Information Congress found that in some ways the Internet builds “barriers which seriously widen the gaps among the people in the world and even among people within a country.” The WLIC states that developing countries should establish IT plans and policies that help educate people about the Internet. Governments that can take advantage of the Internet have the ability to address issues such as *unemployment*, by creating new jobs in information technology and by keeping better statistics about the unemployment rate; *health*, by setting up health information systems and using telemedicine in remote areas; *commerce*, by accessing information about the import and export of products and by developing and marketing new products; and *tourism*, by strengthening international tourism and reducing the cost of advertising.

## SOCIAL AND FAMILY LIFE

A study of Internet users conducted in 2000 by Norman Nie showed that people who spend more than 5 hours a week online are spending less time with family and friends and more time doing work at home. The Center for Internet Studies found that 29% of Internet users report using the Internet to “alter their mood or escape on a regular basis.” According to a college listserv survey regarding the effect of technology on personal relationships and communication, the most frequently mentioned potential problem was electronic communication in the forms of e-mail, discussion groups, and chat rooms. Many of the people surveyed described a feeling of isolation related to Internet use. The lack of face-to-face contact was cited as a contributing factor to feelings of alienation and loneliness. Another study suggests that a small but significant number of people blame excessive online use for the breakup of a marriage.

While there is no official psychological or psychiatric illness called Internet addiction, some psychologists believe that compulsive Internet use is a prevalent problem. Online surveys vary, estimating the number of Internet users showing addictive behavior at anywhere from 6% to 80%. Symptoms of an addiction may include: using the computer for pleasure,

gratification, or stress relief; feeling irritable or out of control or depressed when not using the computer; spending increasing amounts of time and money on hardware, software, magazines, and computer-related activities; and neglecting work, school, or family obligations.

The Nie study also concluded, however, that the Internet is still used mostly as a helpful information resource. Only 25% of Internet users report actually buying something on the Internet. Only 10% of users report that they trade stocks, participate in auctions, or bank online. Most users see the Internet as a positive addition to their lives as a whole, but it is important to realize that time spent on the Internet is time taken away from family and friends.

## SUMMARY

The Internet is a useful tool and a force in society that is not yet fully understood. While it provides indisputable benefits for schools, businesses, and individuals, it causes difficulties for some individuals and populations. Social isolation, Internet addiction, and the vast amount of information available to children are some of the main concerns. Also, developing countries have not yet been able to access all the Internet has to offer, and they suffer a disadvantage compared with the developed world. Most people use the Internet to make their lives easier and to find helpful information. These are the major benefits of the Internet that should be encouraged and distributed throughout the world.

## INTERRACIAL MARRIAGES

---

Interracial relationships have existed for years, though society traditionally has had difficulty accepting these unions. Over the years, attitudes toward interracial relationships have changed dramatically and will likely continue to change as our society becomes increasingly diverse.

An interracial marriage is generally defined as the union between two individuals who come from different racial/ethnic backgrounds, such as an African American woman and a European American male. Interracial relationships have been difficult to clearly define, however, due to changing definitions and classifications of race/ethnicity. The social construction of race is an issue at the heart of interracial relationships as well as multiracial children, and affects discussions of these unique experiences.

### ATTITUDES AND PRACTICES

Historically U.S. society has had difficulties accepting interracial relationships. From colonial times until the 1960s, antimiscegenation laws declaring race mixing and intermarriage illegal were common in most state laws. These laws were intended to protect “whiteness” and thus were not generally enforced for marriages between racial/ethnic minorities. It was not until the case of *Loving v. Virginia* in 1967 when the U.S. Supreme Court repealed antimiscegenation laws. In this case, a black Native American woman named Mildred Jeter married Perry Loving, a European American. This couple, who was married in Virginia in 1958, was subsequently sentenced to a year in prison for breaking the antimiscegenation laws. With this monumental Supreme Court decision, however, all state laws against interracial marriage were repealed on the grounds that they violated the Fourteenth Amendment, providing the right to pursue happiness.

It appears that society is steadily becoming more accepting of interracial relationships. Surveys from the Gallup Poll of African American and European American adults about their attitudes about interracial

marriages demonstrate significant changes. In 1968, for example, 17% of Whites and 48% of African Americans approved of interracial marriage, and by 1997 61% of Whites and 77% of African Americans stated they approved. This shift in attitudes is expected to continue as our society becomes increasingly diverse.

Positive attitudes toward interracial relationships are generally associated with more liberal ideology, higher levels of education, and living in larger cities. Younger generations also appear to be more accepting of interracial relationships. Research with college populations shows that about 50% of students have positive attitudes about interracial dating, though only about 25% report dating someone of a different race. With respect to geographical region, individuals on the West Coast show the greatest approval for interracial marriages, followed by the East Coast and Midwest. Individuals in the South consistently show the lowest approval of interracial marriage, which likely relates to general historical and societal attitudes toward racial/ethnic minorities within this region.

The rate of interracial marriages has also changed significantly over the past years. In 1993 the United States Census reported that almost 5% of all marriages were interracial, which was nearly four times as many as in 1970. Researchers who have studied last names on marriage licenses in Hawaii and California have suggested that the proportion of interracial marriages is higher than 50%. Thus attitudes and practices related to interracial dating and marriage are steadily changing.

### SOCIETAL AND FAMILY CHALLENGES

Individuals in interracial relationships report that they get married for the same reasons that other couples do—because they are in love and care about one another. Nevertheless, these couples often face unique issues that distinguish their relationships from those of people who marry within their same race. At the societal level, it is clear that many myths and stereotypes about racial/ethnic minorities, as well as about couples in interracial relationships, exist and can exert a negative influence over interracial couples. Depending on the environment and context of an interracial marriage, individuals may experience discrimination and hostility or, conversely, tolerance and support.

Couples also report that their own family members can sometimes cause conflict if they are biased and discriminatory toward other cultures. In extreme cases, parents may cut ties with children who marry someone from a different race. Often, these parents report that they are particularly concerned about how society will look upon the interracial couple, and how the children of the interracial relationship will be treated. Perceptions that children of mixed race will have substantial identity conflict and problems abound, even while current research suggests that they will be well adjusted.

Because each individual in an interracial marriage represents a different culture, at times there can be conflict over issues such as how to raise children, communication and use of ethnic language, views about caring for the elderly, and religious beliefs. While these issues can clearly affect any couple, regardless of racial/ethnic background, they may be exacerbated in interracial couples because of potentially different values and experiences.

## **THE RICHNESS OF INTERRACIAL RELATIONSHIPS**

Many researchers, as well as society at large, have focused on the challenges faced by couples in interracial relationships without acknowledging the many strengths and benefits associated with such unions. Interracial couples report that their relationships allow them to experience another culture through values, language, shared customs, and traditions. This diversity adds a richness that might not be possible in a union between two people of the same racial/ethnic background. In addition, individuals in interracial marriages who choose to have children have the opportunity to create families with unique, diverse interests and traditions. Some research has even shown that multiracial children raised in these families show more open attitudes toward other individuals from different racial/ethnic groups.

## **MULTIRACIAL CHILDREN**

Rates of interracial marriages have steadily increased in the United States, and as a result there are more children of mixed heritage than ever before. The offspring of interracial relationships are referred to by names such as biracial, multiracial, multiethnic, and mixed race. The existence of multiracial individuals is

not a new phenomenon, though. In times of slavery, it was not uncommon for slave owners to have sexual relations with female slaves and then have children who would be considered biracial.

The challenge of classification has become increasingly salient with children of mixed heritage. While society attempts to categorize individuals into rigid racial groups, multiracial individuals challenge this long-held practice because they do not fit neatly into clearly define racial categories. In the 2000 United States Census, respondents were allowed, for the first time, to indicate more than one race as their self-classification. This landmark change allowed multiracial individuals to acknowledge their background, and in the 2000 United States Census, 6.8 million (2.4%) of the U.S. population selected more than one racial box.

Research about multiracial individuals is limited and has generally focused on biracial individuals whose heritage is a mix of a minority group (usually African American) and European American, rather than two minority groups. Nevertheless, with increased attention being paid to this growing population, new insights about the identity formation and functioning in multiracial youth have been proposed. One researcher in particular, Maria Root, has written extensively about multiracial individuals and has integrated findings from sociological and psychological fields to begin to understand this unique population.

Maria Root and other researchers have discussed the psychological impact of being multiracial, as well as how an individual's multiracial identity may develop over the life span. While early models speculated that children of mixed heritage would experience marginalized status and identity conflict, more current research suggests that being multiracial does not necessarily equate with being maladjusted. Indeed, psychologists concerned with societal stereotypes have acknowledged that there is a danger of multiracial individuals internalizing negative stereotypes about themselves. Furthermore, multiracial individuals, because of their unique and ambiguous appearances, may frequently be asked about their background, and may feel conflicted to choose one race (parent) over the other. These legitimate challenges can affect multiracial individuals in different ways based on background, appearance, language, family, and geographical location.

Nevertheless, research suggests that a normal developmental trajectory is expected for multiracial individuals. They will attempt to develop their identities much

as any person would, but these identities will likely be more fluid and flexible because of their unique experiences. Similar to research findings on interracial relationships, studies of multiracial children have suggested that in fact their mixed identity can be a source of richness and strength, instead of conflict.

## FUTURE TRENDS AND SUMMARY

Changing views about racial/ethnic diversity within the United States and the ease with which people can cross geographic barriers has led to more interracial relationships, and in turn more multiracial children. Researchers are beginning to understand the positive aspects of such unique experiences, and it is expected that time and effort will continue to be devoted to understanding the challenges and benefits faced by these individuals and couples.

## INTIMACY

---

According to John Bowlby, the propensity to establish intimate connections to particular individuals is a basic component of human nature; it is present before birth and continues through adult life into old age. The intimate connections that people establish are an important source of meaning in their lives, and the level and quality of intimacy in these connections is directly related to their physical and psychological well-being.

### WHAT IS INTIMACY?

Intimacy has been defined in many ways. Yet, there is no single definition on which all agree. There are,

however, a number of characteristics on which there is consensus. First, intimacy is interpersonal. It takes place between two or more persons. Second, intimacy is reciprocal—generated not by unilateral desire but by mutual consent. Third, intimacy has cognitive, affective, and behavioral components. Intimates are willing to reveal themselves to one another, care deeply about one another, and are comfortable in close proximity.

Self-disclosure, the sharing of private thoughts, dreams, beliefs, and emotionally meaningful experiences, is often viewed as synonymous with intimacy. Yet, recent formulations emphasize that self-disclosure is only half of the process; the other half is partner responsiveness. According to Harry Reis and his colleagues, for a relationship to be intimate, self-disclosure must occur in a context of appreciation, affection, understanding, and acceptance. Indeed, an intimate experience has not taken place until there is empathic feedback—until acceptance and acknowledgment are communicated verbally or nonverbally as an indication that trust is justified. Fourth, then, intimacy is validating.

In the absence of empathy, attempts at intimate support can miss the mark. Those making emotional disclosures usually want an emotional response. Those making pragmatic or factual disclosures often want a factual response. In the absence of empathy, emotional concerns may be met with a pragmatic or problem-solving response, or, conversely, pragmatism may be met with emotion. Studies suggest that emotional disclosures lead to greater intimacy than do factual disclosures. But regardless of kind, mismatched responses leave the discloser feeling misunderstood and devalued rather than affirmed and validated. Under these conditions, intimacy will suffer.

### HOW ARE PATTERNS OF INTIMATE RELATING ESTABLISHED?

Considerable research suggests that the capacity to establish affectional bonds begins in infancy and is rooted in the kinds of attachment styles that infants develop with their early caretakers. When parents or caretakers are consistently responsive and warm, infants develop a secure attachment style characterized in adulthood by ease in trusting and getting close to others and a comfort with both intimacy and autonomy. When parents are inconsistent and insensitive, children develop attachments described as anxious-ambivalent or preoccupied. An anxious-ambivalent style of relating

is characterized by overdependency in adulthood. Such relationships are marked by a desperate desire to merge with a partner alternating with a fear of not being loved sufficiently. When parents are cold and rejecting, children develop an avoidant style. According to Kim Bartholomew, there are two types of avoidance—fearful and dismissive. Those who are fearfully avoidant desire intimacy but experience pervasive interpersonal distrust and fear of rejection. Those who are dismissively avoidant place much value on independence. They focus on work or hobbies and defensively assert that relationships are relatively unimportant.

### WHAT ARE THE BENEFITS OF INTIMACY?

Availability and quality of intimacy are associated with well-being for men and women alike. Studies showed that men who reported they felt a lack of emotional support from their wives were far more likely to experience heart attacks. Several other studies showed that both men and women in relationships rated as high in intimacy were less likely to report symptoms of depression and anxiety than those in relationships rated as low in intimacy.

### SUMMARY

In sum, intimacy is interpersonal, reciprocal, and validating. Intimacy is a process that develops, fluctuates and changes over time and is never completed or fully accomplished. Yet intimacy is an important component of human existence that gives meaning to people's lives and is directly related to their physical and psychological well-being.

## IONIZING RADIATION

---

Ionizing radiation in sufficient dosage has been known to disrupt prenatal development almost since the discovery of X-rays. Case reports of birth defects in children prenatally irradiated appeared in medical journals as early as 1929. The effects of high dose prenatal ionizing radiation are smaller stature, microcephaly, eye malformations, mental retardation, and lowered IQ test scores. After the atomic bombs were dropped on Hiroshima and Nagasaki in 1945, the United States and Japanese governments began cooperative research on the survivors, children who were in utero at the time of the bombings, and later-born children of survivors. Dosages of in utero ionizing radiation were reconstructed using data from atom bomb tests in Nevada in the 1950s, research with animals, and the self-reported locations of the pregnant women at the times of the bombings. Probability of severe mental retardation, IQ test scores, and teacher ratings of school performance showed dose–response relations to exposure such that higher doses yielded a higher chance of severe mental retardation, lower IQ test scores, and worse school performance. The dose–response relation for severe mental retardation was steepest for exposure at 8 to 15 weeks postconception, a 43% increased risk, per gray, of exposure. At 16 to 25 weeks the relation was weaker, and was not detectable at less than 8 weeks or greater than 26 weeks age postconception. Small head circumference was associated with radiation exposure 0 to 7 weeks postconception. Seizures of unknown origin were also associated with exposure 8 weeks or more after conception. Likely mechanisms for the effects of prenatal ionizing radiation on brain development include alterations of neuronal proliferation, neuronal migration, programmed cell death (apoptosis), and synaptogenesis. Laboratory experiments show that ionizing radiation alters molecules on the surfaces of neuronal cells that contribute to cell adhesion and migration.

The effects of ionizing radiation on human health are highly controversial. Research controversies about

risk estimates based on the Japanese atom bomb survivors concern whether there is a threshold below which no developmental effects of ionizing radiation occur, whether the “nonexposed” survivors in Hiroshima and Nagasaki are an appropriate comparison group to those who were highly exposed, whether the increase in voluntary abortions following the bombings may have affected the results, the possibility that fetuses and embryos that were miscarried as a result of the bombings could yield a biased sample of survivors, the appropriateness of extrapolating from acute exposure in a single event to low level intermittent or chronic exposure, and the potential effects of other variables in wartime Japan, such as stress and malnutrition.

Other developmental effects of pre- and postnatal ionizing radiation include an increase in childhood leukemia, thyroid cancer, other cancers, and possibly arteriosclerosis. Prior to a landmark study in England by Alice Stewart in the 1950s, diagnostic X-rays of the abdominal area during pregnancy were considered to be safe.

Experts advise that a qualified medical physicist or radiologist be consulted if a pregnant woman has received diagnostic or therapeutic ionizing radiation. It is important that the dosage be calculated accurately in order to estimate risks. Most diagnostic X-rays are estimated to have an extremely low risk to the fetus or embryo. Avoiding unnecessary diagnostic irradiation during pregnancy because of risk is advised, but is separate from the issue of choosing to terminate a pregnancy because of the very small chance of disease or malformation. For example, even if the risk of leukemia is elevated by approximately 50% over a 10-year period due to 2 rads of prenatal diagnostic ionizing radiation, elective abortions would sacrifice approximately 1,999 unaffected children in order to avoid the birth of one child who would be subject to leukemia.

## IQ TESTS

---

IQ tests provide us with a quantitative measure of intelligence, known as the Intelligence Quotient (IQ for short). This type of testing has a long and rich history, beginning in Europe over a century ago. Though we still use variations of many of these early tests today, there is much controversy over measuring intelligence in this way. The current pressing question is: How useful are IQ tests to us today?

### THE HISTORY OF IQ

As a society we have long had an interest in quantifying the concept of intelligence. From measuring head size, to judging intelligence by facial features, many individuals have made efforts to develop ways to measure intelligence. When the above measures were proven invalid, researchers began to explore the idea of measuring intelligence with a series of performance tests. Alfred Binet and Theodore Simon developed the first intelligence test considered to be valid in 1905. This test, the Binet-Simon scale, was designed to identify children, then termed the “mentally handicapped,” who were struggling in school. Soon after this test was introduced, Lewis Terman of Stanford University translated this test from French into English and brought it to the United States.

It was in the scoring of this revised test, the Stanford-Binet, that the term “IQ” was first coined. Terman used a formula dividing a child’s *mental age* by his or her *chronological age* (actual age). This result was then multiplied by 100, yielding the Intelligence Quotient (IQ). Terman, however, did not use the test for the purpose it was intended; he decided instead to use the Stanford-Binet to compare children of varying ages with regard to intelligence. Though this type of quotient system worked well with children and teens, there were problems with this formula when testing adults; how could one fairly distinguish between the developmentally appropriate capabilities

of a 40-year-old in comparison with a 45-year-old? David Wechsler led the charge to find an accurate measure of intelligence, and devised new strategies to obtain a number that used norms to compare adults to an “average” score. The Wechsler intelligence tests are some of the most commonly used tests in the field today. These tests include the Wechsler Adult Intelligence Scale, third edition (WAIS-III), the Wechsler Intelligence Scale for Children, third edition (WISC-III), and the Wechsler Preschool and Primary Scale of Intelligence, revised (WPPSI-R). The Stanford-Binet, fifth edition (SB5), is also used frequently to measure ability today.

## POPULAR IQ TESTS OF TODAY

The Stanford-Binet remains a popular test for assessing the intelligence of children and adults today. Now in its fifth revision, the SB5 measures intelligence in individuals aged 2 to 85, using five main factors—fluid reasoning, knowledge, quantitative reasoning, visual-spatial processing, and working memory—and the ability to compare verbal and non-verbal performance.

The Wechsler tests also remain a common choice for today’s psychometricians. These tests measure along two subscales: verbal ability (including, but not limited to, such tasks as defining words, finding similarities between objects, and comprehension of certain situations) and performance ability (e.g., tasks such as finding missing details from pictures, completing patterns, and manipulating blocks into particular designs), leading to three scores: verbal intelligence quotient (VIQ), performance intelligence quotient (PIQ), and the full-scale intelligence quotient (FIQ). The average score is 100, with a standard deviation of 25 points. This means that a FIQ score of 100 conveys an “average” level of intelligence. Above this distinction, classifications exist such as “above average,” “superior,” and “very superior.” Below this 100 point mark, classifications such as “borderline,” “low average,” and “very low average” exist.

## CURRENT ISSUES IN IQ TESTING

### Appropriate Interpretation

In past decades, IQ testing was conducted in a more indiscriminant way. For example, tests were given to all children for the purpose of labeling and

ordering them along tracts “appropriate” for their level of intelligence. Today, educators and mental health professionals understand the importance of interpreting these test scores as only part of the child’s true potential and ability. Though it is commonly believed that IQ tests measure a child’s potential, this is not the case; IQ tests are only able to assess current cognitive ability. Without accurate interpretation of these scores, children can be labeled in ways that could be detrimental to their psychological adjustment.

### Multifaceted Nature of Intelligence

A second issue that is currently being debated with regard to IQ testing surrounds the actual definition of intelligence. While tests such as the Stanford-Binet and the Wechsler tests measure verbal and performance-based qualities of intelligence, there are many researchers who say that these types of tests do not capture the true nature of intelligence.

Robert J. Sternberg has defined intelligence in three parts. This “triarchic theory of intelligence” includes a facet termed componential intelligence (the types of abilities measured by common intelligence tests), but adds two more components. Sternberg’s contextual intelligence encompasses an individual’s ability to adapt to the environment. This facet is the “common sense” part of intelligence. Finally, Sternberg includes experiential intelligence, which is defined by an individual’s ability to deal effectively with both new and old tasks and situations placed before him or her.

A second theorist, Howard Gardner, has defined intelligence as having even more facets. In his Multiple Intelligences theory, Gardner states that intelligence cannot be determined by measuring abilities in just one area. Instead he advocates that individuals may be intelligent in areas outside of the traditional view of intelligence. Gardner’s intelligences include areas of linguistic, bodily-kinesthetic, logical-mathematical, spatial, musical, interpersonal, intrapersonal, and naturalistic intelligence. He, too, sees a need for a wider definition, and therefore testing process, to accurately measure intelligence.

### Cultural Bias

Finally, the issue of cultural bias has been an important part of the IQ controversy for many years. It has been found that individuals from racial and

ethnic minority groups in the United States often score much lower on IQ tests when compared with individuals from the majority culture. Many scholars and practitioners feel that some of the types of questions asked on common intelligence tests are biased in the direction of the majority, middle-class culture in the United States. Questions that assume a broad exposure to the majority culture pose a problem for members of the many subcultures that exist in the United States.

To demonstrate some of the links between items on IQ tests and cultural knowledge, Stephen Jay Gould asked Harvard students to point out the missing features of pictures of objects that are not a part of popular culture today, but have been in the past. One such item depicted a Victrola record player that was missing its horn. Almost none of the students in the sample were able to identify this object as it is no longer a part of popular culture. Because many items on IQ tests involve tasks such as these, tests may be unfair to individuals of certain racial and ethnic cultural groups as well as to individuals from certain socioeconomic classes who may not have been exposed to some of the items.

In addition, individuals from racial and ethnic minority groups may score lower on tests because of a concept called *stereotype threat*. Claude Steele, a researcher at Stanford University, posits that there are many negative stereotypes that exist toward certain groups in our society. He states that there are stereotypes that women do not do as well in math as men, and that African American students are not as academically proficient as Caucasian students. While these stereotypes are groundless on an individual level, they are common myths and as such may exert extra pressure on members from these groups when taking tests. Indeed, individuals in Steele's experiments of this phenomenon report that they often feel pressure not to confirm these negative stereotypes. This "pressure" may manifest itself in the form of "testing anxiety" and may lead to lower scores for these individuals.

## CONCLUSIONS

It is important to note the aforementioned limitations when considering the use of IQ tests in today's culture. However, if used correctly and interpreted with caution and consideration of the limitations, IQ tests can be useful in determining areas of cognitive strengths and weaknesses. Professionals in this area of the field, including educators, school psychologists, and counselors, have a responsibility to uphold the

true nature of the scores obtained through the use of IQ testing. In addition, it is important that scores on tests such as these not be used to label or stunt the development of children's cognitive abilities. Having more knowledge about the benefits and limitations of these tests can improve our appropriate use of them.

## ISLAM

---

*In the name of Allah, most benevolent,  
ever-merciful.*

*ALL PRAISE BE to Allah,*

*Lord of all the worlds,*

*Most beneficent, ever-merciful,*

*King of the Day of Judgment.*

*You alone we worship, and to You*

*Alone turn for help.*

*Guide us to the path that is straight,*

*The path of those You have blessed,*

*Not of those who have earned Your anger,*

*Nor those who have gone astray.*

So begins the Qur'an, the holy book of Islam. Islam is one of the three great monotheistic religions in the world, Judaism and Christianity being the other two, all of which, ironically, focus on the same deity, the God of the prophet Abraham. Indeed, for Islam's prophet Muhammad there is but one true faith, and his teachings and transmission of the word of Allah (one of the ninety and nine names for God) are the latest

and definitive message. For its followers, *Muslims*, Islam is the true religion of the prophet Abraham. The word refers to a peaceful submission to God's will. Islam takes for granted that one day all of the peoples of the world will see the wisdom of God's message and will embrace Islam in peace, creating a single *community of the faithful*, an *ummah*. Today, Islam is the second largest religion in the world, second only to Christianity by numbers, and comprises about one fifth of the world's population. Islam stresses that there are only two realms on earth, the *dar al-salam* and the *dar al-harb*. The former, the *abode or house of peace*, and the latter, the *house of war*, refer to the Islamic world, that part of humanity that has embraced Islam, and the rest of the world, which has not and is therefore in constant turmoil or conflict with the forces of disbelief.

The beginning of Islam is popularly associated with the prophet Muhammad. However, Muhammad stressed that his message simply completed the true religion of the God of Abraham. Still, the importance of Muhammad is such that some came to refer to the followers of Islam erroneously as *Mohammedans*, a phrase that is unacceptable to Muslims because it unduly focuses on the prophet rather than God.

## THE SIRAH: THE COMING OF MUHAMMAD

Muhammad was born into the banu Hashim, or Hashimite, clan of the Quaraysh tribe in the city of Mecca in 570. The Quaraysh were the dominate economic and political power along the Red Sea coast, the Hijaz, an area that had become important because of its central location along a number of vital trade routes. In general, the peoples of the Arabian peninsula were all organized by hereditary tribes. The tribes of the interior and the Hijaz were nomadic, *bedouin* (*bedou* in the singular); they made their living by raising animals (goats, sheep, horses, and camels), trade, and by raiding each other. It was a society that was proud of a warrior tradition. The tribes in the south, the Yemen, were largely sedentary and agriculturally based. Blood relationship was the basis of this society. Religiously, each tribe varied according to its particular history. Some were Christian, some Jewish (by faith), but most recognized tribal religions that often made reference to a common ancestor. Most of the tribes recognized the importance of a structure in Mecca that housed a black stone (possibly a meteorite) constructed by the prophet Abraham and known as the

*Ka'ba*. The *Ka'ba* also formed the center of an annual festival, or fair, in Mecca, the *Ukaz*. The *Ukaz* provided the opportunity for trade, worship, and peaceful tribal competitions and proved very lucrative to the Quaraysh. This was the time and culture that Islam describes as the Period of Ignorance, or *jahhiliya*. Ignorant because Muhammad had yet to bring the word of God, and also because of numerous practices that he would condemn including blood feuds, tribal raiding, the poor status of women, and on occasion the infanticide of female children.

Orphaned at an early age, Muhammad was raised by paternal relatives, his grandfather Abdul Muttalib and later his uncle Abu Talib. With the exception of one story, there is little about the youth of Muhammad that yielded great religious significance. But while on a trading expedition with Abu Talib, Muhammad encountered a Christian monk by the name of Bahira who noticed what he claimed to be the seal of the prophets between Muhammad's shoulder blades and proclaimed him as a promised apostle. Muhammad's marriage to the wealthy widow Khadija in 595 proved to be more important. Khadija was something of an exception in early Arabian society. She had inherited her husband's commercial business and was considered a woman of substance and status. Islam allows up to four wives but Khadija was Muhammad's only wife until her death. The marriage allowed Muhammad free time to meditate, usually in a cave in Mount Hira outside Mecca. It is related that while in that cave in 610, Muhammad was confronted by the angel Gabriel who commanded him to *read*. Muhammad replied that he was no reader; he could do the simple arithmetic required as a merchant but was otherwise illiterate. Gabriel again commanded him to read. Muhammad realized at that point that indeed he could read and write. This began the process by which Muhammad became the messenger, *rasul*, of God through Gabriel. Following his experiences with Gabriel, which were the only miracles claimed in his life, Muhammad began preaching God's message in Mecca,

SAY: "HE IS God  
the one the most unique,  
God the immanently indispensable.  
He has begotten no one,  
And is begotten of none.  
There is no one comparable to Him."

The first to embrace his message were his wife, Khadija, his father-in-law, Abu Bakr, and his cousin, Ali. His preaching was viewed as threatening to the leaders of the Quaraysh, who did not object overtly to his religious message, but feared that Muhammad might disrupt the importance of the *Ukaz*, the *Ka'ba*, and accordingly the position of the Quaraysh. The anxieties of Muhammad's own tribe soon deepened. He was nearly stoned to death and finally confined to the city of Mecca.

In 620, the inhabitants of the city of Yathrib invited Muhammad to mediate problems in that community. The reputation of Muhammad as honest and wise served him well in this instance, but the Quaraysh determined that he might be an even greater problem in a new setting and refused him permission to leave Mecca. In 622 Muhammad sent many of his followers ahead to Yathrib while he planned his own escape. On September 24, 622, Muhammad arrived in Yathrib. The flight of Muhammad from Mecca to Yathrib is known as the *hijra*, an event so important that it marks the beginning of the Islamic calendar. Muhammad mediated the problems of Yathrib and was soon accepted as the city's leader. In his new role, Muhammad changed the name of the city to Medina and began to form a new community according to a series of edicts later known as the *Constitution of Medina*. The essence of this community was common faith in God, not blood relationship or tribal lineage, or established territory, thus the reference to the *ummah*, the *community of the faithful*. Possibly as a matter of political practicality, Muhammad announced that Jews (a significant part of the population of Medina) were to be considered part of the *ummah*, and Christians, as *people of the book*, were to be under its protection.

Conflict with the Quaraysh ensued. Following a peace treaty, the Treaty of Hudaibiya, Muhammad arranged for a peaceful return to Mecca in January of 630. The Quaraysh accepted Muhammad and the *umma* expanded to include first this tribe and then most of the other tribes of the Arabian peninsula, according to personal treaties or conversion to Islam. In this context alone, Muhammad secured a place in history as the only man to unify the tribes of Arabia. Muhammad was a prophet, hero, statesman, author, conqueror, and a social reformer. He created the Arab nation, and dramatically reformed an ancient tribal system. He replaced blood relationship with common faith, and tribal custom with a singular law, God's law, the *shari'a*.

## ISLAMIC BELIEF (IMAN) AND PRACTICE (IBADAT)

The body of Islamic belief and practice can be summarized in Islam's *Articles of Belief* and *Articles of Practice*. Adherence to these articles, along with acceptance of God, is generally considered a personal obligation based on a personal relationship with God. There is no church, no church hierarchy or administration, no formal clergy. There are, however, clerics that gained recognition based on the respect of their local communities and their knowledge of the Qur'an and the *shari'a*. The terms *mullah* and *ulem* (*ulema* pl.) apply in this instance. A more honored title is applied among *Shia* Muslims, *ayat Allah* (reflection of God), or *ayatollah* in the Western translations.

The particular tenets of Islamic belief are found in the *Iman* or *Articles of Belief*, also known as the *Doctrines of Belief*. The first article is *The Doctrine of the Unity of God*. The fundamental element of Islam is that there is no God but God. Islam recognizes no deity save the God of Abraham, *Allah*. Islam describes God as a purely spiritual and universal being. References to God the father are rejected in that they suggest an anthropomorphic figure. The second article is *The Doctrine of Prophethood*. Muhammad related that, in his wisdom, God has provided mankind with a prophet for each era in history. The first prophet was Adam, but the final prophet, the *Seal of the Prophets*, was Muhammad, thus denoting the final era and the pending final judgment. Islam accepts all of the prophets of the Old Testament including Abraham and Moses. Jesus of Nazareth is also recognized, but as a prophet, not the Son of God. Often a distinction is made between the reference to *prophet* and *messenger*. The latter designation is sometimes used to refer to Moses, Jesus, and Muhammad because their messages were recorded in writing. Thus they are both prophet and messenger. The third article is *The Doctrine of the Book*. The reference here is literally to the word of God as recorded in the Old and New Testaments, but of course also the Qur'an (the *reading* or *recitation*). The earlier testaments are not rejected out of hand, but it is believed that through mistranslation and corruption much of the true meaning of each work has been lost. Only the Qur'an has remained as the definitive word of God. The Qur'an is divided into 114 chapters, known as *surahs*, organized according to length from longest to shortest with the exception of the very brief prologue. The Qur'an also provides the essence of

traditional Muslim education, learning reading and writing from the Qur'an, in the *madrassa*. Purists still hold that the only way to truly understand the Qur'an is in the original Arabic because that is Allah's favored language. It was also generally believed that the only acceptable means of copying the Qur'an was by hand. The fourth article is *The Doctrine of the Final Judgment*. As the Seal of the Prophets, Muhammad was the last of God's agents before the final judgment of mankind, which is at hand. All people will be judged personally by Allah. Those who led good lives will go to paradise, a resplendent and well-watered garden. Those who did not are doomed to the fires of hell. The judgment will be preceded by a physical resurrection, but not by the arrival of a *messiah* or even the *second coming* of Muhammad. It is emphasized that those who die in the service of God are *martyrs* who go straight to paradise. *Martyrdom* is not generally encouraged, however. Suicide is a sin without exception. *Sunni* Islam focuses much less on martyrdom than *Shi'i* Islam which is due to the vital significance of the death of Muhammad's grandson, Husayn, at Kerbala. The suffering and final death of Husayn have become part of the fundamental body of belief among the *Shia* Muslims often portrayed in *Shia* versions of *passion plays*. The final article is *The Doctrine of Angels and Jinns*. Angels are those creatures created by God from fire to serve both God and man. *Jinns* are creatures that are generally associated with the fallen angel *Iblis* or *Shaytan*.

Islam also incorporates a set of good acts to be practiced by Muslims. The *Ibadat* or *Articles of Practice* are also known as *The Pillars of Islam*. First and foremost among these pillars is the *shadada*, the witness or profession of faith. To become a Muslim, there is no formal ceremony, no baptism, but one must accept in one's heart and mind the basic notion that there is no God but God, and that Muhammad is His messenger. The second pillar is *salah*, prayer. Muslims are to pray five times a day, before dawn, at dawn, noon, afternoon, and evening. If one prayer is missed it should be made up later in the day. Islamic prayer involves a certain amount of ritual. One must wash their hands and feet before prayer to symbolize the cleansing of the mind of worldly thoughts. Ritual bowing, standing, and sitting all demonstrate respect for God, as does covering one's head (generally at all times, but especially during prayer). One should pray in a *mosque* (a house of prayer and study) though this is not always possible. Both men and women can pray

in a mosque but, as with other activities, women must be separate from men. One should also face toward Mecca during prayer. The hour of prayer is announced by the song of the *muezzin*, usually from the towering minaret of a mosque. The third pillar is *zakah*, or *alms-giving*. Muslims should attempt to care for the unfortunate. But if the act does not come from the heart it should be avoided. The fourth pillar is *sawm*, or *ritual fasting* during the holy month of *Ramadan*, the ninth month of the Muslim calendar that marks the celebration of Muhammad's revelations through Gabriel celebrated on the 27th as the *Night of Power*. During *Ramadan*, eating, drinking, and other activities (sexual conduct) are forbidden during daylight hours but allowed after sundown. In practical application, most Muslim communities close down during the day and most people sleep during that time, while at night the holy month is celebrated. The end of the fast of *Ramadan* is celebrated on the first day of Shawwal with the *eid al-fitr*. The fifth pillar is *hajj*, or *pilgrimage*. Muslims should make pilgrimage to Mecca and pray at the *Ka'ba*. Muhammad emphasized that the importance of the *Ka'ba* was in the simple fact that the inner structure had been built by the prophet Abraham, thus retaining the significance of both the *Ka'ba* and Mecca in Islamic tradition. Originally, Muslims were urged to make pilgrimage once a year, but when this became difficult, if not impossible, the obligation changed to as often as possible but at least once in a lifetime. *Dhul Hijjah*, the 12th month of the Muslim calendar, is the month of *hajj*. Those who make *hajj* are referred to as *hajji* and sometimes add this as a title to a name. Often a sixth pillar is included, *jihad* or *holy war*. The literal translation of *jihad* as a struggle or as striving comes from the Arabic phrase *jihad fi sabil Allah*, or *striving in the path of God*. There are two definitions of *jihad* and both can be traced to Muhammad. One, *greater jihad*, refers to the constant threat of disbelief in every individual, which requires spiritual battle and vigilance for the believer to remain faithful. The other, *lesser jihad*, involves the possible necessity of defense of the *umma* or its people from outside attacks, invasion, or threat. As a form of defensive war, *jihad* is comparable to the concept of *jus bellum* or *just war* in the West. It was limited exclusively to self-defense and was required to adhere to the strict limitations of part of the *shari'a*, Islamic law, known as *siyar*. *Jihad* also became somewhat problematical because only the legitimate leader of the Islamic community could declare

it. But once declared it became the religious obligation of all Muslims to defend the community. *Shia* Islam does include *jihad* as a sixth pillar along with a seventh pillar, the invocation to do good acts and avoid evil thoughts. Islam considers a number of things as *haram*, or strictly forbidden. The eating of pork and the consumption of wine or any alcoholic beverage are forbidden.

Lacking a church, formal clergy, and many of the formal rituals found in Christianity such as baptism, Islam is a very simple religion. This simplicity is accentuated in the fact that all men, regardless, of nation, class, or economic status are equal before God. Generally, this is true of women, as well, although the particular roles of women are prescribed by the Qur'an. The extreme subservience of women in some modern Muslim countries is not based on the *shari'a*. Indeed, in cases of marriage, inheritance, and a host of other instances, the rights of women are clearly established by the *shari'a*, but they are not always recognized by society.

Islam permeates the daily lives and activities of all Muslims. This is symbolized by the inclusion of a variety of phrases that are integrated into common conversation. *Allah hu Akbar, God is most great. Bismillah, in the name of God. Inshah Allah, if God wills. Al-hamdulillah, praise be to God.* The standard Muslim greeting is simply *salam*, the Arabic word for *peace*, which, in this case, is an invocation of *God's peace*. Some rare individuals are believed to have God's special blessing, the *baraka*.

There are numerous holy sites in Islam. The most important of these are the city of Mecca and the *Ka'ba*, and Medina, the first place of worship in Islam. Second to these places are Jerusalem, in general because of Islam's inclusion of Old Testament and New Testament prophets and figures, but also because of two great mosques, the al-Aqsa Mosque and the Dome of the Rock. The Dome of the Rock holds dual significance in that it is believed to be the place where Abraham offered sacrifice, and the place where Muhammad ascended to paradise, which is celebrated as the *Night of miraj, lalat-ul miraj*, on the 27th of *Rajab*. *Shia* Islam adds two cities to this list—Najaf, where Ali was buried, and Kerbala, the city where Husayn, Muhammad's grandson and Ali's son, was *martyred* according to *Shia* interpretation.

Questions usually arise involving comparisons of Islam with Christianity. As noted earlier, in Islam references to God, or Allah, as the father are considered

abhorrent because it suggests a sense of physical generation. Accordingly, Jesus is described as being conceived of the breath of God as was Adam. He was one of a series of prophets with perhaps an additional sense of importance as a *messenger of God*. Islam rejects the death of Jesus by crucifixion suggesting that it was one who was made to resemble him. Ironically, beyond this point, Islam accepts a good deal of the Christian interpretation of Jesus. Miracles occurred, but were the work of Allah. Mary, the mother of Jesus, was a virgin. And Islam has no problem with the resurrection, which is, of course, fundamental to Islam's fourth article of belief.

## ISLAMIC LAW: THE SHARI'A

The cornerstone of Islam is the *shari'a*, the body of Islamic law, which is characterized as the *straight path*. The *shari'a* is *God's law*. The three sources of Islamic law are the Qur'an, the *hadith*, and *sunna*. The *hadith* are traditions, sayings, and actions attributed to Muhammad through a variety of individuals that are not all accorded the same level of authenticity. Therefore, some *hadith* have a greater weight than others. The *sunna* includes more general traditions related to the prophet, but also may include certain pre-Islamic traditions or elements of customary law not in violation of the Qur'an. Legal questions are generally considered through a process of analogical deduction known as *qiyas*. The Qur'an is the first source considered. If it does not produce a specific answer, the *hadith* are examined. *Sunna* comes into play if the previous sources fail to produce an answer. *Consensus* or *ijma* is sought in all legal questions rather than a personal interpretation. Indeed, the personal interpretation of the law, *ijtihad*, became severely restricted in *Sunni* society after the 9th century. *Shia* Islam, with a much greater recognition of religious clerics, has traditionally made much greater use of *ijtihad*. One who is deemed capable of *ijtihad* based on knowledge of the *shari'a* is a *mujtihad*. There are no traditional judges in Islam, but the title of *qadi* is a rough equivalent. Again, all clerical titles are expressions of local recognition of an individual's knowledge about the law and the Qur'an.

Local approaches to the *shari'a* are based on the views of four traditional legal schools of thought, which can be distinguished according to their particular stance on interpretation. The *Hanafite* school began with Abu Hanifa (d. 766) and can be considered

liberal. The *Malakite* school started by Malik ibn al-As (d. 795) is essentially conservative. The *Shafi'ite* school of Imam al-Shafi (d. 820) considered both of the previous schools as overly extreme and suggested a more methodological approach emphasizing *qiyas* known as *fiqh*, often referred to as Islam's science of jurisprudence. The fourth school, the *Hanbalite*, began with Ahmad ibn Hanbal (d. 855), a reactionary who equated *innovation* or *bida* with sin. The impact of ibn Hanbal effectively stifled the general use of *ijtihad* in *Sunni* Islam and replaced it with the concept of *taqlid*, literally a legal decision based on the authority of an established predecessor, but in practical use came to be simply blind imitation. Islamic law was, for a long time, remarkably flexible, but in *Sunni* society it became more and more stultified.

### ORTHODOXY AND HETERODOXY IN ISLAM: SUNNI AND SHI'I ISLAM

The vast majority of Muslims in the world today are *Sunni* or, according to Western terminology, *orthodox*. The largest Muslim populations are found in Indonesia, Pakistan, India, and Egypt, and the predominant sect in every one of these countries is *Sunni*. The largest minority sect is *Shia* Islam, which accounts for some 90% of the population of Iran and about 60% of the population of Iraq. While *Sunni* and *Shi'i* Islam represent the majority and the most significant minority, it is important to note that historically there have been at least 72 sectarian offshoots of Islam. Most of these heterodox interpretations have themselves been variations of *Shia* Islam.

Curiously, most of the early divisions in Islam had little to do with religion and much to do with politics. *Shia* Islam began as a dispute over which of the Prophet's companions should succeed Muhammad as the first *caliph*, *commander of the faithful* or *lieutenant of the prophet*. A very demonstrative group supported the claim of the Prophet's son-in-law and cousin, Ali, though it seems that Ali himself was never as committed to this issue. Known as the *shia tu Ali*, quite literally the *party of Ali*, these followers demanded that the successor be a male, blood descendant of Muhammad. The *shia tu Ali* only grudgingly accepted the first three *caliphs* (Abu Bakr, Umar, and Uthman) and upon the murder of the third proclaimed Ali to be the rightful caliph. Ali seemed to be happy with his predecessors as caliph and with his followers'

support of himself as the fourth commander of the faithful. Other factions in the community, relatives of the third caliph, Uthman, were not, however. The Umayya clan of the Quaraysh tribe challenged Ali's claim based on the accusation that Ali had been part of a conspiracy to murder Uthman, the scion of the Umayya. The Umayya claimant was the governor of Syria, Muawiya. In 660, Muawiya declared himself to be the rightful heir and Islam appeared to be on the road to sectarian disaster. The conflict came to an effective end the next year when Ali was murdered by a former supporter who, along with a group known as the *Kharijites*, had broken with Ali over a dispute involving Ali's prerogative to negotiate with Muawiya during the Battle of Siffin in 657. The *shia tu Ali* led by Ali's son Husayn attempted to renew the conflict, which was put to a final end near the city of Kerbala where Husayn and many of his *Shia* followers were killed. The *Shia* interpretation of the *martyrdom* of Husayn became one of the defining events of that sect. Accordingly, he and his followers were betrayed, tortured horribly, and then put to death. The event is still commemorated by the *Shia* as *ashura* on the tenth day of the month *Muharram*. It is at this point that religious elements began to form. Following Husayn's death, the *Shia* proclaimed that he, his father, and his brother, Hasan, were all martyrs and were also acclaimed as *Imams*. The word *imam* had been in common usage before this but as something of a generic term for a leader in prayer.

The foundation of the religious separation between *Sunni* and *Shi'i* evolved from the nature of the *Shia Imam* and the attributes attached to the individuals who were given this title. Eventually, it would be believed that *Imams* were infallible, could communicate with God, were impervious to harm, and cast no shadow. This was totally unacceptable to the *Sunni* for whom only the Qur'an and God were infallible, and who perceived the whole notion of the *Shia Imam* as a clear violation of the *Doctrine of Prophethood*. The religious separation has been deep and at times quite violent.

Most of the variations within *Shia Islam* follow from which or how many of the *Imams* are venerated. The majority of *Shi'i* are *Twelvers*, that is, they accept a line of twelve *Imams* beginning with Ali as the first *Imam*, Hasan as the second, Husayn as the third, and Muhammad al-Muntazar as the twelfth. The *Twelvers* believe that al-Muntazar, also referred to as the *mahdi*

or *expected one*, went into occultation in 878, that is, he went into hiding, but will reveal himself at the moment of the final judgment. The *Doctrine of the Return* thus became a central element of belief for most *Shi'i*. Other *Shia* offshoots include the *Zaydis* who accepted only the first five *Imams*, a line that ended with the fifth *Imam*, *Zayd*; the *Ismailis* who embraced seven *Imams* and focused on a disputed member of the line, *Ismail*; an *Ismaili* offshoot, and the infamous *Assassins*, a sect that practiced ritual, political, and religious murder, often under the influence of certain drugs (hemp or hashish). Relatively few of the minor *Shia* sects have survived. Islam did, however, produce a mystic variation often in a monastic fashion, *Sufi* Islam, the *darwish*.

## JOINT CUSTODY

---

Child custody issues can arise for a number of reasons, including parental death, unmarried motherhood, and the severance of parental rights by the state because of abuse or neglect. Today, however, child custody issues arise primarily as a result of divorce.

When parents divorce, decisions must be made regarding who has the present and future legal decision-making responsibility for the child's well-being, where the children will reside physically, and most important, what postdivorce relationships their parents will or will not be permitted to have with their children. Custody determinations set the framework that structures postdivorce life for parents and children as well as child support.

From a life-span developmental perspective, the major shortcoming of custody determinations is that they are static. They fail to acknowledge that all members of the family triad—fathers, mothers, and children—will have different postdivorce developmental trajectories that cannot be known at the time of divorce, are guaranteed to occur, and will require future modification for the best interests of all parties.

Family law must come to recognize that change is inherent to development at all stages of the life cycle and make custody modifications both readily available and affordable for families at all income levels.

### DEFINITION

Joint custody arrangements typically refer to two quite different types of custody. *Joint physical custody* focuses on which parent the child is with, where they are with each parent, and the amounts of time they spend with each parent. *Joint legal custody* focuses on which parent has what legal rights to make what kinds of decisions concerning which aspects of the children's life and well-being.

It is difficult to ascertain accurately who gets what kinds of custody because each state has different laws, different terminology, different court practices, and different reporting procedures. Thus, our focus will be on the advantages and disadvantages of two custody arrangements for each family member. Each family member will be considered because a core reality of divorce—unless a parent is willing to abandon their children—is the focus on *changed* relationships between former spouses rather than a “clean break.”

## WHO GETS CUSTODY

The most powerful determinants of who gets custody are the *presumptions* embedded in state divorce law and the ideologies of individual judges because they determine the starting point for divorce deliberations and often the end point as well. Historically, if one goes back far enough, the presumption embedded in oppressive patriarchy was that the children belonged to the father. Later, the family law pendulum swung 180 degrees toward an oppressive matriarchy presumption favoring mothers, which was embedded in either the “tender years” or “primary caregiver” doctrines. The tender-years doctrine *presumed* that children belonged with their mothers, whereas the primary-parent doctrine *presumed* that the parent who engaged in the most caregiving activities during the marriage would make the best postdivorce parent. Under these presumptions, family court judges virtually always gave sole physical and legal custody to mothers.

More recently, these doctrines have been replaced by the “best interest of the child” standard that, unfortunately, represents nothing more than “the eye of the beholder.” Tragically for children, this standard gives family court judges unbridled latitude to reach any determination they wish as long as they proclaim that it is in the best interest of the child.

At this writing, the pendulum has swung back to dead center with the presumption of joint custody in, of all places, Iowa. Effective July 1, 2004: If joint legal custody is awarded to both parents, the court may award joint physical care to both joint custodial parents upon the request of either parent. In signing this legislation, Iowa Governor Tom Vilack emphasized the importance of having two parents following divorce based on his own experience as a child of divorce and his reading of the divorce literature. From a developmental perspective, this presumption offers the advantage of beginning divorce deliberations from a position of equality for all parties and deviating from this position only based on the individual difference characteristics, capacities, and situations of individual mothers, fathers, and children.

## WHAT ARE THE ADVANTAGES AND DISADVANTAGES OF SOLE AND JOINT CUSTODY ARRANGEMENTS?

The advantages and disadvantages of sole versus joint custody arrangements are fairly straightforward.

The advantages of sole maternal custody with paternal visitation are as follows. For the child, there is a sense of residential, neighborhood, and school stability perhaps paid for by a sense of paternal abandonment and a loss of the father as a parent. For the mother, there is virtually total control over the child and their socialization along with an exclusive and emotionally intense relationship with her child. The maternal disadvantage is potential burnout as she works the “second shift” of both paid employment and full-time 24/7 on-call child care. This burnout may be exacerbated if the child develops behavior problems as a consequence of the reduced involvement or absence of the father. For the father, there is a sense of loss and a loss of meaningful contact with his children. To become a visitor in his child’s life, after having been an involved father with a meaningful father-child relationship, has many negative outcomes for the father, including substantially higher rates of suicide, depression, alcohol abuse, drug abuse, poor health, work problems, relationship problems, and social isolation. The core argument is that postdivorce father-child relationships are of critical importance not only for the well-being of children but also for the well-being of fathers.

In joint physical custody, for the child there may be residential, neighborhood, school, and friendship network instability with transfers from one home to the other. This instability may or may not be compensated for by the gain of meaningful, everyday relationships with both the mother and the father and the avoidance of a sense of abandonment and loss of either parent. For the mother, there is the loss of an exclusive relationship with and total control over her child, which may or may not be compensated by a loss of maternal role burnout, the gain of likely enhanced mental health of her child, and a greater opportunity to move on with her own life as an adult woman. For the father, there is an opportunity to maintain a meaningful and nurturant relationship with his child and enhance his own emotional balance.

## WHAT CAN RESEARCH TELL US ABOUT CUSTODY DETERMINATION?

There is an inherent and confounding fatal flaw to all custody-outcomes research—self-selection. Neither parents nor children ethically can be randomly assigned to different custody arrangements to do a true experiment. Thus, it is not possible to ascertain the independent contributions of the “before”

individual differences of mothers, fathers, and children that led them to choose joint custody and the “after” consequences or outcomes of having experienced joint custody.

Within this limitation, however, there are two lines of research that suggest Iowa may be on the right track. First, studies undertaken in Arizona and Florida report that young adult children of divorce wanted more time with their fathers (more custody time) and more emotional quality time (companionship, sharing activities, leisure, fun, play) than young adult children from intact families. Second, literature reviews uniformly conclude that gender similarities are far greater than gender differences in a parenting capacity. Mothers and fathers, in short, make equally competent parents. What makes these findings striking is the fact that this empirical research has rendered wrong and overruled decades of false legal presumptions.

## SUMMARY

Today, both joint custody and child support are highly controversial social and legal issues. Both are in flux, both will change, and both have clear sides. Generally speaking, children and fathers of divorce perceive their best interests to be best served by joint legal and physical custody. Some mothers also see it this way, but other mothers see their interests as best served by sole legal and physical custody. Custody battles are not likely to disappear, but their costs to all parties involved appear to be best mitigated with the equal opportunity principles embedded in joint legal and joint physical custody presumptions.

## JUDAISM

---

The term *Judaism* generally connotes the religion practiced by the Jewish people. Many, however, ascribe to it a much broader definition, most accurately as “a way of life” encompassing the expressed heritage of wisdom and creativity of the Jewish people, and subsuming such modes of expression as (nonsacred) literature, music, and graphic art. Here we will limit our discussion of Judaism to the religion of the Jewish people, speaking of it on both the horizontal (more or less contemporary) plane and on the vertical plane of its historical evolution.

Judaism might more properly be called the *Religion of Israel* (as did the renowned scholar of Judaism, Ezekiel Kaufman, in his magnum opus by that title). The term Judaism more accurately refers to a later title for the religion of an ethnic group that was the majority population in the geographic region that first became called Judah in Hebrew Scriptures, that area having been designated by Moses as the divine allotment for the tribe of Judah. Nearly a dozen more allotments were simultaneously designated for other tribal members of the tribal confederacy of the people of Israel, who were the descendants of the clan of Jacob—son of Isaac and grandson of Abraham, and often referred to as the *Israelites*—and who had later become mighty in number during their four-century sojourn in Egypt. Sometime after the Mosaic allotment, the tribes banded into a single polity under David as monarch, only to relatively quickly coalesce into two kingdoms—the northern called *Israel* and its southern counterpart *Judah*—following the death of his son, Solomon. When the northern Israelite kingdom was overrun by the Assyrians in 722 BC and its inhabitants exiled to Assyria, they ostensibly were forcibly assimilated, ultimately losing their ethnic

(and religious) Israelite identity; hence the popular term “the Ten Lost Tribes” of Israel. The southern kingdom at that time was able to ward off the Assyrian invader and remained intact until 586 BC, when it was overrun by the Babylonian tyrant Nebuchadnezzar. Like its brethren to the north a century and half earlier, its inhabitants—virtually all from the tribe of Judah (along with a substantial number of Levites, who being custodians of the religious cult were never given their own tribal allotment and therefore lived spread among the various tribes)—were exiled northward. Unlike members of the exiled northern Israelite kingdom, however, they maintained their identity and, after Nebuchadnezzar’s dynasty was displaced by the Persian Cyrus some 60 years later, eventually were allowed to return to their homeland in Judah. Many returned and rebuilt their central religious shrine, the Holy Temple. Coupled with the disappearance of the northern kingdom, the restoration of Judah—albeit as a vassal of Persia—probably represents the point at which the Israelites became better known as “the Jews” and when the “religion of Israel” permanently took as its new name “Judaism.”

## BELIEF SYSTEM

Judaism professes the belief in one God, who calls on believers to practice a system of ethics emanating from a body of wisdom called Torah. Belief and practice originated about 4,000 years ago in the lives of the patriarch Abraham and his wife, Sarah, whom God called to venture forth from their home in Mesopotamia to go to “the Land that I will show you”—the land of Canaan, which has been known ever since as “the Promised Land.” God soon brought Abraham into a covenant, calling on him to rear his not-yet-born offspring in righteous ways; thus was initiated an ever-accumulating spiritual heritage, which has come to be known as *ethical monotheism*.

The next major stage of religious development took place a half millennium later, in the time of Moses, when, according to the Biblical record, God rescued Abraham’s descendants—who had lately been fruitful and multiplied—from Egyptian servitude. Once free, God brought the entire people—by scriptural estimates, some 2 million souls—into a new covenant at Mt. Sinai, revealing Himself while giving the Ten Commandments, which He later inscribed on stone tablets and gave to Moses to bestow on the people. In its most basic understanding,

the new covenant provided mutual consideration: from God to the people of Israel, the land of Israel; from the people of Israel to God, performance of the mitzvot—the Commandments.

Since that time, Judaism has taught that it is incumbent on members of the covenant—all Jews 13 and older (see entry on Bar/Bat Mitzvah)—to scrupulously adhere to practice of the mitzvot, which can be broken into two main categories: ritual and ethical. (With the advent of Reform Judaism some century and a half ago, Reform Jews have placed the main focus on ethical commandments.) From a theological standpoint, performance of the mitzvot is said to ensure the additional reward (besides the Promised Land) of material security, not to mention spiritual gratification. In reality, it has come to be understood that such assurance is fraught with problems, attested to by an ethnic history replete with a litany of disasters. Nor are large-scale episodes the problems of theodicy.

Nevertheless, at least at its outset, Jewish theology was held to be a significant advance beyond the polytheistic notion not just of many gods but of an arbitrary primordial realm held responsible for bad things happening to good people (and vice versa), to borrow a phrase from the title of Rabbi Harold Kushner’s timeless book on the subject. Jewish religious thought was a breakthrough in that it claimed that human behavior produces the properly commensurate divinely ordained outcome: Virtue is appropriately rewarded and vice likewise punished. So promises Scripture at its most direct, especially Deuteronomy 11.

## SACRED LITERATURE

One often hears Jews referred to as “People of the Book.” Justifiably. From its inception, Judaism has been a “book religion.” Its earliest collection of sacred literature is, of course, the Bible. Fundamentally, Judaism teaches that the Bible is the word of God. Many Jews, albeit the minority nowadays, believe every word of the Bible is divine in a literal sense. Others hold that the Bible as it stands is propositional—that is, divinely inspired. Others still would refrain from claiming any supernatural involvement in the Bible, describing it as the product purely of human creativity. No matter, all agree that it represents the earliest written collection of sacred literary accounts stemming from the Israelite/Jewish religious impulse to seek the Divine.

The Hebrew Bible consists of some two dozen separate books, varying according to the historical context, voice, and theme. On a larger scale, the Bible is divided into three main sections: the Pentateuch, the Prophets, and the Holy Writings. The first letter of each section in Hebrew forms the Hebrew name for the Bible, the TaNaKh. It is worth noting that of the three, Jews most venerate the Torah, which is chanted in synagogues in its entirety each year, following a format of weekly sequential portions. Additionally, in terms of Jewish law, the Pentateuch carries an authority that by far exceeds that of the two other sections of the Hebrew Bible.

Alongside the Bible in Sacred Literature is the Talmud. Unlike the Bible, the Talmud originated and long remained oral in character, giving the evolving Jewish religious tradition enormous flexibility and dynamism during a period of a millennium or more, up to its publication in approximately 500 AD. There are actually two Talmuds, the Babylonian and Jerusalem versions, which, although they bear much resemblance to each other, are nevertheless discrete collections. Of the two, the Babylonian version is the more popular, as well as more legally authoritative. The Talmud consists of two types of literature: law and lore. It no doubt is best known as a compendium of religious law and is especially noteworthy for its invariable penchant to include the extensive jurisprudential argumentation involved in discoursing most issues of Jewish law.

Because of its popularity (even outside the Jewish world) of late—literally in the past several years—we would be remiss not to mention the existence of a substantial body of mystical literature among Jewish sacred literature. Best known by its generic term, *kabbalah*, the Jewish mystical tradition is built around a sizeable collection of literature called the *Zohar*. Tradition holds that the *Zohar* is the outcome of a 12-year experience of divine revelation received by Rabbi Simeon bar Yohai and his son, while hiding in a cave during the Hadrianic persecution in Judaea some 1,800 years ago. This tradition further holds that, once received, the revelation remained mostly dormant for another thousand years, until finally being brought to light by the Spanish Rabbi, Moses de Leon. The *Zohar* and much other kabbalistic literature derive their purported mystical powers and properties through the application of an exceedingly esoteric symbolic system based on a scheme of types and degrees of combinable divine emanations, decipherable

from kabbalistic literature by only highly trained mystics. Because of the extensive background required—not to mention the purported potency of the religious experience kabbalah can unlock—it has popularly been held that no one is permitted to delve into kabbalah before the age of 40.

## HOLY DAYS

Foremost among Jewish holy days is the Sabbath, thought to be an Israelite innovation. Jews celebrate the Sabbath each Friday night and Saturday as the weekly anniversary of God's resting after 6 days of creating. In addition to refraining from labors, Jews join together for special prayers and meals. Some Jews refrain from using most kinds of technology, such as electricity and automated travel. The Sabbath is the Jewish holy day, par excellence.

Next in importance among Jewish holy days is a twofold observance consisting of Rosh Hashana (New Year) and Yom Kippur (the Day of Atonement), which fall 10 days apart and form a conceptual unit of a season for repentance. Traditional Jews celebrate Rosh Hashana over a 2-day period, as with the Sabbath reciting special prayers for the day and eating festive meals. Yom Kippur is a 1-day observance whose most outstanding characteristic is a full-day fast, refraining from all food and liquid. Many Jews wear a special white robe symbolizing purity on this day, and also refrain from wearing leather shoes, which symbolize comfort. Additionally, Yom Kippur features the largest array of special prayers for any holy day, many Jews spending the better part of the day in synagogue in prayer. The theology behind this holy period, known as the Days of Awe, was laid down in the Torah as a time of judgment, when the Almighty decrees the fate of each Jew during the new year. Hence, the period's emphasis on repentance, which along with prayer and good deeds forms the triumvirate of prescribed activities for this 10-day period.

During the nearly millennium-long period when the Holy Temple stood in Jerusalem (from roughly 950 BC to 70 AD, with an interruption between 586 and 512), Jews celebrated Judaism's three pilgrimage festivals—Passover, Shavuot (Pentecost), and Sukkot (Tabernacles)—by making pilgrimage to that central religious shrine. The practice was discontinued for obvious reasons after the Holy Temple was destroyed. (Although the Temple was never rebuilt, Jews have

continued to venerate the site, specifically the Western Wall of the mount on which it was erected.) The three pilgrimage festivals form a conceptual unit on an agricultural theme. Passover marks the earliest point of harvest, when barley ripens. Shavuot celebrates the fructification of other produce and, while the Holy Temple was standing, called on worshippers to bring “first fruits” to the altar. Sukkot is the full-blown harvest festival, celebrating the bounty of produce realized at the end of harvest. Passover and Shavuot also have historical and theological facets equally important to their agricultural significance. Passover famously commemorates the Exodus from Egypt, and Shavuot recalls God’s revelation and bestowal of Torah at Mt. Sinai exactly 7 weeks later.

Each of the three pilgrimage festivals is celebrated in a unique way. Two of them, Passover and Sukkot, are weeklong festivals, featuring a Sabbath-like holy day on each end. Sukkot’s end-day is a self-contained holy day called Shemini Atzeret, which marks the end of the entire pilgrimage festival season for a given year. Shavuot, on the other hand, is a daylong holy day. Among the unique aspects of Passover is a special diet for the week, eschewing ingestion of foods and liquids that have gone through the process of leavening. The most notable Passover food is matzoh, an unleavened cracker bread reminding Jews that their ancestors fled Egypt before giving their dough time to rise before baking. Passover’s other notable characteristic is the popular Seder meal, usually celebrated in each family household, which retells the story of the Exodus through food and recitation of a special liturgy called the *Haggadah*. Whereas Sukkot doesn’t impose any dietary changes, it does call for each household to construct a special booth, whose roof must be made from natural material, usually wood branches and leaves, so as to remind Jews of the simple structures their ancestors used in the Sinai wilderness. Jews eat their meals in these booths throughout the Sukkot festival week. Additionally, during Sukkot, Jews make use of a four-species collection comprising a palm branch, willow and myrtle branches, and a citron bound together for purposes of waving before God during prayers. This ritual thanks the Almighty for the blessings of nature’s beauty and bounty.

## LESSER HOLIDAYS

Unlike the major holy days, Judaism’s lesser holidays are “later developments,” insofar as they are not

part of the divine legislation of the Pentateuch. Best known of these lesser holidays (likely because it falls on or around Christmas) is, of course, Hanukkah. Hanukkah is an 8-day holiday commemorating the rededication of the Holy Temple, following its occupation and desecration by Hellenists in 165 BC. Often called the *festival of lights*, Hanukkah’s primary observance entails the kindling of a candelabrum called a *menorah*, beginning with one candle for the first day and adding a candle on each successive day until eight are lit. (Practically speaking, there are nine because an extra candle is lit each night as the shamash, or guardian candle.) The eight candles follow the 8 days of Hanukkah, whose length comes from the legend that, when the Holy Temple was rededicated, the quantity of holy oil found for the Temple’s candelabra was enough for just 1 day, but miraculously lasted 8 days. Many Jews celebrate Hanukkah by eating fried foods—a reminder of the miracle of the oil—such as potato pancakes and jelly doughnuts. Jewish children play a game with a special spinning top called a *dreidel*. In many families, children are given monetary gifts by their parents.

Although not nearly as widely known by gentiles as Hanukkah, the holiday of Purim is at least as significant in Jewish life. Purim is a 1-day holiday celebrated each year, usually in March, which commemorates the salvation of the Jews of Persia from annihilation some 2,500 years ago. The central observance of Purim is the communal cantillation of the Bible’s Book of Esther in its entirety (a half-hour-long ritual), accompanied and followed by merriment and gaiety. Some Jews consume food and alcohol in abundance. Jewish children usually dress up in costume, often playing one of the principal characters of the Purim story, Esther or Mordecai—some even come dressing as the villain, Haman, whose name, incidentally, inspires jeering from the community while the Book is being chanted. Purim observances also include the exchange of food gifts, as well as mandatory gifts to the poor.

Other minor holidays can be briefly noted. Jewish arbor day, Tu b’Shvat, is marked each year in January or February, coinciding with late winter in Israel. This is the birthday of trees in the Land of Israel, when sap starts to rise. Jews mark this holiday by buying trees for planting in Israel. Some hold a special Seder meal, similar to the Passover Seder, featuring foods and wines native to Israel. Next, ever since the destruction of the Holy Temple, the Jewish calendar has featured

3 days of fast, marking the progression of ruin to Jerusalem during the two periods of destruction, first in 586 BC and then in 70 AD. Each fast day falls on the anniversary date of a significant stage in the impending ruin. The first, the 10th of Tevet, marks the beginning of siege; the second, the 17th of Tammuz, marks the breach of the city walls; and the final, the 9th of Av, marks the actual destruction of the Holy Temple. Whereas the first two are so-called minor fasts, insofar as they obligate fasting from only sunrise to nightfall, the 9th of Av is one of Judaism's two major fasts (it will be recalled that the other is Yom Kippur), calling for a full-day fast, lasting from the beginning of twilight 1 day until nightfall the next. The 9th of Av—usually called *Tisha b'Av*—also calls for the chanting of the Bible's Book of Lamentations, alongside with a litany of poetic dirges composed through the ages in commemoration of the black day.

Finally, a relic of what once was a much larger holy day celebration: Rosh Hodesh, or the New Month. In the days of the Holy Temple, Jews celebrated each Rosh Hodesh as a Sabbath-style holy day. Since its destruction, celebration of this occasion has been greatly reduced, to the point at which the only significant departure from an ordinary day is a fairly small segment of additional liturgy, coupled with a short chanting of scripture associated with the day.

## JEWISH PRACTICE

The Jewish religion is structured around a system of Mitzvot—divinely ordained behavior, stemming from Scriptures, principally the Pentateuch. Several of these Mitzvot are especially notable and will be discussed herewith, in no particular order of importance.

Jewish dietary practice, known as *kashrut* (or, “keeping kosher”), is in essence a conglomeration of several Mitzvot. They can be briefly delineated as follows.

### Forbidden Species

Best known in this category is the prohibition against consuming pork products. Along the same lines, Scripture forbids the eating of shellfish—that is, any fish not having both fins and scales. The Pentateuchal books of Leviticus and Deuteronomy also have extensive lists of various forbidden birds and insects. Finally, consumable beasts must both chew their cud and have cloven hooves.

### Ritual Slaughter

Consumable land and flying animals require ritual slaughter—*shehitah*—by a certified practitioner. Ritual slaughter entails taking animal life by slicing open the jugular, preceded by a special blessing. Following *shehitah*, the carcass is inspected for signs of lethal disease; if such signs turn up, the carcass is declared nonkosher.

### Forbidden Mixtures

Thrice the Pentateuch adjures, “Thou shalt not boil a kid in its mother's milk.” Scriptural interpreters extended this prohibition to include all admixtures of milk and milk by-products with beef or fowl. Additionally, *kashrut* requires an interval wait of several hours (how many varies among communities) between the consumption of milk products and meat products. Most Jews who adhere to prohibitions against forbidden mixtures retain completely separate implements for storing, preparing, cooking, eating, and cleaning after milk products on the one hand, and meat products on the other. Again, it must be noted that, because Reform Judaism teaches that many rituals are optional, few Reform Jews keep kosher.

Traditional Jewish prayer is structured around an inherited liturgy, as well as certain mandated junctures of the day, and additionally in certain situations. Not to be overlooked is the fact that, outside Reform Judaism, Jewish prayer takes place nearly uniformly in Hebrew. The Jewish day comprises three unique liturgical services: morning, afternoon, and evening. Among the main elements, common to each service is the Amidah, or standing prayer, which, aside from the Sabbath when it is considered unfavorable to make requests of God, is a sequence of very ancient blessings on themes of thanks and request. Morning and evening services also have in common a three-section affirmation of faith, known as the *Shema*. (This prayer contains the most famous line of prayer in all of Judaism, “Hear O Israel, the Lord is our God, the Lord alone.”) Especially important is to note that Jewish teachings place the highest value on community prayer. A prayer quorum consists of 10 or more Jews aged 13 and older. (In Orthodox Judaism, as well as some conservative synagogues, only Jewish men may count toward a quorum.) As for prayer garb, Jewish men don skull caps and prayer shawls (for morning prayers), as well as special phylacteries for the arm

and forehead called *tefillin*—all of which are optional in Reform circles. It is preferable, though not strictly necessary, for community prayer to take place in a synagogue or any other space with a Holy Ark containing a Torah scroll. In Orthodox Judaism, men and women pray separately. Beyond prayer services, Judaism has prayers for myriad special and mundane (such as after using the restroom) occasions, known as blessings or in Hebrew, *berakhot*. Best known blessings include those over eating bread and drinking wine.

In its lengthy history, Judaism has developed a sequence of Rites of Passage, herewith described.

Jewish males require ritual circumcision at 8 days old. The ceremony is called *Brit Milah*—often elided to *bris*—and usually is performed by a trained functionary called a *mohel*. Conceptually, the ceremony brings the baby boy into God’s covenant. This rite goes all the way back to the patriarch Abraham (who, it will be recalled by those familiar with Scripture, circumcised himself). The *Brit* ceremony also bestows the child’s Hebrew name. Although no such covenant ceremony was prescribed either in the Bible or Talmud for girls, modern Judaism has begun exploring ceremonies for baby naming and covenant invoking.

Judaism’s puberty rite is the Bar and Bat Mitzvah at age 13.

Judaism’s concept of marriage has been thoroughly monogamous since 1000 AD, when the illustrious Sage Rabbi Gershom issued an edict forbidding polygamy. Marriage in Judaism is a holy covenant between husband and wife, affected by a formal marriage ceremony built around legal acquisition through witnessed ring exchange. In Judaism, marriage may be brought to an end through divorce, although implementing divorce is somewhat more complicated than marriage (owing to Judaism’s reluctance that marriage end except in completely irreconcilable circumstances), requiring that a divorce decree (in Hebrew called a *get*) be handwritten by a licensed scribe while two valid witnesses watch, then delivered to the wife by a specially designated emissary. Once again, it is necessary to add that Reform Judaism by and large has done away with the requirement of the traditional divorce procedures, recognizing in their stead civil divorce decrees.

Finally, when a life ends, Judaism has a highly developed set of rituals regarding burial and mourning (bearing in mind again that Reform Judaism has declared optional most if not all traditional rites associated with

death). Jewish law requires that, except in extenuating circumstances, burial take place as soon as possible after death, usually the next day (unless that day is a holy day). In Jerusalem, burial often takes place on the same day as death, often within just a few hours. The reasoning behind such insistence on quick burial stems from the concept of *kvod ha’met*—or, “honoring the deceased.” According to Jewish law, cremation is forbidden, and burial must take place underground (rather than in an aboveground vault) unless local ordinances require otherwise. Mourning practices include a 7-day period of cessation from all workday pursuits, known as *shiva*, and shaving and cutting hair is frowned upon for an additional 23 days. The entire monthlong period is called *sheloshim*. A person is designated a mourner for purposes of the above rituals upon losing a direct relative—parent, spouse, sibling, or child. Perhaps the most well known of mourning rites is the “mourner’s kaddish,” an Aramaic prayer recited by mourners at public prayers during the *sheloshim* period and during an additional 10 months following the loss of a parent.

A word about afterlife in Judaism: Unlike many Christian traditions, Judaism does not place enormous emphasis on the speculative realm of afterlife. Judaism lacks a clear, unambiguous concept of heaven and hell—hence its emphasis on perfecting the here and now. Nevertheless, traditional Jewish thought long ago developed a notion of life after death, featuring a singular notion of bodily resurrection followed by final judgment, and only then subsequent eternal reward. In this conceptual framework, body and soul die and are resurrected together, then part ways only after final judgment, when worthy souls live with God for eternity.

## THE SYNAGOGUE

Jewish communities have long erected facilities for prayer, fellowship, and learning. Usually called *synagogues*, in the early 20th century some—most Reform—congregations began calling their structures *temples*. In either case, the focal point of the synagogue is the chapel or sanctuary, within which lies the Holy Ark, which houses the community’s Torah Scrolls—handwritten on parchment by a trained scribe. Most synagogues have an educational arm and administrative area, along with a banquet facility. Some also have a ritual bath, used for conversion and purity purposes.

## MODERN DENOMINATIONS

The Jewish religion today consists of four primary denominations, one of which is further subdivided into various self-segmented groups. Denominational distinctions began to emerge in Germany in the mid-19th century, when several traditionally ordained rabbis banded together to commence a project of reformation. Their ideas and followers coalesced into a formal movement, Reform, and soon established a growing body of leaders and synagogues. Among their major reforms were de-emphasis of ritual law, removal of Hebrew as the main language of prayer, and repudiation of the hope of return to Zion.

Amidst the early move to reform, some rabbinical leaders felt uncomfortable with the pace and degree of recommended reforms. So began an incipient counter-reformation movement, which came to be known as *Conservative Judaism*. Likewise, at about the same time, leading traditional rabbis who opposed altogether any major reforms began calling themselves *orthodox*. Thus was born the term *Orthodox Judaism*. It should be noted that, whereas Reform and Conservative Judaism are considered “movements” (a concept subsumed within their names), Orthodox Judaism never has considered itself as such.

Nearly a century after Reform and Conservative Judaism emerged, in the early 1960s, a fourth denomination—Reconstructionism—was born in America from the thought of Rabbi Mordecai Kaplan, whose most notable innovation was a thoroughly naturalistic concept of God. Like its counterparts, Reconstructionism has its own synagogue arm and seminary but remains substantially the smallest of the four denominations. Orthodox is the next largest (in North America), followed in order by Conservative and Reform, which, until recently, were at virtual parity in affiliation. Reform has eclipsed Conservative Judaism in the past decade or so, probably owing to its more liberal definition of Jewishness. To elaborate, in an atmosphere where the intermarriage rate exceeds 50%, Reform Judaism is at an advantage in that it holds that Jewishness is passed to children through either parent, as opposed to the Orthodox and Conservative traditional position that it comes from the mother only.

As mentioned earlier, one denomination—Orthodox—is further subdivided in several ways, most noteworthy by a split between Hasidic (pious ones) and non-Hasidic (often referred to by the Hebrew term, *Mitnagdim*, or opponents). This split

occurred in mid-18th century Eastern Europe, after the advent of a charismatic leader affectionately known as the *Baal Shem Tov* (Master of a Good Name). Unlike its counterpart, Hasidic Judaism revolves around the charismatic leadership of several dynastic “Rebbes,” and such leadership almost invariably passes from father to son. Hasidic Judaism is even further subdivided into dozens of sects, each with its own dynastic leader. Within the *Mitnagdim*, Orthodoxy is likewise further subdivided along the lines of Modern Orthodox and Ultra-Orthodox, each group having its own set of seminaries, synagogues, and international leaders. Among the primary differences between Modern and Ultra Orthodox are appearance and mode of dress; Ultra-Orthodox men invariably wear long beards and black clothing. Ultra-Orthodox Jews also are more prone to live in insular enclaves, isolated as much as possible from the outside world. A notable exception among the Ultra-Orthodox is the Chabad Movement, whose recently deceased charismatic leader urged his followers to spread out in the world and missionize among Jews, hoping to attract followers.

## THE 20TH CENTURY AND BEYOND

Judaism underwent two major upheavals in the 20th century, the first tragic and the second triumphant. The first, the Holocaust, resulted in the death of 6 million European Jews, murdered by the Nazis between 1939 and 1945. The Holocaust has had an inestimable impact on Jewish thought in the second half of the 20th century, which no doubt will carry over into the 21st and thereafter. Jewish thought has struggled to integrate the staggering loss of fully one third of world Jewry into its theology. A number of prominent Jewish theologians, among them Rabbi Harold Kushner, propounded a radical and controversial theology many say represents a return to the idea of a realm beyond God’s control. Alternatively, many others, including survivor Elie Wiesel, suggest that the only appropriate response to the theological problem posed by the Holocaust is silence.

Triumphantly, only 3 years after the Holocaust ended, the State of Israel was born, representing the culmination of more than a half century of effort by the Zionist Movement, formally initiated by Theodore Herzl in 1897. Although its first six decades have been little other than struggle for acceptance and survival, the existence of Israel has provided a “shot in the arm”

to a Jewish world devastated by the Holocaust. Since the birth of the Jewish state, fully one third of world Jewry has relocated into the Jewish state, whose Jewish population now exceeds 5 million.

Despite the lessons of the Holocaust, anti-Semitism unfortunately continues to rear its ugly head in some quarters. At the time of this writing, French Jews, numbering some 600,000 and Europe's largest Jewish community, have seen a dramatic upsurge in anti-Semitic incidents in the past half decade, leading several thousand to depart each year for haven, mostly to Israel. Equally troubling, many quarters of the Muslim and Arab world, although virtually bereft of Jews, have recently begun to spout an especially virulent type of Jewish hatred, blaming them for many of the ills affecting their societies and even harking back to the medieval blood libel—the accusation Jews murder children to use their blood for ritual purposes.

In the United States, which still houses the world's largest Jewish community, the concern is not anti-Semitism; rather, it is assimilation. Now in its fifth generation since the great migration of some 2 million souls from Eastern Europe, U.S. Jewry is showing signs of erosion. More than 50% of Jews getting married marry non-Jews. Many century-old Jewish communities in smaller cities are deeply on the wane. Still, Judaism has many pockets of great vibrancy. Judaic studies programs at major universities are on the rise and increasingly popular. Books on Jewish subjects are published by the hundreds each year and eagerly read by thousands. Many once-lapsed Jews are returning to the fold, in some cases composing the bulk of entire synagogue communities.

“Ahm Yisrael Chai”—The age-old tradition lives on.

## JUVENILE DELINQUENCY

---

Juvenile delinquency has traditionally been defined as behavior exhibited by children and adolescents that has legal ramifications, such as engaging in illegal activity (statutory and criminal). Juvenile delinquents include youth who have contact with law enforcement and those who are adjudicated through juvenile court for a crime. These are behaviors that violate the rules of a society and result in contact with the juvenile justice system. Originally, the juvenile justice system was created as a separate entity from the adult legal system in recognition of the developmental differences between children and adults. As such, the juvenile justice system was primarily concerned with early intervention and rehabilitation of children and adolescents. It is generally acknowledged, however, that the system has become more punitive, which has led to increasing calls for reform of the system. For example, the U.S. Surgeon General has recently asked that youth involved in delinquent behavior be identified appropriately and that empirically validated treatment programs be implemented with them and their families.

### INCIDENCE

Rates of delinquency are often underrepresentations of actual behavior. Because most statistics rely solely on official contacts with law enforcement, all other illegal activity that is undetected remains unreported. To enhance information obtained from official records, self-report data from children and adolescents have become a beneficial component of juvenile delinquency research. Arrest rates for violent crimes, including criminal homicide, robbery, aggravated assault, and forcible rape, increased from 1983 to 1993–1994. Factors hypothesized to have played a significant role in this increase were youth involvement in gangs, increased drug use, and access to and use of guns. Data from 1993 to 1999 have shown a decline in arrests. The overall arrest rate for all crimes committed by juveniles was 2.4 million in 1999. During this time period, juveniles

were involved in 16% of all violent crime arrests and 32% of all property crime arrests. Another indicator of juvenile violence, self-report of crime, showed no decrease in the amount of violent behavior between 1993 and 1999. One potential reason for this discrepancy between arrest rates and self-report of problem behavior may be that there has been a decline in youth's use of firearms and some decline in gang membership that has resulted in less severe problem behavior that may not be detected by the authorities. Other statistics show that 30% to 40% of boys and 16% to 32% of girls have committed a serious violent offense by the age of 17. There are differences in arrest rates across gender and race, with significantly more boys than girls arrested and significantly more African Americans arrested than whites or other minority groups.

**RISK AND PROTECTIVE FACTORS**

Research examining risk and protective factors involved in juvenile delinquent behavior has typically focused on four core domains: individual, family, peer, and school/community. A summary of key risk and protective factors for each domain is presented in Table 1.

**CORRELATES**

Youth who display delinquent behavior often have significant co-occurring problems. Comorbid mental health disorders and substance abuse have been found to be more prevalent among delinquent youth, as well as early sexual activity, truancy, and school failure. Family correlates of delinquent behavior include family conflict, marital conflict, and parental inconsistency with rules and consequences.

**ASSESSMENT**

Assessments of children and adolescents who exhibit delinquent behavior are often court ordered and have a primary focus of assessing the youth's potential for future harm and his or her amenability to treatment. Evaluations are used to assist officials in planning probation requirements for the youth as well as potential placement decisions. A standard evaluation should assess the risk factors associated with future behavior, including past behavior, substance use, social stressors and support, opportunity to commit problem behavior, and characteristics of a future residence. In addition, there are several key areas that

**Table 1** Risk and Protective Factors Associated With Delinquent Behavior in Juveniles

<i>Domain</i>	<i>Risk Factor</i>	<i>Protective Factor</i>
Individual	Low intelligence Early problem behavior Substance use Hyperactivity/risk taking behavior	High intelligence Prosocial behavior
Family	Poverty Abusive parents Antisocial parents Poor parent-child relations	Parental monitoring Supportive, nurturing relationships with parents/adults
Peer	Antisocial peers Peer rejection	Nondeviant peers
School/ community	Poor academic performance Low academic goals Neighborhood disorganization Access to weapons	Commitment to school Involvement in prosocial activities

should be evaluated in order to accurately assess delinquents, including individual, family, peer, and community factors. Individual factors include the range of antisocial behavior, cognitive skills, and personality functioning of the youth. In addition, vocational skills may also be assessed to see how the youth may be able to adapt to his or her environment. Another important area is family dynamics, including parenting strategies, family conflict, and warmth. Deviant peer relationships are one of the best predictors of delinquent behavior and as such ought to be included in any assessment. Finally, community factors need to be considered, such as support systems for the youth and family, as does neighborhood cohesion or support of delinquent behaviors.

**TREATMENT**

Effective treatment of juvenile delinquents has historically been a challenge. During the past decade, however, several programs have been empirically validated for the prevention and treatment of delinquent behavior. In general, studies have shown that programs

targeting multiple systems that are short term, family based, and intensive are more effective in treating difficult behavior. Particular programs identified to show change in juvenile behavior and that are cost-effective include Functional Family Therapy, Multidimensional Treatment Foster Care, Multisystemic Therapy, Prenatal and Infancy Home Visitation by Nurses, and the Seattle Social Development Project. Unfortunately, many communities continue to fund programs that have not been shown to be effective, such as gun buy-back programs, boot camps, residential programs, milieu treatment, waivers to adult court, and individual counseling.

## PROGNOSIS

Much research has been done on the risk factors and developmental trajectories for delinquent youth. Most of the research to date has identified two developmental pathways, including early-onset and late-onset problem behavior. Youths with early-onset delinquency are more likely to increase in severity of problem behavior over time and continue to engage in behaviors across adolescence and into adulthood. Risk factors have been identified by age and also across individual, family, school, peer group, and community domains (see Table 1). In addition, some protective factors have been identified that may assist youth in having a more positive outcome. Having a risk factor does not guarantee that a youth will develop problematic behavior, but the more risk factors that accumulate, the greater the likelihood that the individual will develop more severe delinquent behavior.

Researchers have identified three potential developmental paths of antisocial behavior. An *overt pathway* begins with minor aggression to physical fighting and then leads to violence. An *authority conflict*

*pathway* moves from stubborn behavior to defiance and disobedience to authority avoidance. Finally, a *covert pathway* proceeds from minor covert behavior to property damage, more serious delinquency, and then serious delinquent acts. Further research will continue to delineate the factors related to persistence of delinquent behavior in order to strengthen our treatment of this population.

—Stephen R. Lassen

## KIBBUTZIM

---

The first kibbutz, a cooperative communal farming settlement called Degonia, was established in 1909 near the Sea of Galilee. It was followed in the 1920s by a number of variations on the basic model, and today there are more than 200 kibbutzim featuring a host of political and organizational characteristics and producing an array of goods, including toys, shoes, pharmaceuticals, and produce. Although there now exist a range of governmental organizations, there remains an effort to rule by committees, which oversee finance, education, child care, and other aspects of kibbutzim life. Nevertheless, the utopian socialist approach that underwrote the earliest kibbutzim has been largely diluted, leaving mixed forms of government, new labor practices including the use of hired laborers from outside of the kibbutz, and a host of new products bringing profits to kibbutz industries in ways that resemble conventional market dealings.

The original communal organization aimed to establish shared responsibility for administrative and labor tasks by promoting the idea that partnership and shared responsibility provide balance between the individual and the whole and between the whole and

the individual. This was effected in part by equal sharing of all responsibilities and an obligation to take an active role in the life of the community under the credo of each man according to his ability and giving to a man according to his needs. The more utopian of the kibbutzim were established as Kibbutz Artzi by Hashomer Hatzair; these had their own individual and separate settlements but in 1927 joined the kibbutz movement to promote greater mutual aid and to provide a focus for the world organization. At its inception, the Kibbutz Artzi numbered four kibbutzim and 200 members, but as Hashomer Hatzair spread throughout the Jewish world, its impact began to be felt in Jewish communities everywhere, and new adult members emigrated to Palestine to join up. In 1937, the very first kibbutz of Americans was settled at Ein Hashofet, named in honor of Justice Louis Brandeis, a strong supporter of Hashomer Hatzair's objectives. On the eve of the Second World War, the Hashomer Hatzair youth movement numbered 70,000 members worldwide, and their kibbutzim promoted a vanguard of socialist ideals.

From a progressive social standpoint, the early kibbutzim sought to minimize arbitrary direction and release fundamental motives for individual expression, the latter releasing the motive of the intellectual curiosity and the former the motive of economic

cooperation. This emphasis on freedom and creativity, along with the ways in which the kibbutzim were isolated from mainstream culture, distinguishes this movement from others in existence during this period. The work carried out by those on Mishmar Ha'emek, one of the more representative of the utopian socialist kibbutzim, is indicative of the type of agrarian-based, socialist-style kibbutzim that was considered the ideal for that time. Indeed, the Kibbutzim Artzis were founded on a belief in the kibbutz as an instrument for fulfilling the Zionist ideal, furthering the class struggle, and building a socialist society. The objective was to promote the fullest possible development of all members of the group in order to advance the causes of rational planning, shared decision making, and the growth of individual well-being. The "maximum social effectiveness" of this type of organization was best demonstrated by the important successes it had for family life, the status of women, and the education of children. Concretely, these kibbutzim offered women an equal role in the administration and planning of the community, whereas children were provided the best available housing, hygiene, and health care, along with a progressive education.

For people from all over the world to get to know Israel, to learn Hebrew, and to get an understanding of kibbutz life, there exists the "Ulpan," a 5-month period in which members study half the week and work in a branch of the kibbutz for the other half. Kibbutzim also welcome "volunteers" who come from many different countries for varying periods of time to learn about the kibbutz by taking an active part in the social and work life of the kibbutz. To be part of the kibbutzim is also a way of life, captured by the idea of "to build and be built."

Kibbutzim, <http://www.kibbutz.org.il/eng/welcome.htm>

views of readiness, which advocate school entry only for those children deemed to be developmentally ready, dominated ideas about school readiness. According to this view, readiness for school is determined by children's level of biological development. A child who is developmentally young needs only extra time to develop those characteristics that define readiness. This view manifests itself in holding children responsible for acquiring skills and characteristics needed for a good fit with the school environment and the characteristics that will allow them to be academically and socially successful. More recently, there has been a call by organizations such as the National Association for the Education of Young Children (NAEYC) for schools to accept the responsibility for adapting to the needs of all children. This view posits that all children are "ready" for school; schools and teachers must accommodate children of varied learning and behavioral styles, maturational levels, languages, and cultures by adjusting instruction so that every child can succeed.

### DEVELOPMENTAL SCREENING VERSUS READINESS TESTS

Two types of tests often associated with school readiness are developmental screening tests and readiness tests. Preschool children may be evaluated with either or both of these measures, which have very different uses. Developmental screening tests are designed to identify children who need further assessment and evaluation. After a developmental screening test shows reason for concern, the NAEYC suggests a child undergo a multidisciplinary assessment. Only after this assessment should placement decisions (e.g., into a "developmental" kindergarten or pre-first grade program) be made.

Readiness tests focus on a child's level of preparation for school in comparison with other children of similar age. The primary use of such information is to give teachers an understanding of the achievement levels of their students and improve their ability to plan instruction. The function of readiness tests should not be to sort children or advocate delayed entry for some children and school entry for others.

Neither the developmental screening test nor the readiness test should be used to make placement decisions, such as whether or not a particular child should attend regular kindergarten, should attend a

---

## KINDERGARTEN READINESS

---

Whether or not a child is "ready" for school has been a topic of considerable debate. In the past, maturational

developmental kindergarten, or should have entry delayed. As stated earlier, such decisions require a multidisciplinary assessment.

## DELAYED SCHOOL ENTRY

Concerns about children's readiness and perceived potential negative impacts of being the youngest in a class, as well as the maturational view of readiness, continue to exert influence on many parents' decisions to delay school entry. However, quality research shows that children who appear to be "immature" at school onset overwhelmingly catch up to their peers by second grade. Additionally, delaying entry has recently received more attention for the potential problems associated with it, including possible increases in children's behavioral problems and difficulties for teachers with classes where large variations in age exist.

## SUMMARY

In summary, the most widely accepted notion of readiness among experts in early childhood education today is the view advocated by the NAEYC. Schools and teachers bear the responsibility of being ready to accommodate the needs of all children in developmentally appropriate classrooms. All children are ready to learn, although they may come to school with different experiences and capabilities. Parents should be encouraged to send their children to school on time, as per district guidelines. The goal of kindergarten testing and screening is for schools to obtain helpful information that will enable teachers to optimally serve their students, as well as allow schools to provide appropriate additional services to those children who require such services.

## KINSEY INSTITUTE

---

The Kinsey Institute for Research in Sex, Gender, and Reproduction was founded as a not-for-profit corporation in 1947 by pioneering sex researcher Alfred C. Kinsey. The Kinsey Institute is a research institute affiliated with Indiana University. The Kinsey Institute's mission is to promote interdisciplinary research and scholarship in the fields of human sexuality, gender, and reproduction. The institute has research, archival, and educational components. Kinsey's landmark studies, published as *Sexual Behavior in the Human Male* (1948) and *Sexual Behavior in the Human Female* (1953), created the foundation for the institute and for modern sex research. The two books, known collectively as "The Kinsey Reports," included data from more than 11,000 interviews.

Integral to the mission is a research program that fosters diverse, creative approaches to significant questions in the field of sex research. The Kinsey Institute conducts research in various aspects of sexuality. Current topics include the study of high-risk sexual behavior, the effect of mood on sexual arousal and decision making, sexual well-being and distress in women, hormonal effects on sexuality, sex and the Internet, the psychophysiology of sexual arousal, condom use errors, and sexual compulsivity.

The Kinsey Institute initiates, cosponsors, and contributes to special events, exhibitions, lectures, and workshops and symposia that promote the interdisciplinary research and study of sexuality, gender, and reproduction at Indiana University and internationally. Workshops encourage useful discourse between researchers from different epistemological backgrounds and facilitate future interdisciplinary research on topics of pressing interest, such as methodology and theory in sex research. Visiting scholars add to the interdisciplinary dialogue.

The institute's extensive collections provide a resource for scholars in many different disciplines, including the arts, humanities, social sciences, natural sciences, medicine, education, and law. The library

houses more than 100,000 books, journals, scientific and scholarly texts, erotica, popular culture materials, and archival documents that span 2,000 years of human history. The collection includes monographs, journals, unpublished papers, reports, manuscripts, reprints, vertical file materials, sexual ephemera, erotic literature, microforms, audiotapes, phonograph records, CD-ROMs, and sex-related books, magazines, newspapers, and pulp fiction. The film collection includes historical "stag" and sex education films as well as contemporary videos and DVD collections. The library catalog, KICAT, can be accessed through the institute's Web site.

Historical and contemporary art and photography collections of the Kinsey Institute include more than 8,000 items from the United States, Europe, South America, Africa, and Asia and more than 75,000 photographs. The gallery displays selections from the collections. These diverse collections provide data for scholars studying sexuality across a wide range of academic areas of inquiry.

Through Indiana University, the Kinsey Institute codirects a graduate minor in human sexuality and a summer research institute, and it operates a sexual health clinic for people with problems in their sexual lives.

The institute's information services direct students, scholars, media, government officials, and the public to research-based information on a wide range of topics related to sexuality. The Web site provides information about current research and research publications, direct access to the library catalogue, information about events and services, and links to related resources on sexuality and research.

The Friends of the Kinsey Institute is an international organization created in 1997 to support the goals and mission of the institute. Monthly tours are offered of the institute collections. For more information, contact [kinsey@indiana.edu](mailto:kinsey@indiana.edu).

## KLINFELTER'S SYNDROME

---

Klinefelter's syndrome is a male sex chromosome disorder affecting 1 in 500 males across all ethnic groups. Men with Klinefelter's syndrome possess an additional X chromosome, resulting in a 47,XXY genotype. The additional X chromosome comes from sporadic errors during sperm or egg formation. In an individual with Klinefelter's syndrome, the extra X chromosome forms a dense mass, or Barr body, within the nucleus of cells, but exactly how the presence of this extra chromosome leads to the characteristics of Klinefelter's syndrome remains a mystery.

Individuals with Klinefelter's syndrome have testicular failure, which results in impairments in both sperm and testosterone production. Klinefelter's syndrome can be diagnosed at almost any age: in utero (after amniocentesis), in a prepubertal boy, in a male adolescent, or even in an adult male presenting to a medicine or infertility clinic. Because testicular failure occurs before puberty, many of the normal developmental changes of puberty either do not occur or progress slowly. This leads to some typical adult characteristics of individuals with Klinefelter's syndrome, including tall height with long arms and legs, increased breast tissue (gynecomastia), decreased muscle mass, decreased facial and body hair, and small testes—which often measure less than 5 milliliters in volume (normally greater than 15 milliliters). The penis may be decreased in size but is often of normal length. Gynecomastia is variable but is often prominent and may require surgical correction. Infertility secondary to impaired sperm production is almost universal. In childhood, common presenting features can include delayed speech development, learning difficulties at school, and unusually rapid growth in middle childhood.

At one time, individuals with Klinefelter's syndrome were thought to be at increased risk for criminal behavior; however, these conclusions were based on flawed studies of preselected (usually committed or incarcerated) populations and are probably inaccurate. When tested, groups of individuals with Klinefelter's syndrome can exhibit deficits in language processing skills, including reading and spelling, verbal processing speed, judgment, and motor dexterity. In general, this leads to lower than average school performance. It is important to remember that individual variation in mental function is marked; some individuals with Klinefelter's syndrome perform well above average on

intelligence tests. Moreover, it seems likely that early developmental interventions and language tutoring in boys can assist in preventing disabling difficulties with language skills later in adult life.

Laboratory analysis of an individual with Klinefelter's syndrome reveals low or low-normal serum testosterone and elevated serum gonadotropin levels. The diagnosis is confirmed using chromosomal analysis (karyotyping), which usually reveals a 47,XXY genotype, although infrequently additional X chromosomes may be present or an individual may be mosaic (47,XXY/46,XY).

Testosterone therapy of individuals with Klinefelter's syndrome results in a more "male" phenotype, with improved mood and increases in facial and pubic hair, muscle size, strength, libido, and bone mineral density. Optimally, testosterone therapy is begun at puberty, allowing boys with Klinefelter's syndrome to experience pubertal changes in tandem with their peers. In addition, this allows for optimal enhancement of bone mineral density. Even if testosterone therapy is not initiated until adulthood, it is still associated with beneficial improvements in mood, behavior, and sense of well-being. Testosterone therapy has no beneficial impact on either infertility or gynecomastia, which are optimally treated with surgical resection if bothersome to the individual.

For most men with Klinefelter's syndrome, artificial insemination with donor sperm or adoption are the only options for fatherhood. Recently, however, new approaches to the treatment of infertility, including intracytoplasmic injection of sperm aspirated from the testes, have been reported for Klinefelter's syndrome patients and may be successful in the subset of patients in whom sperm are present on testicular biopsy.

—John K. Amory

---

## KOHLBERG, LAWRENCE (1929–1987)

---

Lawrence Kohlberg developed a landmark theory on moral development that has generated much research, application, and controversy in many fields. Kohlberg was born in Bronxville, New York, to a wealthy family and was educated in private schools. Facing the immorality of the Holocaust as a young man, he helped smuggle Jewish refugees from Europe. He enrolled at the University of Chicago and, because of his brilliance on admissions tests, earned his bachelor's degree in 1 year, continuing on to do graduate work in psychology.

Kohlberg was much influenced by works of Dewey and Piaget, particularly Piaget's views of moral reasoning and use of problems to ascertain children's thinking levels. Kohlberg's dissertation, published in 1958, proposed a six-stage theory of moral development, based on his study of 72 middle-class white boys in Chicago, expanding Piaget's two-stage model. This brought him instant recognition in psychology because he broke with earlier approaches to morality. His research challenged the view that adults shaped moral behavior to avoid bad feelings in children. Kohlberg believed children construct their own moral judgments through interaction with others and their own positive emotions to become moral agents.

In 1968, at age 40, Kohlberg assumed a position at Harvard University. He was revered by students and colleagues and spawned a great deal of research, activism, and controversy. In later years, he developed physical illness and mental instability and committed suicide at age 59, walking into the frigid Atlantic Ocean in January 1987, although his body was not recovered until April of that year.

Kohlberg used "moral dilemmas" to study moral reasoning, first studying teens in the United States, and later in Great Britain, Malaysia, Mexico, Taiwan, and Turkey. He found moral reasoning to be gradual and developmental, in stages (like Piaget), with all people going through each level in order, but at different

rates and with rare regression to earlier stages. There are three levels, each with two stages—six stages total (see entry on Moral Reasoning).

Kohlberg's earlier work was questioned because his research had not been cross-culturally validated and there was an issue finding so few individuals at stage 6, the highest level. Kohlberg went on to do cross-cultural research and found the same sequence, but varying end points, based on a given society's levels of social interaction. There were questions about whether a nation's values affect moral reasoning, with group-oriented cultures having somewhat different responses.

Issues also arose about differences between moral thought and moral behavior and whether self-reports, rather than behavioral outcomes, should be assessed (e.g., do our thoughts predict our acts?). Yet Kohlberg found that 15% of individuals reasoning at level III, 55% of those at level II, and 70% of those at level I cheated when given the chance, indicating that moral reasoning and behavior are connected.

Some have questioned the assumptions of "ordinality" and domain specificity. Is moral reasoning the same for a teacher concerning a problem in education as for a lawyer, coming from a different domain? Particular dilemmas also elicited differences in stage, known as *stage mixture*, with the modal response being the stage assigned.

A major concern was gender differences in moral reasoning, questioning the generalizability of Kohlberg's longitudinal work on young males to females (and perhaps to non-Western cultures). Women were found to base moral decisions on caring, personal relations, and attention to human needs, rather than rules, rights, and justice.

Kohlberg's theory of moral reasoning, despite its controversies, has influenced many fields, including education, psychology, theology, law, and even politics, spawning a vast amount of research and a focus on moral issues. His approach to moral education through moral controversies is still very much alive.

## KÜBLER-ROSS, ELISABETH (1926–2004)

---

The first born of triplets in Zurich, Switzerland, on July 8, 1926, Elisabeth Kübler-Ross became a psychiatrist, best known for her pioneering work in the care of dying patients. Her pathway to medicine was not without obstacles. Her father wanted her to join him in his business as a secretary, and when she refused, he insisted her only alternative was to work as a domestic. After working for a family in Germany, she rejoined her family in 1943 and again defied her father by entering an apprenticeship in biomedical research. Elisabeth was restive in the laboratory and found herself drawn to direct interactions with patients. She volunteered as a relief worker in rebuilding the French town of Ecurcey after World War II and later served as a volunteer in the International Volunteers for Peace organization, helping the survivors of the war rebuild their lives and villages. Such experiences convinced her that she could contribute most through a life in medicine and claimed as one of her sources of inspiration the work of Albert Schweitzer.

Kübler-Ross entered medical school at the University of Zurich in 1951 and graduated in 1957. She married an American whom she had met in medical school, Emanuel R. Ross, MD, and together they served as interns at Glen Cove Community Hospital, Long Island, New York. After her internship, she accepted a research fellowship at Manhattan State Hospital, where she went beyond her initial job description to provide compassionate care for her mentally ill patients. Kübler-Ross then entered a psychiatry residency at Montefiore Hospital in 1961. She broke with traditional Freudian practices in the care of patients

and had remarkable success in helping patients through intuitive and innovative practices.

In 1962, she and Emanuel accepted joint positions at the University of Colorado, and Kübler-Ross served as assistant professor of psychiatry at Billings Hospital in Chicago from 1965 to 1970. Although she was hired to teach the psychiatric aspects of patient care to medical students, she was increasingly drawn to share the lessons she had learned in caring for dying patients through seminars and lectures on this topic.

Her research and clinical experiences with dying patients took the form of a book published in 1969, *On Death and Dying*, in which she chronicled her observations that many patients go through five “stages” after being diagnosed with a fatal illness: *denial*, *anger*, *bargaining*, *depression*, and *acceptance*. The book was an immediate success and had a profound affect on the subsequent behavior of health care professionals, many of whom were empowered by Kübler-Ross to emulate her compassionate treatment of the dying.

Kübler-Ross subsequently moved her home to Scottsdale, Arizona. Her health was impaired by a series of strokes in 1995 and 1996 and afterward lived

in a group home that provided appropriate care. Kübler-Ross died on August 24, 2004. Just before her death, she was interviewed by National Public Radio and filmed by a crew from Vermont making a film about hospice. Stefan Haupt, a Swiss film maker, recently completed a film on her life that has received popular acclaim in the country of her birth.

## LABOR

---

Labor is defined as contractions that change the uterine cervix, which results eventually in the delivery of the fetus. Labor is considered one of the most intense experiences of pain widely encountered. The cause of pain might be explained by hypoxia of the contracted uterine muscle (as in myocardial infarction), stretching of the cervix during dilation, or compression of nerves in the cervix.

Labor starts with mild contractions or tightening of the muscles of the uterus. Regular uterine contractions cause softening and effacement of the cervix (i.e., thinning of the cervix) and dilation of the cervix. The degree of cervical effacement is expressed in terms of the length of an unaffected cervix. Before labor, the uterine cervix is about 4 centimeters long and tightly closed. Thus, when the length is reduced by one half, it is defined as 50% effacement, and thinning of the cervix to the thickness of a piece of paper means 100% effacement. The dilation is ascertained by estimating the diameter of the cervical opening. The final stage of dilation, enabling the passage of the baby into the birth canal, is of 10 centimeters opening

(i.e., full dilation). Uterine contractions that do not cause cervical dilation are called Braxton-Hicks contractions, which may be observed at any time during pregnancy, but are more common near the end of pregnancy.

Two phases of cervical dilation are the latent phase and the active phase. Latent phase is characterized by contractions leading to cervical softening and the beginning of dilation of the cervix. Active labor means that contractions are regular (three contractions in 10 minutes) and strong, usually beginning at cervical dilation of 3 to 4 cm, resulting in progressive dilation. Much energy is expended during this process, which expresses the term *labor*. A clinical sign of the impending onset of active labor is the discharge of a mucus plug with a few drops of blood that occluded the cervical canal during pregnancy (i.e., “bloody show”).

Active labor is divided into three stages. The first stage is defined as regular contractions leading to effacement and progressive dilation of the cervix, ending when the cervix is fully dilated to 10 centimeters. The second stage is the expulsion of the fetus, starting at 10 centimeters. When the cervix is completely open, the patient feels a strong urge to push, which

drives the baby down the birth canal. This stage of labor ends as the baby is born. The third stage, involving several contractions, is the delivery of the placenta and fetal membranes, starting immediately after the delivery of the baby. Disproportion between the contracted uterus and the implantation area of the placenta enables its complete detachment from the uterine wall.

Spontaneous rupture of the membranes, characterized by a sudden gush or trickle of amniotic fluid from the vagina, typically occurs during the active phase of labor. This is a signal that the amniotic membranes have broken. However, rupture of the membranes before the onset of labor is referred to as *premature rupture of membranes*.

Friedman had first described the normal progress of labor in different curves for nulliparous (women at their first delivery) and multiparous women (second delivery and more). According to Friedman, the normal progress during the first stage of labor is cervical dilation rate of about 1.2 cm/hour for nulliparas and 1.5/cm hour for multiparas. The length of the second stage of labor was limited to 2 hours in nulliparous women (or 3 hours if epidural analgesia was applied) and 1 hour in multiparous women (or 2 hours if epidural analgesia was applied). Deviation from these curves has been defined as failure to progress in labor (labor dystocia, or abnormal labor). When time breaches in normal labor limits occur, interventions such as augmentation of labor or even instrumental or operative delivery might be considered.

## LANGUAGE ACQUISITION DEVICE

---

The language acquisition device (LAD) was proposed by Noam Chomsky to explain how children, when exposed to any human language, are able to learn it within only a few years following birth. Chomsky argued that all humans are born with the knowledge of what makes a human language. Included in this innate knowledge must be details of important characteristics of all the world's languages. The term *universal grammar* has been used to describe the knowledge contained in the LAD. The process of language development is envisioned as one in which the child discovers which grammar rules contained within universal grammar apply to the language that the child is learning.

According to Chomsky, humans are born with the LAD, but other species are not. Nonhuman primates and other species do not spontaneously learn human languages. Furthermore, attempts to teach nonhuman species language have yielded mixed results. Chimpanzees and gorillas have learned to use signed languages, such as American Sign Language (ASL). Washoe the chimpanzee and Koko the gorilla have each learned hundreds of signs and can use them to refer to concrete objects and concepts, such as *hunger*. However, neither has been able to master the intricacies involved in construction of grammatically correct sentences.

Chomsky's view of the LAD is consistent with there being specific structures in the brain involved in language learning and language processing. Such brain structures are presumably present in human brains, but absent in nonhuman brains. No specific claim was made regarding the specific location of the LAD in the brain. Although there have been locations in the brain identified as language processing areas, such as Broca's area and Wernicke's area, a location corresponding to the LAD has not been found.

Chomsky's claim that knowledge of language is innate was supported by Eric Lenneberg's *critical period hypothesis*. In 1967, Lenneberg published the book *Biological Foundations of Language*, in which he argued that humans are biologically capable of learning language only until puberty. After puberty, humans are biologically unable to master the intricacies of natural language. For many years, researchers in zoology

had recognized the existence of critical periods of development for a range of nonhuman animal species, such as songbirds, ducklings, horses, dogs, and sheep. Evidence for the Lenneberg's critical period hypothesis for human language was drawn from a variety of sources. Case studies of children raised without sufficient exposure to human language appeared to support the critical period hypothesis. Such individuals, such as Victor, the wild child, and Genie, had not been able to master the grammatical intricacies of sentence construction. Individuals born with severe hearing loss who were not exposed to a signed language until after puberty typically had not been able to achieve native-like proficiency. Furthermore, there was ample anecdotal evidence that individuals who attempt to learn a second language after puberty rarely achieve a level of proficiency comparable to that of one who learns the language during childhood.

Some researchers have rejected the notion that language acquisition is aided by innate knowledge. In 1957, the behaviorist B. F. Skinner published the book *Verbal Behavior*, in which he argued that all types of language behavior were learned after birth through the same learning processes that are used for all human learning. Some contemporary cognitive scientists, such as David Rumelhart and James McClelland, as well as others, view language learning as the result of general learning principles, rather than language-specific mechanisms. According to Chomsky, the primary challenge for this alternative approach to language learning is adequately explaining how children produce word forms and sentences that they do not experience in the environment and, thus, have no opportunity to learn.

## LANGUAGE DEVELOPMENT

The first words spoken by an infant may seem to mark the beginning of the infant's language development; however, by the time the first word has been spoken at about the age of 12 months, language development has been underway for more than a year. After birth, all normally developing children master the skills necessary for listening and speaking within a few years. Regardless of the language or languages spoken in the home, research has shown that language development proceeds in a remarkably similar fashion.

### BEFORE BIRTH

In the 12 weeks before birth, sounds from the world outside of the womb can be heard. By the 24th week of pregnancy, the auditory system of the growing fetus is well developed. Expectant mothers may feel movement by the fetus in response to a loud noise. The startle response can be consistently observed by the 28th week of pregnancy.

The early memories of speech sounds that are formed in the womb represent infants' very first experiences with language. Research conducted with newborns has shown that newborns treat some sounds as familiar while treating other sounds as unfamiliar. Treating a sound as familiar suggests that the newborn gained familiarity with the sound before birth. For example, in research reported in 1980, DeCasper and Fifer showed that soon after birth, newborns prefer to hear the sound of the mother's voice versus the sound of a stranger's voice. Similar research reported in 1988 by Jacques Mehler and colleagues showed that newborns only 4 days old treated sounds from the mother's language as familiar, whereas they treated sounds from another language that was not spoken in the home of the expectant mother as unfamiliar. In 1986, DeCasper and Spence reported one of the most compelling studies of this type. They instructed expectant mothers to read a particular Dr. Seuss book aloud during pregnancy. After birth, newborns showed a preference for hearing the familiar story over a different story that had not been read during pregnancy. A second group of newborns who had not heard either story before birth did not show a listening preference.

## LISTENING

At birth, all newborns demonstrate the remarkable ability to distinguish speech sounds occurring in all the world's languages. This phenomenon has been referred to as *categorical perception*. The inborn ability to make fine-grained perceptual distinctions is not unique to humans. Chinchillas, which are small fur-bearing rodents, also demonstrate these perceptual abilities. Of course, chinchillas never acquire human language. An important difference between the perceptual abilities of children and other species is that the perceptual abilities of children change during the first year of life as a result of their listening experiences. By the end of the first year of life, children gradually lose the ability to distinguish speech sounds not occurring in the language or languages spoken in the home.

Young infants' ability to recognize syllables in speech has been shown to be influenced by the frequency with which they are experienced. Research conducted by Peter Jusczyk and colleagues showed that infants as young as 9 months could distinguish single syllables that were frequently experienced from those that were infrequently experienced. In contrast, infants who were 6 months old were unable to distinguish the two types of syllables. Furthermore, research conducted by Eleanor Saffran and colleagues has shown that infants who were 6 months old could distinguish two-syllable sequences, such as *bida* and *kupa*, when presented in a continuous stream of syllables, such as *ibidakupadotigolabubidaku*. In the study, some two-syllable sequences occurred frequently; others occurred infrequently. The results suggested that infants' ability to recognize two-syllable sequences was influenced by the frequency with which the specific syllables occurred in the speech stream played for infants during the study.

Research studies confirm what many new parents may have guessed—children may understand some language even before they have produced their first words. Research conducted by Roberta Golinkoff and Kathy Hirsch-Pasek and colleagues showed that young children who had only one to two words in their productive vocabulary demonstrated the ability to understand certain aspects of meaning contained in spoken sentences. In the study, children were seated in between two television monitors. The children sat comfortably on a caregiver's lap and viewed two videos simultaneously. Both videos depicted the well-known Sesame Street characters Cookie Monster and Big

Bird. In one video, Big Bird was carrying out an action and Cookie Monster was being acted upon. For example, Big Bird was feeding Cookie Monster or tickling Cookie Monster. In the other video, the roles were reversed. Cookie Monster was carrying out the action and Big Bird was being acted upon. As children viewed the videos, a spoken sentence was presented to the children, such as "Where is Big Bird feeding Cookie Monster?" The results showed that children preferred to look at the video that matched the meaning of the spoken sentence. This clever study showed that months before children are producing full sentences, they appreciate the fact that the one who performs an action, or the *subject*, is mentioned first in an English sentence, and the one who is affected by the action, or the *object*, is mentioned second.

## SPEAKING

Infants' first spoken utterances after birth are most certainly crying. Crying can be viewed as the first important form of communication. In the first 3 months following birth, infants develop distinct cries to indicate hunger, discomfort, or anger. By the third month, children have begun laughing and cooing. When infants coo, they produce elongated vowel sounds, such as *oooh* and *aaaah*. In the months that follow, infants' productions become more and more complex. By the end of the first year of life, infants are generally producing their first words. Table 1 summarizes the different types of vocalizations produced during the first year of life and the ages at which each type of vocalization is generally observed.

By the sixth month, infants begin to practice the sounds of language. This stage of language development has been referred to as the *babbling stage*. Children begin babbling by repeating a single syllable, such as *babababa* or *dududu*. This type of babbling is called *canonical babbling*. Later on, children's babbling becomes more complex, as they produce sequences that contain different syllables, such as *bagada* and *dabuga*. This type of babbling is called *variegated babbling*. Of the speech sounds that are produced during these babbling stages, the 12 most common speech sounds found in the world's languages make up 95% of children's babbled productions. Infants will babble speech sounds that do not occur in the language or languages that are spoken in the home. As the infant nears 1 year of age, the infant produces fewer and fewer speech sounds not represented

**Table 1** Language Productions in the First Year

Age	Type of Utterances
Newborn	Crying
1–3 months	Cooing (“oooh,” “aaah”) Laughing Distinct crying to indicate hunger, anger, or discomfort Vocalizes in response to speech
4–6 months	Single syllables emerge (“ba,” “ga”)
6–8 months	Canonical babbling (“bababa,” “dadada”) Attempts to imitate sounds
8–12 months	Variiegated babbling (“bagadabu,” “dabuga”) Babbling is produced with sentencelike intonation
12 months	First words, <i>mama</i> , <i>dada</i> , <i>baba</i>

in the language or languages of the home. It turns out that as children lose the ability to distinguish speech sounds that are not regularly experienced during listening, they are less and less likely to produce those speech sounds.

Children’s first words may be *mama* or *dada* or the name of a favorite toy or pet. However, among a child’s first words may be invented words. Such words are used consistently by the child to refer to a specific object or action, but are not used by adults. These word inventions are called *idiomorphs*. For example, the child may consistently refer to a favorite food with an invented word, such as *gump*. In the book *Mirror of Language: The Debate on Bilingualism*, Kenji Hakuta describes a child who used the word *Whew!* as a greeting, when others might say *hello*. A possible explanation for the child’s choice of greeting was the fact that the child’s mother often said *Whew!* when first entering the child’s room in the morning, in response to an odor indicating that the child’s diaper needed changing. Children’s uses of idiomorphs are usually short-lived because they exchange their invented words for the words preferred by adults.

Parents and caregivers may find it relatively easy to decipher the intended meaning of children’s production of words; however, there may be notable differences between children’s pronunciations and those preferred by adults. Table 2 displays five common phonological errors that children make when producing words.

Reductions occur when children omit sounds from the target word. Reductions may occur with reduplication, as when children’s productions involve both a loss of sounds from the target word and a repetition of a syllable from the word. Substitutions occur when the infant replaces a phoneme with a different phoneme. Assimilations occur when the infant changes a speech sound in a word so that it is similar to a speech sound appearing later in the word. Coalescence errors occur when a word is shortened, by the loss of intermediate sounds.

The quality of children’s productions improves over time; however, some sounds are mastered more quickly than others. For English-speaking children, it may take years to master the articulation of all the speech sounds. English-speaking children between the ages of 4 and 8 years may make errors in the articulation of a number of consonants. The initial consonants in the words *red* and *long* are typically mastered by the age of 5. The initial consonants in the words *church*, *shirt*, *zoo*, *joke*, *van*, and *thumb* are typically mastered by the age of 6. The initial consonant in the word *them* is typically mastered by the age of 7. The most difficult consonant in English is the intermediate consonant in the words *treasure* and *measure*; children typically master it by the age of 8. Although most children eventually achieve adult-like pronunciation on their own, some normally developing children may be referred to speech classes, sometimes called *speech therapy*. In speech therapy sessions, children receive directed instruction and practice for specific speech sounds.

## BUILDING A VOCABULARY

The typical adult speaker of American English may know more than 40,000 words. Considering the fact that the child produces the first word at the end of the first year, the task of building an adult-sized vocabulary is a daunting one. In order for children to achieve an adult-sized vocabulary by the age of 18, it is necessary to learn at least six words a day, on average. Parents and researchers have observed that the acquisition of vocabulary by young children does not occur at a steady rate. Between 18 and 24 months, children’s vocabularies may double or triple over a short period of time. This phenomenon has been called the *word spurt*. Researchers have discussed the possible explanations for the word spurt. One possibility is that children experience a naming insight, at which point they realize that everything has a name. Children then

**Table 2** Children's Phonological Errors

<i>Type of Error</i>	<i>Examples</i>
Reduction	"ba" for "bottle"
Reduction with Reduplication	"baba" for "bottle"
Substitution	"tandy" for "candy"
Assimilation	"nance" for "dance"
Coalescence	"paf" for "pacifier"

may set out to learn as many new words as possible. A second possibility is that there are internal changes occurring in children's understanding of words. These internal changes may facilitate the learning of new words. For example, children may come to understand that objects in the world can be grouped into different categories, such as animals, vegetables, fruits, tools, and many others. Children may set out to learn additional members of a category after the category label has been learned.

The earliest strategy used by children to learn words has been called *referential learning*. Children learn words that refer to concrete aspects of the environment. The vocabulary of the 18- to 24-month-old contains far more nouns than other types of words, such as verbs and adjectives. One of the most effective strategies that children can use to learn new words involves asking an adult for help. Children may point to an object and ask, "What's that?" This has been called *the original word game*. The adult provides the answer. The child may then attempt to say the word, and the adult provides a correction, if needed.

Children employ other less obvious strategies when learning new words. When provided with a new word in response to the question—*What's that?*, children as well as adults show a strong tendency to assume that the new word refers to the entire object, rather than to a part of the object or some other aspect of the object, such as color or texture. This strategy has been called the *whole object bias*. The philosopher Quine discussed this bias in his well-known Gavagai Problem. The problem was formulated as a hypothetical case. Imagine you are in a country where you do not speak the language and no one in this country speaks your language. You are walking along with a person native to this country. A rabbit darts across the path, and your companion points toward the rabbit

and utters, "Gavagai." What do you assume Gavagai means? Usually, *gavagai* is taken to mean *rabbit*, rather than other comparably plausible meanings, such as *hopping*, *fur*, *ears*, or *white*.

Children approach word learning with two additional biases. These are the *taxonomic bias* and *mutual exclusivity assumption*. The taxonomic bias refers to the fact that children generally assume that a new word refers to a type of object, rather than a specific object. For example, the child will assume that the word *dog* refers to a group of animals, not just Toto. The mutual exclusivity assumption refers to the fact that once an object has been associated with a particular label, it will not be assigned a second label. This assumption leads to useful inferences about unknown objects. Consider the case in which a child is shown two objects. Assume that the child has already learned the label of one of the objects and knows it to be a *wrench*. If the child is then told *Hand me the hammer*, the child will infer that *hammer* refers to the object that is not the *wrench* because a wrench cannot be both a *wrench* and a *hammer*.

As any parent can attest, children's usages of newly learned words may not always conform to the usages preferred by adults. A child may use a word, such as *cow*, to refer to cows as well as other types of animals, such as any four-legged animal. Such errors have been called *overextensions*. Other examples of overextensions include using the word, such as *hot*, to refer to any object that is forbidden or using the word, such as *hat*, to refer to any object placed on the head. When children produce overextensions, they use a word to refer to a set of objects that is larger than the set referred to by adults. In contrast, *underextensions* occur when children use a word to refer to a set of objects that is smaller than the set referred to by adults. For example, a child may use the word *shoes* to refer to a single pair of shoes, such as Mommy's shoes, rather than any and all pairs of shoes. Other examples of underextensions include when children use the word *lights* only to refer to the headlights on a car, rather than all types of light, and when children use the word *milk* to refer only to milk in a glass, rather than milk in any container.

## CONSTRUCTING SENTENCES

Children's single-word utterances may be produced with sentence-level intent. The term *holophrase* refers to children's single-word utterances that have meaning

more complex than that of a single word. For example, the utterance *Daddy* may mean a variety of things. *Daddy* may name the presence of the person daddy. *Daddy* may be a request for Daddy to perform some action. *Daddy* may be a reference to a location, if Daddy were holding a desired object. *Daddy* may also refer to some meaning comparable to the meaning of an adult sentence, such as *I want Daddy to come here*.

By 24 months, children are regularly producing two-word utterances, such as *Daddy go* or *eat cookie*. (See Table 3.) These two-word utterances can be viewed as miniature sentences. Roger Brown showed that there are 11 types of semantic relations typically occurring in children's two-word utterances. Approximately 75% of English-speaking children's two-word utterances can be classified in these 11 categories. Research conducted by Dan Slobin has shown that these semantic relations also appear in other languages, including Samoan, Finnish, and Russian.

Between 24 and 36 months, children's utterances become more and more similar to the sentences produced by adults. During this time, children are producing longer utterances, on average, such as utterances that contain a subject, a verb, and an object. Furthermore, children begin producing words that contain grammatical word endings or morphemes, such as the suffix *-ed*, which is used to create the past tense form of verbs, as in *walked and talked*, and the suffix *-s*, which is used to create the plural form of nouns, as in *cups* and *dolls*. Classic research conducted by Jean Berko-Gleason showed that children learn to form new words, such as past tense verb forms and plural nouns, by learning rules. Berko-Gleason devised the Wug test to demonstrate children's knowledge of word formation rules. In the task, a child is presented with a picture of an unusual bird-like creature. The child is told, "This is wug." There is an accompanying picture depicting two of the odd creatures. The child is told, "Now, there are two of them. There are two. . . ." Children are asked which word comes next. Children as young as 3 can provide the plural form of *wugs*, a specific word form that they could not have heard before because the word singular word *wug* was a word created for use in the study. Berko-Gleason also tested children's ability to use the English rule for using the past tense suffix *-ed*. Children saw a picture of a man holding a large unusual object in his hands and moving the object from side to side. Children were told, "This man is ricking. Yesterday, he. . . ." Again, children as young

**Table 3** Semantic Relations of Two-Word Utterances

<i>Semantic Relation</i>	<i>Example</i>
Nomination	That book
Recurrence	More ball
Nonexistence	All gone ball
Agent and action	Mommy sing
Action and object	Throw ball
Agent and object	Mommy book
Action and locative	Go store
Entity and locative	Book table
Possessor and possession	Daddy chair
Entity and attribute	Big house
Demonstrative and entity	That box

as 3 can fill in the past tense form, which they could not have heard before.

The learning of word formation rules may lead children to produce forms of words that adults would not produce. In English, there are some plural nouns and some verbs that are not formed by adding the suffixes *-s* or *-ed*. For example, the plural of the noun *foot* is *feet*, rather than *\*foots*. The past tense form of the verb *eat* is *ate*, rather than *\*eated*. When children discover the rule for forming plural nouns from singular nouns or the rule for forming past tense verbs from verb stems, they may sometimes apply the rule inappropriately, as when they say *foots* instead of *feet* or *eated* instead of *ate*. These errors are called *over-regularization errors*. It is typical for children to produce an over-regularized form of a word that was used correctly before the rule was learned. For example, many young children produce the correct forms of the verbs *go*, *went*, *gone* in the first 24 months. Later, when the rule for forming past tenses is learned, children may produce errors, such as *\*goed* or *\*wented*. After rule learning occurs, children must then determine which words follow the rule (or are regular forms) and which words do not follow the rule (or are irregular forms). Children's productions of over-regularization errors become more and more infrequent in the year following the learning of particular word formation rule.

Children's mastery of complex sentence forms suggests that children master sentence production in a series of stages. Children initially appreciate what a particular type of word means, but then must figure out how to use the word appropriately in a complete sentence. Research conducted by Edward Klima and Ursula Bellugi suggests that children's use of

*wh*-questions, such as *what did you eat?*, is mastered in a series of stages. The first stage occurs in the first half of the third year of life. During this time, children produce questions with the *wh*- word located at the beginning of the question, but the subject and the verb are ordered as they are in an affirmative sentence, as in *Where I should put it?* In the second stage, children appropriately order the subject and the verb in affirmative questions, as in *Where should I put it?* However, children do not use the appropriate subject-verb order for negative questions, as in *Why you can't sit down?* In the third and final stage, children produce questions with appropriate subject-verb order for negative as well as affirmative questions. Children are typically between 48 and 54 months when they are producing well-formed *wh*- questions.

Edward Klima and Ursula Bellugi's research also suggests that children's production of negative sentences progresses in a series of stages, progressing from an initial stage at which the meaning of a negative word, such as *no*, is learned to a final stage at which children are positioning a negative word or morpheme appropriately within a sentence. Young children's first negative sentences have the form *No eat cookie*. The negative word *no* is placed at the beginning of a sentence. In the second stage, the negative word is produced in the middle of the sentence immediately before the verb, as in *Doggie no bite*. In the third and final stage, the child uses the negative word contracted with the verb in a form that adults use, as in *Doggie doesn't bite*.

## HEARING-IMPAIRED CHILDREN

Many children are born each year with some form of hearing impairment. About 1 in 1,000 children is born with a severe hearing loss. In the first months of life, the vocalizations of deaf infants and hearing infants may not be easily distinguished. Deaf infants will cry, coo, and begin to babble. The amount of babbling and the quality of the babbling produced by deaf infants may be reduced when compared with the babbling of hearing infants. Deaf infants are unlikely to produce repeated consonant-vowel syllables characteristic of the canonical babbling stage.

Deaf infants who are exposed to sign language from birth develop sign language skills in a series of stages similar to those observed when hearing infants develop spoken language skills. Signed languages such as American Sign Language (ASL), British Sign Language (BSL), and Chinese Sign Language (CSL)

are unique languages, each having their own rules of grammatical structure. Deaf infants exposed to a signed language will spontaneously produce gestures that can best be described as *manual babbling*. They will later produce one-sign utterances and later multisign combinations. Just as with hearing children, as deaf children mature, their multisign combinations become more and more complex in terms of the grammatical properties of the sign sequences. Signing children also make errors in sign production that are similar to the spoken errors made by speaking children. Signing children may produce idiomorph signs, sign overextensions, sign underextensions, and sign over-regularizations. Children's signed sentences also become more and more complex over time. In summary, regardless of language type, the development of language proceeds in a remarkably similar fashion.

## NATURE VERSUS NURTURE

An age-old question in the study of human behavior is the classic nature versus nurture debate. How much of children's ability to acquire language is the result of nature, or innate knowledge, and how much is the result of nurture, or general learning influenced by what is occurring in the environment. A number of prominent language researchers have argued that the relative speed and ease with which all normally developing children acquire language is best accounted for by assuming that certain aspects of language knowledge are innate—the child is born “hard-wired” for language. The most notable of these researchers is Noam Chomsky, who argued that all children are born with a *language acquisition device* (LAD) containing knowledge of the essential properties of all human languages. Opponents of this view argue that language learning can be explained as any other type of learning can be explained. Children's exposure to language and experiences with language can account for the language learning that takes place.

Although the nature versus nurture debate in the study of language development is unlikely to be settled in the near future, there is mounting evidence that biology plays an important role. Since the publication of Eric Lenneberg's book *Biological Foundations of Language* in 1967, researchers have recognized the possibility that there may be a critical period for learning language. The critical period for learning language is generally thought to be from birth to puberty. Some researchers, including Steven Pinker, have suggested that the critical window

for language learning is from birth to the age of 5. After the critical period has passed, learning language is more difficult and less successful. Individuals who do not receive adequate exposure either to spoken or signed languages during the critical period may find it impossible to achieve native-like proficiency.

The most compelling evidence for the view that biology plays a key role in certain aspects of language development comes from studies showing the existence of inheritable language disorders. The term *specific language impairment* (SLI) has been used to describe cases in which children show difficulty processing language, whereas they perform normally on tests of general cognition. Research suggests that SLI affects about 3% of the population. Researchers have shown that the incidence of SLI is much higher among family members of an individual identified as having SLI than the incidence in the general population. A family case study reported by Myrna Gopnik and Martha Crago in 1991 showed that of 30 members in an extended family, 16, or 53%, were identified as having SLI. The pattern of inheritance observed in this family suggested that a single dominant gene may be responsible for the disorder.

## SUMMARY

All normal developing children who receive adequate exposure to human language will learn language within the first few years of life. By the end of the first year, children are producing their first words and understanding much of the language spoken around them. By the end of the second year, children have amassed a vocabulary of several hundred words. By the end of the third year, children's utterances are becoming more and more similar to the sentences of adults.

## LATER ADULTHOOD

---

The period of later adulthood, defined here as ages 60 through 75 years, is characterized by physical, psychological, and social changes, including both gains and losses. We will examine the multifaceted aspects of successful versus usual versus pathological aging. In examining the changes that occur in later life, researchers often distinguish between primary aging and secondary aging. Usual aging or primary aging refers to gradual, time-related biological processes that are seen as inevitable and universal when comparing young adults to older adults. Some primary physical changes generally associated with later adulthood include a decline in sensory capacity; declines in heart, lung, kidney, and muscle function; and declines in memory. However, within every cohort of older adults, there are those who do not show such declines. These individuals are often considered to be aging “successfully.” Pathological aging or secondary aging refers to the changes that occur as a result of particular conditions or illnesses. The changes that occur because of secondary aging tend to be more common in older ages but are caused more by health habits, heredity, and other influences that vary by person. Some secondary aging processes include heart disease, cancer, dementia, and arthritis.

## PHYSICAL CHANGES IN LATE ADULTHOOD

Changes in appearance include both primary and secondary aging. For instance, skin becomes dryer, thinner, and less elastic in older age (primary aging);

however, the rate of these changes may depend on sun exposure, lifelong nutrition, and genetics (secondary aging). Dark patches of skin, called *age spots*, become more apparent in the transition to older adulthood.

Sensory changes are also common with aging. As the average person ages, the lens of the eye becomes harder and less flexible, resulting in a decreased ability to view objects that are close to the eye. Many older adults require eyeglasses to correct for these changes. In addition, the lens also becomes yellowed with age, which results in a change in the quality of light that is absorbed. One consequence of this is glare. Older pupils are smaller than young pupils in the same light. Both of these changes affect the eye's ability to adapt to changing light conditions that make night driving more difficult for older adults. There are those eyes, however, that age successfully and never show these types of declines.

Three of the most common diseases of the aging eye are cataracts, glaucoma, and macular degeneration. Cataracts are an extreme condition of lens opacity and are usually correctable with a simple operation to remove the faulty lens and replace it with an artificial lens. Glaucoma involves increasing pressure and atrophy of the optic nerve, which yields abnormalities in the visual field. Macular degeneration involves deterioration of the retina and is a leading cause of blindness in older adults.

Sharp increases in hearing difficulties often start around age 60. About 33% of people older than 70 years report some type of hearing loss. Hearing problems involve the loss of hair cells in the cochlea and disturbances of the inner-ear metabolism. Older adults generally have the most trouble hearing under what are called "masked conditions," when sounds are obscured or rendered inaudible by other sounds.

The probability of disease increases considerably after the age of 60. In the United States, people older than 65 years account for 33% of the nation's health care expenditures while only representing 12% of the population. Common chronic conditions of later adulthood include arthritis, heart problems, and high blood pressure. In people older than 65 years, heart disease accounts for almost 40% of all deaths, whereas cancer accounts for an additional 25%. Neither heart disease nor cancer is an inevitable consequence of aging. Both environmental or lifestyle factors, such as smoking, and genetic factors, such as family history, increase the likelihood that people in later life will develop these diseases. Nevertheless,

many of the conditions that are associated with aging can be prevented or remediated with adaptive lifestyles, including good nutrition and exercise.

## PSYCHOLOGICAL FUNCTIONING IN LATE ADULTHOOD

Our exploration of the psychological changes that occur with aging will include cognition, mental health, personality, and beliefs. The continued potential for growth and the possibility of decline exists in each of these areas. Cognitive changes in late adulthood are multifaceted. At one end of the spectrum, in later adulthood, we have more experiences and therefore more knowledge with which to face the challenges of daily life. At the other end of the spectrum, we are faced with declines in reasoning, speed of processing, and memory that are often concomitant with the primary physiological changes that occur.

Short-term memory refers to information stored for relatively brief periods of time (<60 seconds). Studies have shown that with usual and successful aging, there is very little decline in late adulthood in short-term memory. However, considerable age-related changes are found on working memory tasks, which involve the active manipulation of different pieces of information in short-term memory. Older adults are more likely than younger and middle-aged adults to experience difficulty holding several items of new information in mind while also trying to analyze and manipulate that information. Long-term memory deficits have also been shown to increase in later adulthood. Older adults seem to have more difficulty on episodic memory tasks such as remembering word lists and text recall. It has, however, been consistently shown that some of these deficits can be remediated by techniques such as training in strategy use and learning.

Dementias are secondary aging processes, which involve a pathological loss of brain functioning in any of the following areas: language, memory, visuospatial skills, emotion or personality, and cognition. Types of dementias include Alzheimer's disease, Parkinson's disease, multi-infarct dementia, and cortical-subcortical atrophies. The incidence of dementias increases with age. The most common form of dementia is Alzheimer's disease, which is characterized by a progressive deterioration of intellect, memory, and personality. Certain abnormalities in the cerebral cortex, called plaques and tangles, are markers for the disease. As

with all of the dementias, Alzheimer's disease is not part of normal aging; however, the incidence of Alzheimer's disease does increase progressively with age. Current findings suggest that about 3% of the population older than 65 years has Alzheimer's disease. Several studies have shown that the occurrence of Alzheimer's disease doubles every 5 years starting at age 65. Multi-infarct dementia is characterized by an irregular, yet progressive, loss of intellectual functioning. The cause of multi-infarct dementia are multiple mini-strokes, in which brief obstructions in the blood vessels of the brain prevent adequate blood flow from reaching different parts of the brain. Finally, subcortical dementias involve the progressive changes to the motor region of the brain, which results initially in losses in motor abilities but eventually often produce cognitive impairment in the late stages. Examples of subcortical dementias include Parkinson's disease, Huntington's disease, and multiple sclerosis.

Another related area of interest in the psychological development in late adulthood is the changes and continuities associated with control beliefs. Control beliefs are a two-part construct encompassing both beliefs about one's abilities to bring about outcomes and beliefs about the role of external factors on outcomes. Older adults tend to believe that age-related declines in memory performance are inevitable, which may in turn influence memory performance. Beliefs about control over one's health also may become more important in later life because of the impact of such beliefs on health care-seeking behavior and treatment adherence.

The research findings on personality across the life span are ambiguous. Some researchers have suggested that personality traits remain stable across the life span, whereas others have suggested that personality traits may vary significantly across the life span. Several variables (age, gender, marital status) have been shown to be important in individual differences in personality change in older adulthood.

Specific psychological problems, such as anxiety and depression, have not been shown to increase in late adulthood. Clinical depression is defined by the presence of several symptoms, including either depressed mood or loss of interest in nearly all activities over a period of at least 2 weeks, significant weight loss or gain, sleep difficulties, fatigue, and psychomotor slowing; whereas mild depression involves fewer symptoms and less impairment. In the

past, clinical depression was often thought of as a major problem of advanced age, but there has been little support for this claim. Several studies have shown the rate of depression in adults older than 65 years was significantly lower than for younger adults. Older adults may, however, be at greater risk for mild depression. Some risk factors for late life depression are bereavement, insomnia, chronic health problems, and prior depression. Anxiety disorders, such as panic attacks, phobias, and generalized anxiety disorder, are actually more common than depression in older adults. As with depression, anxiety is often associated with a variety of medical conditions, such as hypertension, dementias, and heart problems. Risk factors for late-life anxiety disorders include sensory problems, spousal bereavement, and high neuroticism.

Changes in sleep patterns are common in later adulthood. Sleep apnea, heartburn, and periodic leg movements are some of the major causes of significant sleep disturbances in old age. In addition, quality of sleep is reduced by many conditions that affect brain function, including heart disease, dementias, and arthritis. As we discussed earlier, these conditions become more frequent with advancing age, thereby increasing the likelihood of impaired sleep in late adulthood, which can in turn affect cognitive functioning.

## **SOCIAL FACTORS IN LATE ADULTHOOD**

There are a variety of social changes that may occur as we enter late life, including change in work status or loss of spouse and other significant others. In most industrialized countries, the age of retirement has been decreasing over the past few decades. Research on retirement has shown that older adults who retire or go to part-time work adjust very well to this change, with some even showing improvement in health and well-being. With retirement come significant changes in time and type of leisure activities, such as continuing education and volunteering. Retirement also brings a shifting of roles within the home and social system.

Many older adults are in long-term marriages. The best predictor of the nature of these relationships in later life is the nature of the relationship in earlier life. This means that although there are often fluctuations, the nature of relationships tends to be fairly stable over time. Because the probability of death increases with age, becoming widowed or losing other loved

ones is an inevitable part of late adulthood. Adjustment to bereavement is therefore often an important part of this time period. Research has shown that social support and emotional stability are important to bereavement recovery. Family and friends typically play an important supportive role in later life. It is not necessarily the number of people in one's social network, but the quality of the relationships that makes a difference. In later life, those who have good social support networks, with low social strain, typically show greater psychological and physical well-being.

## SUMMARY

What is successful aging and what is pathological aging are questions that continue to prove a challenge to scientists and lay people around the world. With the population of the world living longer, late adulthood is an important area of research and exploration. In every area of late-life development, there are important improvements, continuities, and declines. Continued research and development will allow us to understand the mechanisms and processes to understand biological, psychological, and social aging. Although we have focused on the period of later life between ages 60 and 75, it is important to note that there is much variability in the timing and extent of gains and losses during this time period. Moreover, the transition to the "old-old" period, which is usually considered to begin between 75 and 80 years of age, is also marked by large interindividual differences in functioning.

## LEAD POISONING

Lead has been used by mankind for more than 6,000 years because of its resistance to corrosion, its low melting point, and, ironically, sometimes for its sweet taste. Therefore, it is one of the most studied environmental toxins, and its toxicity has been known for more than 2,500 years. The major exogenous sources and associated pathways of lead exposure are lead-based paint, the combustion of leaded gasoline, occupational exposure in lead-related industries, lead-contaminated water or food, and industrial and mining activities. Both children and adults are susceptible to health effects from lead exposure, although the typical exposure pathways and effects are somewhat different. Children who live in houses that were built before 1978 and adults who are occupationally exposed are at greatest risk. Lead mining, lead smelting, and use of leaded gasoline are common in many developing countries, where children and adults may receive substantial lead exposure. Effects in children generally occur at lower blood lead levels than in adults (Table 1) because children are more sensitive to lead exposure in a given environment due to their behavior and physiology.

Because of the high hand-to-mouth activity of infants and young children, absorption of lead is estimated to be as much as 5 to 10 times greater in them than in adults. Most human exposure to lead occurs through ingestion or inhalation. Lead exposure in the population occurs primarily through ingestion, although inhalation may be the major contributor for workers in lead-related occupations. Gastrointestinal absorption of lead in children is increased with dietary deficiencies of iron, calcium, zinc, and vitamin C. After it enters the human body, the absorption and biological pathways of lead depend on a variety of factors. Especially important determinants are the

**Table 1** Toxic Effects of Lead at Various Concentrations in Children and Adults

<i>Common Toxic Effects of Lead</i>	<i>Blood Lead Levels (µg Pb/dl blood)</i>	
	<i>Children</i>	<i>Adults</i>
Encephalopathy	85	100
Frank Anemia	75	85
Decreased hemoglobin synthesis	45	55
Increased infertility (men)	—	45
Increased erythrocyte protoporphyrin	18	25
Low IQ	10	—
Decreased hearing and growth	10	—
Hypertension	—	10

physiologic characteristics of the exposed person, including nutritional status, health, and age, along with the type and level of lead exposure.

Lead primarily affects the peripheral and central nervous system, kidneys, red blood cells, and calcium metabolism. It can also cause hypertension, reproductive toxicity, and developmental effects. The blood lead levels associated with encephalopathy in children vary from study to study, but levels of 70 to 80 µg/dl or greater appear to indicate a serious risk. Even without encephalopathy symptoms, these levels can create problems. Although it is often impossible to determine the effects of low blood lead through clinical examination, the developing nervous system of children can be affected adversely with less than 10 µg/dl of lead in the blood. Lead exposure may cause low IQ levels, poor classroom performance, greater absenteeism, reading disabilities, and deficits in vocabulary, fine motor skills, and reaction time. It can also affect hand-eye coordination in young adults more than 10 years after childhood exposure.

Acute, high-level lead exposure has been associated with hemolytic anemia. In chronic lead exposure, lead induces anemia by interfering with heme biosynthesis and by diminishing red blood cell survival. Lead's impairment of heme synthesis can affect other heme-dependent processes in the body outside of the hematopoietic system, including neural, renal, endocrine, and hepatic pathways.

Chelating agents are drugs that bind with heavy metals in the bloodstream, causing them to be discharged from the body in urine and bile. They can be effective at reducing the total body lead burden and acute toxicity effects in individuals with high blood lead levels. However, because of the risk for potentially harmful effects of the chelating agents and the remobilized lead, chelation therapy is generally not recommended for individuals with blood lead levels below 45 µg/dl.

A change in the pro-oxidant-to-antioxidant ratio in favor of the former, because of the production of reactive oxygen species (ROS) by mitochondria, defines *oxidative stress*. The effects of redox active metals on ROS production have been known for years. However, the theory of lead's ability to induce oxidative stress as a redox inactive metal has begun to gain support during the past 10 years. Lead-induced oxidative stress has led scientists to study the protective qualities of antioxidants against lead toxicity, along with their possible chelating abilities. Nevertheless, the use of antioxidants in conjunction with chelating agents as a therapeutic strategy has not been thoroughly investigated.

## **LEARNED HELPLESSNESS**

---

Learned helplessness is a behavior pattern involving a maladaptive response characterized by avoidance of challenges, negative affect, and the collapse of problem-solving strategies when obstacles arise. Three components are necessary for learned helplessness to be present: contingency, cognition, and behavior.

Contingency is the idea that there is an identifiable relation between one's actions and the environmental response, such as tapping a drum and the ensuing sound. In learned helplessness research, contingency is more often operationalized as its converse—uncontrollability—so that when an agent acts, there is no identifiable relation with a specific response. Cognitions are also necessary. These are thought of as the way one understands and explains contingency or lack thereof. How individuals explain environmental contingencies leads to the third component of learned helplessness—behavior. Thus, learned helplessness exists in a situation in which there is no observable contingency and in which one expects that this uncontrollability will continue and behaves accordingly, such as by quitting.

### **ORIGINS OF THE THEORY**

This theory emerged in the mid-1960s as Martin Seligman and Steven Maier's attempt to explain why some dogs failed to attempt to escape electric shocks while others easily escaped. Initially, dogs were placed into a harness and strapped down so that they would not be able to escape the shock. At first, they jumped around trying to evade the shock. Eventually, however, these dogs began passively accepting the shock, failing to respond. What was particularly disconcerting to the researchers was that when these dogs were moved into a different box, they continued to passively accept the shock, failing to even attempt escape even though it was now quite easy. Contemporary learning theory was unable to explain this behavior adequately, and learned helplessness theory was born.

As researchers applied the theory to humans, it became clear that human responses are considerably more complex than animal responses. Initial studies were modeled on the animal studies, using aversive events, experimenter-determined controllability or uncontrollability, and examination of subsequent

responses. Early results were generally supportive of the theory while continuing to raise new questions.

As attribution theory gained prominence in the 1970s, learned helplessness theory was reformulated to include more specific information about cognitive processes. In particular, Abrahamson, Seligman, and Teasdale incorporated humans' tendency to ask "why" when something happens and noted that their answers can often lead to specific and predictable reactions to events. As the theory now proposed, a person need only expect that an outcome is noncontingent for learned helplessness to result. How the expectation of noncontingency is arrived at is less important, whereas causal attributions of why the outcome is noncontingent become more important in predicting the nature of subsequent deficits. These adjustments in the theory proved more powerful in predicting behavior.

### **PROCESSES IN LEARNED HELPLESSNESS**

Uncontrollability seems to be associated with increases in negative emotions such as anger, anxiety, and depression, reduction in observable aggression, and increased arousal. Self-esteem is particularly susceptible to learned helplessness. Research findings imply that individuals who experience noncontingent outcomes may become increasingly likely to display the helpless pattern. An early question in the human learned helplessness literature was whether or not helplessness actually generalized from one situation to another, as it did in animals. Hiroto and Seligman demonstrated that failure to avoid the aversive event was associated with subsequent failure at a cognitive task, and that failure at a cognitive task was associated with failure to avoid the aversive event, effectively establishing "cross-modal helplessness"—generalization from one type of task to another. This was crucial to the advancement of the theory. Critics had claimed learning was situation specific; Hiroto and Seligman's results effectively countered their arguments.

These findings continue to support the idea of helplessness as a coherent set of deficits, rather than simply a task-specific problem. Individuals who demonstrate helpless patterns make statements suggesting that they believe themselves to be personally responsible for failure, to attribute their failures to stable circumstances, and to state that these characteristics encompass their whole selves. In other words, they seem to believe that they have failed because they are stupid,

they are going to remain stupid, and everything they do is stupid—controllability, cognitions, and behavior. This pattern is often referred to as “explanatory style,” and much research has gone into supporting the idea that humans tend to use a particular style to explain both good and bad events.

Critics suggested that perhaps it is adaptive for an individual to stop responding in the face of failure and that failure to solve the problem, not uncontrollability, underlies the helplessness phenomenon. To test this idea, Kofta and Sedek set up an experiment that separated uncontrollability from failure. They demonstrated that, whereas failure resulted in decreased mood, it was the condition of uncontrollability that resulted in task performance deficits. Their data support the idea that participants can distinguish uncontrollability and failure and that passivity as a behavior is a deficit, rather than an appropriate response.

### WHO DOES LEARNED HELPLESSNESS AFFECT?

In 1991, Villanova and Peterson conducted a meta-analysis of the literature on learned helplessness in humans. Meta-analysis is a statistical procedure that combines data from many different studies. Findings suggest not only that humans tend to reliably demonstrate deficits in subsequent performance after failures, but also that the magnitude of this tendency is relatively robust. Furthermore, these findings appear to be consistent across age, gender, and type of task. Evidence of generality is surprising, considering that many researchers believed that certain types of people (e.g., women) may be more susceptible to helplessness than others.

Carol Dweck and colleagues have studied the presence of helplessness deficits in children, finding evidence that children as young as 4 and 5 are susceptible. They demonstrate many of the same characteristics as older children and adults. In a related study, O'Donnell found that 41% of 4- to 6-year-old children who failed on three unsolvable puzzles showed the helpless pattern when later presented with solvable puzzles, lending further support to Dweck's findings. Children exhibiting this pattern have difficulty acquiring and demonstrating cognitive skills in the face of adversity. They demonstrate dramatically poorer outcomes in a wide variety of domains, including social relationships, sports, moral development, and academics. It is apparent that a child's orientation

toward challenging tasks has a compelling impact on the child's future adjustment in a variety of areas.

There is very little evidence at this point describing the antecedents of learned helplessness. Some research suggests a genetic component, noting that monozygotic (identical) twins are more alike in their explanatory style than dizygotic (fraternal) twins. This is thought to be due to their higher level of genetic similarity but could also be explained by their greater degree of shared experiences. Others have looked for correlations between parental explanatory style and children's, finding only slight relations. One promising area is looking at parental provision of structure and intrusiveness. Results suggest that paternal intrusiveness disrupts environmental contingency and may result in adoption of a helpless pattern in early childhood. Clearly, more work needs to be done in this area.

### APPLICATION OF THE THEORY

The primary application of learned helplessness has been to depression and other emotional disorders. Susan Nolen-Hoeksema and colleagues have studied the precursors of depression. They discovered that explanatory style (i.e., cognitions) is a more powerful predictor of depression than negative life events. Pessimism and a general tendency to explain events as internal and stable are correlated with depression. However, it may be that the reverse is true; individuals with a learned helplessness pattern may be more likely to see problems when another person in a similar circumstance sees opportunities.

Much of the empirical work on perceived control has been conducted in academic environments. To understand the relation of control to helplessness, researchers have examined the interaction of the teacher's behavior in the classroom (social context) and children's perceptions of what they have to do to succeed (strategy) and whether they have the capability to do what it takes (confidence). Results indicate that strategy and confidence combine to produce the child's actions (engagement in the classroom) and subsequent outcomes.

We have also learned through several different studies that learned helplessness can be unlearned. Just as dogs in a box can be taught to escape, schoolchildren who are told that they will probably get better at a task also tend to improve. Dweck in particular found that teaching children to attribute failure to lack of effort rather than lack of ability was helpful in

changing subsequent performance. Other researchers have made similar contributions to understanding the retraining process. Peterson has gone so far as to refer to retraining as an immunization against depression, making a comparison to Salk's polio vaccine.

Further research on learned helplessness will consider better ways of conducting research, understanding the relations between explanatory style and behavior, learning how parents contribute, and, perhaps most important, learning how to prevent it.

—Susan L. O'Donnell

## LEARNING

---

Learning is a relatively permanent change in behavior due to experience. As the individual interacts with the environment, certain events promote behavior.

In some cases, the outcomes produced by those responses inform the individual about likely consequences for behavior in future situations. Behaviors include a wide array of events, from basic physical processes to complex higher-order cognitive functions. Thus, behavior is anything the individual does. Given sufficient information about the experience of the individual, predictions can be made about likely behaviors in future settings.

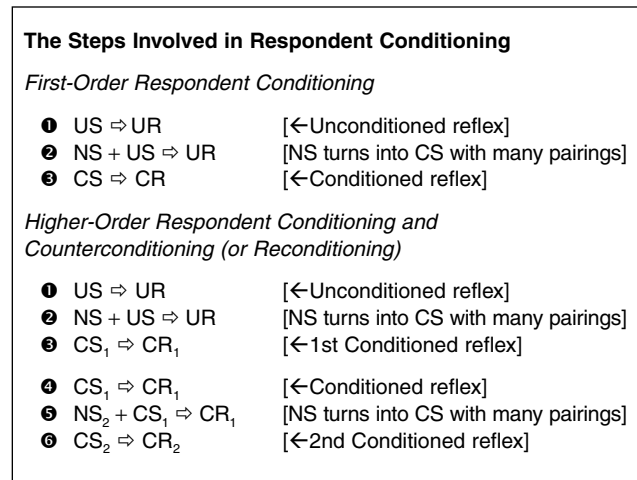

The contribution of biology is unique for each individual and lays the foundation for characteristic interactions with the environment. The particular repertoires of behavior, reflexes, and species-specific patterns of responding that are inherited within a group or organisms are referred to as learned, though at the level of *phylogeny*. In contrast, learning that occurs within the lifetime of a given organism is called *ontogenetic*.

In these interactions, learning can be affected by two general processes. Learning, or conditioning, that occurs in the lifetime of the individual can be produced through association of events or through the arrangement of consequences. Respondent conditioning is the process by which responses are elicited by stimuli that come to control behavior through their relationship with other known events. In contrast, operant conditioning is the process by which the likelihood of behavior is changed by the consequences that follow it in particular settings.

Learning can be the product of naturally occurring environmental relations or through intentionally arranged contingencies. When learning occurs through the use of programmed contingencies, an effort should be made to transfer stimulus control to naturally occurring contingencies to promote generalization and maintenance.

### RESPONDENT CONDITIONING

Respondent conditioning has also been known by other names. Frequently, it is referred to as *Pavlovian conditioning* because of Ivan Pavlov's famous research with the learned salivation of dogs. Additionally, it came to be described as *classical conditioning* to distinguish it from operant conditioning in both entry into the scientific vocabulary of psychology and in how behavior is produced. Both terms, classical and Pavlovian, however, neglect the importance of the automatic nature of responses in the presence of certain stimulus events.

**Figure 1** The Respondent Conditioning Model

Referring to Figure 1, you will see the three-step process involved in respondent conditioning. First, an unconditioned stimulus elicits an unconditioned response. Innate patterns of responding to particular events that occur involuntarily are referred to as *reflexes*. Responses that are present at birth, such as reflexes, are described as unconditioned. Unconditioned responses are behaviors that occur because of the action of unconditioned stimuli. Stimuli are described as persons, objects, or events in the environment that affect behavior. In respondent conditioning, stimuli are said to elicit responding because of automatic or innate behavioral patterns. Elicitation is the process whereby a stimulus has the power to cause a response. Think of the image of a rock flying toward the windshield of your car. You are aware that the windshield will protect you from the rock, but as it hits, you startle and blink anyway. In this case, we would say that the rock elicited, or brought forth, your startle response. It caused you to blink, you did not choose it voluntarily. In fact, you may have had difficulty preventing or minimizing the response because of its automatic or unconditioned nature.

The power that the stimulus has to cause a response in respondent conditioning is great; thus, we say that the stimulus has strong control over responding. Other stimuli may have differing degrees of control. The concept of stimulus control simply refers to how likely a given stimulus is to cause a particular response. Stimulus control is also a factor in how long a given unit of learning is maintained and how readily it is generalized.

The second step of respondent conditioning involves the pairing of a neutral stimulus and the

unconditioned stimulus to elicit the unconditioned response. In addition to reflexes present at birth, new stimulus events that have no previous significance to the individual can also come to control, or elicit, previously known responses through the pairing of these new, or neutral, stimuli with unconditioned, or known, stimuli. Such pairing typically requires many practice trials. However, one trial learning can occur if the association between the neutral stimulus and the unconditioned stimulus is sufficiently strong. The frequency of pairing, saliency of the stimuli, timing of the stimulus presentation, and intensity of stimuli effect how quickly stimulus control will transfer from the unconditioned stimulus to the neutral stimulus to form the conditioned stimulus. It is also important to note that the order of stimulus presentation affects the learner's ability to form associations. Presenting the unconditioned stimulus before the neutral stimulus is called *backward conditioning*, and it is rarely effective at transferring stimulus control from the unconditioned stimulus to the neutral stimulus. Instead, short delays between the presentation of the neutral stimulus and the unconditioned stimulus, or overlapping presentations produce the strongest associations between the two stimuli. It is this association that allows stimulus control to transfer from the unconditioned stimulus to the neutral stimulus.

After a transfer of stimulus control from the unconditioned stimulus to the neutral stimulus has occurred, the neutral stimulus is renamed the *conditioned stimulus* because it will now have the power to elicit the response independently. In the final phase of the conditioning event, we also rename the response, calling it now the *conditioned response* to indicate that it is elicited by the conditioned stimulus. Note that even though seven terms are present in the respondent conditioning event, there are really only two stimuli (one known and one novel) and a single response. The different names for terms at each step indicate the source of control over behavior.

The initial associations established through relationships with reflexes are called *first-order conditioning*. There are many stimuli that elicit responses automatically. For example, think of how you react to a loud noise in a quiet room or a warm cup of soup on a cold day. Stimuli that impact our senses directly are best considered in first-order conditioning events, such as sights, sounds, smells, physical sensations, and tastes. Others may pose that certain social stimuli as smiles or hugs can be included here as well. More

complex patterns of responding can also be established through the association of conditioned stimuli with additional neutral stimuli, producing further conditioned responses. This process is referred to as *higher-order*, or *second-order, conditioning* because both stimuli are conditioned. Through higher-order conditioning, treatments such as systematic desensitization can establish new respondent associations to reverse the effects of such reflexive responding as that seen in phobias.

To determine whether a stimulus is unconditioned or conditioned, one can consider how an adult and a young infant may respond to it. If they respond the same, as in the case of a loud sound in a quiet room, then it is unconditioned. If their responses are different, as would be the case in presenting a \$100 bill to the adult and the infant, then the different response must be the product of ontogenetic learning occurring during the lifetime of the individual, and thus the stimulus is conditioned.

Although the respondent conditioning model may seem complex, it is highly useful in establishing strong and consistent responses to certain events. Stimuli can be conditioned to a variety of responses and even emotional reactions. In fact, kindergarten teachers often use this procedure to establish the classroom as a pleasurable and desired environment by filling it with stimuli most children enjoy, thus creating an association between school and fun and increasing the child's inclination to attend.

Once behavior is learned through respondent conditioning, it can be maintained, reconditioned, reduced through extinction, or generalized. Behavior may also come under the control of operant conditioning contingencies.

## OPERANT CONDITIONING

In operant conditioning, behaviors are said to operate on and to be changed by the environment. Specifically, particular stimuli are present in a given setting and come to occasion responding, which in turn produces certain stimulus effects. The stimuli present before behavior are referred to as *antecedents*. Antecedent stimuli function to set the occasion for, or evoke, behaviors in that they signal appropriate times for the individual to emit each behavior. Antecedents gain strength in their ability to evoke responding through their reliable occurrence in the presence of certain consequences. Consequences are stimuli that are produced as a result of behavior and affect the

**The Operant Five-Term Contingency**

**Figure 2** The Operant Conditioning Model

probability that the behavior, and similar responses, will occur again in similar settings. It is a misconception to think of consequences as something to be avoided; rather, they are defined by their ability to influence the occurrence of a particular behavior again in the future. Some consequences increase the likelihood of a response, and some diminish this probability. Either way, consequences are neither good nor bad; they merely help us to make predictions about what we are likely to do and why behavior persists.

Operant conditioning is described by a five-term model. As seen in Figure 2, the most basic portion of this model is the A-B-C analysis. Antecedents evoke behaviors, which then produce consequences. The evocative function of antecedent stimuli is distinct from the eliciting function of stimuli in the respondent conditioning model. Although both evocation and elicitation rely on stimulus control, the control stimuli exerted in operant conditioning are dispersed across the antecedent stimulus, the setting, the motivation of the learner, the control exerted by competing stimuli, and other factors. Antecedents are said to set the occasion for responding. In this conceptualization, stimuli might be thought of as signals, predictors, or influencing factors, but not causal events.

This A-B-C event occurs in the context of a particular setting and is further influenced by setting events present before the individual enters the setting. Setting events include elements that function to motivate the individual because of states of satiation and deprivation, sometimes called *establishing*, or *motivating, operations*.

The operant conditioning model includes four principles of learning: reinforcement, extinction, punishment, and stimulus control. Stimulus control was discussed previously. Thus, the remaining principles will be examined in more detail.

## Reinforcement

Reinforcement is the process by which consequences are applied to increase the future probability of a given response. Reinforcement, like all principles of learning, is defined functionally, that is, by the effect that the consequence has on behavior. If a stimulus is presented or removed following the occurrence of a particular behavior, and that behavior occurs again in a similar setting in the future, we would say that reinforcement was in effect. When a pleasant stimulus is presented and behavior reoccurs, then we would say that positive reinforcement has been provided. In the context of this definition, the term *positive* refers to the presentation of a stimulus immediately following a response and should not be confused with the common use of the word positive to refer to something as good or encouraging. Conversely, when an aversive stimulus is removed following the emission of a behavior and that behavior becomes more likely to occur again in the future, the process is called negative reinforcement. The term *negative* in this context refers to the removal of a stimulus following a response and should not be confused with the common use of the word negative to refer to something as unpleasant or harmful. In both cases, whether the behavior is changed by the presentation or removal of a stimulus, behavior must always have an increased probability of occurrence following the consequence to be defined as reinforcement. Quite simply, behavior must continue to happen or happen more often after a stimulus follows behavior for reinforcement to have taken place.

When one is attempting to establish a new behavior, it is important to provide a reinforcer following each occurrence of the target behavior. This is called *continuous reinforcement*, and it facilitates the acquisition of new repertoires by providing a consistent set of consequences for behavior. Once behavior has been established, the schedule of reinforcement can be thinned such that every other behavior, for example, can be reinforced and still maintain a consistent performance on the part of the learner. This thinning of the delivery of reinforcement has the advantage of more reliably approximating the reinforcement delivered in everyday settings. This will facilitate the transition of the learner from a programmed teaching environment to a more natural setting.

An intermittent schedule of reinforcement can be changed in two ways: in a fixed or variable manner. Fixed schedules of reinforcement have a preset amount

of behavior that must occur before reinforcement is delivered. In contrast, variable schedules work around an average amount of behavior. Behavior can be measured along the dimensions of ratio, duration, or interval. A ratio schedule requires that a fixed or variable number of responses occur before a reinforcer is delivered. Duration schedules measure the amount of time that a behavior occurs. Interval schedules measure the amount of time between the first behavior and the repetition of that same behavior. Thus, one might use an intermittent schedule of reinforcement to maintain a known behavior on a fixed or variable ratio, duration, or interval schedule.

In common nomenclature, the terms reinforcement and reward are used synonymously. This use is incorrect in that it fails to distinguish the characteristic effect on behavior that reinforcement has. Consider the example of a reward for a lost kitten. This may function as an antecedent for some, but not others, to search for the kitten. A bully might steal the kitten from me and claim the reward; the reward will not change the bully's searching behavior (although bullying might be reinforced). The behavior of searching may "pay off" if you are the first to bring the correct pet to its owner. Additionally, one must consider that not all stimuli are equally reinforcing to all learners all of the time. If searching happens more often after receiving a monetary reward, then reinforcement of searching behavior has occurred.

## Extinction

Once a behavior is conditioned through the use of reinforcing consequences, it can be maintained, changed, diminished through extinction, or generalized. Maintenance is when a behavior persists over time, even after the contingencies that established it are no longer present. A behavior that was once reinforced, such as thumb-sucking in a young child, can later be punished. This change in consequences will change the likelihood of that behavior reoccurring. An operant behavior may be extinguished by withholding or changing the consequence that established it. Withholding reinforcement for a previously reinforced response is referred to as *operant extinction*.

A common outcome of extinction is an extinction "burst," or an increase in the previously reinforced response immediately after an extinction procedure has been introduced. Extinction bursts are common because the individual is conditioned to receive a certain

reinforcer following a specific response, and when that reinforcer does not follow the response, the individual repeatedly emits the response as in the past to produce the reinforcer. Over time, the rate of the response decreases to zero in the absence of reinforcement. Occasionally, after a period in which the behavior is not observed, it may reemerge. *Spontaneous recovery* occurs when the individual emits the extinguished response after a period of time has passed from the extinction procedure. If the response still produces no reinforcement, it again is extinguished. A final possible outcome for an established response is that it may generalize to occur in new settings. There are two types of generalization: stimulus generalization and response generalization. In the case of stimulus generalization, a class of functionally similar stimuli can come to evoke a known response. Response generalization occurs when a class of functionally similar responses comes to be evoked by a single known stimulus.

## Punishment

Punishment, like the other principles of learning, is defined functionally by its effect on behavior. Punishment is a process that produces a decrease in the probability of that behavior occurring in again the future. Punishment is often mistakenly thought of as something painful, cruel, or at least unpleasant. Although it is true that aversive control is exercised in punishment, that is, stimulus conditions that the learner does not prefer are arranged, the use of punishment should be governed by the highest standards of ethics, and it should always be used as an intervention of last resort.

Punishment can operate in two ways. First, positive punishment is defined as the presentation of a stimulus immediately after a response, which decreases the probability of that response occurring in the future. Some examples of positive punishment include overcorrection, positive practice, and physical restraint. Overcorrection is a punishment procedure that calls for the individual to restore the environment to a more improved state than it was in when the behavior occurred. Positive practice procedures involve requiring the individual to correctly complete a task repeatedly, following an instance of incorrectly performing the task. For example, the individual throws trash in the sink as opposed to the garbage. To reduce the probability of performing the incorrect form of the behavior,

a positive practice procedure would involve requiring the individual to repeatedly throw trash in the garbage. Physical restraint procedures are also considered to be positive punishment in that a physical restraint is presented after the behavior to reduce that behavior in future settings.

The removal of a stimulus immediately after a response, which decreases the probability of that response occurring in the future, is the second type of punishment: negative punishment. Time-out and response cost procedures are examples of negative punishment. Time-out procedures involve removing the individual from a reinforcing situation following the target response, or not allowing reinforcement for a specified amount of time following the target response. Response cost is a procedure usually associated with a token economy. A response cost procedure entails removing tokens, or similar items already earned, as a result of an occurrence of the target behavior.

Regardless of the type of punishment used, it must always have the effect of decreasing the probability of that response, and similar responses, in the future. In light of this definition, it is interesting to consider the prison system. Most would consider it a punishment system. However, it can only be punishment if the probability of the criminal behavior that produced the incarceration is decreased. For the many inmates who commit the same crime again following release, prison might be more appropriately defined as a reinforcement system, or one that has no consequential effect on behavior for that learner.

There are many considerations to make before implementing a punishment procedure. Punishment procedures can produce a wide array of side effects. These side effects include negatively reinforcing the behavior of the punisher, aggression, an increase in escape-motivated and avoidance-motivated behaviors, modeling of future punishment behaviors, and ethical conflicts.

### *Ethics of Punishment*

There are many ethical issues associated with the use of punishment procedures in clinical settings. An important rule to remember is that professionals should always be seeking the most effective and efficient strategies to promote the success of the learner that are the least restrictive for the client. Punishment procedures are intrusive by nature, and the client's fundamental human rights must be carefully considered.

A thorough review of prior intervention plans and reasons for their failure should also be considered when considering the adoption of a punishment procedure. A punishment procedure should have a clear rationale. Informed consent should be obtained before starting any punishment procedure. Meeting with the client or the parent or guardian of the client and reviewing the history of the client and prior methods that have failed to produce a lasting behavior change is part of the process of obtaining informed consent. The proposed punishment procedure should be carefully explained, including possible side effects of the procedure. All of the members of the team should have ample opportunity for questions and suggestions and to experience the punishment procedure themselves. If the individual or parent or guardian demonstrates an understanding of the procedure and provides written consent, the procedure may be put in place under the supervision of a qualified professional. As with any learning program, the learner's level of behavior before, during, and after the intervention should be carefully measured and constantly evaluated.

## MODELING AND IMITATION

In addition to biological inheritance and respondent and operant conditioning, learning can also occur through the process of modeling and imitation. In social settings where learners are present who have acquired a particular skill, they may demonstrate that behavior in the presence of other learners. Behaviors are more likely to be modeled if there is similarity between the learner and the model, if the consequences of behavior for the model are favorable to the learner, and if the learner has a history of reinforcement for the imitation of the behavior of others. Once a learner performs a behavior, it can be shaped by the environment. Thus, it may be strengthened through reinforcement, weakened through punishment, or changed in other ways by the action of the environment.

Imitation of the behavior of a model may occur immediately, or after a time delay. Models can be present directly to the learner or can appear through other media, including video, books, games, or even verbal descriptions. In some applications of modeling for teaching new skills, the learner may even serve as an appropriate model for later imitation through the use of video recording. Self-modeling has been used in many settings to establish many behaviors.

## PRINCIPLES AND THEORIES

Important distinctions can be made among principles of learning, theories of learning, and learning theorists themselves. The scientific study of how individuals learn has revealed the fundamental principles of learning that govern the behavior of all living organisms. These principles include reinforcement, punishment, extinction, stimulus control, and respondent conditioning.

The study of human behavior has demonstrated that certain patterns of responding can be observed in individuals with similar characteristics when placed in similar types of settings. These consistencies have given rise to a variety of theoretical analyses of learning. Unlike principles of learning, theories of learning may not have universal applicability. However, they may have useful and broad explanatory appeal and often shape social and political policy.

## TEACHING AND LEARNING

The science of learning is a rich source of information for the design of effective and efficient teaching and learning environments. Learning can be facilitated through the application of sound teaching practices. All learners can benefit from the application of maximally effective practices; although in the case of learners with special needs, the power of remedial and accelerated learning programs is dramatically enhanced by the adoption of teaching and learning practices with demonstrated effectiveness.

Creating learning environments that maximize motivation without being distracting is important. Learners' unique repertoires of strengths and learning opportunities should be assessed. Individualized curricula, goals, and monitoring programs are appropriate for students of all types. Many classrooms will employ peer groups, learning stations, and carefully selected lessons matched to each student's repertoire to facilitate simultaneous instruction of learners at the appropriate level.

## LEARNING DISABILITIES

---

*Learning disability* is a general term that describes specific kinds of learning problems. It is thought to be a neurological or processing disorder that affects the brain's ability to receive, process, store, and respond to information. It can cause a person to have difficulty learning and using certain skills despite having at least average intelligence. The skills most often affected are reading, writing, listening, speaking, reasoning, and doing math.

The legal definition of learning disability comes from the Individuals with Disabilities Education Act (IDEA). This is a federal law that guides how schools provide special education and related services to children with disabilities. IDEA defines a specific learning disability as "a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculations, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia." However, learning disabilities do not include learning problems that are mainly the result of visual, hearing, or motor disabilities, of mental retardation, of emotional disturbance, or of environmental, cultural, or economic disadvantage. Many states use a discrepancy formula to define learning disability. That is, the student shows a gap, often of 2 years or more, between his or her IQ score and achievement level in a particular area.

### HOW COMMON ARE LEARNING DISABILITIES?

As many as one in five people in the United States has a learning disability. About 5% of the total population of all school-age children receive special education or related services because of a learning disability. The percentage of children classified as learning disabled has increased substantially—from less than 30% of all children receiving special education services in 1997–1998 to a little more than 50% today.

About three times as many boys as girls are classified as learning disabled. The gender difference has been given several explanations, such as greater biological vulnerability for boys and because boys are more likely to be referred as a result of their disruptive, hyperactive behavior. Social class is associated with learning disability because the risk for exposure to harmful toxins, such as lead and tobacco, at early stages of development is greater in low-income communities.

The most common learning disability is reading disability, especially phonological skills, which involve understanding how sounds and letters match up to make words. Dyslexia is a severe impairment in the ability to read and spell.

One of the most talked about learning disabilities is attention deficit disorder (ADD) or attention deficit hyperactivity disorder (ADHD). About one third of people with a learning disability also have ADHD. It is characterized by extreme hyperactivity and distractibility, which makes it difficult for them to concentrate, stay focused, or manage their attention to specific tasks. Treatment has typically been in the form of either mild stimulants such as Ritalin or behavior modification techniques.

### CONSEQUENCES OF LEARNING DISABILITIES

Learning disabilities affect every person differently. Most learning disabilities are lifelong. Compared to people without a learning disability, those with a learning disability are more likely to show poor academic performance, high dropout rates, and poor employment.

Children with a learning disability who are taught in the regular classroom without extensive support rarely achieve the level of competence of even children who are low achieving and do not have a disability. However, with appropriate help, people with learning disabilities can and do learn successfully. They can be high achievers and can be taught ways to get around the learning disability. Despite the difficulties they encounter, many children with learning disabilities grow up to lead normal lives and carry on productive work.

### CAUSES OF LEARNING DISABILITY

Experts are not exactly sure what causes learning disabilities. A leading theory is that learning disabilities stem from subtle disturbances in brain structures and functions, which in many cases begin before birth. Heredity may be a factor because learning disabilities

tend to run in families. Learning disabilities may be caused by drug or alcohol use during pregnancy, illness or injury during pregnancy or labor, low birth weight, lack of oxygen, and premature or prolonged labor. After birth, the occurrence of head injuries, nutritional deprivation, and exposure to toxic substances such as lead are associated with learning disabilities. Learning disabilities are not caused by economic disadvantage, environmental factors, or cultural differences. In many cases, there is no apparent cause for the learning disability.

## IDENTIFICATION

There is no one sign or set of clues that a person has a learning disability. Experts look for a noticeable difference between how well a child does in school and how well the child could do, given his or her intelligence and ability. Some signs of learning disabilities are listed here. Most of them relate to elementary school tasks because learning disabilities tend to be identified in elementary school. If a child shows a number of these problems, the possibility that a learning disability is present should be considered. When a child has a learning disability, he or she may have difficulty learning the alphabet or rhyming words, have difficulty with spelling, struggle to express ideas in writing, have messy handwriting or hold a pencil awkwardly, learn language late and have a small vocabulary, not know where to begin a task or how to proceed, or not be able to retell a story in order. These are only a few of the potential signs of a learning disability.

If there is reason to believe a person has a learning disability, it is important to collect observations by parents, teachers, doctors, and others regularly in contact with that person. If there does seem to be a pattern of difficulty that is more than just an isolated case of trouble, the next step is to seek help from school or consult a learning specialist for an evaluation.

It is better to identify learning disabilities early so that appropriate educational opportunities can be provided. Observe the way the child develops language, motor coordination, and social skills and behaviors important for success in school. Not all children who are slow to develop skills have a learning disability. There are very large individual differences in development.

## INTERVENTION STRATEGIES

There is no single intervention or treatment for learning disability. In general, effective interventions

that use a combined model of strategy instruction and direct instruction in the skill area are most effective. Recommended instructional strategies include small interactive groups, peer tutoring or mentoring, technology such as computer training programs, augmentation of teacher instruction using homework or other extra practice, directed questioning, and strategy cueing.

Reading disability has received the most research attention. The most common core deficit for those with reading disability is a deficit in phonological processing skills, especially phonological awareness, which is associated with difficulty learning to decode and recognize words. Individuals typically have difficulty translating a written word into units of sound. In other words, most cases of reading disability are associated with a deficit in verbal language skills, not in visual skills. It is a common misperception that dyslexic people reverse letters. Interventions designed to improve phonological awareness and letter knowledge skills have proven to be moderately effective. This is especially true if the intervention is begun early, is intensive, and is carried out by trained personnel.

## LEARNING DISABILITY AND THE CLASSROOM

Depending on the type and severity of the learning disability, as well as the person's age, different kinds of assistance can be provided. In 1975, the U.S. Congress passed Public Law 94-142, the Education for all Handicapped Children Act, which mandated for the first time that all U.S. children, regardless of handicap, were entitled to a free and appropriate education in the least restrictive environment possible. Under the Individuals with Disabilities Act (IDEA) of 1997, which renamed the 1975 law, and the Americans with Disabilities Act (ADA) of 1990, people of all ages with learning disability are protected against discrimination and have a right to different forms of assistance in the classroom and workplace. These protections are not designed to provide an advantage for the person with the learning disability but instead to provide them with the assistance they need to learn in an appropriate environment. This assistance is prescribed by law and is to be provided at public expense.

Mainstreaming, the educational practice of including special education students in regular classrooms for parts of the school day, and full inclusion, placing the special education student in the regular classroom for the full day, have become more common. This has

been partially in response to calls to reduce the stigma of being labeled as learning disabled, to expose the learning disabled child to the real world, and to provide the learning disabled child access to more advanced curricular content. The research on the effects of mainstreaming are inconclusive, based on a small number of studies, and focused more on children with mild learning disabilities than with moderate and severe disabilities. The general conclusion at this time is that there is a small to moderate beneficial effect of inclusive education on the academic and social outcomes of special-needs children. However, this effect should be evaluated in terms of the type and severity of the learning disability, the quality of training provided to the teacher, and the level and kinds of support available in the school system.

## SUMMARY

Learning disability is a complex topic. It is very common, but there remains much debate about how to identify and serve the needs of those with a learning disability.

## LESBIANS

A lesbian is a woman or girl who is sexually or romantically attracted to females, or who engages in same-sex behavior or relationships. The word *lesbian*

was coined in the 17th century based on the Greek island of Lesbos, where the female poet Sappho wrote erotic poetry about love between women in the 7th century BC. In the late 18th and early to mid-19th century, lesbianism was considered sexually deviant by notable psychiatrists such as Sigmund Freud (1856–1939) and Helene Deutsch (1884–1982), who viewed lesbians as manly or having penis envy. Even today, it is difficult to estimate the prevalence of lesbianism due to continuing negative stigma. Although some lesbians are “out” or openly identified as lesbian, many more are “closeted,” hiding their sexual orientation.

The 20th century broke new ground for lesbians because of the emerging urban subcultures such as Harlem in New York City and Berlin, Germany, where bars and parties created an early gay and lesbian community in the 1920s and 1930s. The late 1960s and 1970s were especially significant for U.S. lesbians (and gay men). First, in 1969, the Stonewall Inn Bar in New York City’s Greenwich Village became a site of activism that changed the gay and lesbian community forever. Police raided the bar, and for the first time in the United States, gays and lesbians fought back against discriminatory harassment. The modern Lesbian, Gay, and Bisexual Movement arose from this protest.

Additionally, in the 1960s and 1970s, the second wave of the U.S. Women’s Liberation Movement helped to further develop individual lesbian identity, connecting political affiliation and sexual choice together under Lesbian Feminism. Classifying oneself as a woman-identified-woman or a lesbian separatist became a political statement against, among other things, economic dependence on men.

In the 1980s and 1990s, third-wave feminists increasingly used the term *queer* to refer to all sexual minorities, including lesbians. There was also increasing awareness of the diversity of the sexual minority experience, including race, ethnicity, socioeconomic class, and cultural and national differences. A new development was the concept of *gender* as continuous, changing, and socially constructed rather than as binary, static, and biologically determined. Changing notions of gender identity influenced definitions of sexual orientation—someone who used to identify as a heterosexual man might now identify as a woman (still attracted to women, as before), thus as a lesbian.

Changing concepts of gender also influenced the meaning of masculinity and femininity. Before second-wave feminism, lesbians imitated the gender

roles of heterosexual couples; a lesbian was either *butch* (acting, dressing, and identifying as masculine) or *femme* (correspondingly feminine). During the women's movement of the 1970s, wearing androgynous, comfortable clothing, having short hair, and using no makeup were standard appearance for lesbians. Now there is a reemergence of butch and femme roles among lesbians, although with more fluidity and flexibility than before. Thus, lesbians of different age cohorts may have different norms about appropriate and desirable ways to look like a lesbian.

Resulting from the explosion of gay activism in the United States during the 1960s and early 1970s, the psychiatric field began to reevaluate its classification of homosexuality. In 1973, the American Psychiatric Association removed homosexuality as a mental illness from the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*. Social science research on lesbianism changed from a focus on pathology to an emphasis on the lesbian experience. Recent research has included the coming-out process, lesbian parenting, lesbians in couples, and issues facing lesbian youth, among others. There is still little research (and much controversy) about the origins of sexual orientation and developmental stages in the coming-out process.

## LESCH-NYHAN SYNDROME

Lesch-Nyhan syndrome is an X-linked recessive inborn error of purine metabolism caused by absence of, or deficiency in, hypoxanthine-guanine phosphoribosyl transferase (HPRT). HPRT metabolizes hypoxanthine and guanine to uric acid. First described in two brothers by Lesch and Nyhan in 1964, the disorder is fortunately rare, occurring in less than 1 in 200,000 births. It affects almost only males and is apparently equally distributed geographically and among ethnic groups. The disease is either inherited or arises through genetic mutation. The expression of the gene is fully recessive, making the disorder virtually exclusive to males by transmission from their mothers. Females can be carriers, but rarely exhibit the disease. A few reported cases in females are believed to have occurred through genetic mutation.

### DIAGNOSIS

Owing to its similarities to other brain disorders such as cerebral palsy, Lesch-Nyhan should be diagnosed through appropriate laboratory tests. These include HPRT-activity testing in tissue samples, prenatal enzyme assay, and DNA analysis through amniocentesis or chorionic villus sampling.

### CHARACTERISTICS

The disorder is characterized by numerous neurological-behavioral motor abnormalities, the most horrific being severe and chronic self-injurious and aggressive behaviors. Self-injurious behaviors (SIBs) are so persistent and potentially damaging that physical restraint is generally required. The most frequent SIBs are hand biting and lip chewing, which often lead to considerable tissue loss. Because pain perception is normal, affected children may scream while emitting SIBs and beg to be physically restrained. Lip chewing can be so self-mutilating that teeth extraction is necessary, even in infancy. Other motor dysfunctions include choreoathetosis (slow, wormlike large muscle movements), spasticity, hypertonicity, and articulation and

chewing-swallowing problems. Although mental retardation has been seen as a regular feature of Lesch-Nyhan syndrome, the motoric dysfunctions make interpretation of standard intelligence test scores difficult. Some affected boys have shown normal memory skills, range of emotions, concentration abilities, self-awareness, and social skills, suggesting that the degree of general cognitive deficiency may often be overestimated. Sensory functioning appears to be normal. Morales presents a detailed description of characteristics of Lesch-Nyhan individuals.

The extreme overproduction of uric acid results in gout, hyperuricemia, and other manifestations of renal dysfunction.

## DEVELOPMENTAL COURSE

Lesch-Nyhan individuals appear normal at birth. The earliest sign of the disorder occurs at about 10 to 30 days of age when high levels of uric acid, indicative of renal dysfunction, lead to orange crystalline deposits in diapers. Affected infants show normal motor development usually until 3 to 6 months of age, when they begin to show marked hypotonicity, delays in motor development, and loss of previously acquired motor skills. At about 6 to 12 months of age, hypotonicity is replaced by hypertonicity: arching of the back, poor head control, choreoathetosis, spasticity, and other involuntary motor movements. Affected individuals are generally unable to sit or stand without assistance. Speech is greatly delayed and limited.

Self-mutilation begins at about 2 years of age and may lead to differential diagnosis from cerebral palsy. Self-injurious and aggressive behaviors become more severe and destructive with age. The earlier the onset of SIBs, the worse they become over time. Motor dysfunction is also progressive, with greatest deterioration occurring in later childhood; hip dislocation and leg scissoring may result in serious injury unless the individual is closely monitored.

## TREATMENT

Allopurinol effectively reduces HPRT-based hyperuricemia and its various renal effects, including gout, but does not reduce neurologic abnormalities. Serotonin reuptake inhibitors, used to correct dopamine and serotonin levels, have shown short-term improvements, but over time, effectiveness significantly diminishes. Benzodiazepines may be prescribed for

behavior control, although they do not have long-term effects on self-injury.

Treatment of motor dysfunctions has limited effect. The best preventative strategy for self-injurious and aggressive behavior has been stress reduction and protective restraint. Behavior modification successfully reduces such behaviors in some cases, as described by Olson and Houlihan, but no commonly effective treatment is available. Differential reinforcement of other (DRO) behaviors and differential reinforcement of incompatible (DRI) behaviors are perhaps most effective and relatively unlikely to have iatrogenic effects. Extinction, although sometimes effective, is both slow and risks danger of bursts of SIBs owing to frustration. Punishment with electric shock actually increased SIBs in one case, whereas punishment with spraying vinegar solutions in combination with reinforcement for other behaviors reduced SIBs in another. Particularly with explicit programming, generalization across settings and long-term effects may occur.

Research suggests that self-mutilation is based on reduced dopamine-neuron function and norepinephrine turnover. Recent development of HPRT-deficient animal models, as well as research with affected humans, may lead to understanding of the biochemical basis of self-mutilation and more effective treatment.

## LITERACY

---

The acquisition of reading and writing skills—especially reading—always an important element in American education, has received growing attention in recent years, as exemplified by the No Child Left

Behind (NCLB) Act enacted by Congress in 2001 and signed by President Bush in 2002. The legislation begins with a concentration on reading and mathematics achievement, with attention to other content areas added over a period of time. The goal for reading is that by 2014 every child in the United States will be a proficient reader at grade level, as documented by rigorous, standardized, criterion-referenced, statewide tests. All children will demonstrate competency by the end of third grade. NCLB is designed to support programs to help children build language and pre-reading skills before they start kindergarten, and it mandates that all reading instruction should follow scientifically based research.

An elaborate system has been set up to document progress. In the case of reading, each state is required to test all children annually in grades 4 through 8 and once in high school. Annual goals are established on a statewide basis for the percentage of children projected to demonstrate proficiency. Goals are set for school enrollment in general and for categories including gender, race/ethnic status, income level, and disability. States, school districts, and individual schools are expected to make adequate yearly progress toward the stated goals, with consequences for those not demonstrating progress. Present achievement gaps that now exist by gender, race, income, and disability will be erased by the year 2014.

The stated goals are laudable and ambitious. It would be helpful to contrast them with the extant data on reading achievement on American children. This is difficult because there is no one consistent set of instruments for the assessment of reading in children across the country. There are some international assessments, but these typically are norm referenced, are given to small samples, and are of questionable validity. The best resource presently available is the National Assessment of Educational Progress (NAEP), also known as *the Nation's Report Card*. NAEP has been in existence since 1969 and tests samples of children from public and private schools in each state at grades 4, 8, and 12 in 11 different subjects, including reading and writing. State-level results were reported for approximately 350,000 children for reading in 2003 and for writing in 2002.

The data present a picture of the challenge presented by the goals of no child left behind. In 2003, less than one third of fourth graders tested across the nation were rated proficient or above in reading, 33% of females and 26% of males. By race, 39% of white

children, 12% of black children, and 14% of Hispanic children were rated proficient. In only one state, Connecticut, did more than 40% of children achieve proficiency. The eighth grade results were quite similar, with comparable gaps by gender and racial category, except that in no state did 40% of children achieve proficiency.

The results for the writing assessment were similar. Only 27% of the national sample of fourth graders were rated proficient, but the gender gap was more pronounced, 35% of females and 18% of males. By race, 32% of white children, 14% of black children, and 17% of Hispanic children achieved competency. In only two states, Connecticut and Massachusetts, did more than 40% achieve proficiency. As in the reading assessment, the eighth grade results were similar, with comparable differences by gender and racial status.

Clearly, there is a gap between the real and the ideal. The goal of 100% proficiency by 2014 seems unrealistic given the evidence that in 2002 and 2003, fewer than 30% of American fourth and eighth graders were rated as proficient readers and writers, with males, minority children, and children in several states falling far below the averages. Ultimately, success will be measured by how close we come to the ideal goal, not its actual attainment.

On the surface, the acquisition of reading and writing skills should be relatively simple. It has been likened to training the eye and hand to do the work of the ear and tongue. Because children typically have already mastered the basic structure and functions of spoken language before they are exposed to formal literacy instruction, it would seem that it would be relatively easy to match speech to print, a process of phoneme (sound) to grapheme (print) correspondence. Once the connections are made, the child should be literate. Of course, the situation is not quite so simple. Large numbers of children never learn to read and write competently. The NAEP and thousands of research reports document this. Although spoken languages and print languages are quite complex and involve processing on several different levels, there are also some fundamental differences. The most obvious difference is that children learn a spoken language naturally, without direct instruction. They are active learners who, to a large degree, have mastered phonological, morphological, syntactic, semantic, and pragmatic aspects of a language in a relatively short period of time without conscious effort. They are active learners and do not have to be directly taught.

In fact, if a child does not demonstrate linguistic competency well before the beginning of schooling, this, in itself, is reason for concern.

The phoneme-grapheme correspondence between speech and print is inexact, and the 43 or 44 phonemes of American English, depending on dialect, are represented by only 26 letters. Even there, the representation often is not logical, with readers aware of almost endless inconsistencies in the spelling of spoken words. To compensate for this and other inadequacies in the print code on English, we resort to devices such as upper- and lowercase letters, commas, periods, hyphens, sentences, and paragraphs. The apparent simplicity of a print system hides significant complexities.

Over the years, the inability to develop satisfactory levels of literacy in the population as a whole has led to ongoing conflict that at times has been referred to as the *reading wars* or the *great debate*. Although there has been tremendous diversity within each camp, three distinct approaches may be identified. One approach has been characterized as a top-down model, also referred to as using *whole language*, or *look-and-say, instruction*. In this, the emphasis is on content and the child constructing meaning from print. The child begins with inferences and expectations and proceeds through text to verify or modify predictions and generate new ones. Relatively little emphasis is given to spelling, sounding out of words, or other word-attack skills. The same philosophy is applied to writing. Young children are encouraged to express themselves, and their ideas are given precedence over technical concerns such as spelling, punctuation, and subject-verb agreement. It is assumed these skills will develop over time.

In opposition to the top-down model is the bottom-up model, which may be characterized as utilizing a building-block, elemental, word-attack strategy. Children are encouraged to sound out words, and there is an emphasis on what has been labeled “phonics.” Meaning is in the text, not in the child. The goal of instruction is to provide the child the skills to “break the code” and to establish the relationship between sound and print. To a large degree, a bottom-up approach involves drill and practice and rote learning. Writing instruction emphasizes spelling, punctuation, grammar, and vocabulary development.

A third, or interactive, model holds that reading and, by extension, writing are a complex interactive process that simultaneously involves bottom-up

(text-based) and top-down (cognitively based) processes that interact with and complement each other. The implication is that either a top-down or bottom-up model is insufficient for the development of true literacy and that an interactive, parallel processing model is preferable.

Research in relative effectiveness of the different model, from our perspective, has been mixed. In American education, the traditional approach to literacy followed a bottom-up paradigm, albeit under different labels. This began to change as early as the 1920s, with the introduction of look-and-say readers and a shift to holistic instruction. Conflict over the perceived success or failure of top-down models flared over the last third of the 20th century, with concerns that “Johnny can’t read.” In recent years, the pendulum has swung back toward a bottom-up approach, and a concentration on “phonics.” In fact, the No Child Left Behind legislation that calls for instruction to be scientifically based and research based states that instruction in literacy should be grounded on instruction utilizing phonics. It has been widely reported that, regardless of prevailing trends, teachers, with pragmatic concerns of teaching real children, tend to utilize elements of both top-down and bottom-up models, hopefully approaching the idea of an interactive system.

## LOCKE, JOHN (1632–1704)

---

Born in Somerset, England, John Locke was a noted philosopher and academician, political adviser, and physician. Educated as a child at the Westminster School, Locke endured an educational regimen that stressed strict adherence to rules, severe punishments, and rote memorization. Undoubtedly, Locke's dissatisfaction with his education at Westminster was responsible, to a significant extent, for both his stalwart support of home schooling and private tutors and his forceful criticism of institutional education.

Much of Locke's views on education and human development—set forth in a series of letters to a cousin

and later published as *Some Thoughts on Education*—reflected his philosophical writings on the nature of knowledge and human understanding (although scholars differ on the precise relationship between these two bodies of work). In *An Essay Concerning Human Understanding*, Locke argued that the human at birth is a *tabula rasa* (blank slate), entirely devoid of any ideas or other mental content. All the content of the human mind is derived from the data of sense experience, which is then transformed into increasingly complex ideas through reflection and reason. Crucial to Locke's philosophical view, and of great significance for his thoughts on education, was his emphasis on the role of experience in the acquisition of knowledge. In the first paragraphs of *Some Thoughts on Human Education*, Locke contended that the depth and breadth of one's knowledge are overwhelmingly a product of education and experience, as opposed to natural intellect. Locke recognized that children were born with different aptitudes that, for the most part, could not be significantly altered. Furthermore, Locke believed that children possessed a natural disposition for reason. In this regard, Locke's view on childhood challenged the prevailing attitude of his day, according to which children were to be viewed suspiciously because they were inherently prone to vicious behavior. According to Locke, children should be thought of and treated as rational beings, with an inherent disposition for virtuous behavior. And children are best able to develop their intellectual and social skills, according to Locke, through various kinds of play and the practicing of certain skills, rather than through rote memorization of assorted rules.

Locke's writings on education influenced successive work in education theory long after his death. By the end of the 19th century, *Some Thoughts on Education* had been through numerous English editions, as well as several editions in French, German, and Italian.

## LOCUS OF CONTROL

---

*Locus of control* (LOC) is a term used to refer to individual perceptions regarding personal control, particularly with regard to control over important outcomes. For example, have you ever tried to convince someone to vote, emphasizing the impact his or her vote could have in an election? Have you ever known someone who did not apply for a job promotion, deciding instead that his or her hard work did not matter as much as “who you know”? These examples illustrate how our motivation for performing a particular task may be influenced by how much we feel our actions influence certain outcomes or, conversely, the extent to which we feel end results will be due to forces outside of our control.

### WHAT IS LOCUS OF CONTROL?

Julian Rotter first proposed the concept of LOC in 1966 while attempting to develop a more accurate model of social learning theory (SLT), a theoretical model that predicts the likelihood that a person will exhibit a particular behavior. Much of the work calculating human behavior up until that point adhered to a strict behavioral model. That is, it examined the execution of behavior as being contingent primarily on how rewarding the end result would be for an individual. Rotter was one of the first to incorporate a cognitive component to this model, stating that behavior is not simply contingent on the value of the reinforcer, or end goal. Rotter theorized that the extent to which a person believed that his or her behavior could affect the outcome of an event would also contribute to whether the behavior was executed. SLT has since been expanded on, but this expectancy component is still considered to be an important factor in predicting behavior. It is this expectancy belief regarding an outcome that is referred to as LOC.

A person's LOC can be either internal or external. Internal LOC is the belief that a person's actions or involvement in a given situation can directly affect the attainment of a particular reinforcer. For example, if Tom thinks that studying will better prepare a person for an exam, and that this preparedness will increase the likelihood of getting an “A,” then Tom likely possesses an *internal* LOC and will probably study diligently for his exam. Conversely, external LOC is the

belief that the attainment of a goal has little to do with one's involvement or actions, but is instead due to outside forces such as luck, chance, or the control of powerful others. Relating this to the previous example, Ty may believe that a person cannot predict the exam's content, thereby leaving his or her performance up to chance. Ty would be less likely to study for the exam because he presumes that individuals' actions have little influence over the outcome of the test.

As LOC theories gained popularity, many other theories were proposed examining constructs incorporated into a person's perceived control of a situation. One of those components, self-efficacy, is often confused with LOC, and for that reason, a distinction should be made. LOC is a person's belief regarding the degree to which external events are a product of individual effort or of forces outside of individual control, in general. Self-efficacy, on the other hand, is a person's perceptions of his or her own specific ability to perform the behavior necessary to achieve a particular outcome. It is more orientated toward a person's opinion of his or her own personal competencies in pursuing a goal.

### PROBLEMS DEFINING LOCUS OF CONTROL

When the concept of LOC was first introduced, a wealth of literature was published exploring the concept. One of the major criticisms of many of these earlier studies was that it examined the concept in isolation, neglecting other facets of Rotter's SLT. The exclusion of other components (such as the value of the reinforcer to the individual) was misleading because it examined LOC out of context and affected its capacity to predict behavior. Most of the current literature attempts to place LOC within an SLT framework. For instance, when assessing the extent to which Lisa will attempt to quit smoking, we examine more than simply the degree to which Lisa believes quitting smoking will improve her health (LOC). We must also take into account how much Lisa appreciates her health (reinforcer value) and how capable she sees herself of being able to quit (self-efficacy).

A second criticism of early research is that it frequently mislabeled LOC as a trait characteristic (i.e., a personality characteristic that is fixed throughout the life span). Although this issue is still debated, the majority consensus is that LOC evolves as a person

develops and encounters new experiences. Additionally, research also suggests that LOC can change depending on specific situations. Although it is possible to assess a person's general LOC beliefs, a more accurate account measures their beliefs as they relate to the situation being examined. For instance, a measure of a person's political LOC would be more predictive of their voting behavior than their general LOC. Thus, unlike some early perceptions of LOC as a fixed and invariant construct, more recent conceptualizations suggest that LOC is responsive to an individual's experiences, circumstances, and level of development.

A third criticism of the LOC literature is that an internal LOC is frequently misperceived as being intrinsically beneficial. This stems from the increased motivation often associated with an internal LOC. Although an internal LOC is sometimes beneficial, this is not always the case. People who view themselves as the operative force in attaining a desired result may also place unnecessary blame on themselves when they do not achieve their goal. They may think they have more power to influence a situation than they actually do. This inflated sense of effectiveness may also affect the person's adaptability, including the person's ability to take direction or work as part of a team.

## ASSESSMENT OF LOCUS OF CONTROL

LOC is measured using self-report assessments typically created for specific age groups. These assessments are available for populations spanning from preschool age to the elderly, as well as for people of various races and ethnicities. In general, LOC assessments do not simply identify someone as internal or external, but place individuals on a continuum spanning the two. Along this continuum, people may be identified as being "more internal" or "more external." Some common LOC measures include the *Internal-External Locus of Control Scale*, the *Adult Nowicki-Strickland Internal-External Control Scale*, the *Nowicki-Strickland Internal-External Control Scale for Children*, *Crandall's Intellectual Achievement Responsibility Scale*, and the *Multidimensional Health Locus of Control Scale*. Validity for LOC scales typically relies on the scale's ability to predict behavior, the degree to which a measure correlates with other established LOC measures, and the extent to which it discriminates between conceptually different LOCs.

Consistent with modern conceptualizations, LOC assessments can be structured towards a person's general LOC beliefs or LOC beliefs with regard to a specific situation, event, or condition. Some of the more popular situation-specific LOC scales target areas such as health, school, and work and have helped predict variables such as adherence to medical regimens, academic achievement, and vocational success. In general, these specific LOC measures have demonstrated superior predictive validity when compared with the more general LOC measures. The knowledge gained from LOC scales can help guide interventions striving toward helping people achieve maximum benefit in their respective circumstances.

## LOCUS OF CONTROL AND DEVELOPMENT

Developmental trends in LOC are best examined using general LOC measures (as opposed to situation-specific measures). This is because many of the situation-specific measures target experiences that occur only within certain developmental stages. When examining age trends among more general measures, it is important to consider the role of a person's cognitive development in how that person views his or her environment. Historical and cultural contexts are also important to take into account because societal values may influence a person's perception of control.

LOC beliefs have been shown to change across development, in that children's LOC beliefs tend to become more internal with increasing age. However, this is not a strictly linear trend. Research has shown a large increase in internal LOC at about sixth grade and a small decrease just before high school. This overall increase in internal LOC across childhood makes sense within the context of development: as children become more independent and self-sufficient (i.e., less reliant on parents), they tend to view their actions as being more instrumental in the attainment of goals. These internal LOC beliefs have been shown to stabilize in adulthood. Research has suggested that LOC beliefs later become more external as a person enters old age. This may be related to an increased dependence on others for personal needs such as health and finance.

## SUMMARY

LOC refers to a person's beliefs regarding how instrumental individual effort is in achieving a desired

result. A person who believes goal attainment is dependent on his or her personal efforts in a given situation is said to have a more internal LOC. On the other hand, a person who believes outcomes are the result of outside forces, such as luck or powerful others, is said to have a more external LOC. In general, LOC becomes more internal as a person develops through childhood and adolescence, remains consistent during adulthood, and becomes more external as one progresses through old age. Although general LOC measures are available, the most accurate predictor of a person's behavior in a particular circumstance is a LOC measure specific to that situation.

## LONELINESS

---

In everyday language, loneliness describes feeling disconnected from important others by virtue of physical separation or emotional conflict. In psychology,

loneliness is defined as having an inadequate or less satisfying network of friends and family than is desired. Loneliness and aloneness are distinct; solitude is enjoyed when one wants to be alone, whereas loneliness can be experienced in a crowd.

Loneliness is highly unpleasant, but quite common—one large survey estimated that 25% of the adult U.S. population experience loneliness during any 2-week period. Although loneliness typically is transitory, its importance mostly derives from its potential to become chronic, thereby changing the interpersonal perceptions and behavior of the lonely person in ways that tend to perpetuate loneliness (e.g., by inhibiting the restoration of old relationships and the development of new ones). For example, research shows that high lonely as compared with low lonely participants are less skillful and more rejecting when given the opportunity to interact with strangers. Similarly, although virtually all forms of therapy appear to be effective in reducing loneliness, there is evidence that the lonelier the person, the less likely that he or she will seek professional help. Also, whereas mild feelings of loneliness are associated with interpersonal overtures toward others, chronic and severe loneliness appears to elicit coping strategies that exacerbate rather than address the problem (e.g., withdrawal, use of alcohol and drugs).

Loneliness can be easily and reliably measured with brief self-report instruments. The UCLA Loneliness Scale is the most widely used and thoroughly validated case in point. Although most scales yield a global index of loneliness, there is utility in distinguishing between the loneliness of inadequate friends and companions (social loneliness) and loneliness associated with the absence of an intimate partner (emotional loneliness).

With respect to developmental continuity and change, an important issue is the age at which loneliness first appears. Early writers on the topic argued that loneliness did not emerge before preadolescence, whereas recent research suggests that it may occur much earlier. Attachment processes have been implicated in the development of loneliness. For example, the quality of the parent-child relationship predicts childhood and adolescent loneliness. There also is evidence that loneliness is transmitted across generations.

The developmental processes involved in the development of loneliness appear to be stable across the life span. For example, at all ages, the same dispositional variables (e.g., self-esteem, social anxiety)

and psychological processes (e.g., internal and stable attributions for social failure) are related to and predictive of loneliness. Similarly, regardless of age, qualitative measures of relationships (e.g., satisfaction) are better predictors of loneliness than quantitative measures (e.g., number of friends). On the other hand, specific interpersonal deficits appear to be different but age appropriate among various age cohorts. Lonely adolescents tend to lack friends, whereas lonely young adults are more frequently without romantic partners, for example.

People who appear to be most vulnerable to the experience are young, unattached, and socially unskilled (e.g., shy), often experiencing disruptions in their interpersonal networks by virtue of geographical mobility (e.g., going away to college) or changes in interpersonal status (e.g., divorce). Indeed, it is generally held that loneliness usually originates from the combination of personal vulnerabilities and disruptions of relationships. Although women appear more vulnerable than men in some studies, this is likely a measurement rather than a gender difference.

Loneliness is related to assessments of adjustment and mental health, which is not surprising given the negative thoughts and emotions involved. However, there is also evidence that loneliness is associated with basic physiological processes (e.g., production of white blood cells) in such a way as to increase the lonely person's susceptibility to illness.

## LONGITUDINAL RESEARCH

Longitudinal research refers to research that investigates events or phenomena over an extended period of time. Longitudinal research studies can be as brief as 1 or 2 years, for example, when evaluating the effects of a particular learning strategy, technique, or treatment. They can also run over several decades, as when examining changes in adult personality and health behaviors. They allow changes to be assessed over a variety of levels and take into account the natural development and growth that occurs across the life span. For example, consider a study that follows children over a several-year period to assess the consequences of media exposure, as opposed to a study done over a few months to evaluate the effects of exposure to violent images on levels of overt aggression. The first would be longitudinal, whereas the second study would not be considered a longitudinal study unless the children or age cohort was repeatedly assessed over a longer period of time.

### TYPES OF LONGITUDINAL STUDIES

There are four principle types of longitudinal studies: trend studies, cohort studies, panel studies, and case-based studies. All four types tend to be descriptive, in that they generally do not manipulate *variables* (a variable is any clearly described item or construct that can be observed and analyzed), but describe how selected variables change over time and how these changes are related to other variables. Trend, cohort, and panel studies typically use instrumental measures, such as surveys, questionnaires, pencil-and-paper tests, and other standardized instruments, supplemented by descriptive measures. Case-based studies typically use descriptive measures, such as interviews, projective techniques, observations, and narratives and are supplemented by instrumental measures.

Trend studies examine changes within a defined sample population that does not stay constant. For example, if you are interested in changes in the amount of television or video exposure in preschool-age children, you could take a survey sample from preschool-age children repeatedly, over several years, and look at the trend. The children from whom you draw the sample would be constantly changing, and you would be measuring the patterns of change in the

viewing exposure of a defined sample population, 3- to 5-year-old children, over time.

Cohort studies examine changes within a defined sample population that is stable. For example, if you are interested in changes in employment and health status of American Vietnam-era combat veterans, you could periodically sample from a directory of U.S. military personnel who were listed as serving in combat between 1962 and 1974. The sample may contain different individuals at each data collection point, but it would represent the same population cohort at each time.

Panel studies examine changes over time within a selected sample that remains constant. For example, you are interested in describing the changes that occur over time as people age. You could select a group of people and have them complete a variety of measures at repeated intervals over several decades. The people in the study remain the same at each data collection point, with natural attrition (e.g., an individual's death) being the primary cause of the panel sample changing.

Case-based studies examine changes within organizations, groups, or individuals, often with regard to some intervention. The intervention could be training, a new policy or procedure, an educational program, or therapy. For example, you are interested in changes in an organization resulting from the introduction of a training program for a new technology. You could collect a set of measures from a sample of employees or students before the introduction of the program and then repeat the measures at set intervals. Similar to a cohort or panel study, a case-based sample would remain stable (in the case of employee or student samples in an organization) or the same (in the case of group or individual participants).

### ADVANTAGES OF LONGITUDINAL STUDIES

Longitudinal research is an effective and powerful method for investigating developmental variables and is essential in understanding outcomes for most naturally occurring or socially imposed interventions. One of the chief advantages of longitudinal research is that, since the same subjects or cohorts are being followed and repeatedly sampled over time, changes that are observed can be attributed to individual changes, rather than variations over individuals (referred to as *sample variance* or *statistical error*). This allows a

reliable description of patterns of change in individuals or groups, and a description of the direction and magnitude of causal relationships between variables, that would be available no other way.

### DISADVANTAGES OF LONGITUDINAL STUDIES

Longitudinal studies are considered nonexperimental, meaning that they are not conducted using randomized selection of participants who are compared with a matched control group through manipulation of a variable to expose the effect of that variable on the (experimental) participants. Nonexperimental studies are considered inferior by experimentalists, who place primary importance on the causal inference that randomization, control, and manipulation theoretically provide. However, as mentioned earlier, longitudinal studies can be used to describe the direction and magnitude of casual relationships, even though they are not as theoretically precise as experimental studies in determining causal relationships.

From a more practical perspective, the central disadvantage to longitudinal research is the length of time it takes to complete a study, with the attendant problems of attrition (in both participants and research assistants), costs, and measures. Conducting a research project that follows a group of participants over the course of years or decades requires significant investment of time from both the participants and the research team, significant financial support to maintain contact with participants and involvement of investigators, and significant foresight on the part of the investigators in selecting measures that will not become antiquated during the course of the study.

### EXAMPLES OF LONGITUDINAL STUDIES

The Study of Adult Development at Harvard has followed two panels of people over a long period of time: a panel of 268 Harvard students selected from the sophomore classes between 1939 and 1942 representing a socially advantaged, predominately male group and a panel of 456 disadvantaged inner-city males from Boston born about 1930. This Harvard-based study has focused on the physical and psychological health of the panel members, using social histories, biennial questionnaires, face-to-face interviews (every 15 years), and complete physical examinations

(every 5 years). It has provided numerous insights into the components of healthy aging as well as insights into social and cultural constraints on aging, adaptation to stress, habits and coping skills, and childhood risk factors.

The Seattle Longitudinal Study, a study of adult development from midlife through old age, has followed a panel of people since 1956. The research has focused on psychological development during the adult years. The original panel of 500 participants was randomly selected from a community health program and ranged in age from early twenties to late sixties. The study has continued since 1956, with data collected in 1963, 1970, 1977, 1984, 1991, and 1998. At each interval, a new group of people randomly selected from the same community health program have been asked to participate. As of the 1998 data collection, nearly 6,000 people have participated at some time in this study. Of the original participants from 1956, 38 people remain who have now been in the study for 42 years. The study collected data from the primary participants as well as siblings and offspring over the years, and it has been the source of numerous academic publications, as well as congressional presentations and policy discussions regarding issues related to aging, retirement, and other public policy considerations.

Numerous other databases have been created over the past several decades. Many agencies and institutions make these databases available to qualified researchers at no cost or for a nominal fee.

## SUMMARY

Longitudinal research studies investigate events or phenomena over extended periods of time. They follow the same or a similar group of people and are essential in understanding human change and development. However, they demand significant investments of time and resources and are usually descriptive because they do not provide the precise cause-and-effect logic of experimental studies. They provide reliable descriptions of patterns of change and of direction and magnitude of change that would be available no other way.

## LONG-TERM MEMORY

---

Long-term memory encompasses all learning or knowledge that is stored in the mind for longer than a few seconds or minutes. It encompasses all forms of learning and memory: memory for past events, facts, motor skills, perceptual skills, and conditioning.

Long-term memory interacts with short-term memory (also called *working memory*). Short-term memory consists of information currently being held in mind—the current contents of consciousness. The interactions between short-term memory and long-term memory are described in the Modal model of memory. In this model, perceptual information from the world is first stored in sensory system-specific buffers; in vision, this is referred to as *iconic memory*, and in audition, *echoic memory*. Some information can then pass from sensory memory into short-term memory; the amount of information is limited by attentional resources and the size of the short-term memory store. Once in short-term memory, information can be rehearsed; some information in short-term memory is transferred to long-term memory, generally information that receives more attention or is processed more deeply.

If information is not transferred to long-term memory, it cannot be retrieved later. A good illustration of the interactions among sensory, short-term, and long-term

memory is in the common situation of looking up and calling a telephone number. When the telephone number is viewed in the phone book, it enters sensory memory, along with all the other information on the page. However, only the attended phone number moves from sensory to short-term memory. Once in short-term memory, the number can be rehearsed over a period of several seconds, allowing time to go to the phone and dial the number. However, if distracted, the number is lost from short-term memory and must be looked up again. The telephone number is only likely to enter long-term memory, and be accessible later, if the person pays attention to the number and processes its meaning and patterns. This deeper processing can include the use of mnemonic strategies.

There are several qualitative distinctions made within the area of long-term memory based on the type of material being maintained. The primary distinction is between declarative memory and nondeclarative memory. *Declarative memory* consists of knowledge that can be verbally stated (declared) and can be further subdivided into two forms, semantic and episodic. *Semantic memory* refers to memory for facts and definitions that are isolated from the specific point in time in which they were acquired. For example, the meaning of the word *astronaut* or knowledge that George Washington was the first president of the United States would be semantic memory.

Episodic memory refers to memory for the events of one's life, for example, remembering what happened at your 6th birthday party, or what you ate for breakfast this morning. Episodic memories tend to be complex memories in which specific persons and objects are related to each other and to time (what time of day, season, year) and place (what location). Episodic memory is typically assessed through tests of recall and recognition; in a recognition test, the person is presented with the memorized material and novel items and just has to indicate whether it was one of the memorized items or not; in recall, a person is given cues but must access the information from memory.

Nondeclarative memory, as its name implies, consists of all the forms of memory that are not declarative. These range across a wide variety of phenomena. One large group is motor skills, such as learning to ride a bicycle. Another is perceptual learning, such as learning to recognize new type scripts or being faster at reading a word when it is repeated. A third is simple forms of learning such as habituation, sensitization, and some forms of classical conditioning.

Cognitively, declarative and nondeclarative memories differ in several interesting ways. First, the information represented in declarative memory is more fully available to consciousness than that represented in nondeclarative memory. This has led to the alternative terms *explicit* and *implicit memory* being used to refer to declarative and nondeclarative memory, respectively. Declarative memory requires more attention for encoding and recall than nondeclarative memory; the latter can often be gained while subjects are simultaneously performing demanding tasks. Declarative memory is more prone to forgetting across time than nondeclarative; this is the basis of the common observation that one never forgets how to ride a bicycle.

The neural bases of declarative and nondeclarative memory also differ. Declarative memory requires structures in the medial temporal lobe (including the hippocampus), the fornix, and the mammillary bodies. These structures serve to encode new memories. People who sustain damage to these areas develop a condition known as *global amnesia*, in which they lose the ability to form new long-term memories. They can still access memories from before their brains were damaged, however. Common causes of global amnesia include stroke, anoxia, Korsakoff's syndrome, and Alzheimer's disease, although the damage in the latter case is not limited to the medial temporal lobe. The medial temporal lobe and related brain structures interact with other areas of the brain, particularly the lateral anterior and middle temporal lobes, and long-term declarative memories are primarily stored in the latter areas.

An important future research question is whether the different parts of the medial temporal lobe serve different functions. Some research indicates that the hippocampus proper is important for learning relationships between items (and thus is important for episodic memory because it involves learning relationships between the person, other elements of the memory, and the time and place of the memory). Memory for specific items involves areas in the parahippocampal gyrus surrounding the hippocampus.

Nondeclarative memory systems have in common that they do not require the medial temporal lobe, but otherwise differ in their neural substrates. Motor skill learning is generally thought to be reliant on changes in motor areas of the brain, including the basal ganglia, cerebellum, primary motor cortex, and premotor cortex. Perceptual learning involves changes in

secondary perceptual cortexes. Classical conditioning is dependent on changes in synapses within circuits connecting perception of the conditioned stimulus and unconditioned response.

Nondeclarative memory is generally considered to have a relatively smooth developmental trajectory. It is present in roughly similar degrees across the entire life span, from infancy to old age. It is thought that much of the learning in prelinguistic children is attributable to nondeclarative memory processes. However, some nondeclarative memory tasks are impaired in older adults, particularly those requiring frontal lobe functioning, which is impaired in old age.

Declarative memory, on the other hand, shows decided changes across the life span. In general, memory is best in early and middle adulthood. One reason for the changes in declarative memory across the life span is developmental changes in the frontal lobes. The frontal lobes are important in implementing strategies to recall information from long-term memory. The frontal lobes are also one of the last areas of the brain to develop fully (full maturation isn't finished until early adulthood) and one of the first areas of the brain to show age-related decline in old age. Thus, older people are particularly impaired in recall and less impaired at recognition.

One interesting developmental phenomenon in memory is childhood amnesia, the finding that permanent long-term memories that can be recalled later in life are rare to nonexistent before an average age of 3.5 years. Young children do form long-term memories; even infants can remember a particularly interesting toy across a time delay of days. However, these memories are typically not accessible later in life. It is unclear what mechanism underlies this phenomenon. Freud postulated that it was due to repressing memories of trauma, although this theory is not generally accepted now. Others have hypothesized that memories become inaccessible as children move from prelinguistic to linguistic phases of development because the conceptual structures in the mind change qualitatively.

Another interesting developmental phenomenon is the distinction between memories of the distant past (e.g., one's 6th birthday party) and memories of more recent events (e.g., breakfast this morning). Older adults often report more difficulty with recent events than events of the distant past. Both are considered to be long-term memory, but they may differ in some

psychological and neural mechanisms; this is an important current area of research.

## LOW BIRTH WEIGHT (LBW)

---

The United States is unsurpassed in its ability to rescue the very smallest infants; infants who weigh only 750 g at birth are now surviving. However, these rescue efforts are often associated with significant long-term health and developmental problems among survivors. In 1950, the World Health Organization adopted the figure of less than 2,500 g (5 lb, 8 oz) as a universal definition of low birth weight (LBW). Below that, two subgroups are very low birth weight (VLBW—1,500 g; <3 lb) and extremely low birth weight (750 g; 1 lb, 10 oz). In the United States, the LBW rate of 7.6% in 2000 was twice that of other developed nations, and it has not improved. As a result, LBW has become a public health concern focusing on its impact on infant mortality.

### TERMINOLOGY: PREMATURE VERSUS SMALL FOR GESTATIONAL AGE

LBW infants are also classified according to whether they are preterm or small for gestational age (SGA). Preterm delivery is the most accurate term to use in describing babies born chronologically too soon, and is defined as a live-born infant born before the end of the 37th week of gestation (compared with full-term gestation of 40–42 weeks). For many years, LBW and prematurity were essentially synonymous.

In contrast, infants who are SGA are those whose birth weight is below normal when the length of the pregnancy is considered. They may be preterm or full term, and they weigh less than 90% of all babies of the same gestational age. Inadequate nutrition and smoking are among the main factors in producing SGA infants.

### **NEONATAL INTENSIVE CARE UNIT**

The development and availability of neonatal intensive care have saved the lives of many LBW infants. Technological and pharmacological improvements during the 1970s and 1980s included fetal monitors, cesarean delivery, neonatal monitoring of heart rate, respiration and blood pressure, intravenous nutrition, phototherapy to treat jaundice, and drugs to treat apnea and heart conditions. Currently, federal child abuse regulations mandate care for all live-born infants unless the infant is irreversibly comatose or is in a condition in which treatment would be “virtually futile” and inhumane by prolonging death. Ethical questions arise for health care providers, families, and society when they must decide if an infant is so sick that neonatal intensive care should be stopped. The probability of survival, pain and suffering, future quality of life, and the economic cost of care must be considered in the care for the very smallest infants.

### **FREQUENCY**

In the United States, there has been an increase in the number of LBW infants in the past two decades (from 6.8 per 1,000 in 1980 to 7.8 per 1,000 in 2002), in part due to the increasing number of adolescents having babies, drug abuse, and poor nutrition. Race differences are also apparent. In 2002, the LBW rate for white infants was 6.8%, compared with 13.3% for black infants. Despite the fact that black infants constitute 17% of all births, 33% of all LBW births, and 38% of all VLBW births, black infants are more than twice as likely as white infants in the United States to be born before 37 weeks' gestation. Race differences are not entirely explained by ethnic differences in the occurrence of various health conditions or behaviors (e.g., smoking, drug use, lack of prenatal care).

### **CAUSES AND RISK FACTORS**

Very little is known about the absolute causes of LBW and preterm birth despite the extensive amount of research. LBW that results from poor fetal growth

is associated with cigarette smoking, low maternal weight gain, and low prepregnancy weight. These account for nearly two thirds of all growth-retarded infants. Other risk factors are black race, first birth, prior LBW birth, maternal illness, fetal infections, and a variety of metabolic and genetic disorders. Although many of these risk factors provide important clues about the causes of LBW, many of them are only weakly related to LBW and are generally not modifiable by intervention programs or changes in public policy. Even less is known about the risk factors for early delivery.

### **SOCIAL DISADVANTAGE AND LIFESTYLE ISSUES**

LBW is the primary biological link in the relationship between socioeconomic status and infant mortality in industrialized countries. Researchers have found that virtually all of the indicators of parents' social position (occupation, education, achievement, income, marital status) impact the birth weight distribution. In addition to sociodemographic factors that affect birth outcomes, lifestyle issues also contribute, such as mother's nutrition (weight gain, diet, and nutrient intake); health choices (smoking, alcohol, caffeine, drugs); stress and physical activities; social support; experience of violence; and sexually transmitted diseases. Sadly, this fosters the belief that women are solely to blame for their undesirable behaviors without acknowledging the lack of support from the health care system and society.

### **COST**

The number of children born and surviving LBW has increased, and in parallel, medical technology has continued to improve, and the number of services for LBW children has continued to increase. These advancements come with a price. LBW infants make up 7% of all infants, but 35% of the dollars spent on health care designated for infants goes toward their care, with nearly half of these dollars going toward the care of the tiniest infants. Hospital bills for rescuing only one of these tiny babies can reach more than 1 million dollars. Initial hospitalization costs associated with LBW include physician fees and an average hospital stay of 3 to 4 months, much of which is spent on life-support equipment. Rehospitalization costs during the first year of life and long-term support services

(e.g., institutional care, special education) also contribute to the high cost of surviving LBW babies. The extra time that parents of sick LBW babies devote to their care is another component of cost not typically factored in.

LBW children do not necessarily outgrow many of their health problems as they mature. For those who survive infancy with chronic health problems, use of inpatient and outpatient health care services may remain high and access to specialized developmental services may become important. In comparison with normal birth weight children, LBW preschoolers are twice as likely to be hospitalized, and they spend more time in the hospital once admitted. They are also 50% more likely to be enrolled in special education programs, more likely to miss school days because of illness, and more likely to repeat grades in school.

## PREVENTION AND TREATMENT

From a public health perspective, two major strategies to reduce the number of infant deaths in the United States are to (1) prevent LBW and preterm delivery, and (2) improve the survival of LBW infants. Where available, prevention and enrichment programs have been effective in servicing families with LBW children. A relatively simple recommendation for prevention involves smoking cessation; up to 20% of *all* LBW births could be prevented if no pregnant woman smoked cigarettes. The most common public health recommendations for preventing LBW and preterm births include developing women's health programs that include prepregnancy counseling, and providing health care resources and insurance coverage devoted to prenatal smoking cessation programs.

If preventive actions are not taken, intervention programs may be accessed. Many early hospital-based interventions incorporate human touch, or massage, which has been proven to improve infant activity levels, alertness, and performance on developmental tests. Several neonatal programs include infant educational enrichment in combination with parent support programs. Intensive enrichment programs that provide medical, educational, and social support services for the parents and child have been shown to improve short-term developmental outcomes for LBW children. Infants who benefit the most from these programs have mothers who have high school or less than high school education levels.

## DEVELOPMENTAL CONSEQUENCES

### Survival and Risks

The increase in the rate of survival for LBW infants is so large that it is now having an impact on the childhood population. Most infants born at 24 or more weeks of gestational age (GA) survive. For infants born before 24 weeks' GA, 10% to 40% survive, and at 22 weeks' GA, almost no infants survive. The risk for severe handicap in VLBW survivors (e.g., cerebral palsy, epilepsy, or blindness) is about 20%, and of the nonhandicapped remainder, at least one third will experience substantial school difficulties. Medical and biological factors that contribute to the risk associated with LBW include birth defects, male sex, birth asphyxia, and neonatal complications including severe brain damage, chronic lung disease, meningitis, seizures, hypoglycemia, and jaundice.

A different picture emerges for *moderately* LBW groups who do *not* require intensive care; this group has not been well studied. Most moderately LBW children function within the normal range, yet when compared with normal birth weight children, LBW children have higher rates of mental retardation, cerebral palsy, blindness, deafness, psychomotor problems, school failure, and subnormal growth health problems. The number and severity of these problems increase as birth weight decreases.

### Outcomes

Depending on the severity of health problems, LBW children may experience combinations of various health, neurosensory, and developmental problems that can worsen clinical and educational outcomes. LBW children experience more physical and health problems than children with normal birth weights, beginning with lower average weight, height, and head circumference. Poor health outcomes increase as birth weight decreases, including asthma, upper and lower respiratory infections, and ear infections. Rehospitalizations for medical conditions and surgeries may be needed for the eyes, ears, nose, and throat; orthopedic surgery may also be warranted for cerebral palsy.

Cerebral palsy is the most common major neurological abnormality seen in LBW children, and cognitively, these children score significantly lower on intelligence tests than do children of normal birth weight, even when sociodemographic risk factors are taken into account.

Evaluations may reveal problems with specific cognitive functions, such as language abilities, memory, attention, fine and gross motor coordination, perceptual-motor skills, and nonverbal reasoning and problem solving. By school age, LBW children are more likely than those with normal birth weights to have a learning disability or attention deficit disorders.

In addition to the various health outcomes possible for LBW children, social and environmental factors can worsen long-term outcomes. For example, the combination of severe neonatal illness and a deprived environment that can barely meet basic food and shelter needs can be devastating. Impoverished environments may also include elements of neglect ranging from exposure to environmental hazards to financial devastation to abuse.

## POLICY IMPLICATIONS

Fortunately, public laws have come into place, and this reflects the importance of early intervention services for infants born LBW. Public Law 94-142, passed in 1975, mandated services for disabled children 6 years of age and older. Part B of Public Law 99-457, passed in 1986, mandated services for disabled children 3 to 5 years of age, and Part H of

this legislation created a family-based service model for children from birth to 2 years. In addition to these policies, public health recommendations call for provisions to prevent prematurity as part of prenatal care and mandate comprehensive follow-up of LBW children until school age. Such a mandate would include referral to early intervention services for those most in need and offering parent support and education programs to enable parents to meet the complex needs of preterm children.

## MADD (MOTHERS AGAINST DRUNK DRIVING)

---

Mothers Against Drunk Driving (MADD) is a grassroots organization with more than 2 million members and local chapters throughout the United States, Canada, Guam, and Puerto Rico. It is estimated that since MADD's inception in 1980, alcohol-related traffic fatalities have declined 43%. In 1980, 55% (28,100) of the nation's 51,091 traffic deaths were alcohol related. By 1999, alcohol-related deaths comprised 38% (15,794) of the nation's 41,345 traffic fatalities.

The organization began in 1980 as Mothers Against Drunk Drivers. It was inspired when 13-year-old Cari Lightner was killed by a drunk driver in California who just 2 days earlier had been released on bail for a hit-and-run drunk driving accident. He had two prior drunk driving convictions, and a third charge had been plea-bargained to "reckless accident." Cari's mother, Candace Lightner, gathered forces with a group of friends in Sacramento to fight to keep drunk drivers off the road, and Mothers Against Drunk Drivers was formed. Another chapter was formed shortly afterward in Maryland by Cindi Lamb, whose

5-month-old daughter Laura had become a quadriplegic the year before when they were hit by a repeat drunk driving offender speeding at 120 mph. MADD's growth began to accelerate as it started receiving national attention. In 1982, President Reagan formed a presidential task force on drunk driving and invited MADD to serve on it. In March 1983, NBC produced a made-for-television movie about Candace Lightner's story and the formation of MADD, and more than 120 new chapters were formed that month alone. In 1984, the name was changed to Mothers Against Drunk Driving, reflecting the emphasis on the act of drunk driving, not on the individuals involved. Currently, MADD has over 600 chapters and is the nation's largest crime victim's assistance organization.

The stated mission of MADD is to stop drunk driving, support the victims of drunk driving, and prevent underage drinking. This mission is supported by efforts in four main areas: public awareness, victim assistance, youth programs, and public policy.

## VICTIM ASSISTANCE

MADD sponsors a 40-hour advocate education training program that has been completed by more

than 1,200 victim advocates. These advocates assist drunk driving victims through toll-free numbers, local advocate services, and assistance with the legal process, as well as a range of books and publications developed by MADD.

## **PUBLIC AWARENESS**

MADD popularized the concept of “designated drivers” in the 1980s as a means to help keep drunk drivers off the roads. Project Red Ribbon was also introduced in the mid-1980s, and red ribbons were displayed by motorists who pledged to drive sober during the Christmas and New Years holidays. MADD continues to focus on public awareness through media campaigns and various education efforts.

## **YOUTH PROGRAMS**

Preventing underage drinking has increasingly become a focus of the organization. MADD currently conducts a host of programs targeting youth, including alcohol-free prom parties, speeches in high schools, and resource materials such as classroom newsletters and even coloring books for the younger grades. Since attitudes about drinking are formed at a young age, MADD begins with elementary age children and has developed the program Protecting You/Protecting Me, which has been recognized by the federal government as a scientifically proven effective prevention program. In 1997, the first MADD National Youth Summit to Prevent Underage Drinking was held, and in 1998, the first youth representative to MADD’s Board of Directors was elected.

## **PUBLIC POLICY**

MADD claims that their efforts have resulted in the passage of thousands of federal and state drunk driving laws since the early 1980s. These have included the passage in 1984 of a federal law requiring all states to increase the legal drinking age to 21 or lose highway funding, the 1988 Omnibus Anti-Drug Abuse Act, which grants victims of driving while intoxicated (DWI) crashes the same compensation rights as victims of other crimes, and a push for states to reduce the legal blood alcohol concentration from .10 to .08. MADD has been involved in the passage of more than 2,300 state and federal anti-drunk driving and

underage drinking laws and has advocated for stricter penalties for repeat drunk driving offenders across the country.

## **MAGICAL THINKING**

---

Magical thinking involves the belief that one’s ideas, thoughts, actions, words, or use of symbols can influence the course of events in the material world. Magical thinking presumes a causal link between one’s inner, personal experience and the external physical world. Examples include beliefs that the movement of the sun, moon, and wind or the occurrence of rain can be influenced by one’s thoughts, or by the manipulation of some type of symbolic representation of these physical phenomena.

Magical thinking became an important topic with the rise of sociology and anthropology in the 19th century. It was argued that magical thinking is an integral feature of most religious beliefs, such that one’s inner experience, often in participation with a higher power, could influence the course of events in the physical world. Prominent early theorists suggested that this type of thinking characterized traditional, non-Western cultures, which contrasted with the more developmentally advanced rational-scientific thought found in industrialized, Western cultures. Magical thinking, then, was tied to religion and “primitive” cultures and considered developmentally inferior to the scientific reasoning found in more “advanced” Western cultures.

This perspective influenced 20th-century psychological theorists, notably Sigmund Freud and Jean Piaget. Freud argued that there are two fundamental forms of thought: primary and secondary process. Primary process thought is governed by the pleasure principle, whereby id-driven instinctual desires seek fulfillment without consideration of the constraints of the external world. Magical thinking—the belief that wishes can impose their own order on the material world—is a form of primary process thought. Secondary process,

in contrast, is a more advanced development, resulting from the emergence of the ego, which provides rational assessments under the direction of the reality principle, that allow for adaptive responses to the environment. Freud used this model of individual development to explain the stages of cultural development proposed by anthropologists. That is, the ontogenetic development of the individual—from the id impulses and magical thought of childhood, to the ego constraints and rationality of adulthood—mirrors the phylogenetic development of human cultures from magical-religious to rational-scientific.

Piaget's investigation also placed magical thinking at the center of young children's thought. Piaget queried children about their understanding of events in the physical world and discovered that children, prior to the age of 7 or 8, impute their own activity as the causal source for physical events. So, for example, children believe that their own activity causes the motion of the sun and moon and that waving their hands causes the wind. Magical thinking, Piaget argues, results from a profound egocentrism, of experiencing oneself as the center of the universe, and a lack of differentiation of intrapsychic experience and physical causality. This qualitatively distinct developmental stage is superseded by a differentiation of the intrapsychic from the material world, a decentration of thought, and the capacity for logical, scientific reasoning. Again, magical thinking is replaced by rational, scientific thought. And while less programmatically explicit than Freud, Piaget also argued that these stages of ontogeny recapitulate the progressive stages in the development of cultures, from magical-religious to rational-scientific.

Recent research suggests that magical thinking is both less and more pervasive than previously thought. First, evidence suggests that although young children do utilize magical thinking, their egocentrism is much less pervasive and profound, and they are capable of a much more sophisticated understanding of physical causality, at a much earlier age, than Piaget proposed. Second, adults, despite their capacity for scientific reasoning, do hold religious beliefs that often involve features of magical thinking, engage in magical thinking at times, and can be influenced to think thusly under some circumstances. Third, the magical thinking of children may be distinct from the religious beliefs of adults, which address metaphysical considerations about ultimate questions of life, meaning, being, and mortality that involve more sophisticated

cognitive considerations than found in children's magical thought.

## MALNUTRITION

---

In most normal, healthy children, the genetic potential is helped toward fulfillment by healthful, invigorating environmental conditions. The quality of children's nutrition and health care strongly influences their development and the general quality of life they experience.

Unfortunately, a majority of children in the world, and many of the children in the United States, receive neither proper nutrition nor adequate medical attention. They do not get enough protein for building body cells, enough vitamins and minerals for structural development, or enough carbohydrates for energy. All over the world, tens of thousands of children die each day of hunger, a situation that is difficult to believe can actually happen. In the United States alone, the estimates of children who experience hunger range from 2 to 5 million, which is likely to increase as economic circumstances for the poor become even more precarious. What makes these tragedies even more unbelievable is that the reason for these deaths is not food shortages, but the politics of food.

When people are poor, they are usually malnourished. Chronic malnutrition, which more often than not begins before birth, can produce permanent physical deformities and mental incapacity. Unfortunately, this damage stays with the child and may interact with other dimensions of the child's development. Sandy Zeskind and Craig Ramey studied the effect that two settings, different in their intellectual stimulation, might have on fetally malnourished children.

The results of the study showed that the negative effects of malnutrition on intellectual, behavioral, and social development continued through 3 years of age when the environment was not supportive. On the other hand, in a supportive environment, the effects of malnutrition continued to decrease.

Malnutrition can result from the consumption of “junk foods” that provide only “empty calories,” that is, refined carbohydrates. In a consumer-oriented culture like ours, it is difficult to keep a child from eating presweetened cereals and candy bars and drinking soft drinks. Day after day the child sees this kind of food recommended on television by favorite cartoon characters and TV personalities. Yet when junk foods make up a large part of the diet, the result may be nutritional deficiencies, often accompanied by obesity. It is not unusual for the child who is overweight to also be undernourished.

Illness in young children because of nutritional deficiencies is also a particularly serious problem among the poor in the United States, and as the number of poor children increases and as health care availability declines, even more children are suffering the effects of malnutrition. Although each generation tends to produce larger, healthier babies than the generation before it, millions of children continue to suffer from respiratory illness, bad teeth, and other conditions related to an inadequate diet. Many pediatric specialists in this country have assailed the health care system, especially its inadequacy for poor children.

Children who eat poorly will suffer as adults as well. According to some nutrition researchers, the average American’s diet promotes heart disease, tooth decay, diabetes, high blood pressure, and certain common cancers. A report by the National Institutes of Mental Health discussed the link between diet and cancer and how reducing red meat and fat consumption and increasing fiber intake may lessen one’s chances of contracting cancer.

Preferences for foods that constitute an unhealthy diet start early in life. Parents may offer sugar-rich foods as a reward or a distraction or an attempt to show their affection (“Here, have a cookie and stop crying”). Desserts rich in sugar and fat may be served to the family as a show of love and affection, and in some cases this can be the beginning of more serious eating disorders of the kind we will discuss later. Salty foods are now considered by many medical researchers to be even more unhealthy than sweets. A cursory look at cereal packages in the stores finds

that even the “high-nutrition” packaged cereals contain 10 times the necessary sodium levels in a 1-ounce serving. The saltine or pretzel so often offered to placate children is really no better than a cookie. A raw carrot, a quarter of an apple, or a slice of rye or whole wheat bread will soothe a child just as well. In order to reduce salt intake, salads and cooked foods can be liberally seasoned with herbs. A variety of foods should be offered, although many children tend to be conservative in their food choices. A nutritious (and delicious) dessert can be part of the meal and not a reward. Another good principle is to allow children to leave food on their plates if they wish. Better yet, give small servings to start and then more if desired. This strategy helps avoid wasting food and eliminates some of the tension that can arise over “cleaning your plate.” After a great deal of controversy, the federal government has finally settled on a set of nutritional guidelines. The typical four food groups (cereals, dairy, meat, and vegetables and fruit) are gone, replaced by a pyramid with bread, cereal, rice, and pasta at the bottom (signifying the most servings) and fats, oils, and sweets at the top (signifying the least). The guidelines suggest a change in the federal government’s view on nutrition, now stressing a low-fat and low-cholesterol diet.

## MARIJUANA

---

Although the marijuana, or cannabis, plant first appears in human history approximately 10,000 years ago, there is limited research that tells us about its role in human development. Indeed, this plant with hundreds of active chemicals when smoked remains a mystery to many, although with over hundreds of millions of

people in the world having used it at least once, it is by far the most widely used substance. What many people believe to be true of this plant is often more myth than fact.

## A BRIEF HISTORY

The industrial strain of the cannabis plant, known as hemp, has been used at least as far back as 8000 BC, when it was used in Taiwan as decoration. Industrial hemp plants do not contain enough of the most potent chemical, tetrahydrocannabinol (THC), which is found in strains of cannabis, to produce euphoria and other mild mind-altering effects, in addition to pain relief and other assorted effects. Medical uses for cannabis, or marijuana, began in China around 2700 BC. This hardy plant is extremely pest resistant and currently grows wildly on six continents.

Marijuana is actually a slang term, originating in Mexico, for the cannabis plant. Cannabis was first used prominently in North America at the beginning of the 20th century, and largely by Mexicans and Mexican immigrants in America. As alcohol prohibition waned, and the federal government in the United States saw a new scourge in this intoxicating plant from the south, they used its Mexican slang name in order to enhance its foreign association and encourage its prohibition among the general public.

## CURRENT EFFECTS

That history is important, because although widely used, marijuana is much misunderstood. It has been a schedule I drug, meaning the United States government deems it to have no medical application or value, since the beginning of drug scheduling in the United States. Some relevant facts that are often overlooked by the lay public include (a) marijuana has never been linked to a fatal overdose; (b) it has been shown to give effective relief for some ailments, including glaucoma and the pain and shaking of multiple sclerosis, to increase appetite in patients with acquired immunodeficiency syndrome (AIDS) wasting, and to ease discomfort associated with chemotherapy; and (c) it is less toxic than either tobacco or alcohol. An estimated 30 million Americans currently use marijuana at least once a month, and some would say they are using its properties to self-medicate. Yet there is little we can say regarding scientific surveys into marijuana's role in human development, as it has been virtually impossible

to conduct meaningful research on the drug itself, because its schedule I classification makes it extremely difficult to study legally in the United States.

What little research that been done has demonstrated that the cannabinoids are the primary chemicals in marijuana that produce effects in the human brain. The human brain has cannabinoid receptors, which also react to chemicals produced within the body, producing such effects as "runner's high." These cannabinoids, especially delta-THC, generally affect aspects of memory, perception, and complex reaction time. They also seem to enhance senses and increase euphoria and relaxation, but may impair some concentration.

At young ages, while the brain is still forming, it is thought that there may be long-lasting effects with continued use, but there is scant evidence to either prove or disprove this theory.

## CONCLUSION

Although not a benign drug, marijuana does have documented applications for certain illnesses when administered in appropriate doses. More study is certainly needed to obtain definitive answers to marijuana's short- and long-term effects on human development.

## MARITAL EQUITY

---

Marital equity refers to the degree of balance of authority, power, or influence between spouses. There are multiple domains related to marital power, including, for example, each partner's education background and economic contribution; each spouse's ability to

use communication skills to influence the other partner; and how much each partner has a say in decision making. In all of these areas, there can be equity or there can be imbalances in power. Marital equity also can be seen as the extent to which each partner has status in the relationship and whether that status is equal between partners.

Marital equity has been studied in many ways. Researchers have learned valuable information through several methods. First, spouses can be asked about their own background and their perceptions of their own and their spouse's power and influence in the relationship. They can also be asked about who makes the final decisions in the relationship and whether there are differences in who has the final say across different areas, such as how to spend money or raise children.

Second, couples can be observed while discussing important issues in their marriages, such as how to solve problems. Observing these problem discussions has revealed that there are different types of power distribution across couple relationships. There are "egalitarian" couples, where both partners share equally in decision making and appear to have the same levels of influence on one another. Some couples have a female partner who is more forceful, may talk more than a male partner, and may appear more influential. These couples have been labeled as "female dominant," while "male dominant" couples show the opposite pattern. A fourth group of couples has been labeled "imbalanced" or "power struggle," in which partners appear to be struggling with each other for control or the upper hand in the interaction.

By asking spouses about their relationships and by observing couples in problem discussions, researchers have learned that the health of a marriage can be affected by the balance of power or equity in the relationship. For example, if one partner feels bullied by the other, it can lead to dissatisfaction in the marriage and high levels of conflict. On the other hand, if both partners feel they have equal status and are listened to by each other, they may report higher levels of satisfaction in the marriage. It may also be the case that with certain types of decisions, one partner has the final say, while with other types of issues, the other partner may make final decisions.

The distribution of power in a relationship may vary by culture and ethnicity. Some evidence suggests that Anglo-American couples tend to value egalitarianism highly, and if there is an imbalance in power, it may lead to relationship dissatisfaction. There is also

some evidence in some other cultural groups that egalitarianism may not be as highly valued, and therefore partners may have separate spheres of influence, or varying levels of influence, which may not lead to dissatisfaction.

One important research finding about marital equity is that it can be related to one of the most significant disruptions in a couple relationship: domestic violence. Evidence exists that domestic violence in a relationship can coincide with high levels of power imbalances. Violent spouses sometimes report that they feel powerless in relationships, and some researchers have suggested that because they feel powerless, partners who are violent toward their spouses may do so in order to regain power in the relationship. It is therefore very important to address issues of marital equity with couples, since they may be dealing with varying levels of happiness or, in some cases, dangerous behavior associated with the balance of power within the relationship.

## **MARRIAGE**

---

### **MARRIAGE AS AN INSTITUTION**

The first recorded history of marriage as an institution was gleaned from the ancient civilizations. In "civilized" societies, women were considered property owned by men, first by their fathers and then by their husbands. Early Romans and Greeks often gave women to men as prizes for some heroic deed. Wives had to be faithful to their husbands, while husbands could have concubines. Archeological and

anthropological studies have shown that other early forms of marriage were thought to exist in Polynesia. Before Christian missionaries arrived, the Polynesian men and women were thought to have had many partners who formed unions out of love. The Christian missionaries defined marriage as a union between one man and one woman (monogamy) and changed the nature of Polynesian marriages to fit their beliefs. Other cultures condoned polygamy, in which one man could have several wives.

When royal families dominated the Western world, the motive for marriage was often to create a political alliance between countries through royal blood. Later, when the power of royalty declined, money replaced bloodline as a source of power. Then marriages were entered into for economic convenience. Although the Polynesians were believed to marry for love, marrying for love was not a typical reason for marriage in the Western world until the Victorian Age. Whereas many cultures still had arranged marriages and marriages of convenience, marriage by choice was popular in the newly formed United States. However, the choice of marriage partner was officially made by the man, not the woman. A woman had no legal rights of her own in many cultures. In Western society in the 17th through 19th centuries, she was known legally as “the wife of Mr. Smith or Mrs. John Smith,” for example, and continued to be her husband’s property. A woman’s status in society was determined by the status of her husband. Thus, if a woman wanted some semblance of power, she had to marry a powerful man. Even then, whatever status she did have was only obtained through marriage.

In the United States and much of the Western world, the definition of marriage has changed to include many different forms of marriage. Marriages between same-sex couples have been legalized in some jurisdictions. This legalization has heightened the controversy surrounding gay and lesbian couples. On the one hand, same-sex couples want the same legal rights as married heterosexual couples. On the other hand, the major religions of the United States do not condone same-sex marriages. Such critics believe that legalizing gay marriage would violate the sanctity of marriage. Yet research shows that marriages began to change long before gay couples sought legal recognition. Heterosexual couples often live together without marriage, and many stay committed to the relationship without a marriage license. Women now choose to have children without marrying or involving fathers in child rearing. Divorce occurs frequently and no longer

carries the stigma it once had. To some, legalizing same-sex marriage is just another step in the path to redefining marriage as an option for couples, whether or not children are involved. At the time of this writing, the controversy over gay marriage continues.

## MARRIAGE AS A RESEARCH TOPIC

The history of marriage as a research topic did not begin until the 1920s. Before that time, ideas about marriage were not scientific, but rather in the form of traditional religious prescriptions for an ideal marriage. At the turn of the 19th century, when problems in marriages and families were acknowledged as societal problems, a focus on the marital ideal was replaced with a focus on direct observations of actual marriages. The desire to solve problems in marriage led to many years of research on marital quality. The goal of these studies was to determine what predicted marital success.

The first research studies on marriage were primarily sociological studies, surveying large segments of the population and using demographic data (e.g., age, income, education) to identify the individual factors that predict marital satisfaction. Then clinical psychologists became interested in marital research in order to design therapeutic techniques to solve marital problems. However, demographic data did not explain the reasons that problems occurred. Researchers began to realize the need for studying the behaviors of spouses during interactions with each other. Such research demonstrated that interpersonal interactions capture valuable information that cannot be found by examining individual characteristics. Behavioral observations of marriages became a very popular and useful method for distinguishing the behaviors between happy and unhappy marriages. Often couples were observed while discussing their own marital problems. It was assumed that knowing how happy and unhappy couples behaved during discussions of problems could help design marital interventions. Such interventions would presumably teach couples what to do and what not to do in order to improve the quality of their marriages.

In the late 1970s and early 1980s, the study of personal relationships began to emerge. Such research gave marital researchers who were not clinically oriented a forum in which to present their work. Sociology and clinical psychology once dominated the study of marriage, but relationship research is now a multidisciplinary endeavor, including such disciplines as social

and organizational psychology, communication studies, and anthropology. Although marital quality remains as a major focus of research on marriage, many other areas of study have been examined. Behavioral observation is still a valuable method, and research on marriage has expanded to include spouses' perceptions and thoughts about themselves and each another. Coupled with observational research, investigators can identify what spouses are thinking while they are interacting, paving the way for a multilevel image of marital interaction.

There are so few studies examining marriage in different cultures that it is not possible to present a universal definition of an ideal marriage. Much of what is presented below as the successful marriage is based on research in the United States, Canada, and Western Europe and thus reflects the values of the Western world.

## **MARITAL QUALITY**

There are many different processes and characteristics that make up a successful marriage. Marital satisfaction and stability are thought by most researchers to be the barometer of marital quality and are thus predominant foci of marital research. Instead of presenting an exhaustive list of behaviors and characteristics that comprise a successful marriage, this entry will focus on one process that many researchers agree to be important to marital satisfaction—communication.

Communication is often touted as the crucial component of successful marriages without specifying the type, style, and context of communication. A distinguishing characteristic of satisfied versus dissatisfied couples is the way they communicate about a disagreement, problem, or conflict. Happy couples are less likely to blame each other for problems and more likely to shift the conversational focus to more constructive ways of communicating. If one partner starts saying something destructive or negative, the other partner does not automatically respond with another negative statement. In satisfied marriages, one partner or the other is able to reframe the problem in constructive terms. They are more able to shift focus to see their problems as something they work on together, rather than as the responsibility or fault of the one spouse. Satisfied spouses are flexible and can shift from a focus on the self or the other partner to a focus on the relationship.

Unhappy marriages are those in which conversational styles are rigid and inflexible. When one spouse

says something negative, the other spouse responds in kind. Thus, a negative remark can turn into a series of negative exchanges without resolution. When discussing a problem or conflict, the couples seem stuck in a vicious cycle in which the conversation becomes more and more destructive. If time and again they are unable to shift their focus from partner blame to a relationship problem, negative feelings toward one another can eventually turn into contempt. Once that vicious cycle starts, it is very difficult for distressed couples to stop the negativity. Satisfied couples, on the other hand, are able to shift from a destructive to a constructive conversational style.

## **CONCLUSION**

In the past century, beliefs about marriage as an institution have undergone rapid change in the United States. In addition to adapting to the industrial and technological changes in this society, attitudes about marriage also responded to increases in the freedoms and choices among women. As women gain more status in society in general, they also seek more power in the marital relationship. Because men were thought to be the traditional heads of households, more power for women was expected to lead to more equality in marriage. As women gain more status in the workplace and household, men are expected to take on more tasks traditionally thought of as women's work (e.g., housekeeping and child rearing). Research has shown that attitudes do not match behavior in marriage. Husbands are not increasing their share of the household labor to match that of wives, but there are some marriages that are built on equity and equality. These are termed peer marriages, marriages that distribute power in ways that satisfy each partner and at the same time preserve the relationship and do not rely on traditional gender roles as guidelines. These are marriages in which the spouses are equals. Although true peer marriages are in the minority, the majority of marriages strive to be more egalitarian. It is these marriages we know the most about. Peer marriage remains a model to which most marriages aspire.

If a young couple gets married today, projections indicate that at least 40% of them will end in divorce. Unfortunately, the majority of couples seeking marital therapy do so when the marriage seems beyond repair. Thus, several marital researchers and therapists want to help couples by teaching them about making relationships work before they get married. Educating

premarital couples about marriage is a hopeful trend that holds the promise of preserving marriages of the future.

## MASLOW, ABRAHAM (1908–1970)

---

Abraham Maslow pioneered and led the humanistic psychology movement. He was born in 1908 in Brooklyn, New York. The oldest of seven children from parents who immigrated to the United States from Russia, Maslow was quoted as describing his childhood as miserable and his family as unhappy and unloving. For Maslow, study and education provided a way to overcome poverty and loneliness. His desire was to study “everything,” earning a bachelor’s degree from City College in New York and his PhD from the University of Wisconsin in 1934 in experimental psychology. Learning was matched by a passion for his friend and cousin, Bertha Goodman. He was 20 and she was 19 years old when they married on December 31, 1928. The marriage provided Maslow with a feeling of belonging and a sense of direction.

Mentored first by Harry Harlow and later by Alfred Adler, anthropologist Ruth Benedict, and Gestalt psychologist Max Wertheimer, Maslow is credited with developing humanistic psychology, the “third force” in psychology, which provided an alternative to the prevailing psychoanalytic and behavioral models of his time. Rather than working with individuals in a clinical setting, Maslow wanted to study and focus on the best examples of humanity in order to gain insight into human nature.

Maslow laid the groundwork for what has now become his classic theory on self-actualization by making the assumption that each of us has an intrinsic nature that is good, or, at the very least, neutral. He conceptualized a hierarchy of needs that activate and direct human behavior. These needs, arranged in order from strongest to weakest, include physiological, safety, belongingness and love, esteem needs (from self and others), and ultimately self-actualization. The lower needs must be at least partially satisfied before higher needs become influential, and according to Maslow, only a minority of individuals actually progress to the highest, self-actualizing level.

Self-actualization depends on the maximum realization and fulfillment of our potentials, talents, and abilities. Self-actualization is not limited to particular occupations or interests. It is the process of maximizing personal abilities and reaching the fullest personality development. Environments that threaten the individual and do not allow for the satisfaction of basic needs are detrimental to growth, while those that are supportive and provide for the gratification of needs promote growth toward self-actualization.

Maslow taught at Brooklyn College for 14 years, and then at Brandeis University from 1951 to 1969. Maslow was President of the American Psychological Association in 1967. That same year, he accepted a fellowship at the Laughlin Foundation in Menlo Park, California, to devote all his time to writing. Unfortunately, he died of a heart attack in 1970, at the age of 62, leaving behind his profound influence on psychology.

## MATERNAL HEALTH

---

Pregnancy and childbirth is perhaps one of the most awe-inspiring feats of the female body. During the perinatal period, a woman's body transforms so as to promote and support the development of a new life. Throughout this process, the health of the mother and developing offspring are inherently intertwined. Not only is maternal health critical for the mother, but it is the fundamental necessity for the successful unfolding of potential of the developing child.

### WHAT IS MATERNAL HEALTH?

Maternal health involves unique functions and abilities of the female body and generally refers to physical and psychological functioning before and during pregnancy, childbirth, and labor, continuing to postpartum status. A more limited definition views maternal health as simply the absence of disease and even goes so far as to define childbirth and pregnancy as a pathological process. Critics of this "illness" model suggest that maternal health is not merely the absence of illness, but is a process of moving toward optimal functioning and well-being with the woman playing an active part.

A holistic definition of maternal health emphasizes that health is influenced by how a woman thinks, feels, and behaves, with bidirectional influences between the individual woman and her social and contextual surroundings. This definition recognizes the importance of support from significant individuals and the community and delineates a more active role for the mother in her health. The traditional "illness"

model depicts the individual as more passive and dependent on health care providers to eliminate or treat illness and achieve health. Current models employ a more self-empowered view of a person's health by which women have more responsibility for the management of their prenatal and postnatal terms. This paradigm shift has changed the role of health care providers to not only treat pregnancy-related complications, but to additionally provide support and suggestions (teacher/adviser role) and to help mothers acquire the knowledge and skills necessary to choose and employ optimal health behaviors.

### MATERNAL HEALTH INDICATORS

Whereas an obvious measure of health is assessed by physical indicators (e.g., complications), it is important to recognize that maternal behaviors and experiences are important aspects of health as well. The existence of a positive and supportive environment for the psychological and physical needs of the mother, as well as infant and family, is critical in promoting optimal conditions for a successful gestational term and delivery.

### Pregnancy-Related Physical Complications and Deaths

*Maternal mortality* is the number of deaths from complications related to or aggravated by pregnancy or its management that occur during or within 42 days after pregnancy. Maternal mortality can be due to the direct effects of pregnancy or medical interventions as well as to indirect effects where pregnancy aggravates a preexisting or unrelated physical condition.

Monitoring and measuring maternal mortality is difficult and subject to misclassification and other measurement errors, especially in countries where deaths are not adequately and standardly reported and classified. However, the World Health Organization (WHO), United Nations Children's Fund (UNICEF), and United Nations Population Fund (UNFPA) estimate that 529,000 maternal deaths occurred globally in the year 2000, with the highest death numbers and rates in Africa and Asia. More developed regions in the world account for a very small percentage of pregnancy-related deaths. However, even in the United States, maternal mortality rates have not dropped since the early 1980s, and black and Hispanic women have disproportionately high pregnancy-related

deaths. It is thought that many of these deaths could be prevented through improvements in health care quality, access, and utilization, as well as changes in lifestyle and health-related behaviors. The most common causes of pregnancy-related deaths in the United States are hemorrhage, embolism (artery blockage), pregnancy-induced hypertension (high blood pressure), sepsis (infection), anesthesia complications, and cardiomyopathy (disease of the heart muscle).

*Maternal morbidity* refers to the number of cases of pregnancy-related complications before, during, and after delivery at a certain point in time. The three most common complications of pregnancy include pregnancy-associated hypertension, diabetes, and anemia. Women over 35 years of age have higher rates of complications such as diabetes, cardiac disease, and chronic hypertension compared with younger women. Medical complications during pregnancy contribute to maternal mortality as well as infant morbidity and mortality. For women of normal weight prior to pregnancy, a weight gain of approximately 23 to 35 pounds is recommended. Excessive gestational weight gain is associated with greater postpartum weight retention and higher rates of obesity. Psychological morbidity related to pregnancy includes depression and is addressed in the next section.

## Psychological Aspects of Maternal Health

Pregnancy involves a tremendous amount of change in body size, shape, and physiology. This dramatic metamorphosis of the body is accompanied with all the changes and adaptations that come with the preparation for a newborn. It is no wonder that women often feel a range of emotions, from happiness and elation to fear and anxiety, as they anticipate and prepare for motherhood. Pathological reactions (e.g., neuroticism, psychosis) during pregnancy are rare, and it is quite normal and adaptive for a woman to experience some emotional disequilibrium during this major life development.

Dramatic fluctuations in hormones such as estrogen and progesterone occur during pregnancy and delivery and may contribute to depression during and following pregnancy. However, depression is complex and not completely explained by biochemical events. Life stresses, a difficult pregnancy, dysfunctional relationships, ruminative thinking, and poverty are examples of psychological and social factors that also may

contribute to depression during and following pregnancy. Depression is a major health issue and burden among women and appears to be especially prevalent in women during pregnancy and the postpartum period. An estimated 15% to 20% of new mothers experience postpartum depression, with rates even higher for women who have had high-risk pregnancies. Depression following pregnancy can adversely impact the mother-child attachment and other family interactions. Depression during pregnancy can lead to physiological effects that are detrimental to prenatal development and are associated with low infant birth weight and prematurity.

The fluctuations of hormones during and after pregnancy do not necessarily result in negative reactions or depression. A body of evidence shows that oscillations in hormones such as oxytocin and cortisol following pregnancy actually facilitate mother-infant bonding and may even buffer stress reactions. Psychological reactions, whether positive or negative, develop from the interaction of a number of influences such as hormonal changes that occur during pregnancy and delivery, the physical health of the mother, a woman's perception of and attitude toward the pregnancy, and the existence of supportive and positive relationships with others.

## Maternal Health in a Social Context

Women do not have babies within a social vacuum, and the social context of pregnancy and childbirth are important considerations in maternal health. A strong support system can be essential in helping a woman obtain prenatal care as well as engage in behaviors that promote health of both the mother and the infant. A woman's pregnancy and baby's arrival often coincide with the highest rates of strain on the existing marriage or relationship. Simultaneously, it is during this time that a woman's health would benefit significantly from nurturant behavior from her partner—such as massages to alleviate distress and help her manage stress.

Violence against women during pregnancy is increasingly being recognized as a major issue in maternal health, affecting an estimated 4% to 8% of pregnancies in the United States—rates rivaling the incidence of conditions of pregnancy for which women are routinely screened. There is no single profile for a perpetrator or victim; however, intimate partner violence is related to factors such as an unintended

pregnancy and substance abuse. Physical abuse during pregnancy is associated with elevated risks for pregnancy complications such as hemorrhage, low birth weight, and perinatal death.

## MATERNAL BEHAVIORS AND CHILD HEALTH

Maternal health begins prior to conception and is promoted by a healthy lifestyle and proper nutrition throughout the pregnancy and postpartum period. Whereas some risk factors for gestational development and infant health are not modifiable (e.g., genetics), many risk factors can be influenced by maternal behaviors. Recommended behaviors for optimizing infant health include getting prenatal care and infant checkups; taking precautions to avoid infection; eating a well-balanced diet rich in folic acid, calcium, and B vitamins; and avoiding alcohol, cigarettes, and illicit drugs. A deficiency of folic acid is associated with increased risk for neural tube defects such as spina bifida.

Many bacteria, viruses, and chemical substances can pass the placental barrier and harm the developing offspring. These harmful agents are called teratogens and pose a great risk during prenatal development. Alcohol use during pregnancy is associated with birth defects, mental retardation, low birth weight, and miscarriage. Smoking during pregnancy is associated with miscarriage or ectopic pregnancy, low birth weight, and infant death. Despite the risks associated with smoking, a notable percentage of women in the United States (12% in 1999) giving birth report smoking during pregnancy, with rates higher in white women than in other race and ethnic categories.

Medications, even over-the-counter substances, can cross the placental barrier and should be confirmed with a medical care provider before use. Illicit drugs, such as heroine and cocaine, are dangerous to the unborn child and can cause miscarriage, brain damage, low birth weight, and infant death, as well as life-long disabilities such as mental retardation. One caveat—while it is easy to judge the choice to use by pregnant women who smoke or abuse substances as the main problem, the underlying coping needs of such individuals may provide more enlightening answers. In short, the broader social context of these individuals may fail to support women in ways that promote healthy maternal behavior. Therefore, it is important to consider social factors that may lead women to engage in potentially destructive behaviors during pregnancy.

Breast-feeding has many health benefits for women and infants (although certain medical conditions and treatments make breast-feeding inadvisable). In women, breast-feeding reduces postpartum bleeding, facilitates the loss of pregnancy-associated weight gain, helps the uterus tighten up and return to its original size more quickly, and may reduce the risk for premenopausal ovarian and breast cancer. The release of the hormone oxytocin from nursing facilitates social and parental behavior and bonding and buffers from social stress. The infant benefits from more complete nutrients and infection-fighting agents provided in breast milk in addition to the soothing contact.

## SUMMARY

Pregnancy and childbirth can be a very fulfilling development in a woman's life. Whereas not all aspects of maternal health are controllable, a woman's healthy lifestyle and a sufficient support system can help make a pregnancy more noted for the remarkable transformation of the body and psyche in realizing motherhood than for the presence of illness.

## MATERNAL PHENYLKETONURIA

---

Maternal phenylketonuria (MPKU) is an iatrogenic aspect of the dietary treatment of phenylketonuria (PKU). PKU is an autosomal-recessive inborn error of metabolism in which a person cannot metabolize phenylalanine (Phe) into tyrosine and its constituent components. Unmetabolized Phe is toxic to developing brain tissue and results in severe mental retardation. Prenatally, individuals with PKU receive normally digested nutrients through the umbilical cord; neurological damage begins postnatally when the newborn begins digesting food. Until the 1960s, the IQ of individuals with PKU was about 30, and few affected women became pregnant. Beginning at that time, national screening of newborns for PKU and treatment with a synthetic low-Phe diet prevented much neurological damage. Individuals with PKU placed on the diet shortly after birth have IQs only slightly below average in adulthood, although they are subject to attention deficit/hyperactivity disorder, learning disabilities, and frontal lobe dysfunction.

Owing to the success of identification and treatment programs, several thousand women of childbearing age in the United States alone have been treated for PKU, live essentially normal lives, and are likely to become pregnant. Initially, affected individuals stayed on the diet only until late childhood or early adolescence, after which they ate normal food, since brain development was presumably complete. However, the diet did not cure the disorder, and Phe began to accumulate in their blood.

### ONSET AND CONSEQUENCES

MPKU occurs when a woman who is eating normal food or otherwise insufficiently regulated Phe becomes pregnant. The probability of the embryo itself having PKU is relatively low (about 1 in 120), but since the woman cannot metabolize Phe, toxic unmetabolized substance enters the embryo's bloodstream, generally producing massive central nervous system damage. In a collaborative MPKU study, the incidence of defects was as follows: spontaneous miscarriage in 24%, intrauterine growth retardation in 40%, microcephaly in 73%, mental retardation in 92%, and congenital heart defects in 10%. Survivors were also at high risk for growth retardation, neurological disorders, and minor craniofacial dysmorphologies. Frequency and severity of abnormalities were apparently correlated with the degree of maternal Phe levels during pregnancy. Since the adverse effects are irreversible, prognosis varies with the degree of early impairment.

The tragically paradoxical result is that the mother, whose genotype predicted an IQ of about 30, is largely spared the adverse consequences owing to a postnatal environmental influence, the low-Phe diet, whereas her offspring, whose genotype generally predicts a normal IQ, suffers major central nervous system damage owing to a prenatal environmental influence, unmetabolized Phe.

### PREVENTION

Recommendation currently is for those with PKU to remain on the special diet throughout life. However, even women with PKU whose phenylalanine levels have been partially controlled during pregnancy are at risk for having offspring with serious problems. To reduce defects further, women at risk for pregnancy need to have Phe levels maintained at a low level.

Women with PKU who have been treated with the special diet should be informed of the risks of high levels of Phe to their offspring and urged to seek medical and nutritional advice before becoming pregnant. Unfortunately, prenatal control of Phe levels is difficult, and women with treated PKU are at risk for unplanned and uncontrolled pregnancy.

## MATERNAL SMOKING

Maternal smoking during pregnancy is a risk to the fetus, newborn, and developing child. Between one in nine and one in six pregnant women smoke during pregnancy in the United States. Although the prevalence of women who smoke during pregnancy has declined over the past 10 years, the percentage of pregnant adolescents who smoke is actually increasing.

Compared with nonsmokers and women who quit smoking early in pregnancy, maternal tobacco use results in markedly increased maternal and fetal morbidity. A 2004 Surgeon General's report concluded that smoking during pregnancy increases many pregnancy complications (Table 1). Nicotine-mediated vasospasm of maternal placental blood vessels is a likely mechanism of some of the negative effects, along with alterations of uterine, placental, and fetal circulatory homeostasis.

Low birth weight is a leading cause of infant death, resulting in more than 300,000 deaths annually in the United States. If all pregnant women in the United States stopped smoking, there would be an estimated 11% reduction in stillbirths and a 5% reduction in newborn deaths.

Sudden infant death syndrome, childhood respiratory disease, and asthma are also associated with maternal smoking during pregnancy. There is evidence

**Table 1** Summary of Pregnancy Complications Associated With Maternal Smoking During Pregnancy

<i>Condition</i>	<i>Smoker's Risk Compared With Nonsmoker or Early Pregnancy Quitter</i>	<i>Evidence for Causal Relationship</i>
Miscarriage	1.2 to 1.3 times	Suggestive
Ectopic ("tubal") pregnancy	1.3 to 2.5 times	Suggestive
Placenta previa (placenta covering cervix, associated with bleeding and preterm delivery)	2.5 times	Yes
Placental abruption (separation of placental from uterine wall resulting in internal hemorrhage)	1.4 to 2.4 times	Yes
Preterm rupture of membranes and preterm birth	1.6 to 2.1 times	Yes
Fetal growth restriction	~200 g less	Yes
Cleft palate	Possible association	Suggestive
Chromosomal anomalies, gastroschisis (ventral wall defects), cardiac defects, omphalocele (abdominal viscera herniated into base of umbilical cord)	No observed association with maternal smoking	Evidence inadequate to infer presence or absence of a causal effect of maternal smoking
Preeclampsia (hypertension, renal dysfunction, hematologic derangements that can result in maternal neurologic damage)	~0.5 risk for smokers (protective effect)	Suggestive

of a prenatal tobacco dose-related increase in childhood and adolescent obesity among smokers' children, even after adjusting for maternal diet, breast-feeding, maternal obesity, and socioeconomic status.

Behavioral outcomes related to maternal smoking during pregnancy include lower scores on tests of verbal skills, higher activity levels, worse performance on attention tasks, higher rates of aggression as adolescents, and a higher risk for violent crime in adulthood. Differences have been found between siblings born to the same mother who smoked while pregnant with one child and not with the other. Controversies in the behavioral research concern whether genetic vulnerability accounts for the association between prenatal maternal smoking and offspring antisocial behavior, whether maternal smoking is a marker of poor health behaviors such as alcohol consumption that, in turn, cause the behavioral effects, and whether low birth weight and other perinatal complications cause the behavioral effects. Animal research shows that prenatal nicotine alters cellular and genetic processes of early brain development, affects cognitive performance in rats in complex tasks and after pharmacological challenge, and impairs the ability of the brain to repair itself after injury.

## MATURATION

---

Maturation is a biological process where developmental changes are controlled by internal (or endogenous) factors. Events that result from maturation (such as walking or secondary sex changes at puberty) are

characteristic of the species and are never the result of specific practice or exercise. That is, they are not learned.

But is maturation just a process that all humans go through and one not to be used to further our understanding of individual differences? The process does seem to be very important. Waber conducted a fascinating study that examines the relationship between maturation and sex differences. Previous research had shown that males tend to score higher than females on tests of spatial abilities, while females tend to score higher on tests of verbal abilities. Waber asked the following question: Are these differences in performance the result of differences in maturation or differences in sex? She answered it by testing both early- and late-maturing males and females. She found that early maturers, regardless of sex, performed better on tests of verbal abilities, while the reverse was true of late maturers (thus confirming her hypothesis). Research such as this does not discount the importance of sex as a variable for explaining differences in performance, but it does emphasize that maturational processes have a broader influence than might have been earlier believed.

Arnold Gesell was the foremost theoretician to put forth a comprehensive theory of development based on the process of maturation. While he did believe that the environment played an important part in the developmental process, its role was one of support, not of change. According to Frances Ilg, his student and colleague, “Environmental factors support, inflect, and modify but they do not engender the basic norms and sequences of ontogenesis” (or individual development).

## MEAN LENGTH UTTERANCE

---

When does language begin? This question has long been debated. One of the reasons for the debate is the

question of how to measure complexity of language. Under the influence of Chomsky, the transition from single words to two-word utterances was used to mark the beginning of language. Roger Brown (1973) introduced an influential measure of syntactic development that was based on a 5-year-long study. He began this study with three children—Adam, Eve, and Sarah—in 1962 at Harvard University. Eve was observed from 18 months to 26 months, Adam was observed from 27 months to 42 months, and Sarah was observed from 27 months to 48 months. Linguistic growth of these children was assessed in terms of morphemes, that is, meaningful units of speech rather than words. Mean length utterance (MLU) is based on the average length of the first 100 utterances scored on transcripts of spontaneous speech. Length of utterance is determined by morphemes. Morphemes consist of simple-content words such as *Mummy*, *mouse*, *food*, *eat*; function words such as *no*, *yes*, *you*, *me*; and affixes such as *un-* (*un-done*) *-s* (toys, balls), and *-ed* (*walked*). Brown suggested the following rules for calculating the MLU: Researchers should only start counting morphemes on the second page of the transcript and utterances to be used had to be fully transcribed without blanks. All exact repetitions of utterances were to be counted. However, single words were to be counted only once, unless they were used to emphasize a statement, such as a child saying, “no, no, no,” if they really did not want whatever was offered. Fillers such as “mm” or “oh” were not to be counted, but morphemes such as *hi* or *yeah* were to be included. Compound words such as *pussy-cat* or *choo-choo train* were to be counted as one word, as were irregular past verbs such as *went*, *saw*, and *did*. Diminutives such as *doggie* and *sweetie*, as well as *gonna* and *wanna*, were counted as one morpheme, but auxiliaries such as *is*, *have*, *will*, and *can* were counted as separate morphemes. All inflections such as possessive *'s*, as in “daddy’s car,” plurals, such as *cats*, third-person singular *-s*, as in “she plays,” and regular past *-ed*, as in “he played” were counted as separate morphemes. The ranges of utterance length were to be based on the complete transcript rather than only 100 utterances. Brown found that the growth of MLU varied for the three children he studied. He divided the major periods of a child’s language growth into five stages. The first stage is when MLU is between 1.0 and 2.0, while stages 2 to 5 are marked by increments of 0.5. Hence stage II ranges from 2.0 to 2.5; stage III

ranges from 2.5 to 3.0; stage IV ranges from 3.0 to 3.5; and stage V ranges from 3.5 to 4.0. Subsequently, Miller and Chapman (1981) established MLU norms based on a sample of 123 middle-class children living in Madison, Wisconsin. The age range of MLU norms have recently been extended to 13 years of age (Miller, 1991). Most of this work has been performed on English speakers, and extension into other languages may be problematic. MLU has been used as an index of grammatical development in general but has also been extended into the field of stuttering and specific language impairment as well as Down syndrome research.

## MEDICARE

---

Medicare is the federal program that provides health insurance for the elderly (all adults over age 65), disabled recipients of Social Security, and people with end-stage renal disease in the United States. It was established by Congress in 1965 as Title XVIII of the Social Security Act and is the single largest source of financing for health care in the country. Medicare has contributed to improving the quality of life and increasing the life expectancy of the elderly. In combination with Social Security payments, it has effectively reduced the rate of poverty among the elderly from nearly 35% in the early 1960s to approximately 10% in 2000. As originally enacted, Medicare was a combination of compulsory hospital insurance (Part A) and voluntary insurance for outpatient care and physician services (Part B). Currently, Medicare also includes Part C (originally Medicare + Choice, now Medicare Advantage) and Part D (the outpatient prescription drug benefit, which comes into effect in 2006).

## HISTORY OF MEDICARE

Medicare was conceived as the politically feasible first step toward universal, national health insurance. Although President Harry Truman proposed publicly funded, universal, national health insurance in 1945, Congress did not enact any health insurance legislation because of the opposition of the American Medical Association (AMA) and the business community. In the 1950s, Congress provided health insurance for federal employees and for dependents of members of the armed forces. In 1960, Congress enacted the Kerr-Mills Law, which provided a limited program of medical assistance to the aged. President Lyndon Johnson's landslide victory in 1964 and the simultaneous election of large Democratic majorities in both houses of Congress made Medicare's enactment possible.

## COMPROMISE AND INNOVATION

Several of Medicare's features reflected the political compromises necessary to enact the original legislation. As a compromise with the AMA, the American Hospital Association, and the Blue Cross and Blue Shield health insurance plans, fiscal intermediaries and insurance carriers were assigned to administer claims and disburse federal funds to physicians, hospitals, and other eligible health professionals. The original program did not seek to control the practice of medicine, regulate hospitals, or control the costs of physician services. Instead, the program's guiding principle was to ensure that the elderly were able to receive the same standard of care as patients insured through employer-based health insurance. Two of the original features—retroactive cost-based reimbursement for hospitals and payments to physicians based on a usual, customary, and reasonable (UCR) fee—were later changed in an effort to control costs, which had risen rapidly. The 1983 Social Security amendments introduced a new Medicare reimbursement scheme by initiating prospective payment of hospitals. Under this arrangement, compensation is based on the diagnosis-related group (DRG) system, in which payment is dependent on per-case diagnosis. This prospective payment system is widely viewed as successful in moderating the growth of hospital care costs.

In 1989, Congress adopted a fee schedule to pay physicians based on a resource-based relative value scale (RBRVS). The RBRVS was implemented by the Health Care Financing Administration between

1992 and 1996 (renamed the Centers for Medicare and Medicaid Services in 2001). RBRVS became a means of implementing a standardized physician payment schedule set by the federal government in which payments are related to the resource costs needed to provide them. Payments are adjusted by region to reflect geographical differences in resource costs. The fee schedule based on the RBRVS is the mechanism used to control Medicare expenditures for physician services. The RBRVS has also decreased the gap between payments to primary care physicians and procedural specialists.

Long before Medicare pioneered techniques in cost containment, it played an important role in the civil rights movement of the 1960s by enabling the federal government to desegregate the nation's hospitals. Title VI of the Civil Rights Act of 1964 requires equal access to programs funded by the federal government. Under President Johnson's leadership, the Department of Health, Education, and Welfare applied the legislative mandate of the Civil Rights Act to the federal funds available to hospitals through the Medicare program to assure that any hospital participating in Medicare met the requirements of Title VI. Over 1,000 hospitals were desegregated between January 1966 and the implementation of Medicare on July 1, 1966. The desegregation of the nation's hospitals contrasted sharply with the slow pace of school and housing desegregation.

## NATURE OF POPULATION SERVED

The nature of the Medicare population has changed since the program's implementation in 1966. In 1972, with the advent of life-saving dialysis treatment, Congress extended benefits to patients with end-stage renal disease (ESRD), regardless of age. The extension of benefits to patients with ESRD has amounted to a significant source of Medicare expenditures, particularly with the arrival of new types of treatment, such as kidney transplantation. Recent changes in demographic patterns also contribute to the changing nature of the population served by Medicare. Life expectancy is increasing. In fact, people over age 85 account for the sector of the population that is increasing the fastest. Because people over age 85 typically have more chronic medical problems and use more medical resources, changes in population structure can have a profound influence on the financial viability of Medicare. Currently, Medicare spends a major share of its expenditures on a small portion of its

beneficiaries. Five percent of Medicare beneficiaries account for 45% of total spending, while 52% of beneficiaries account for 3% of spending. Although this type of distribution is not unique to Medicare, it is aggravated by the fact that Medicare does not pay for routine physical examinations and preventive care.

### SUPPLEMENTAL COVERAGE AND PRESCRIPTION DRUGS

Although Medicare is widely viewed as successful in achieving its aim of protecting the elderly and their families from the extremely high cost of medical care, it falls short of offering comprehensive coverage to its beneficiaries. To help cover the costs of Medicare's deductibles, the majority of Medicare participants also have some form of supplemental coverage, which is provided by their former employers or Medicaid or paid for out of pocket. In fact, only 13% of Medicare recipients have no supplemental coverage. While Medicare was comparable, and often superior, to private plans when it was enacted and has vastly improved the elderly's access to health care, it has not kept pace with the coverage of health insurance plans in the private sector, particularly with regard to outpatient pharmaceutical coverage.

As early as 1967, then Secretary of Health, Education, and Welfare John Gardner established the Task Force on Prescription Drugs, which recommended adding a prescription drug benefit to Medicare in its 1969 Final Report. In 1988, the first major expansion of benefits, which included the addition of a prescription drug benefit, was enacted. However, the Medicare Catastrophic Coverage Act of 1988 (MCCA) was repealed in 1989 before its implementation because it was widely unpopular with the elderly, largely because of the progressive (means-related) financing of the prescription drug benefit. Many elderly felt that this violated the program's social contract. In addition, the MCCA failed to address the issue of long-term custodial nursing home care, the leading source of catastrophic medical expenses for the elderly at that time.

Nearly 40 years after Medicare's enactment, Congress added an outpatient prescription drug benefit. The politically contentious Medicare Prescription Drug, Improvement and Modernization Act (MMA) of 2003 will pay for outpatient prescription drugs through private plans. It becomes effective in January 2006 and is currently projected to cost \$530 billion over 10 years.

### MANAGED CARE

As in other sectors of health care, managed care has played a role in Medicare since the mid-1980s. Medicare began risk-based contracting with health maintenance organizations (HMOs) in 1985. Many beneficiaries have chosen to enroll in Medicare HMOs to be covered for deductibles and, in many cases, to obtain coverage for outpatient prescription drugs, which were not a standard Medicare benefit at the time. It has been found that favorable selection occurred whereby younger, healthier Medicare beneficiaries were more likely to enroll in HMOs. Since Medicare's payments to HMOs were based on 95% of the average cost of a beneficiary, this favorable selection resulted in overpayments. With the Balanced Budget Act of 1997, several new alternatives were added, collectively known as Medicare + Choice, including medical savings accounts and the option of choosing a preferred provider organization. In recent years, the number of HMOs participating in Medicare has declined, while others have dropped their prescription drug benefit, causing disenrollment by dissatisfied beneficiaries. The Medicare Prescription Drug, Improvement and Modernization Act of 2003 committed \$14 billion to increase payments to managed care plans. With this influx of funds, managed care plans will be paid, at least temporarily, more per enrollee than the average cost of beneficiaries in the traditional fee-for-service plan.

### FUTURE ISSUES

In the future, lawmakers will have to contend with ensuring quality care in the midst of rising costs, which are related to the growing use of expensive medical technologies and the rapidly aging population. Because taxes on current workers pay for Medicare Part A, as the number of retirees and the costs of health care rapidly rise, the increasing tax burden on workers will become a pressing policy issue. Future issues include how to ensure the long-term financial viability of the program, how to cover the rising costs of hospital (Part A) and physician services (Part B), particularly in the face of expensive new methods of illness prevention and care, how to ensure that cost reduction efforts do not result in decreased access to care, and who should pay for long-term custodial care. For the nation's most popular social program, these cost and quality issues pose serious challenges for policymakers.

## MEMORY FAILURE

---

It has long been held that a person's memory gradually deteriorates across the life span. This conclusion has been based on research demonstrating that memory performance gradually decreases as people get older and that self-reports sometimes have shown that memory fails more often for older people than for younger people. There is no doubt that physiological changes across the life span affect the likelihood of memory failure. However, when observations of memory failure or reports of memory are made, a somewhat different picture of the influence of aging on memory emerges.

Research on memory in early childhood reveals that even very young children are clearly capable of remembering events; however, the likelihood of successful future recall for early life events (e.g., those occurring prior to age 3 or 4) is minimal, a phenomenon known as "childhood amnesia." Additionally, research on eyewitness testimony suggests that children under the age of 6 are vulnerable to distortions in recall following exposure to misleading information. Consistent with

the results for performance, self-reports demonstrate that memory failures decrease from childhood to adolescence and from adolescence to young adulthood. Similarly, increased age between young adults and middle-aged adults also corresponds with decreases in the frequency of observed failures (although periods of intense job and family responsibilities in middle age may produce a temporary increase in such failures). Alternatively, recent research has found that older adults recall having experienced fewer memory failures than middle-aged adults.

Overall, it appears that the frequency with which memory fails gradually decreases across the life span in healthy older people (excluding those with dementia or other memory disorders). In childhood as well as adulthood, these decreases appear to be due to maturation and learning. As children develop their language skills and knowledge base, they are better able to understand life experience in ways that lead to less memory failure. As people age, they acquire more effective strategies for learning and retrieval. Although older people report more difficulty learning novel tasks, as well as less confidence in their memory abilities, they also report having everyday memory failures less frequently than are reported by younger people.

Several reasons may be offered for why older adults may report fewer memory failures than younger adults. Older individuals may report fewer memory failures because they are often retired and have a less demanding lifestyle. In addition, there is evidence that older people make more use of external memory aids (e.g., notepads and planners) than younger people. Also, older people value and often remember prospective memory tasks more than younger people. It could be argued that older people may simply forget more of their memory failures than do younger people. However, older people do not report fewer memory failures for all memory asks. For example, older adults report forgetting to turn off the stove more often than younger adults. Nevertheless, it can no longer be assumed that healthy older people have poorer memories than younger people.

## MENARCHE

---

Menarche is defined as the onset of menstruation and signifies that the body is readying for reproduction. Menarche is a significant event for the adolescent girl that affects both the body and the identity. From a physiological standpoint, menarche is a visible sign of puberty. At approximately age 8 to 10 years, changes in the reproductive system begin with the release of ovarian estrogen and pituitary gonadotropins. This causes growth in the reproductive organs and secondary sex characteristics to appear. Concurrently, a growth spurt occurs, accounting for 20% to 25% of the adolescent's final height and 50% of ideal body weight. In addition, the external signs of physical maturation in adolescent girls follow a pattern. Breast budding is first, followed within a few months by pubic hair growth, and then changes in body shape. Axillary hair and activation of axillary sweat glands begin later. Internal changes at this time include uterine and vaginal growth, a more acidic vaginal pH, and an increase in vaginal secretions. Ovarian estrogen production increases, and the pituitary assumes a cyclic rhythm. At this point, late in puberty, menarche occurs. Ovulation does not always occur early on in the menstrual life cycle. Only 23% of females ovulate in the first year after menarche.

The average age of menarche in 1840 was 16.5 and is presently 12.8 years. In developing countries, the age at which menarche occurs has decreased by almost 4 years over the past 150 years. However, it appears as though this trend has ended and the age of menarche has reached a plateau. The decrease in the age of menarche may be due to improvement in socioeconomic conditions, effective public health measures, and nutrition. The timing of puberty, and therefore menarche, is affected by many factors, including genetic and biological influences, stress, socioeconomic status, health, and environmental factors. There is a familial pattern with menarche. It is not uncommon for a girl to

reach menarche about the same age as her mother or sisters. Environmental factors, such as exercise, nutrition, and weight, also affect the timing of menarche. Initiation of menses depends on attainment of a critical body weight and fat. Obesity is a factor contributing to an earlier menarche. Another contributing factor to the age of menarche is ethnicity. Menarche occurs 8 months earlier in African American girls than in white girls.

At menarche, adolescent girls are prone to certain menstrual disorders, including irregularity and dysmenorrhea. Menstrual irregularity is common for the first 18 months after menarche. Dysmenorrhea is experienced by 50% of adolescents and decreases in early adulthood. Ten percent of adolescent girls are incapacitated for 1 to 3 days a month.

Psychological implications of menarche are also important. Menarche is an event that contributes to the meaning of a personal and sexual identity. Societal attitudes affect the meaning of menarche. Some cultures have taboos, where menstruating females are not permitted to perform certain tasks or be with males. Societal attitudes toward menarche in the United States are primarily negative, including the belief that menses is offensive and associated with dirtiness and odor. These negative attitudes affect girls at a time when they are at great risk for identity and self-esteem problems and can lead to anxiety about menarche. At this time, girls often feel an increasing closeness and dependence on their mothers and a distancing from their fathers. In addition, postmenarcheal girls often view themselves as more sexually differentiated than premenarcheal girls. Self-portraits of premenarcheal girls are often androgynous, while self-portraits of postmenarcheal girls contain more adult clothing, jewelry, breasts, hips, and a waist. Parents, too, often view their daughters differently, allowing them more freedom, such as wearing makeup, dating, and later bedtimes and curfews.

Research studies on menarcheal preparation demonstrated that many girls were not adequately prepared for menarche and experienced fear, anxiety, and ambivalence. Studies showed that preparation through menstrual education assisted in allaying negative perceptions. In addition, most research showed that girls remember their first menstruation as an emotionally important event that elicits both excitement and fear.

## MENOPAUSE

---

The point in a woman's life when she stops experiencing monthly menses (periods) for an entire year is defined as menopause. It marks the final chapter in a woman's reproductive cycle and an end to her fertility. Menopause occurs as the woman's ovaries slow in their production of estrogen and eventually stop releasing eggs. In most women, this is a gradual process that develops over several years. The average age for achieving menopause is 51 years.

The time during which a woman begins to experience the transition into menopause is called perimenopause. For most women, perimenopausal symptoms start around age 45. This period of fluctuating hormones may have implications for the woman physically and emotionally. Some women look forward to this time when they can look back at monthly bleeding and concerns over pregnancy with newfound freedom. Others express anxiety and discomfort as the changes of perimenopause impact their feelings of youthfulness and overall health.

The cessation of menstruation caused by the surgical removal of the ovaries and uterus or chemotherapy or radiation treatments is known as induced menopause. This experience differs from natural menopause in that it is an abrupt rather than gradual change.

A woman who has achieved menopause is considered postmenopausal. It is essential that she continue to monitor her health through yearly breast and pelvic examinations, Papanicolaou (Pap) smears, and general health screenings, such as bone density tests and colonoscopy.

A changing menstrual pattern is often the first indication a woman may have that she is perimenopausal. The cycle typically becomes irregular with skipped or missed periods, but may also manifest more frequent, heavier bleeding. It is important to provide contraceptive counseling to perimenopausal women, because until menopause is achieved, fertility and pregnancy are a possibility. Hormonal contraception during this period may also help offset some of the physical discomforts that are frequently experienced during this phase.

In addition to changing bleeding patterns, the majority of perimenopausal women experience some combination of the following symptoms: hot flashes, increased sweating, frequent urination, headaches, vaginal dryness, decreased libido, insomnia, forgetfulness, and mood swings. Perimenopausal women are often also dealing with midlife events that can exacerbate these symptoms.

Hormonal and nonhormonal treatments are available for reducing the symptoms of menopause. Nonhormonal options are varied and may be specific to certain categories of symptoms. For example, although a diet that is rich in vegetables and fruit and minimizes saturated fats is best for overall health, avoiding caffeine and alcoholic beverages and increasing soy foods may actually decrease the number and severity of hot flashes and night sweats. Weight-bearing and aerobic exercise is recommended to help maintain bone density and cardiac function. Kegel exercises, the tightening and relaxing of the vaginal muscles, increases blood flow, increases lubrication, helps maintain bladder control, and may enhance orgasm.

Menopausal women have employed alternative medicine options such as homeopathy and acupuncture, as well as use of herbal supplements, for successful relief of bothersome symptoms.

Hormonal treatments have been a popular choice but do have some associated risks. These options must be tailored to each woman's needs keeping under consideration her relevant health history to maintain risks at a minimum.

Vaginal creams are used by many women to reduce vaginal dryness and enhance sexual function. Non-prescription lubricants and vaginal moisturizers are also available.

Systemic hormonal therapy benefits women by eliminating hot flashes, reducing vaginal dryness caused by thinning vaginal tissue, decreasing insomnia, and possibly improving mood and energy levels. However, these therapies may carry added risks for some women that may outweigh the benefits. These may include an increased risk for breast and uterine cancer, heart disease, blood clots, and gallbladder disease.

In general, the perimenopausal period of a woman's life brings with it many changes—some welcomed, some not. However, the achievement of menopause, a milestone in female development, may be associated with feelings of freedom, relaxation, and overall well-being.

## MENSTRUATION

---

Menstruation is a phase in the female reproductive or menstrual cycle. This monthly cycle involves the release of an ovum, or egg, from the ovary as well as the thickening and shedding of the endometrium, the outer layer of the uterus. Hormones released from the hypothalamus, pituitary glands, and ovaries regulate the menstrual cycle. Each month an ovum matures in one of the ovaries. In the middle of the 28-day cycle, the mature ovum is released from the ovary into one of the fallopian tubes. This is referred to as ovulation. The ovum travels down the fallopian tube and into the uterus. If a sperm fertilizes the ovum, it is implanted in and nourished by the tissues in the endometrial lining. If fertilization does not occur, the lining is shed through the vagina. This shedding is referred to as menstruation. This outer layer, which consists of a small amount of blood (2 to 5 ounces per month), detaches from the uterine wall and leaves the body, along with other cervical and vaginal secretions, through the vagina.

Menstruation is also referred to as having a period, the menstrual flow, menses, or bleeding. Most women menstruate for approximately 3 to 7 days.

Girls experience their first menstruation or menarche around the age of 12 or 13. Menarche occurs within the broader context of puberty and is actually one of the last physical changes that girls experience. The first period, a major developmental milestone, is a sudden and often dramatic event that signals movement from childhood to adulthood. After menarche, girls may experience changes in their identity, body image, and self-esteem. Their new sexual maturity may also influence their social and family status. Many girls report feeling both excited about the onset of menstruation as well as scared or ashamed. Girls who are prepared ahead of time for this major change have more positive experiences and attitudes than those who are unprepared.

Many people share negative attitudes toward menstruation and view menstruation as an unsuitable topic of discussion. Often referred to as “the curse,” menstruation is associated with sickness, debilitation, instability, and pain. This taboo status perpetuates negative attitudes and myths and may cause girls and women to feel embarrassed and ashamed about menstruation. They may avoid certain activities during menses and conceal their menstrual status from others. When asked about positive aspects of menstruation, however, women report that they regard regular menstruation as a sign of good health and an indicator of their fertility status.

Some women experience physical changes, referred to as symptoms, just prior to and during menstruation. These include breast tenderness, bloating, and cramping. For the majority of women, these symptoms do not interfere with daily functioning. However, some women experience disorders such as dysmenorrhea, or the experience of extremely painful cramping during menstruation, that may interrupt their functioning. Some women report psychological symptoms prior to menstruation, such as irritability, depression, anxiety, and moodiness. This collection of symptoms is commonly known as premenstrual syndrome (PMS), although the validity of this “disorder” has been debated. A more severe form of PMS, which is known as premenstrual dysphoric disorder (PMDD), is an official psychiatric diagnosis. However, the prevalence rate for this disorder is quite low.

Most women experience menstruation for four decades. Climacteric, or the gradual cessation of

regular menstrual cycles, takes place over the course of approximately 5 to 7 years. When a woman has experienced the absence of menstrual cycles for 12 months, she has reached menopause. This typically occurs around the age of 51 years.

## MENTAL AGE

---

Mental age is an assessment of performance based on the behavior typical for an age group. For example, a mental age of 7 years indicates that the subject's performance is that of a typical 7-year-old child. Mental age itself does not take into account the subject's actual chronological age. Mental age divided by chronological age times 100 (to eliminate decimal places) is the generic formula for calculating IQ (the intelligence quotient). The concept of mental age was first introduced as mental level in the Binet-Simon Scale of 1908. Binet's goal was to identify the academic skills typical of specific age groups. Binet did not assume that there was one general intelligence underlying different academic areas such as language and math. Binet also did not assume that a hereditary component determined mental age. Early in the 20th century, the theoretical construct of mental age was transformed by research supporting Charles Spearman's theory of a general intelligence factor underlying IQ and of a hereditary component. It was William Stern, in 1912, who first divided mental age by chronological age to take into account the actual age of the child. In 1916, Lewis Terman multiplied the

intelligence quotient by 100 to get rid of the decimal places. Terman's formula for calculating the intelligence quotient became popularized as the formula for measuring IQ. Using Terman's formula, a child with the same mental age and chronological age would have an IQ of 100. Research has shown that IQ tests measure the rate of academic learning for most children by 7 years of age. The average child at age 7 years would have a mental age of 7, and continuing to learn at an average rate, would have a mental age of 8 at 8 years of age, and so forth. Contemporary IQ tests use cumulative indexes to determine scores, rather than using Terman's formula to calculate each individual IQ score. Adult intelligence does not change from year to year, so mental age has much less meaning when discussing adult intelligence. The contemporary equivalent of mental age is the standard age score on the Stanford-Binet IQ tests (1987).

## MENTAL RETARDATION

---

Mental retardation refers to a state of functioning, a person's capacity for functioning in various environments. Although people with mental retardation have historically had limitations in life options due to societal attitudes, the view toward the possibilities and accomplishments of people with mental retardation is changing. People with mental retardation are a heterogeneous population with diverse personalities, interests, and abilities who can achieve given the appropriate supports.

### TERMINOLOGY

As the field and study of mental retardation evolve, so does the terminology used to discuss the disability. Over the course of the past century, various terms

have been utilized to characterize or label this disability. With time each term has begun to carry stigmata, and in an effort to reduce negative consequences, new terms have been periodically adopted. There is concern over the current use of the term mental retardation because it often becomes a global descriptor of a person that focuses on the deficits in functioning rather than abilities and strengths. Although there is general agreement that the term mental retardation carries stigma, there is no consensus from the field as to an appropriate term to replace the current label of mental retardation. Given this lack of acceptance of a single term, various terms, including mental retardation, intellectual disability, and developmental disability, are being used by organizations and advocates. The field continues to seek a common term that references this disability, reflects the current definition, and diminishes the associated stigma of the disability. For the purposes of this discussion, the term mental retardation will be used.

## DEFINITION OF MENTAL RETARDATION

The basic definition for mental retardation includes three components: (a) subaverage intellectual functioning, (b) significant limitations in adaptive behavior skills, and (c) manifestation during the developmental period. Although the definition of mental retardation has continually undergone revision, previous definitions include references to the above components. The organization leading the field in establishing, defining, and classifying the condition of mental retardation is the American Association on Mental Retardation (AAMR). The above components reflect the AAMR definition as well as the definition of other prominent organizations (e.g., American Psychiatric Association, World Health Organization).

## ASSESSMENT AND DIAGNOSIS

Determining if an individual has mental retardation involves utilizing assessment instruments to establish if the individual meets the criteria of the mental retardation definition. That is, a person's intellectual functioning and adaptive behavior have to be assessed to determine if that person has the deficits that are associated with mental retardation. Also, it has to be established that these deficits were evident during the developmental period.

## Assessing Intellectual Functioning

Intelligence is one's mental capacity for reasoning, solving problems, thinking, abstracting, learning from experience, and generalizing knowledge across settings. Mental retardation refers to subaverage intelligence as a measured intelligence quotient (IQ) of two standard deviations below the mean. The mean or average score for an IQ test is 100, and standard deviations are 15-point increments. Thus, subaverage intelligence is typically considered an IQ of 70 or below. Assessment of IQ involves administration of IQ and other assessment instruments by professionals trained in psychological evaluation. The most commonly used instruments for assessing intelligence are the Wechsler Intelligence Scales for Children-III, the Wechsler Adult Intelligence Scale-III, the Stanford-Binet-IV, and the Kaufman Assessment Battery for Children.

Individuals with subaverage intellectual functioning typically display deficits in memory and generalization, as well as decreased motivation. Memory deficits often center on problems with recall and strategies for remembering. Generalization difficulties involve problems with transferring and applying knowledge across environments. Due to repeated failures and excessive help received from service providers and caregivers, individuals with mental retardation often learn helplessness and have decreased motivation.

## Assessing Adaptive Behavior

Deficits in intellectual functioning may cause difficulty in acquiring and utilizing adaptive behavior skills. Adaptive behavior refers to skills necessary for daily life functioning in home, school, work, and community environments. Adaptive behavior includes skills across three domains: conceptual (i.e., language, academic, community, self-sufficiency), social (i.e., social interaction, communication), and practical (i.e., daily living/home living, self-help). Limitations are typically considered performance at least two standard deviations below the mean on either (a) one or more domains of adaptive behavior (conceptual, social, or practical); (b) an overall combined score across the domains of conceptual, social, and practical skills; or (c) two or more skills from any domain (e.g., communication and self-help). Various adaptive behavior scales are available to assess and identify areas of needs. Since assessing adaptive behavior

involves knowing about a person's daily life skills, those who know the individual with disabilities (e.g., parent, teacher) should complete the scales. Some of the more widely used adaptive behavior scales include Vineland Adaptive Behavior Scales, AAMR Adaptive Behavior Scales, and Scales of Independent Behavior.

### Determining Developmental Period

The final criterion for diagnosis is the requirement of manifestation of the disability during the developmental period. The developmental period typically refers to the time from conception up to the age of 18. Thus, as part of the definition, the documented age of onset for mental retardation must be prior to the age of 18.

### CLASSIFICATION SYSTEMS

The definition of mental retardation and corresponding assessment information allows one to determine who has mental retardation, but it does not provide insight into what needs these individuals might have. To determine what services and supports these individuals might need, various classification systems have been adopted and revised. These classification systems assist organizations and service systems in meeting the needs of individuals with mental retardation.

#### Using Categories to Determine Services and Supports

In the past, the primary means of classifying people with mental retardation was to categorize by IQ level. These categories were then used to determine eligibility for assistance and to design programs in health, education, social, vocational, and economic areas. (See Table 1.)

One negative aspect of these categories is the tendency for service systems to view individuals with mental retardation solely by their IQ and level of retardation rather than view them as individuals with unique needs. Thus, when these categories are used, individuals are often grouped together into preexisting services based on their label instead of services and supports being designed to meet specific needs of individuals. Nevertheless, various service systems continue to utilize these categories due to the ease in determining eligibility and in providing services

**Table 1** Categorization of Mental Retardation by IQ Level

<i>Category of Mental Retardation</i>	<i>IQ Range</i>
Mild mental retardation	50–55 to 70
Moderate mental retardation	35–40 to 50–55
Severe mental retardation	20–25 to 35–40
Profound mental retardation	Below 20 or 25

based on this system. Even though use of this classification system persists, the trend in the field of mental retardation is toward a more holistic approach in eligibility and needs determination. The shift is toward viewing each person with mental retardation as an individual with specific needs and characteristics that form a foundation for determining supports.

#### Using Support Needs to Determine Services and Supports

Support needs are an alternative to using categories of mental retardation as a basis for designing and providing services. Supports are resources and strategies for promoting quality of life and individual functioning. Consideration of support needs is strongly encouraged by various mental retardation advocacy organizations in the application of the mental retardation definition. Under this approach, individuals with mental retardation are evaluated to determine supports needed to function across various environments. Those resulting support needs form the starting point for planning and implementing services. Whether supports are natural or service based, they expand life possibilities by meeting needs that allow individuals to perform in a broader range of normal environments.

Individuals with mental retardation may need support across any or all of the following areas: teaching and education, human development, home living, community living, employment, health and safety, behavioral, social, and protection and advocacy. The intensity of support needed in each area is dependent on the characteristics of the individual and may vary across support areas. (See Table 2.)

With the appropriate supports provided with the needed intensity, individuals with mental retardation can be active and productive members of society. Supports create opportunities for persons with mental retardation to achieve success, make contributions, and experience inclusion.

**Table 2** Types of Support Needs

<i>Support Intensity</i>	<i>Description</i>	<i>Example</i>
Intermittent	Provided on an as-needed basis; typically short term	Need assistance locating place of living and securing a checking account
Limited	Consistent monitoring of support needs; support is time limited	Need support budgeting money, shopping for groceries, and planning meals
Extensive	Regular involvement across several environments; typically daily	Need support from staff to complete shopping and prepare meals
Pervasive	Constant, high-intensity support across environments; often life sustaining; requires more staff and more intrusive support	Assistance with self-care needs such as eating and toileting

## CAUSES

Understanding mental retardation leads one to question how often and why this disability occurs. Mental retardation occurs in 1% to 3% of the general population. Causal factors are typically classified as either biomedical, social, behavioral, or educational. Causal factors, when known, can provide useful information for family and service providers ranging from medical or health risks associated with a disorder to specific genetic information related to the heredity of a disorder.

Although specific risk factors vary for each individual and the cause is typically more complicated than a single causal factor, certain factors are more readily associated with specific levels of mental retardation. The suspected cause in most cases of milder mental retardation is an interaction of social (e.g., poverty, inadequate health care pre- and postnatally), behavioral (e.g., drug and alcohol use, abuse and neglect), and educational (e.g., parental mental retardation, lack of

stimulation) factors. For individuals with more severe levels of mental retardation, the primary causal factor is biomedical (e.g., chromosomal disorders, maternal illness, premature birth, degenerative disorders), although secondary causal factors often coexist.

Understanding the causes of mental retardation builds a basis for developing strategies for prevention. Current prevention efforts target various risk factors through support programs (e.g., genetic counseling, alcoholism treatment, early educational intervention). A better understanding of the dynamics between causes and prevention is sought so that greater success in prevention may be achieved.

## MENTOR

The term mentor is one with a long history. As related in Homer's *Odyssey*, Mentor was the noble friend whom Odysseus (known as Ulysses by the Romans) asked to protect his household (including his wife) and to educate and care for his son (Telemachus). Athena, goddess of

war and wisdom, took the form of Mentor on occasion to give wise and useful advice to both Odysseus and his son—advice that would most likely have been rejected had Athena appeared in her true female form. Thus, the term mentor comes to us from an oral saga first told hundreds of years B.C.E. and encompassing behaviors of nurturance, counseling, and support.

Mentors and their protégés typically form a one-to-one relationship in which the mentor, older or more experienced than the protégé, facilitates upward mobility and provides advice, protection, and guidance. Mentors typically provide three types of support to their protégés. Vocational support enhances the career of the protégé by providing advice, sponsorship, or protection. Psychosocial support facilitates the social-emotional stability of the protégé by providing friendship, acceptance, and reassurance. Role modeling promotes growth of the protégé by demonstrating appropriate behavior.

Since the 1980s, many businesses, schools, and nonprofit organizations have instituted mentoring programs to facilitate retention and development of employees, students, and trainees. At the same time, researchers have assessed both formal and informal mentoring relationships to determine the benefits of being mentored and the conditions under which these benefits are most likely to accrue.

Mentoring has been found to have a positive effect on performance, employee retention, income, and career development. While it has been found that a formal mentoring program is more effective than no mentoring, there is evidence that in most instances, informal mentoring programs in which the protégé has the opportunity to choose his or her own mentor produce stronger results. Informal mentoring often results in long-term relationships, greater retention in the profession, more promotions, and higher salaries in the protégé's future career.

Benefits for the protégé are closely related to the quality of the relationship and the interaction between the mentor and protégé. The protégé may feel threatened in accepting guidance and advice, particularly in a formal mentoring program. For example, in a mentoring program for beginning teachers, the less new teachers perceived that their mentors respected their ideas and style of teaching, the less they perceived they could learn from their mentors, and the less satisfied they were with the mentoring program. However, new teachers who had the opportunity to equalize their relationships by helping their mentors expressed more satisfaction with the mentoring

program and more likelihood of remaining in their professions than did those who were not able to establish this equality of relationship.

A formal mentoring program often requires mentors and protégés to be matched by some specific, objective criteria, such as field of training or department of employment. Such criteria may also play a role in an informal mentoring match-up, but most often it is “chemistry” that is the deciding factor. Similarities in such intangible areas as working style, interests, and personality have been found to increase effectiveness of the mentoring relationship even in formal mentoring programs, where this type of “chemistry” happens only accidentally.

Advantages of both formal and informal mentoring programs exist for the mentor as well as for the protégé, potentially helping reduce midcareer burnout. Teachers, for example, who have served as mentors report greater use of their experience, improved skills, and increased satisfaction with their profession. Middle age, according to Erik Erikson's theories of adult development, is often a time in which one feels a need to reassess one's life and contribute to future generations. Mentoring can satisfy this need.

## META-ANALYSIS

---

When attempting to make a decision based on research studies, it is often necessary to compare, contrast, and combine the results from several studies into one general finding. However, this may prove difficult depending on how similar the studies are and how many studies have been performed. There have been hundreds of research studies conducted examining the

effects of day care on children, the best ways to teach reading, and so on, and new reports are being published daily. How can a person read all of these? How is a reader supposed to come to a supported conclusion?

The approach to research integration called meta-analysis is the application of data analysis to quantitative summaries of independent studies. By recording the properties of studies and their findings in quantitative terms, the meta-analysis of research permits the use of statistical approaches.

Researchers have traditionally drawn conclusions about the extent to which research applies to others by conducting literature reviews. A researcher would read all of the relevant published reports and produce a narrative describing his or her evaluation of the studies and overall set of conclusions. Narrative reviews are useful because they organize many studies on a topic. However, the conclusions are based on the subjective impressions of the reviewer.

During the 1970s and 1980s, the use of meta-analysis techniques became a more accepted and popular approach for combining and integrating the results of research studies. Meta-analysis was an attempt to address a number of issues. One was the rapidly growing number of studies available to be reviewed. Another was the recognition that not all research studies provide equally good data.

In a meta-analysis the researcher combines the actual results of a number of studies. The analysis consists of a set of statistical procedures that uses effect sizes to compare a given finding across many different studies. *Effect size* is a general term that refers to the strength of association between two variables.

The main point of emphasis in meta-analysis is obtaining conclusions based on mathematical synthesis of research studies. Instead of developing a narrative report that describes general findings, meta-analysis techniques calculate a measure of effect size. For example, suppose there are three research studies examining the effect of program A on improving reading scores using a computer game. Two of the studies found that the computer game increased reading scores by 7 and 5 points, respectively, whereas the other study found no improvement. In a meta-analysis, the results from the three studies would be averaged to calculate a measure of effect size. The best estimate of program effectiveness would be 4 points.

Meta-analysis results are often reported in terms of effect sizes. Some typical estimates used are the correlation coefficient ( $r$ ) and Cohen's  $d$ . The effect

sizes are often weighted to place more emphasis on studies utilizing more participants. This produces more reliable results. Typically you are seeking reviews that have utilized a weighted average and have included a large number of studies.

There are two important advantages of the mathematical estimate of effect size over the narrative report. First, the statistical analysis takes into account the sample size of each study, includes more studies, and is more reliable. The second advantage is that meta-analysis results typically synthesize the results of studies conducted by independent researchers. Since these researchers are not working together, if one researcher makes a systematic error, the effects of these studies will have less of an impact on the overall result when they are averaged with the results from other independent researchers.

The disadvantages of meta-analyses center primarily around the quality of the studies included. If studies of poor quality are included, then the results are affected. Another difficulty for meta-analysis comes from publication bias. Many studies that fail to find significant differences or relationships are not published. This "file drawer" problem can lead to an inaccurate estimate of the actual relationship between two variables.

## METACOGNITION

---

Cognition refers to the mental processes involved in acquiring and using knowledge. We usually think of knowledge as being about things external to ourselves, but we can also acquire and use knowledge about cognition itself. In addition to all the other things that children come to know about as they mature, they

also learn about how the human mind works. This “cognition about cognition” is known as metacognition.

Psychologists who study the development of metacognition try to understand how and when children acquire knowledge about cognition and how they use this knowledge in cognitive activities such as learning, memory, reading, and problem solving. Research in cognitive, educational, and developmental psychology has revealed that metacognition plays a crucial role in these important areas of development.

John Flavell pioneered the study of metacognition with his work on children’s developing knowledge about memory, or metamemory. Flavell recognized that one important factor in children’s memory development is their growing knowledge about how memory works. Flavell’s early research revealed that, although younger children have some understanding of memory, they have less accurate knowledge about their own memories and about human memory in general than do older children. For example, most kindergarten children know that a long list of items is more difficult to remember than a short list, but they often dramatically overestimate the number of items they can remember. By the end of elementary school, children have a fairly solid understanding of the factors that influence remembering and forgetting and a more realistic picture of the inherent limitations of human memory.

Following this early work on metamemory, researchers extended their study of metacognition to other domains and included adolescents and adults in their investigations. Deanna Kuhn has shown that metacognition plays a central role in scientific reasoning. According to Kuhn, the essence of scientific reasoning is the evaluation of alternative theories in terms of available evidence. Scientists must actively construct mental representations of scientific theories and monitor, regulate, and critically evaluate their thinking about them. Kuhn has shown that this kind of metacognition can be quite difficult even for adults, but educational experiences that emphasize critical thinking can promote the development of scientific reasoning.

In another important area of development, research on reading has demonstrated that good readers display a host of metacognitive skills, and it is largely these skills that distinguish good readers from poor readers. As one example, good readers actively monitor their comprehension, recognize when they have failed to understand a passage, and reread accordingly. Poor readers, in contrast, fail to monitor their comprehension and consequently often do not understand or remember what they have read.

As research has yielded increasing knowledge about metacognition, intervention programs based on this research have been designed with the goal of improving academic performance. One such program, developed by Annemarie Palincsar and Ann Brown, uses the technique of reciprocal instruction. A teacher and a few students take turns engaging aloud in the kinds of metacognitive skills that are associated with effective reading comprehension, such as identifying important themes, summarizing a passage in one’s own words, and asking key questions. This is one example of how basic research on metacognition has been translated into educational practices that appear to produce lasting improvements in essential academic skills.

From a historical perspective, developmental research on metacognition can be seen as one of the earliest manifestations of renewed interest in the human capacity for self-reflection, a subject that was actively ignored in mainstream psychology for much of the 20th century. The pervasive influence of this general theme is evident in numerous entries in this encyclopedia (e.g., emotional intelligence, self-efficacy, theory of mind, wisdom), in addition to this one.

## METHADONE

---

Methadone is a synthetic substance that has effects in human beings similar to opiates such as morphine and heroin. Methadone is widely used medicinally in the treatment of opiate addiction, but is also used in the

management of pain. Opiate addiction is a serious condition in which individuals need to take a drug such as heroin regularly because they feel a strong compulsion to do so and they experience withdrawal symptoms when they cease taking the drug. The compulsion is so strong to use the drug that these people typically take more of the drug than they intend to and continue taking it despite the fact that it is causing them harm. Opiate addiction is a serious medical and social problem. It is associated with high rates of crime and mortality due to a number of causes, including opiate overdose and human immunodeficiency virus (HIV) and viral hepatitis infection.

As early as 1949, methadone was identified as a useful agent for detoxifying people addicted to opiates, and it is still used for this purpose. Detoxification involves administering diminishing doses of methadone until the person no longer experiences any withdrawal symptoms. However, because detoxification is not an effective treatment for opiate addiction, methadone is more commonly employed as a maintenance treatment. In maintenance treatment, a stable dose of methadone is administered on a daily basis.

Vincent Dole and Marie Nyswander developed methadone maintenance treatment in the early 1960s in New York City. A number of features associated with methadone make it particularly suitable for use in maintenance treatment. Methadone is easily absorbed from the gut and so can be taken orally. Once absorbed via the gut, methadone has a long duration of effect, allowing it to be administered once a day. By contrast, heroin needs to be taken three or more times a day. Oral administration obviates the need for injection, thereby reducing the risk for HIV and viral hepatitis infection through the sharing of needles. Oral administration also results in slower absorption, which means that rapid intoxication is avoided. Once patients are stabilized on an adequate dose of methadone, they experience no withdrawal symptoms or craving to use heroin and, if they do use heroin, its effect is attenuated.

After Dole and Nyswander published a series of studies showing the effectiveness of methadone maintenance treatment, it was adopted widely in the United States and soon spread, and it is now the most commonly used treatment for opiate addiction throughout the world. A large number of studies have shown that methadone maintenance reduces opiate use and overdose, crime, and the risk for HIV infection.

The studies conducted so far also show that there are four important ingredients in methadone

maintenance treatment. The first ingredient is methadone. Treatment approaches that have attempted to replace methadone with intensive counseling and welfare services are not effective. The second ingredient is the dose of methadone. Treatment programs that individualize the dose of methadone to meet the needs of patients are more effective than programs that restrict dosing to lower levels. In general terms, higher doses of methadone (greater than 60 mg per day) tend to be more effective than lower doses (less than 40 mg per day). The third ingredient is the length of time that the treatment is offered; long- rather than short-term courses of treatment are more effective. The fourth ingredient is the provision of medical, counseling, and other social welfare services. Programs that provide for patients' medical, social, and psychological needs are more effective. However, programs that simply provide methadone without these ancillary services are still effective to some extent.

---

## METHYLMERCURY

---

Methylmercury is a chemical present in virtually all aquatic ecosystems in some concentrations. The substance was discovered to be a teratogen at Minamata, Japan, in the 1950s. A high rate of cerebral palsy and mental retardation occurred in children whose mothers ate contaminated seafood while they were pregnant. In Iraq, in 1971 a poisoning incident occurred in which people ate seed grain that had been treated with methylmercury as a fungicide. Iraqi and U.S. researchers together studied the children of women who had eaten the methylmercury-treated grain while pregnant.

Prenatal methylmercury exposure was estimated by taking hair samples from the women. A dose-response relation was found between exposure and delay in reaching developmental milestones such as walking, talking, and independent toileting.

After the discovery at Minamata and in Iraq that methylmercury could be a potent neurodevelopmental teratogen, research began on effects of exposure to lower concentrations of methylmercury. At present, human exposure to methylmercury is primarily from consumption of fish and seafood, both commercial and sport caught. Several longitudinal prospective studies have examined the effects of prenatal exposure to methylmercury in fish on children's later cognitive and behavioral functioning. In the Faroe Islands, which are located in the north Atlantic and are part of the Kingdom of Denmark, higher prenatal mercury exposure was related to lower scores on tests of verbal functioning, motor performance, and attention at 7 years of age. There is also some evidence in the Faroes that higher mercury exposure (both pre- and postnatal) is associated with lower heart rate variability and increased latency of brain stem auditory evoked potentials. Heart rate variability is an indicator of the balance of the parasympathetic and sympathetic nervous systems and is also linked to attention.

Controversy over the effects of methylmercury exposure from fish and seafood exists because not all longitudinal studies have shown adverse effects. A study in the Republic of Seychelles, an island nation off the coast of Africa, showed no adverse effects of prenatal methylmercury from fish on children's cognitive functioning. However, another study of contemporaneous, as opposed to prenatal, mercury exposure has shown adverse effects on children's visual contrast sensitivity. In children in Amazon regions where mercury is used in gold mining, motor performance (finger tapping) and memory were negatively related to higher contemporaneous mercury exposure. In adults, color sensitivity, contrast sensitivity, and peripheral vision were all negatively related to contemporaneous mercury exposure.

A panel of the National Academy of Sciences used results from both the Faroe Islands and Seychelles studies and concluded that there was sufficient scientific support for the U.S. Environmental Protection Agency's recommendation that children and women of childbearing age limit exposure to methylmercury in fish to 42  $\mu\text{g}$  per week. This implies that a 130-pound woman should not eat more than one 8-ounce tuna sandwich per week.

Methylmercury biomagnifies up the food chain such that a predator will have a higher concentration than its prey. The longer the food chain, or the more trophic levels, the higher the concentration of methylmercury at the top. Consequently, large predator fish have a higher concentration of methylmercury than fish that feed lower on the food chain. In many areas of the United States and Canada, fish are deemed unfit for human consumption because of contamination with methylmercury. Fish consumption warnings for children and women of childbearing age issued by government agencies recommend that many popular species of sport fish be consumed no more than once a month. The latest national health survey shows a strong relationship between the number of fish meals eaten in the past month and mercury concentration in blood.

## MIDDLE ADULTHOOD

---

Human development is studied by the broad field of psychology and within the subfield of developmental psychology. Developmental psychology is defined as the study of stability and change throughout the life course. From its establishment as a subdiscipline within the social, behavioral, and biological sciences, developmental psychology had proposed the idea that all humans follow a predictable developmental trajectory. Prior to the 20th century, the scientific community assumed that developmental change after adolescence or early adulthood consisted of the attainment of a developmental plateau, followed by inevitable deterioration

or decline in all areas of function. Throughout the course of the 20th century, theorists slowly began to acknowledge the possibility that true developmental processes may extend beyond the early adulthood years. As researchers, and the disciplines they represented, came to recognize middle adulthood as a viable area of study, the discipline of life span developmental psychology was established as a legitimate and worthwhile enterprise. As a result of this important change in how human development was viewed, the field began to grow and expand, which has led to developmental psychology's current prominence as an area of study within the behavioral sciences.

Many advances have been made because of the previously outlined evolution of the field of developmental psychology. One of the most significant of these was the establishment of what is known as the life span perspective of human development. The life span perspective of development has led to a theoretical approach that is more comprehensive, balanced, and integrated in comparison with previous views or approaches, which tended to be more narrow and limited in scope. The life span concept helped to expand the study of human development beyond issues of infancy, childhood, adolescence, and early adulthood to include both middle and late adulthood. These changes, in turn, have led to the establishment of distinct life stages (e.g., early, middle, and late adulthood), as well as identification of specific domains of development (e.g., physical and social) within the life stages. The life span developmental stage of middle adulthood is the focus of this article. Middle adulthood is made up of (approximately) the ages from 40 through 65. Specific domains or areas of development to be addressed include the physical, the cognitive, and the psychosocial.

## PHYSICAL DEVELOPMENT IN MIDDLE ADULTHOOD

Physical development consists of changes that take place with respect to the physical body throughout middle adulthood. Some physical changes in midlife are gradual, others are more obvious in the forties and fifties, and most are much more pronounced than the physical changes of early adulthood. Researchers have divided the process of aging into two distinct types of aging, referred to as primary and secondary aging. Primary aging refers to the age-related changes that occur as a result of the passage of time; they are considered to be universal and inevitable. Secondary

aging refers to changes that result from the consequences of a person's behavior, and/or society's failure to eliminate unhealthy conditions, including disease states and chronic health problems. Physical changes in middle adulthood are the result of both primary and secondary aging processes.

At some point during the years of middle adulthood, the senses begin a gradual decline in functioning. Vision is often the first sense that shows a noticeable age-related deterioration. Difficulty in reading small print is common, as is a decline in the ability to discriminate nearby objects. Presbyopia is a condition of the eye in which the lens loses its capacity to adjust to objects at varying distances. Bifocals or reading glasses can correct these problems. Other common visual changes include decreases in the ability to drive at night, as well as difficulty with color discrimination. Finally, individuals over the age of 40 are at increased risk for glaucoma, a hereditary disease of the eye in which pressure builds up in the visual system. Visual screenings, medications, and surgery can prevent loss of vision secondary to glaucoma.

The auditory system or ability to hear may also show age-related declines in middle adulthood. Presbycusis is the term given to age-related hearing loss. Studies show that men lose the ability to hear more quickly than women do, at midlife, and that loss of hearing is greatest for high tones. People with significant hearing loss may benefit from hearing aids or from modifications in their interactions with others and the environment.

The skin also shows age-related changes in middle adulthood. Human skin is made up of three layers: an outer, protective layer; a second, supportive layer; and a third, inner layer. As individuals age, the outer layer becomes less firmly secured to the second layer, which changes the appearance of the outer layer. These changes cause the skin to sag and wrinkle. There may be an increase in concentrations of pigmentation in the skin, resulting in age spots. People who have spent extended periods of time in the sun or outdoors (unprotected) age more quickly than those who do not.

The skeletal system and the muscle-to-fat ratio begin to change during the course of midlife. Skeletal changes include weakened bones and reduction in bone density. This often leads to a condition called osteoporosis, which results from insufficient calcium levels (especially in women). An increase in overall body fat and loss of muscle mass and lean body mass are common in the forties and fifties. Regular exercise

can serve to offset weight gain and loss of muscle strength or power.

Beyond alterations in the way we look, middle adulthood is also characterized by changes in the sexual reproductive systems. Although experienced by both sexes, these changes are quite different for women and men. Midlife brings a major biological change for women: the end of the ability to bear children. This transitional period, termed the climacteric, (usually) begins in the late thirties or early forties and is complete at some point in the fifties. There is considerable individual variation regarding the timing and experience of these physiological changes. The most significant change during the climacteric is a decrease in women's production of the hormone estrogen. *Menopause* is the term given to the process of the irregularity and eventual end of menstruation. Many women stop menstruating around age 40, others may continue to have regular periods into their late forties or early fifties, but most women have their last period at some point in their forties. Symptoms related to the climacteric and/or menopause include physical or somatic complications, as well as those related to decreased levels of estrogen. Some of these symptoms may be alleviated with hormone replacement therapy (HRT). While many women benefit from HRT, it is somewhat controversial with respect to the risk/benefit ratio. As with most developmental change processes, different individuals' experiences of the climacteric are quite variable, and occur on a continuum from little or no symptomology, to the presence of life-altering symptoms.

Although men do not experience the significant physiological changes that women go through, they do experience a predictable decline in sperm production levels. Production of sperm can decrease by 30% between the ages of 30 and 60. Enlargement of the prostate is also common for men at midlife. A gradual decrease in levels of the hormone testosterone begins around age 30. Other sex-related changes that men often experience include biological alterations in sexual performance, related to processes such as ejaculation, erection occurrence and/or maintenance, or changes in the experience or frequency of orgasm. Erectile dysfunction may be an issue for men in their forties and fifties. However, the advent of medications to correct this problem has provided relief and return to normal function for many men.

Overall health status shows a decline for most people in the stage of middle adulthood. Average adults

at midlife report that they suffer from aches and pains at a higher rate than when they were in their twenties and thirties. About half of adults between 40 and 60 have either a diagnosed disease process or disability or an undiagnosed health problem. Disease-related deaths increase significantly in middle adulthood, the two most prevalent causes being cardiovascular disease (CVD) and cancer. On a positive note, life expectancy for 40-year-olds is higher than ever before and has shown consistent increases over the course of the past two decades. A significant relationship exists between gender and health, with the life expectancy of women exceeding that of men. Despite this fact, women consistently describe their health as poor, suffer more chronic health conditions, and tend to be more restricted in their activities of daily living than men. The question arises as to why it is that men, on average, die younger than women, but are generally healthier while they are alive. Research indicates that the answers to these questions are multifaceted and complex. Three times as many men die from CVD than women between the ages of 45 and 55. Much of this discrepancy can be explained in terms of differences in the physiology of gender. The heart muscles of females who have CVD appear to be better able to adapt to physical stress and exertion. Women also show higher levels of recovery of physical function following a heart attack. Biosocial factors have often been shown to play a role in sex differences related to survival and recovery following CVD and other life-threatening disease processes. In addition, women are more likely to have regular medical checkups and to seek and obtain medical treatment earlier than their male counterparts.

A universal factor that can affect both general health and well-being is the degree of stress present in one's daily life. We all experience stress, which is variable, and highly individualized to the extent that various life situations are considered to be stress producing for a given person. Stress is defined as the physical and psychological effects that result from events and circumstances that one experiences as requiring greater personal, social, physical, or other resources than one currently possesses. These situations represent a threat to one's ability to meet the demands of a given situation. Research indicates that in certain circumstances stress can actually be beneficial in helping people perform at their peak. However, long-term chronic stress or the accumulation of multiple stressors can lead to both physical and psychological health problems.

Stress and its related effects may be particularly important for individuals in middle adulthood for several reasons. Although stress affects people of all ages, it is during midlife that the effects of both short- and long-term stress become most apparent. The fact that it takes time for stress-related disorders to manifest, combined with the gradual loss of physical capacity often experienced at midlife, may make individuals in this life stage especially vulnerable.

Coping with stress, or stress management, is defined as any attempt to deal with stress; coping responses are also variable, and some are more or less effective than others. Positive and effective ways to deal with stress include reducing identified stressors (when feasible) and/or disclosing and discussing stressful life events with a trusted other. Physical exercise has consistently been shown to reduce the negative effects of stress, as well as significantly slow the aging process. Negative attempts at stress reduction include responses that are characterized by increased levels of anger or aggression, avoidance or denial of stressful events, or overuse of drugs or alcohol. The process of stress management in middle adulthood has the potential to limit age-related increases in disease processes as well as reduce the severity of illnesses that may occur. Finally, the fact that mental health diseases and disorders actually occur less commonly at midlife than in adolescence or early adulthood may be related to more effective stress management in middle adulthood.

To summarize, the course of physical development in middle adulthood has been shown to involve some changes that are both universal and inevitable. However, it has also been clearly demonstrated that many aspects of physical developmental change processes are highly individualized and amenable to the positive effects of individual choices, lifestyles, and volitional behaviors. So while there are specific age-related physical decrements that one must come to accommodate and/or accept, one may also live in such a way throughout middle adulthood so as to optimize one's health and physical functioning well into late middle adulthood and beyond.

## COGNITIVE DEVELOPMENT IN MIDDLE ADULTHOOD

Cognitive development at midlife represents the changes that take place with respect to one's thinking, reasoning, decision-making, and problem-solving abilities. A review of the data related to cognition in

middle adulthood reveals that two distinct types of cognition dominate the research. These are fluid intelligence and crystallized intelligence. Fluid intelligence refers to the ability to process and analyze basic information, as well as memory skills and the ability to detect relationships. The speed at which one can perform these tasks is also important in fluid intelligence. Crystallized intelligence refers to abilities that are dependent on accumulated knowledge and experience, sound judgment, and mastery of social conventions. Research has shown that fluid abilities predominate prior to midlife, showing a decrease as one ages, and that crystallized abilities are at their highest at midlife and beyond. However, studies also exist that demonstrate relative stability in a variety of tasks related to both fluid and crystallized intelligence. Furthermore, fluid intelligence is thought to be influenced more by conditions in the brain such as memory and processing speed, as well as by learning that is unique to the individual. The acquisition of crystallized abilities appears to be related to the degree to which these abilities are valued by an individual's culture or society. Related to the concept of the influence of culture and society is the cognitive ability referred to as practical intelligence, which is defined as a broad range of skills related to how individuals shape, select, or adapt to their physical and social environments. These skills require an individual to size up real-world situations and analyze how best to achieve goals that have a high degree of uncertainty.

Cognitive development was once thought to be the exclusive domain of childhood and adolescence, with any changes occurring at midlife limited to the decline and deterioration of function. Jean Piaget, perhaps the best known of the cognitive theorists, developed a four-stage theory of cognitive development with age-specific stages beginning in infancy and continuing into adolescence. Piaget's fourth and final stage of cognitive development is termed formal operations. This stage is characterized by the capacity for abstract, scientific thought processes. Individuals engaged in formal operational thought begin with a general theory of all possibilities related to a specific life situation, then progress to specific hypotheses or predictions about what might occur, and finally test various hypotheses.

More recently, cognitive theorists and researchers have described stages of cognitive development that extend beyond Piaget's stage of formal operations. Termed postformal operations, or fifth stage thinking/ thought, it is now widely recognized and accepted that

cognitive development may continue into early, middle, and later adulthood. The dynamics of postformal operational theory include a progression from dualistic thinking, characterized by thinking in terms of concrete absolutes, or viewing life in terms of black and white, to relativistic thinking, characterized by the realization that multiple perspectives or shades of gray exist with respect to many life situations. This developmental shift in cognitive abilities occurs in early or middle adulthood, if it occurs at all. Research has shown that this advanced form of cognition is primarily the domain of midlife and includes practical intelligence and dialectical thought. Dialectical thought consists of the components of relativistic thought with the additional capacity to consider multiple perspectives simultaneously. As a more advanced level of cognitive functioning, dialectical thinking also entails the ability to integrate and synthesize information with respect to multiple perspectives, ideas, or experiences and the potential contradictions, inconsistencies, or life dilemmas. Acquisition of the capacity for dialectical thought enables individuals at midlife to effectively cope with changing perspectives of oneself, others, and the world. It becomes clear that few questions, experiences, or relationships have a single unchanging and objective answer or response. Finally, those who achieve the capacity for dialectical thought recognize that while there may be multiple perspectives regarding many life situations, some are more valid or just than others, which facilitates more effective decision making. Practical intelligence is defined as a broad range of skills related to how individuals shape, select, and adapt to their physical and social environments. The skills of practical intelligence are related to those of dialectical processes in that they require one to evaluate real-world situations and determine how best to achieve goals having a high degree of uncertainty.

The potential for postformal operational thinking occurs in late adolescence or early adulthood. The acquisition of dialectical thinking abilities most often takes place during middle adulthood. It should be noted, however, that not all adults develop the cognitive ability required for formal operations and/or fifth-stage thinking capacities.

The longheld belief that middle adulthood cognitive changes were restricted to declines in ability and function have also been refuted by the results of several studies that conclude and/or confirm that while fluid abilities often show a decline in late middle adulthood, this decline is not universal, and is subject

to a variety of subjective, individual influences. Much of the data indicate that individuals at midlife can exercise their cognitive abilities, as well as utilize a host of other compensatory strategies to accommodate or make up for decreases in fluid abilities. It is widely accepted that those in the stage of middle adulthood (and beyond) can benefit from cognitive interaction and stimulation, similar to the process of exercise of the physical body. Examples of cognitive exercise include the process of remaining actively engaged with other people in work, leisure, or other situations that enable one to enjoy the benefits of daily, cognitive, human interaction. Other ways to engage or exercise the mind include any activities that involve the acquisition of new learning, problem-solving, or decision-making abilities (e.g., formal education, self-study, reading, creating, or game playing).

A great deal of research is being done on more advanced forms of cognition or intelligence such as expertise, intuition, creativity, and wisdom. The stage of middle adulthood is of particular interest to researchers because many of these cognitive constructs appear to be dependent on or positively correlated with life experience or number of years lived. An expert is defined as someone who is notably more skilled and knowledgeable about a specific intellectual topic or practical ability than is the average person. Not everyone becomes an expert as years pass, but all experts require the passage of years to develop their specific skill level. Expertise is deemed the result of training and long-term practice, which leads to more intuitive, automatic, strategic, and flexible qualities of thought.

Paul and Margaret Baltes developed a theory of adulthood development termed selective optimization with compensation (SOC) to describe the way in which individuals attempt to maintain a balance in their physical and cognitive functioning as they grow older. According to SOC, individuals seek the most effective way to compensate for physical and/or cognitive losses and to become more proficient at the things they can do well.

Cognitive developmental change processes of middle adulthood have been shown to involve much more than decreases or declines in functioning. In response to this fact, developmentalists are now looking closely at patterns of gains and losses in cognition over the course of midlife. Studies have demonstrated that virtually any or all patterns regarding change are possible, and that to ask whether cognitive abilities

increase or decrease may be simplistic. These abilities may demonstrate a variable, up-and-down pattern of change. Questions to be addressed include how many and what distinct cognitive abilities are present in middle adulthood and why a particular person's specific ability might increase or decrease at any given time. Most psychologists have given up on the idea of absolutes with respect to cognitive development at midlife and are instead focusing on concepts and questions related to several cognitive abilities, each of which may show an independent pattern of rise or fall.

### PSYCHOSOCIAL DEVELOPMENT IN MIDDLE ADULTHOOD

Psychosocial development includes the changes that one experiences related to self-concept, personality, life experience, and generativity or personal growth. Many, if not all, of these processes are reviewed and/or take on new meaning for those in the life stage of middle adulthood. Some of these processes are universal in that most people experience a specific individual, familial, societal, or cultural phenomenon with minor variations. Other occurrences are highly individualized with respect to gender, age, ethnicity, race, religion, culture, socioeconomic status, education, and several other individual variables. Many developmental researchers and theorists describe the psychosocial change processes that (typically) occur in middle adulthood with slightly different variations or themes that represent a similar dynamic of change. Erik Erikson addresses these changes in his eight-stage developmental theory of psychosocial development that outlines specific tasks or conflicts to be accomplished or resolved at predetermined ages or stages throughout the life span. In Erikson's developmental theory, the conflict to be resolved in middle adulthood is that of generativity versus stagnation. The dynamic of this stage also involves the successful completion of the conflict/task from the stage of early adulthood (identity vs. identity diffusion), as well as preparation for the crisis/task of late adulthood (ego integrity vs. despair). Generativity is characterized by a desire or interest in helping to nurture and establish the next generation through a variety of activities, thereby achieving a sense that one has made a significant contribution to the larger society. For some individuals, this is accomplished by the process of parenting. For others it may also involve activities such as advising, teaching, mentoring, or volunteering at civic, religious, or other charitable organizations. The

dynamic to be achieved is one of turning outward from a preoccupation with the self to an expansion toward genuine care and consideration for others.

A psychological construct closely related to the concept of generativity is that of personality. Numerous personality theories have been proposed with respect to the life span (generally) and to middle adulthood (specifically). The most widely researched and accepted theory of personality that currently exists is the big-five factor theory. The big-five theory states that there are five traits or factors that have been found to be consistent and stable throughout adulthood. The five factors are neuroticism, extroversion, openness, agreeableness, and conscientiousness. Research has repeatedly demonstrated intraindividual consistency and stability with respect to levels or amounts of the big-five factors in adulthood. However, interindividual variations or differences are also present in middle and later adulthood. Whether a person ranks high or low on each of the big-five factors is determined by a unique interplay of genes, culture, and early life experiences. Continuity of the big-five factors in middle adulthood has been well established, with the general trend for most individuals to become less neurotic and open and more agreeable and conscientious. The concept of the stability of the personality construct has raised many questions regarding the relative influences of biology, environment, and individual variation or choice. One's personality and related influences possess great power over the course of one's life. Midlife is a period in the life course when most individuals choose a lifestyle and related social context. These choices include significant aspects of one's life, such as vocation, neighborhood, friendship/support network, and routine. A reasonable conclusion that may be derived from the research related to personality is that personality appears to shape one's life, rather than one's life (experiences) effecting changes in personality structure. Aspects of personality do occasionally vary in middle adulthood if life circumstances are dramatically altered in some way. Experiences such as the death of a loved one, beginning or ending a marriage or career, or the occurrence of a severe physical or mental illness may cause changes in the ways that people are known to act or behave. Most often, this indicates minor personality shifts, not dramatic changes of the personality structure.

A change process that has long been believed to be an inevitable event of middle adulthood is the midlife crisis. Defined as a period of increased anxiety, radical life reexamination, and unpredictable transformation,

this concept has recently been closely studied and rethought. It is true that midlife is, for many, a time for life review, examination, reflection, and midcourse correction; however, the concept of a true crisis occurring in a majority of people's lives has largely been found to be false. Recent studies indicate that many individuals in middle adulthood (around age 40) experience a shift in life perspective from years since birth to years left to live. This process often coincides with any number of potentially troubling, personal changes. Perhaps the most obvious is a greater awareness of the biological clock coupled with the (previously outlined) physical signs of aging that occur in one's forties and fifties. Many who thought that there was ample time to accomplish life goals suddenly become aware of the finite nature of the life span.

How one reacts to the challenges and changes of midlife has more to do with personality characteristics and less to do with chronological age or present life span developmental stage. It has been proposed that the enduring nature of a true midlife crisis may be related to its ability to help some adults to cope with the frustration and disappointment caused by the previously discussed life events and still consider themselves to be fairly fortunate.

The concept of role provides a different perspective or interpretation of the various transitions of middle adulthood. All people are part of the larger social system that is made up of interlocking positions or statuses such as worker, student, or widow. A role is the content of a given social position, including the characteristics and behaviors of a person occupying that position. Several aspects of the concept of a role are important for understanding development and change processes. Each person must occupy multiple roles at the same time, which can potentially lead to friction or problems with respect to role compatibility. This situation is termed role conflict and refers to those times when two or more roles are incompatible or present differing demands for which we do not possess sufficient resources. A person may experience role strain when one's qualities or skills do not meet the demands of a particular role. The concept of roles may also help explain some changes in adult life, because certain specific roles are known to show a predictable shift as related to age. Every age or stage of adulthood has accompanying roles of greater or lesser influence with respect to role conflict, strain, or continuity.

Other important and influential factors present in middle adulthood include changes in family and other

relationships, changes related to midlife career issues, as well as preparation for retirement. Family and/or relationship issues of midlife range from starting a family, to adjusting to adult children, to caring for aging or debilitated parents, to facing the challenges of divorce or remarriage. The often changing and variable nature of some or all of these factors has led researchers away from the quest for identifying universal, absolute, or predictable stages of midlife development, and more toward an approach that, while acknowledging age-related events, also gives significant consideration to individual variability.

Middle adulthood is shaped by the various life changes and crises that one experiences, both common and predictable, as well as unanticipated. The years between 40 and 65 are in some ways much the same for some individuals and very different for others. In conclusion, it may well be that what is most significant in determining the course of middle adulthood is how one copes with various crises and changes, rather than the changes themselves.

## SUMMARY

The developmental stage of middle adulthood is a time of great physical, cognitive, and psychosocial change and variability. It has been shown that the degree or direction of change regarding the specific physical, cognitive, and/or psychosocial domains of development is determined by the unique interplay of a host of influences or factors. Some physical and cognitive change processes once thought to be inevitable and universal have recently come to be viewed as amenable to positive growth and change and highly dependent on the influence of factors such as lifestyle, individual choice, or social context. Many previously established myths related to midlife have been refuted or shown to be inaccurate. The stage of middle adulthood is currently experiencing a highpoint with respect to research interest and study. These efforts have produced new knowledge and insight related to the dynamics of continuity and change over the course of midlife. While the academic community continues to gather information and present new theoretical understandings, there has been a movement toward a greater integration of previously disparate areas of developmental research and related findings.

This is a very exciting and encouraging time for the field of human development and for the study of middle adulthood. It is exciting and encouraging that

those individuals in the stage of middle adulthood can utilize new information and understandings to maximize and enrich their lives.

## MIDLIFE CRISIS

---

The question has been raised as to whether or not the classic midlife crisis is a real and empirically defined phenomenon or if it represents a culturally sanctioned myth. It is difficult to provide a definitive answer. Not all midlife adults experience what would be called a crisis. Most, however, would admit to a disruption in

their life plans around the ages of 40 to 50. For these individuals, there was an occurrence that required some degree of a personal evaluation of their life. It is said that the midlife crisis is not a marital crisis, or economic crisis, or professional crisis, although it may manifest as such. Underlying this event is the concurrent reevaluation of self ongoing perhaps for different reasons. This deeper evaluation of oneself may produce disturbing results that the individual interprets as a call for a change in one's life. If one makes a change that is inconsistent with societal expectations, it is referred to as a crisis. The typical response is to the act rather than to the precipitating factors.

Although often considered a Western and predominantly male phenomenon, evidence of midlife crises in individuals in middle- and upper-middle-class China and in women has been reported. Perhaps the experience of the self-disturbance has cross-gender and cross-cultural legitimacy; however, the extreme enactment of this crisis is much more of a male behavior. Why might this be so? In general, it has been noted in the literature that men, essentially, have less emotional license than do women. Therefore, when confronted with an emotional upheaval in their lives, men simply do not know how to respond. Their traditional lack of models and belief in self-reliance, emotional control, dramatic action (being a “hero”), and competition may result in stereotypical behavior that is accepted for men experiencing an emotional problem (i.e., getting that hot new sports car, that hot new woman, or drastic lifestyle shift). Unfortunately, the turmoil that precipitated the crisis behavior is not addressed and has the potential to resurface at a later time.

An investigation into the underlying cause of a midlife crisis in two different cohorts of midlifers—those in midlife in the 1960s and 1970s were compared to midlifers in the 1980s and 1990s—resulted in clear cohort differences. The idea of a midlife crisis was still a viable concept for both groups of men. The age of a reported crisis shifted downward to 50 for the midlifers of the 1980s and 1990s. This latter group expressed less of a family focus and emphasized their search for personal fulfillment. The midlifers of the 1960s and 1970s were more focused on escaping an oppressive and forced identity, while the younger cohort was dealing with a quest to find an adult identity at all.

Whether tied to age or life stage, it was concluded that the term *midlife crisis* is commonly used to describe regrets, setbacks, negative feelings, or anxiety about role change. It is clearly tied to the thought patterns occurring at this time. The thought patterns include

increased introspection, realization that time is passing, and regret for lost opportunities. Interestingly, the term *crisis* is defined as “turning point.” This definition presents less of a negative connotation to the idea of a midlife crisis when viewed as a midlife turning point. Given this perspective, the midlifer may see the process of self-examination as a positive action. Taking a positive perspective may result in less extreme behavior and a more supportive response from members of society.

## MIDWIFE

---

The origin of the English word midwife has been traced back to 1303, and the literal translation is “with woman during childbirth.” Midwives are traditionally although not exclusively women, serve as primary caregivers for childbearing women, and can be found throughout the world. In most developed countries, midwives provide care to the majority of women who give birth, and in many countries this care includes well-woman examinations and provision of family planning services. While there is variation in the educational requirements associated with those who use the title midwife, the International Confederation of Midwives, the World Health

Organization, and the International Federation of Gynecologists and Obstetricians have adopted the following definition:

A midwife is a person who, having been regularly admitted to a midwifery educational program duly recognized in the country in which it is located, has successfully completed the prescribed course of studies in midwifery and has acquired the requisite qualifications to be registered and/or legally licensed to practice midwifery.

She must be able to give the necessary supervision, care and advice to women during pregnancy, labour and the post partum period, to conduct deliveries on her own responsibility, and to care for the newborn and infant. This care includes preventive measures, the detection of abnormal conditions in mother and child, the procurement of medical assistance and the execution of emergency measures in the absence of medical help.

She has the important task in health counseling and education, not only for the woman, but also within the family and the community. The work should involve antenatal education and preparation for parenthood and extends to certain areas of gynecology, family planning and child care. She may practice in hospitals, clinics, health units, domiciliary conditions or in any other service.

In the United States, midwifery, as a profession and philosophical approach to care, predates and now coexists with the provision of medical care to childbearing-aged women. The education of midwives begins with the premise that for the majority of women, pregnancy, labor, and birth are normal human events that should not be medicalized unless indicated by a change in the health status of the woman. The education of doctors takes place almost exclusively in settings where women have developed complications during pregnancy and are in need of continuous monitoring and complicated interventions. This core philosophical difference in approach to pregnancy and women’s health care contributed to the elevation of the status of midwifery in the 1970s when women began to express their preference to be actively involved in decisions regarding their health and the health of their babies.

Starting in the mid-1920s, more than 10,000 nurses have been educated as midwives in the United States. Graduates of education programs approved by the American College of Nurse-Midwives Division of Accreditation must take a national certification examination to earn the title certified nurse-midwife

(CNM). CNMs can be licensed to practice in all 50 states and the District of Columbia, and in 2002 CNMs attended over 10% of the vaginal births in the United States. Over 96% of these births occurred in a hospital. The federal government allocates funding for nurse-midwifery education programs and requires reimbursement for CNM services from the Medicaid and Medicare programs.

Additional and more recent educational requirements that are legally recognized in some states include the certified midwife (CM), who is educated in a system designed to be equivalent to the CNM while not requiring a degree in nursing, and the certified professional midwife (CPM). The title CPM grew out of a perceived need to standardize the requirements for those midwives who had traditionally followed the apprentice model of education and to place a higher value on the provision of care in out-of-hospital settings.

In many states, the practice of midwifery is not limited to those who have been licensed by the state; thus, women may receive care from a midwife whose credentials are not clearly defined by law.

## MISCARRIAGE

---

In recent years, scientists have done extensive research on fetal development, with the goal of these efforts being the prevention of deformities and saving the lives of babies endangered by prenatal problems, as well as to ensure that the pregnancy goes to term. In some emergency situations, prenatal blood transfusions have been performed and fetal surgery has been done.

However, most unfortunately, some pregnancies do not last the complete gestational period and result in miscarriage, responsible for the loss of about 30% of all pregnancies. The primary reason that miscarriages occur is probably that the fetus was defective in some way, and the process is a way for the forces of nature to ensure that only the healthiest of offspring and those with the greatest chance of survival will reach term.

Other causes might be a defective ovum or sperm, poor oxygen supply, abnormal development of the umbilical cord, or a lack of nourishment for the fetus to grow. Almost half of all miscarriages also reveal some kind of chromosomal abnormality.

The large majority of miscarriages happen during the first 3 months (or trimester) of pregnancy, and many occur so early that the woman might not have even known she was pregnant. For others, however, the miscarriage that occurs later in pregnancy can be a devastating event, especially for those who had difficulty conceiving. Miscarriages that occur between the first trimester and the time when the fetus might survive on its own (about 25 weeks) leave the parents in a position similar to that of parents who have experienced the death of a child. There are feelings of helplessness and despair. Trained professionals such as grief counselors are recognizing the need to acknowledge this loss, rather than bury it deep in our emotions where it can hurt for years and years. In the past, the father seems to have been left out of the process, perhaps because he was not "physically" involved or because of our cultural beliefs that men are supposed to be strong in spite of their own traumatic experiences.

## MONTESORI METHOD

---

Maria Montessori, the first Italian woman physician, began to study education with mentally retarded

children using sensorial materials invented by the French educator Seguin. When the children under her tutelage passed the state examinations given to normal children, Montessori took up the challenge of determining why children in normal schools were not performing even better. Her approach to education was to watch children in a carefully prepared environment, giving them freedom within the bounds of constructive behavior. By observing and reasoning about their responses to the environment, she developed a method of education that appeared to work with their natural tendencies. In this sense she is in the tradition of Rousseau, Pestalozzi, and her contemporary John Dewey. Many of the principles she derived from studying normal children were later discovered in psychology and education research. For example, she believed that children go through sensitive periods when they are drawn to certain stimuli that particularly assist their development during that period; that young children are in a sensitive period for language acquisition; that children have an innate mechanism that assists language learning; that movement and cognition are closely entwined; that concentration leads to self-regulation; and so on.

Although Montessori education is often considered exclusive to preschool, that is only its most popular level. Montessori elementary schools are becoming increasingly common, including in public school systems in the United States. Montessori classrooms for children under 3 years of age and for adolescents are also becoming more common. Montessori classrooms generally have 3-year age groupings: 0 to 3, 3 to 6, 6 to 9, 9 to 12, and 12 to 15.

During infancy (as at all periods), Montessori's emphasis was on freedom of movement, encouragement of independence, and an optimal amount and level of stimulation. To assist young children's development, she recommended that children sleep on mattresses on the floor of a clean, safe room; have a small choice of interesting, developmentally appropriate toys and books that were to be changed regularly; and have their own small table and chair for eating as soon as they were able to sit independently. Infant-toddler classrooms are furnished with what she called "the exercises of practical life," involving sets of materials that allow children to take care of the classroom (sweep, mop, water plants, clean windows, and so on) and their own needs (e.g., prepare snacks) as well as activities to improve their motor control. For example, one set of materials might be for wood polishing. It would be a tray or basket containing a small bottle of polish that a child could easily open and

close, a bowl to put polish in, an application rag, and a polishing rag. To do this exercise, the teacher shows the child how to choose a wooden object in the classroom to polish and the series of steps needed to carry out the exercise. From then on, the child could choose wood polishing as an optional activity in the classroom. Children are gradually shown, individually, how to use all the materials in a classroom. They arrive in the morning and choose what activity they want to do. They do it until they are satisfied, then put it away and choose another one. When they have learned to use all the materials in the classroom competently, they are ready to move up to the next level.

Primary classrooms (for 3- to 6-year-olds) also have the practical life exercises, as well as materials for sensorial, math, language, culture, music, art, and geography education. Each area of the curriculum is housed in a different area of the classroom, with the materials all easily accessed by the children. Again, the teacher shows children how to use each material, after which children are free to choose their activities. There are specific ways to use the materials. Some find this too limiting and prefer that children be allowed to explore with the materials. However, the materials are designed to teach specific concepts that Montessori believed were building blocks of intelligence (like attention to dimension, or color). Only when children use the materials in prescribed ways, she believed, are they able to derive the concepts the materials were designed to communicate. In addition, particular uses of materials were intended to help children control their movements and establish self-discipline. She also believed children were attracted to such order. Freedom and choice abound in Montessori education, but at a higher level: what to do, but not how to do it (at least as regards particular Montessori materials).

Another limitation on freedom in Montessori schools is that children are expected to behave in socially acceptable ways. Children who misbehave are redirected to constructive activities and may need to stay near the teacher. Their freedom is thus taken away. Montessori urged that children who misbehave be given their favorite activities but be made to stay in one place, alone, to do them, and allowed to observe the other children. She believed that this process would allow children to observe what they had lost—freedom—by not behaving responsibly and would inspire them to behave better in the future.

Montessori believed that the development of concentration is crucial, because through concentration

children's personalities became "normalized"—her term for an absence of unhealthy behavior. Research on attention and self-regulation is consistent with this idea. Children who are high in self-regulation are able to sustain attention on a single activity or stimulus for a more prolonged period and also are looked on more positively by teachers and other children.
