Interestingly, the results of this survey are remarkably similar to those reported by researchers at Brigham and Women's in their ambulatory care division, despite this group's use of an in-house-developed EMR system. Using the same QUIS instrument, researchers there discovered that attending physicians scored their EMR lowest in the areas of system speed (although they did not distinguish between launch speed and speed of navigating within the application), helpfulness of error messages, and flexibility of system (Sittig, Kuperman, & Fiskio, 1999). The pattern of responses are quite similar, although MUSC physician reactions were less positive in terms of screen design and layout ($p<.01$), terms and system information ($p<.01$) and learning ($p<.001$). Brigham and Women's may have a more advanced training environment, and because they developed the EMR in-house, they have more flexibility in customizing the screens and layout to accommodate their physicians' preferences. No differences were found among overall user reaction and system capabilities. The physicians participating in the study at Brigham and Women had two or more years EMR experience.

Our study evaluated responses from both relatively new and experienced users. One might assume that due to the learning curve in moving from a paper-based system to an EMR, more experienced EMR users would be more satisfied with the system than less experienced users as Gamm et al. suggest (Gamm, Barsukiewicz, Dansky, & Vasey). We did not find that to be the case in our study. EMR users with less than one year of experience were equally satisfied overall with the system as were those who had used the application for two or more years.

Participants in this study provided a host of important suggestions for improving the EMR's use at MUSC. Other institutions would do well to address these issues and concerns up front to avoid problems later.

Our study has two primary limitations. First, the study is limited to a single healthcare organization and one EMR product. Thus, the results may not be generalizable to other healthcare organizations or those who use a different EMR system. Second, response bias is a concern. We compared the demographics of our physician and nurse participant populations with the general physician and nurse EMR population at MUSC and found no differences, yet response rate remains a limitation.

The real value of this study to other healthcare organizations may not be the results per se found at MUSC, but rather the methods and process used. Using the QUIS instrument, we were able to identify the aspects of our EMR system that stood out as problematic to clinician users—launch speed, navigation speed, and the clarity and helpfulness of error messages. Equally, if not more importantly, we provided all clinicians with the opportunity to offer suggestions on how to improve the system, and since this survey, we have incorporated many of their suggestions into our environment. Our leadership team has taken a number of steps to address the most widespread concerns identified by this survey and validated through other avenues. We believe other institutions will find the methods used in this study helpful in assessing clinician satisfaction and in soliciting suggestions for improvement.

CONCLUSION

Results of this survey suggest that MUSC physicians and nurses recognize and value having access to a single electronic patient record that is shared across the ambulatory care enterprise. However, they view the current system as less than ideal. Speed, performance and the user interface (e.g., need to simplify data entry) are of concern. Likewise, additional training and resources are needed to more effectively support the system and its users. Our leadership team has taken a number of steps to address the most widespread concerns identified by this survey and validated elsewhere. Steps to enhance system speed/performance and reliability are being taken, and multi-modal programs of improved training and user support are being implemented. We expect to observe the results of these initiatives and report outcomes in due course.

Assessing user satisfaction with the EMR is important in providing leadership with additional insight into the issues and concerns. Conducting formal evaluation studies, however, are often not done because of lack of available expertise and resources. We believe that surveys such as this one can prove to be a useful resource not only to our healthcare organization's leadership team, but to those in other healthcare institutions interested in easily assessing EMR satisfaction across the enterprise.

Chapter 4.16
Computerization of Primary Care in the United States

James G. Anderson
Purdue University, USA

E. Andrew Balas
Old Dominion University, USA

ABSTRACT

The objective of this study was to assess the current level of information technology use by primary care physicians in the U.S. Primary care physicians listed by the American Medical Association were contacted by e-mail and asked to complete a Web-based questionnaire. A total of 2,145 physicians responded. Overall, between 20% and 25% of primary care physicians reported using electronic medical records, e-prescribing, point-of-care decision support tools, and electronic communication with patients. This indicates a slow rate of adoption since 2000. Differences in adoption rates suggest that future surveys need to differentiate primary care and office-based physicians by specialty. An important finding is that one-third of the physicians surveyed expressed no interest in the four IT applications. Overcoming this barrier may require efforts by medical specialty societies to educate their members in the benefits of IT in practice. The majority of physicians perceived benefits of IT, but they cited costs, vendor inability to deliver acceptable products, and concerns about privacy and confidentiality as major barriers to implementation of IT applications. Overcoming the cost barrier may require that payers and the federal government share the costs of implementing these IT applications.

INTRODUCTION

The adoption of information technology (IT) to support the delivery of healthcare is recognized increasingly in many countries as an essential tool to improve patient care (Dick & Steen, 1997; Leaning, 1993; President's Information Technology Advisory Committee, 2004). Until recently, IT products available for healthcare providers mostly were designed for large organizations, were business-oriented, complex to implement, and costly. Recent advances in technology have made IT applications more available to primary care physicians in smaller practices. Products are available that are modular; able to be integrated with different systems, and designed to fit the physician's practice pattern without substantial investments in hardware, software, and maintenance (McDonald & Metzger, 2002).

As a result, the introduction of computers and IT applications into primary care in countries with favorable government policies and financial incentives has been rapid (Kidd, 2000; Mount, Kelman, Smith, & Douglas, 2000; Purves, Sugden, Booth, & Sowerby, 1999; Thakurdas, Coster, Guirr, & Arroll, 1996). A number of English-speaking countries has experienced widespread implementation of information technology. The Harvard School of Public Health and the Commonwealth Fund's International Symposium survey of primary care physicians found the following proportions of primary care physicians in the following countries who were using electronic medical records: U.S. (17%); Canada (14%); Australia (25%); New Zealand (52%); and the U.K. (59%). The survey also found the following use of electronic prescribing by primary care physicians: U.S. (9%); Canada (8%); Australia (44%); New Zealand (52%); and the U.K. (87%) (Harris Interactive, 2001a).

The U.S. trails European countries in the use of information technology in patient care. Overall, 29% of general practitioners in the European Union use electronic medical records compared to only 11% in the U.S. Only three countries from the Organization for Economic Cooperation and Development (OECD)—Portugal, France, and Spain—lag behind the U.S. (Harris Interactive, 2002b). Despite its potential to improve efficiency and quality of care, use of information technology in healthcare lags behind other sectors of the economy in the U.S. In 2001, most of the $20 million invested in healthcare information technology was used to computerize financial systems (Goldsmith, Blumenthal, & Rishel, 2003). Less than 10% of U.S. hospitals had adopted electronic medical record systems and less than 5% had implemented computerized physician order entry by 2001.

Given the increasing public attention to the importance of health information technology, the rate of IT adoption among primary care providers is important (Hillestad, et al., 2005). Accurate estimates of the adoption rate for information technology form the basis for policy regarding how to stimulate its use by physicians. The overall aim of this study was to determine primary care physicians' use of information technology in patient care. The specific objectives included the following:

1. Estimating the proportion of primary care physicians who have adopted information technology applications in their practices.
2. Determining physician perceptions of the benefits of these IT applications.
3. Determining physician perceptions of the barriers to the adoption of IT applications in their practices.

Primary care in the U.S. is delivered by physicians who comprise several specialties; namely, family practice (FP), internal medicine (IM), pediatrics (PEDS), and obstetricians and gynecologists (OBGYN). One other group of physicians was included in the survey comprising medical specialties such as geriatrics and occupational medicine.

Four IT applications were selected for investigation. First, electronic medical records (EMRs) are promoted as more comprehensive and accessible to healthcare providers. Studies have shown that EMRs have the potential to reduce medical errors, especially when integrated with other applications such as decision support (Bates et al., 1998). Electronic prescribing involves the use of computers or hand-held devices to submit prescriptions to pharmacies electronically. E-prescribing has the potential to improve efficiency, to reduce prescription errors, and to improve compliance with managed-care formularies (Miller, Gardner, Johnson & Hripcsak, 2005; Schiff & Rucker, 1998). Third, point-of-care decision support tools can improve the quality of patient care; for example, an antibiotic decision support system (Evans et al., 1998) and automated decision support alerts for contraindicated medications (Galanter, Didomenico & Polikaitis, 2005). Fourth, patients consistently have expressed a strong desire for online communication with physicians (Harris Interactive, 2005). This may involve e-mail queries as well as online consultations. Electronic communication allows physicians to deliver better care and patients to assume greater responsibility for their own care.

METHODS

Survey Method

A Web-based survey was developed to investigate primary care physicians' use of the four IT applications described previously. These applications were selected because healthcare providers in the U.S. and the EU find them helpful and effective (Harris Interactive, 2003, 2005). Comparative data also exist from earlier surveys on the use, perceived benefits, and barriers to these applications. At the same time, earlier studies failed to differentiate primary care physicians by specialty.

We describe the design and administration of the survey. A Web-based survey method was chosen, because it permitted us to survey a national sample of primary care physicians with a reasonable budget (Eysenbach, 2005; Lazar & Preece, 1999; Wyatt 2000). Also, we wanted to sample an Internet-literate population that is most likely to be early adopters in their practices (Rogers, 1983).

Survey Design

The study was sponsored by the Quality Improvement Working Group of the American Medical Informatics Association and the School of Public Health at St. Louis University. The e-mail that was sent out inviting primary care physicians to participate in the study contained a link to the Web-based survey (see Appendix).

In order to facilitate comparisons to earlier surveys, items were adapted from other widely cited surveys; in particular, the annual Health Care Information and Management Systems Society (HIMSS) Leadership Survey (HIMSS, 2002) and the Harris Interactive polls that were conducted in the U.S. and the EU (Harris Interactive, 2002b, 2003).

The questionnaire was divided into seven sections. The first section included information about the physician's specialty and practice. The second section asked physicians to rate the priority of a number of Internet technologies. The next three sections listed specific financially focused, clinically focused, and patient-focused IT applications. The physician was asked to indicate for each IT application if he or she (1) had implemented, (2) planned to implement within one year, (3) had no plans to implement but was interested in learning more, or (4) had no interest. Physicians also could respond by indicating that they didn't know or that they chose not to answer that question. The sixth section asked physicians to rate the benefits of using IT applications on a Likert scale. Responses ranged from (1) high benefit to (4) not a benefit. The final section asked about barriers to implementing IT applications. Responses ranged from (1) not a barrier to (5) insurmountable barrier. A copy of the survey is included in the Appendix.

Factor analyses were performed on the items that measured perceived benefits of the IT application and on the perceived barriers to implementation. A single factor accounted for 63% of the variance in the benefits items. The reliability based on Chronbach's Alpha was 0.93. For the barriers items, a single factor accounted for 48% of the variance. The reliability was 0.86 based on Chronbach's Alpha.

Sample

We contracted with SK&A Information Services to broadcast an e-mail invitation to primary care physicians to participate in the study. This company maintains a comprehensive list of physicians based on the AMA Physician Masterfile. The list is updated weekly through the use of surveys, publication mailings, and the U.S. Postal Services Address Correction Services. E-mail invitations to participate in the study were sent out to 31,743 primary care physicians. Of these e-mails, 1,101 were rejected due to invalid e-mail addresses. A total of 2,145 physicians responded, representing a 7.3% response rate to the survey. The software prevented respondents from completing the survey more than one time. Questionnaires from physicians who were not currently practicing or who were not currently engaged in primary care were eliminated as were questionnaires with significant missing data. This resulted in a final sample of 1,665 that was used in the analysis.

Table 1 presents demographic data and practice information about the study sample. Sixty percent of the physicians were between 41 and 60 years of age, while 29% were younger. Three-fourths of the responding physicians were male. Almost 75% practiced family medicine, internal medicine, or pediatrics, while 15% practiced obstetrics and gynecology and 9% other medical specialties. More than 88% of the respondents were primar-

Table 1. Physician characteristics of the study sample

Characteristic	N	%
Age		
30 or less	16	1.1%
31–40	259	17.9%
41–50	537	27.0%
51–60	484	33.4%
61–70	108	7.4%

Hospital	232	13.9%
Group: 10 or more	298	17.9%
Group: Less than 10	607	36.5%
Solo	327	19.6%
Other Settings	201	12.1%

ily clinicians. The other 12% held primarily administrative positions in their practices and were excluded from the final analysis.

About 14% of the respondents were hospital-based. Almost 18% of the physicians were in group practices of 10 or more; more than one-third of the respondents were in small group practices with less than 10 physicians, and 20% of the physicians were in solo practice. The remaining 12% were in integrated health delivery service organizations, managed care organizations, and so forth.

RESULTS

Use of Information Technology

Table 2 shows the extent to which physicians in each specialty have implemented each of the four IT applications. Overall, only one out of four has implemented electronic medical records and report using point-of-care decision support tools. About 23% communicate electronically with patients. Only one out of five primary care

Table 2. Use of information technology by primary care specialty (%)

Application	FP	IM	PEDS	OB/GYN	Other	Total
Electronic Medical Records

No interest	33.9	35.9	35.6	43.6	35.6	35.9
NA	10.7	15.8	21.5	15.1	13.5	14.8
Electronic Communication						
Implemented	25.5	26.6	20.4	21.2	26.2	23.2
Plan to implement	11.4	7.1	8.2	10.1	1.6	8.7
Interested in	9.3	6.5	12.1	11.1	9.5	9.9
No interest	29.0	28.1	28.9	31.7	29.4	28.9
NA	24.8	31.7	30.4	26.0	33.3	29.4

NA=don't know or I choose not to answer physicians utilizes electronic prescribing. A surprisingly high number of physicians indicated no interest in all of the IT applications. Thirty-six percent indicated no interest in decision support tools, while 31.3% and 23.5% evidenced no interest in electronic prescribing and electronic medical records, respectively. Almost 30% stated that they were not interested in electronic communication with patients.

A greater proportion of internists report having implemented all four of the IT applications in practice ($p<0.05$). Thirty-one percent have implemented electronic medical records; about 26% have implemented electronic prescribing, decision support tools, and e-mail communication with patients. In general, OBGYNs are the least likely to have implemented any of the IT tools with the exception of electronic communication with patients ($p<0.05$). Less than one out of six of these physicians have implemented electronic medical records or electronic prescribing or decision support tools, and only one out of five have implemented electronic communication with patients. OBGYNs also expressed the least interest in IT applications ($p<0.05$). More than 30% indicated no interest in electronic medical records, electronic prescribing, and e-mail communication with patients. More than 40% indicated no interest in implementing decision support tools. There may be several major reasons for this low use of IT and lack of interest by OBGYNs. Most of the IT applications are general and may not meet the specific needs of this specialty. Also, there appear to be few published studies involving the use of IT by OBGYNs.

Perceived Benefits and Barriers

Overall, the majority of primary care physicians surveyed perceived benefits from implementing IT applications (see Table 3). Almost 75% indicated that these applications could reduce errors; 70% perceived IT as potentially increasing their productivity; more than 60% indicated that IT tools have the potential to reduce costs and to help patients assume more responsibility. Physi-

Table 3. Perceived benefits of implementing IT applications (%)

Benefit	High	Medium	Low	None
Patients assume responsibility for monitoring symptoms/ disease	23.6	38.7	22.1	15.6
Shorter consultations	17.0	29.1	20.9	32.9
Patients not seeking medical care when it was not needed	22.5	28.2	24.4	25.0
Patients coming in sooner for necessary treatment	33.8	29.6	18.4	18.3
Fewer unnecessary tests	29.4	27.9	16.1	26.5
Fewer unnecessary treatments	32.8	24.9	16.9	25.4
Fewer errors	53.4	21.4	10.5	14.7
Increased productivity	39.2	30.3	14.2	16.3
Reduced costs	37.5	25.5	15.4	21.6

cians are less certain about some of the other potential benefits of IT applications. About half of the physicians surveyed evidenced skepticism that IT applications would shorten consultations and reduce the number of patients who seek unnecessary healthcare. More than 40% felt that IT is unlikely to reduce unnecessary tests and treatments.

More than 80% of primary care physicians report the lack of financial support for IT applications as a major barrier to adoption. This is followed by their perceptions that vendors fail to deliver acceptable products as primary barriers to implementing these tools (79.3%) (see Table 4). In general, physicians perceive these barriers as difficult to overcome. Almost two-thirds of the physicians surveyed also cited the lack of a strategic plan for implementing applications and difficulty in recruiting experienced IT personnel as major barriers, while more than one-half cited lack of sufficient knowledge of IT as a barrier to implementation. At the same time, physicians indicated that these last three barriers easily could be overcome.

Table 4. Perceived barriers to implementing IT applications (%)

Barriers	**No Barrier**	**Easily Overcome**	**Overcome some effort**	**Overcome great effort**	**Insurmountable**
Lack of financial support	7.6	5.0	35.3	41.3	10.7
Vendors' inability to deliver acceptable products	12.4	8.3	34.8	36.3	8.2
Acceptance by staff	17.8	23.9	41.6	15.3	1.3
Difficulty proving quantifiable benefits	14.8	18.0	38.7	24.6	3.9
Lack of strategic plan for implementing	19.7	15.2	35.7	25.3	4.1
Recruiting experienced IT personnel	22.0	17.6	31.7	24.0	4.8
Retaining experienced personnel	24.6	17.9	36.6	18.1	2.8
Insufficient knowledge of IT applications	15.0	22.5	41.4	19.3	1.7
Considerable investment in IT applications	6.1	6.9	28.8	47.6	10.6

Predictors of IT Implementation

Table 5 provides the logistic regression models and predictors for implementing each of the IT applications. Demographic factors, specifically age and gender, were not associated significantly with the implementation of the four IT applications. In only one instance was there a significant difference between male and female physicians. Males were almost twice as likely to implement e-prescribing as females.

Physicians' specialties did predict whether or not they had implemented certain IT applications. Pediatricians and obstetricians and gynecologists were significantly less likely to have implemented electronic medical records. In contrast, family practitioners were almost three times more likely to have implemented point-of-care decision support tools. Specialty was not a significant predictor of implementation of electronic prescribing and communication with patients.

Table 5. Predictors of the implementation of IT applications (odds ratios)

Characteristic	EMR	E-Prescribing	Decision Support	E-Communication
Age				
30 or less	1.000	1.000	1.000	1.000
31–40	0.668	1.474	0.761	1.360
41–50	0.421	0.401	0.760	1.614
51–60	0.568	0.392	0.660	1.157
61–70	0.530	0.503	0.606	1.393
70 or above	0.503	0.706	0.499	1.393
Gender				
Male	1.175	1.942**	1.094	1.066
Female	1.000	1.000	1.000	1.000
Specialties				
FP	1.420	1.433	0.591**	0.924
IM	0.712	1.125	0.957	0.851
Pediatrics	0.513**	0.622	1.206	0.616
OBGYN	0.406**	0.957	1.180	0.586
Other	1.000	1.000	1.000	1.000
Benefits				
Fewer Errors	1.541**	1.574**	1.238*	1.086
Increased Productivity	1.023	1.282*	1.157	0.919
Reduced Costs	0.804*	0.724**	0.788*	0.868
Barriers				
Lack of Financial Support	1.591**	1.452**	1.296*	0.960
Vendors' Failure to Deliver	1.169	1.211*	1.309**	1.108
Considerable Investment	1.207	1.271*	1.221	1.278

***p<0.01* **p<0.05*

Perceived benefits and barriers appear to be consistent predictors of whether or not primary care physicians implemented three of the four IT applications. Physicians who perceived that IT can reduce medical errors were one and one-half times more likely to have implemented electronic medical record, e-prescribing, and decision support tools. In contrast, physicians who cited lack of financial support and the considerable investment required to implement these applications as significant barriers were less likely to have implemented all three of these IT applications. Physicians who perceived vendors as failing to deliver useful and acceptable products were significantly less likely to have implemented decision support tools. The decision to implement electronic communication with patients did not appear to be affected by demographic characteristics, specialty, or perceptions of benefits or barriers.

DISCUSSION

Adoption of electronic medical records has been the most widely surveyed IT application. A review of 22 studies of outpatient electronic medical record (EMR) adoption from 1998 to 2002 suggested a utilization rate of 20% to 25% at the time of the surveys (Brailer & Terasawa, 2003). However, data from the U.S. National Ambulatory Medical Care Survey (NAMCS) indicated that in 2001, only 17% of office-based physicians used electronic medical records (Burt & Hing, 2005).

These studies vary considerably in terms of how respondents were selected and their generalizability to a physician population. Many of the studies are unscientific and utilized surveys of meeting attendees. Only three of the 22 studies reviewed were rated as generalizable. Also, most of these studies do not differentiate among physicians by specialty. Consequently, there is only limited data on adoption of EMRs by specialty. The 2002 Health Care Information and Management Systems Society (HIMSS, 2002) survey administered to attendees and exhibitors at the annual conference found that 42% of internal medicine practices and 30% of family medicine practices reported using EMRs. These rates show little change from the HIMSS survey in 2001. However, since only meeting attendees were surveyed, it is impossible to extrapolate these results to the U.S. primary care physician population as a whole.

There are fewer studies of the adoption of other IT applications such as electronic prescribing and online communication between physicians and patients. The National Ambulatory Medical Care Survey (NAMCS) indicated that only 8% of office-based physicians in 2001 ordered prescriptions electronically (Burt & Hing, 2005). The Harris Interactive study that compared use of IT by U.S. general practitioners to European physicians found that 17% of physicians in primary care practices reported that they used EMRs, and 9% reported using electronic prescribing (Harris Interactive, 2002a). This survey also dates back to 2000-2001. Neither study differentiates physicians by specialty.

More recent information is needed about the extent to which primary care physicians use information technology for patient care, patterns of use, and perceived barriers to use of IT. Many of the surveys discussed earlier were undertaken before the year 2000. The NAMCS statistics on uses of computerized clinical support systems in medical settings are based on office-based physician practices rather than only on primary care physicians (Burt & Hing, 2005). The Harris Interactive study reports aggregate statistics for primary care physicians and specialists. Our survey examined IT applications that appear to offer the greatest potential to primary care physicians in providing high-quality patient care. It also differentiates primary care physicians by specialty.

This study provides evidence from a large sample of U.S. primary care physicians that there is limited implementation of clinical and patient care IT applications. Overall, only about 25% of primary care physicians have implemented electronic medical records, e-prescribing, point-of-care decision support tools, or electronic communication with patients. These results are similar to those from a Harris Interactive survey of 400 U.S. physicians conducted in 2001 and other earlier studies indicating a slow rate of adoption However, the proportion of physicians who have implemented e-prescribing has almost doubled from 11% to 20% since 2001. This may be due in part to improvements in the technology, such as the use of wireless devices.

Of concern is the finding that almost one out of three primary care physicians surveyed expressed little or no interest in the four IT applications. This may indicate that while two-thirds of primary care physicians perceive that implementation of IT can reduce costs and errors and help patients assume more responsibility for their medical conditions, a significant number of these physicians does not perceive the advantages of implementing IT technologies to provide patient care. One way of overcoming this barrier may be for medical specialty societies to offer seminars, short courses, and/or Web seminars on IT for CME credit with a focus on those features that are most useful to physicians in that specialty.

Age and gender on the whole do not appear to predict implementation of these four IT applications. However, there are significant differences in implementation among the specialties. A greater proportion of internists report having implemented all four IT applications. Pediatricians and obstetricians and gynecologists are less likely to have implemented EMRs, while family practitioners are more likely to have implemented decision support tools. OBGYNs, in particular, have been slow to adopt IT in practice. Only 16% have implemented EMRs and decision support tools. Even less, 13%, have implemented electronic prescribing. The slow adoption of IT applications by this specialty group may be due to the fact that these tools fail to address the special needs of this group of physicians. Also, OBGYNs may need to see more studies that demonstrate how these tools can help them to improve their practices.

This finding suggests that future surveys that assess adoption of IT applications by physicians need to differentiate by specialty rather than to treat primary care physicians or office-based physicians as homogeneous groups. Efforts to encourage IT adoption by physicians need to be tailored to specific specialty groups by emphasizing features of the technology that are particularly useful to that specialty.

Perceptions of benefits and barriers are significant predictors of implementation of three of the four applications. Physicians who perceive that EMRs, e-prescribing, and decision support tools can help them to reduce medical errors are significantly more likely to have implemented these technologies. At the same time, perception of barriers is a significant impediment to implementation (Anderson, 1997, 1999; Harris Interactive 2001b). Those physicians who perceived lack of financial support and high investment cost required were much less likely to have implemented these three IT applications. Also, physicians cited lack of experience and knowledge of IT as barriers. This may indicate that physicians may feel that learning to use IT applications in practice may require too much time and energy by them and their staff in order to achieve the perceived benefits. Consequently, a key to increased use of patient care IT applications by primary care physicians may be to convince them that the benefits significantly outweigh the barriers, primarily cost. Also, physicians do not perceive vendors as delivering acceptable IT products that meet their needs. More than 70% of physicians who responded to the survey perceived vendors' unresponsiveness as a barrier to implementation of IT. It may be necessary for vendors to examine more thoroughly the needs of primary care physicians and how their IT applications fit into clinical practice in order to convince physicians to adopt them.

Other studies have indicated that lack of funding and costs are the largest barriers to the adoption of EMRs. Surveys have found that 50% or more of respondents cited lack of adequate funding as the major barrier to implementation (HIMSS, 2002; Medical Group Management Association, 2001; Medical Records Institute, 2002; Miller & Sims, 2004). This perception is based on the fact that implementation of some IT applications such as EMRs requires large up-front investment and ongoing maintenance costs. A study by the California Health Care Foundation (2003) estimated that the cost of implementing a computerized physician order entry (CPOE) system in an ambulatory care practice ranges from $15,000 to $50,000 per physician with a median cost of $30,000 per physician.

Overcoming the cost barrier will be difficult and may require incentives by payers and the government. An example is New Zealand, Australia, and the U.K., which have introduced government funding programs to stimulate adoption and use of EMRs (Bates, Ebell, Gotlier, Zapp & Mullins, 2003). Professional associations also can facilitate adoption of IT. The American Academy of Family Physicians, through a nonprofit foundation, is developing low-cost, open-source EMR software that will be available to physicians with no licensing fee.

Decisions to implement electronic communication with patients appear to be independent of perceptions of benefits and barriers. Barriers to electronic communication with patients may be different than barriers to the other IT applications. Physicians generally express concerns about the legal status of these communications and concern about the security of patient information sent over the Internet.

One of the limitations of this study is the low response rate (7.3%). Low response rates are one of the major limitations of Web-based surveys in general (Eysenbach, 2005). A systematic review of 17 Internet-based surveys of health professionals found that reported response rates ranged from 9% to 94% (Braithwaite, Emery, de Lusignan & Sutton, 2003). Most of these studies utilized professional e-directories. Some used commercial organizations' e-mail directories or recruited volunteers via Web sites of electronic discussion groups. Six of the 17 studies reviewed did not report response rates. A meta-analysis of response rates in Web- and Internet-based surveys found that the mean response rate for 68 surveys was 39.6% with a standard deviation of 15.7% (Cook, Heath & Thompson, 2000). Other researchers have reported similarly low response rates of 18% for a study of physicians in Hong Kong (Leung, Johnston, Ho, Wong & Cameo, 2001).

One study of general practitioners' use of decision support for management of familial cancer sent five separate e-mail reminders and achieved a response rate of 52.4% (Braithwaite, Sutton, Smithson & Emery, 2002). In the case of our study, the high cost of sending additional reminders to physicians precluded our doing so.

Since our survey was administered online and did not include an alternative mail survey, there is a risk of over-sampling respondents who are more likely to utilize computers in their practices. Our sample was drawn from physicians with e-mail addresses listed by the American Medical Association (AMA). These physicians may be knowledgeable about IT applications and more likely to implement them in patient care. This sample design was adopted since we wanted to sample an Internet- and computer-literate population of primary care physicians. These physicians are most likely to be early adopters of IT applications in their practices. Consequently, estimates of implementation reported in this study are likely to be higher than for the entire population of primary care physicians.

At the same time, limitations on the generalizability of the results apply to many of the earlier reported studies of IT adoption by physicians

(Brailer & Terasawa, 2003). The HIMSS surveys were voluntary surveys administered to conference attendees (HIMSS, 2002). The MediNetwork 2002 Medical Group Office Management Systems Survey was voluntary and reported a 7.52% response rate. The AHA Most Wired Survey 2002 and the Medical Records Institute Survey of Electronic Health Record Trends and Usage sponsored by SNOMED were online voluntary surveys and did not report response rates. Comparative data for the U.S. and the E.U. reported by Harris Interactive did not report response rates. Data on the E.U. countries were based on the EuroBarometer 104 conducted in June/July 2001. U.S data were collected by Harris Interactive. Our study is an improvement over a number of these earlier studies in which there are serious questions about the reliability and the generalizability of results due to flawed study design or industry sponsorship (e.g., the HIMSS Leadership Survey). Also, earlier studies with few exceptions failed to differentiate primary care physicians or office-based physicians by specialty.

In this study, no attempt was made to specify specific features of each of the four IT applications. Physicians simply were asked if they had implemented or intended to implement each application. However, features of each application vary considerably from practice to practice. For example, an EMR in addition to patient problem lists, medications, allergies, tests, and personal information and medical history may be linked to an electronic prescribing system and evidence-based decision support tools.

CONCLUSION

The present study has documented the extent to which primary care physicians use IT in providing patient care. Variation among different primary care specialty groups is an important finding as is the finding that one out of three primary care physicians expressed no interest in using any of the four IT applications for patient care. Moreover, the finding that perceived that benefits and barriers are the most significant predictors of IT implementation has implications for strategies to promote implementation of IT in clinical practice. Primary care physicians will need to be convinced that the benefits of these tools outweigh their costs. Also, vendors will need to be more responsive to the needs of primary care physicians. Finally, overcoming the costs barrier will require incentives and/or cost sharing by payers and the federal government.

ACKNOWLEDGMENT

This study was supported by the Center for Education and Research in Information Assurance and Security (CERIAS). Data were collected by the Purdue University Social Research Institute. Marilyn Anderson, Don Malott, and Heather Rodriquez assisted with the data analysis and manuscript preparation.

APPENDIX

Dr. <name>

The Quality Improvement Working Group of the American Medical Informatics Association in conjunction with the School of Public Health at St. Louis University is undertaking a survey of physician experience with information technology at the point of care. The survey is being performed under contract with the Social Research Institute at Purdue University and funded by the Center for Education and Research in Information Assurance and Security.

To participate, simply click on the link below and you will be directed to the Social Research Institute Web site at Purdue University. Please complete the short survey. Your responses will be kept strictly confidential and will be used solely for academic research purposes. We are grateful for your willingness to provide your valuable perspective on the real implementation experience of a physician using information technology at the point of care.

If you have any questions, please contact:

James G. Anderson, Ph.D.
Professor of Medical Sociology
Purdue University
Chair Elect, Quality Improvement Working Group
American Medical Informatics Association
Andersonj@soc.purdue.edu

E. Andrew Balas, M.D.
Dean and Professor
School of Public Health
St. Louis University
Chair, Quality Improvement Working Group
American Medical Informatics Association

ABSTRACT

Poor infrastructures in developing countries such as Ethiopia and much of Sub-Saharan Africa have caused these nations to suffer from lack of efficient and effective delivery of basic and extended medical and healthcare services. Often, such limitation is further accompanied by low patient-doctor ratios, resulting in unwarranted rationing of services. Apparently, e-medicine awareness among both governmental policy makers and private health professionals is motivating the gradual adoption of technological innovations in these countries. It is argued, however, that there still is a gap between current e-medicine efforts in developing countries and the existing connectivity infrastructure leading to faulty, inefficient and expensive designs. The particular case of

Ethiopia, one such developing country where e-medicine continues to carry significant promises, is investigated and reported in this article.

INTRODUCTION

Healthcare consumers in general tend to seek access to affordable health services that will meet their needs. From an ethical standpoint, healthcare has to be available when and where consumers need it; physical separation between consumers and healthcare facilities must not pose severe limitations on the delivery of efficient healthcare, even if patients are located in remote areas. In this sense, information and communications technology (ICT) has been demonstrated to offer a competitive choice for accessing affordable and effective health services, especially when access is difficult and limited (Horsch & Balbach, 1999; Kirigia, Seddoh, Gatwiri, Muthuri, & Seddoh, 2005; Tan, Kifle, Mbarika, & Okoli, 2005). More recently, with the continued maturity of network such as Integrated Services Digital Network (ISDN) and Asynchronous Transfer Mode (ATM) networks and related technologies (Perednia & Allen, 1995; Tan, 2001), e-medicine implementation has entered a stage where both the health providers and consumers can now benefit significantly.

IT-based horizontal and vertical communications among the healthcare facilities within the organizational structure of the healthcare system are essential. Such communications facilitate efficient information exchange and help the delivery of essential health services to underserved rural areas. These communications can be supported through a nationwide e-medicine network that is based on affordable telecommunications infrastructure. The network should connect all regional clinics to urban area hospitals. The benefits of such a network include: (a) establishing reliable horizontal-vertical communications and information sharing among facilities, thereby driving up quality, improving efficiency, and enhancing cost-effectiveness of services; (b) achieving e-health commitments and bringing healthcare closer to underserved and un-served rural areas; (c) strengthening collaboration among hospitals within a multi-provider care management context; (d) minimizing long distance travels among rural people in need of proper medical care to urban areas or the capital city; and (e) providing medical information to clinical practitioners that will help them keep abreast of clinical breakthroughs as well as new technological advances.

For Ethiopia, a lesser developing country with significant challenges in meeting basic healthcare needs, it is argued that e-medicine development is emerging and can be fruitfully cultivated over the coming years if a vision and long-term strategy for this technology can be used to help increase the number of citizens receiving care and decrease the subsequent healthcare costs. This article lays out such a vision and strategy for a nationwide e-medicine infrastructure to be designed. It is organized as follows. First, the background and various design considerations for a nationwide e-medicine network is presented. Next is an overview of the requirements for the network design followed by a more in-depth description of the local and wide area network (LAN/WAN) architecture envisioned. The focus of the discussion will then shift to the existing Broadband Multimedia Network (BMN) and Very Small Aperture Terminal (VSAT) infrastructures and how these networks may be integrated into the nationwide e-medicine infrastructure. Finally, the article concludes with insights into potential future work in e-medicine for developing countries.

E-MEDICINE NETWORK DESIGN CONSIDERATIONS

E-medicine refers to the electronic delivery of healthcare and sharing of medical knowledge over a distance employing ICT. A national e-medicine network allows sharing and exchanging of clinical data among physicians, administrators, even patients or other participating health professionals regardless of physical distance separation or geographical terrain of the whereabouts of these network participants within the national boundaries. The network also facilitates communications among physicians and academics across diverse cultures, affiliated healthcare organizations, and publicly or privately funded research institutions. Since there is lack of transportation and communication infrastructure in developing countries, medical and clinical data exchanges can be further secured and facilitated through an existing e-medicine network.

In developed nations, e-medicine services (Wright, 1998) can benefit remote locations that may not be easily accessed due to unpredictable or harsh weather conditions found during certain times of the year, for example, parts of North America and Scandinavian countries are often heavily affected by snow and other natural hazards such as avalanches, falling boulders and closure of highways due to multi-vehicle accidents or other calamities. Mountainous terrain in certain parts of North American regions such as Alaska, British Columbia, Alberta and New Territories implies the need for viable distance healthcare delivery solutions. E-medicine allows health professionals around the world to establish faster communication and exchange information with clients and regional authorities irrespective of geographical locations. It may also support rural dwellers to get healthcare services delivery similar to their urban counterparts. A mobile e-medicine system, for instance, provides a convenient platform for acquisition, transmission and delivery of health-related data to healthcare providers through 2G/3G-based wireless networks (Wootton, 2001). Recognizing these benefits, the International Telecommunications Union (ITU) has set a global agenda to promote e-medicine applications in developing countries. Ethiopia, one of the beneficiaries of such an initiative, has commissioned some ICT projects such as SchoolNet, WoredaNet and BMN to enable fully-fledged connectivity to make better use of the ICT in the health and education sectors.

Network Architecture

The design of suitable national e-medicine network architecture in a lesser developing country such as Ethiopia requires several key components to be integrated into a dynamic and enterprising communication infrastructure. Major architectural components include: (1) LAN architecture for local networking and sharing of health-related information; here, communications may be established using wireless cellular or ordinary fixed telephone lines; (2) WAN architecture for national networking and sharing of health-related data; this will allow communications among local and national physicians, healthcare workers and clients covering urban and rural communities; and (3) designing a suitable back-end database and front-end user interface applications that integrate seamlessly with the (prototype) implementation of the proposed architecture. The overall goal of the nationwide e-medicine network architecture is then to provide an affordable and a low-cost system that facilitates uninterrupted communications among physicians and health professionals across the country. The system bolsters connectivity among rural clinics and urban area hospitals to support primarily clinical e-consultation and maintenance of stored patient records.

This network should also be cost-effective, expandable, and secure. It must support a state-of-the-art ICT access schema and connectivity to rural area clinics. Existing ICT infrastructure will be given priority to minimize the cost of implementing the nationwide network. In the Ethiopia design, expandability is a concern. First, few hospitals are built in the country while more clinics are being added every year. Moreover, there is a chance to incorporate private hospitals in the nationwide e-medicine network as and when necessary, which will further increases the number of future connected sites. As well, the area of e-medicine applications will not be limited to just some specific diseases, but will be expected to increase in type and number over the long haul. In fact, the network should also support advanced applications, which require real-time connectivity such as videoconferencing capabilities for future use.

During e-consultation or patient referral, most of the data exchanged over the network are sensitive patient information. Confidentiality of patient information must therefore be respected. For secure communications, protocols such as Secure Socket Layer (SSL) could be used. SSL ensures secured communications over web-based applications and provides the ability to safely exchange patient information across the network (Elmasri, 2000). When doctors exchange patient information, they could adhere to medical protocol that defines the rules to be followed during this process. In addition, the network and accompanying servers could be protected by firewall against hacking from external parties. Firewalls are software or hardware for the sole purpose of keeping digital pests such as viruses, worms, and hackers out of the network (http://www.cisco.com, Tanenbaum, 2004).

NETWORK DESIGN REQUIREMENTS

As cost must be one of the driving factors for choosing among existing or emerging ICT infrastructures in the country, implementing nationwide e-medicine network infrastructure may seem at first to be more expensive than building clinics or supplying existing regional clinics with medical personnel and equipment. Yet, a cost-benefit analysis comparing various IT investment approaches will provide best directions to achieving a lower cost solution to the problem of delivering adequate and proper healthcare and disseminating confidential health information to and from various connecting points throughout the country. With today's oil prices at a premium, network connectivity among the healthcare facilities, both in the urban and rural areas over an existing ICT infrastructure is now considered a cost-effective solution. Of course, set-up costs depend on the type of WAN to be used—to ensure low installation cost, it is proposed that the network design will incorporate an existing WAN provided by the Ethiopia Telecommunication Corporation (ETC).

In Ethiopia, most of the inter-hospital communications are traditionally dependent on telephone and hand-delivered referral messages. During referrals patients have to travel afar to one of the urban referral hospitals, carrying the written messages of the referring physician. Clinics located in the telephone coverage areas communicate using telephone to exchange information about availability of specialist(s) or bed in another hospital. Yet, the communication needs of hospitals have grown over the years ahead of its technological capabilities. Geographically dispersed clinics lack modern telecommunication technology access. Among them are instantaneous access to patient information, access to electronic medical records, and access to the Internet. These and other communication needs of health providers also require the development of e-medicine application software backed by electronic patient record systems. Design of such communication networks will also require the understanding of organizational structure of the clinics involved in the network.

Since the government/public clinics are owned and organized under their respective regions, the WAN design should follow the organizational structure of the administrative regions in the country. A detailed study about the inclusion of various clinics, their locations relative to the nearest access point to existing ICT infrastructure, traffic load and its characteristics, security, LAN/WAN protocol, topology and bandwidth requirements and utilization, and allocation of bandwidth, among other issues, have to be considered while trying to design a nationwide e-medicine network architecture. For example, issues of communicating patient information electronically may further raise question on medical ethics, the need for developing standard medical protocols, and detailing policies for use in routine activity via the e-medicine network.

LAN Architecture

To design the LAN for each hospital, we consider the central site, *Tikur Anbassa Specialized Hospital* located in the capital Addis Ababa, as a model. The hospital is organized into 16 departments with each department further divided into smaller units as necessary. For instance, the Internal Medicine department has several units such as the Renal Unit, the Cardiology Unit, the Neurology Unit, and other units. Physicians in these departments and units need to communicate whenever a patient visits more than one of the units. It is proposed that the LAN follows the hierarchical structure of the hospital.

The decision to make the selection between various LAN technologies was based on: (a) expected application to run on the network and their traffic patterns; (b) physical locations of the offices and users to be connected in campus; (c) the rate of network growth; (d) the abundance of the network technology in the market; and (e) simplicity of installation and maintenance. Each of these criteria will now be explored in more depth.

Expected Application to Run on the Network and their Traffic Patterns

Currently we expect a Web-based e-medicine application to run on the network. The application will use a central database server where all the user and patient information will be stored. The type of data to be transmitted on the network should accommodate both text and image formats. Since all communications are to be channeled through the server, the traffic pattern around the center is expected to be heavy. Higher speed devices should be installed at the center of the LAN where servers will be located.

Physical Locations of Offices and Users to be Connected on Campus

The sample hospital (*Tikur Anbassa Specialized Hospital*) is housed in a series of five buildings (Blocks A-E). These blocks are not physically separated. Even though precise figures were unavailable, these five buildings are built on roughly 8,000 to 10,000 square meters. While the main offices and departments in the hospital are located in one of the respective blocks, most of these offices are in either of the first two stories of the block they belong. Having routers switches in each of the departments is ideal to design a high-speed and expandable LAN, but it will also make the design expensive to install, support and maintain. A more cost-effective approach is to put switches per building and then get the departments to be connected into various groups by using Virtual LAN technology.

The Rate of Network Growth

The rate of the hospital LAN growth depends on the level of computerization in the hospital. Currently in this central hospital site, there is a LAN that connects a few offices and a computer room. The network employs star topology, using a centrally located hub and Unshielded Twisted Pair (UTP) cables forming a peer-to-peer LAN. The purpose of this LAN was to enable offices to share printer and students to get access to research documents. In this design, it is anticipated that as the use of Web-based applications becomes commonplace, there will be opportunities to add more applications and connect more computers and offices to the LAN. The switches-routers selected in this design should therefore have many free ports to help cascade the growing number of anticipated future connections.

The Abundance of Network Technology in the Market

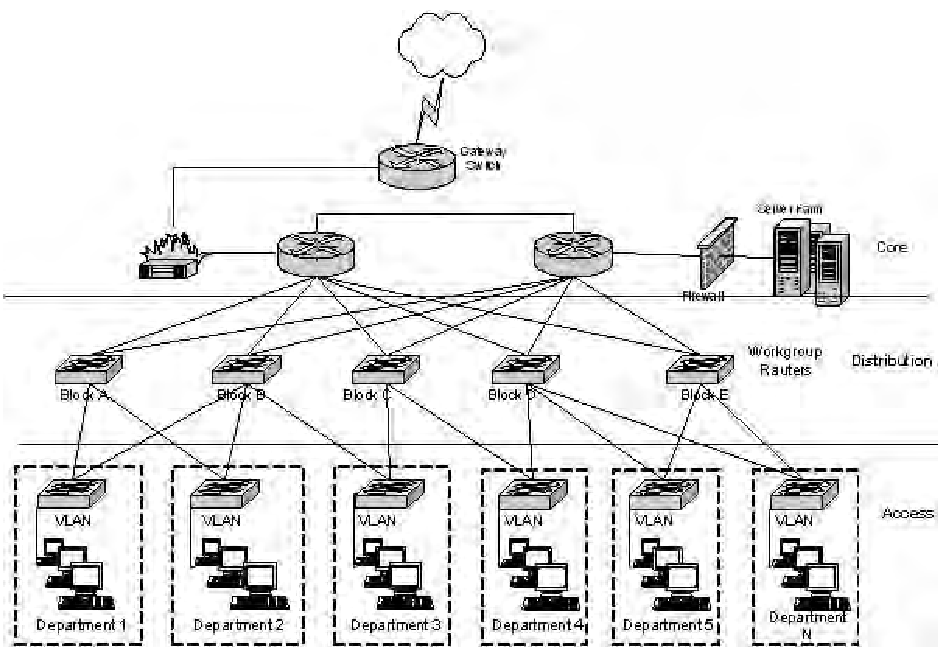
Capitalizing on the abundance of emerging network technology in the Ethiopia market, we gathered data from existing network technology vendors and organizations that implement computer networks in the capital city, Addis Ababa. Ethernet technology is common in organizations that implement computer networks, such as Addis Ababa University (AAU Net). AAU Net is a network backed by triangular shape fiber optic cable connecting the three main campuses. The topology is an extended star topology that fastens together fiber optic cables for vertical cabling (backbone cabling) between buildings that house various faculties and departments. These backbone cabling provide interconnection between wiring closets and Point of Present (POP). The zones that fall within a departmental area are served by internetworking devices such as hubs and UTP cables.

Interestingly, what is described so far appears to be the dominant design of the small number of networks existing in the capital Addis Ababa. As such, it is not surprising to find that suppliers of network technology devices and support in Ethiopia are restricted to only a limited number of vendors.

Simplicity of Installation and Maintenance

To design the LAN architecture we have therefore selected the hierarchical model. This enables us to design and arrange the inter-network devices in layers. Figure 1 depicts the hospital-based LAN architecture.

Figure 1. Hospital LAN design



It is a model preferred by most of network design experts for its ease of understanding, expandability and improved fault isolation characteristics (http://www.cisco.com). The model encompasses the following three layers: (a) first layer (core layer); (b) second layer (distribution layer); and (c) third layer (access layer).

Core Layer

Core layer high performance switches, capable of switching packets as quickly as possible, are to be deployed. Essentially, this layer connects the LAN backbone media as well as connects to the outside world via a firewall through WAN. In this design, the devices in the core layer will be placed at a central location in the hospital. The devices will then be connected with high-speed cables such as fiber optics, or fast Ethernet cables. The servers will also be connected to switches, shielded by a firewall.

Distribution Layer

Distribution layer will contain switches and routers capable of Virtual LAN (VLAN) switching and allow defining departmental workgroups and multicast domains. The devices should also support connectivity of different LAN technologies since they also serve as the demarcation point between the backbone connections in the core layer and the access layer. In this hospital-based LAN design, the distribution layer represents switches/routers at each building connected to the core layer on the one end and to the access layer on the other. Redundant links will be used for maximum availability and the departments could be grouped forming their own Virtual LAN.

Access Layer

Access Layer is where the end-users are allowed into the network. This layer contains switches/hubs from which PCs in each department gain access to the hospital-based LAN. Each department will have at least one switch/hub, which will in turn have redundant links to more than two of the switches in the distribution layer.

WAN Architecture

Designing the WAN architecture for a nationwide e-medicine network raises the issue of WAN service provider. Unlike LAN, WAN connectivity depends on the availability of WAN infrastructure in the country. The sole WAN service provider is the Ethiopian Telecommunications Corporation (ETC).

ETC provides a number of services (http://www.telecom.net.et) from which the WAN infrastructure suitable for the e-medicine network may be derived. Existing WAN services include: (a) Internet Services, or, providing basic Internet services over dial-up or leased lines; (b) Digital Data Network (DDN), supporting dedicated Internet, ISDN and frame relay services; (c) SchoolNet VSAT, covering services for secondary schools and institutes of higher learning; (d) WoredaNet VSAT, covering services for districts (Woreda) administrations; and (e) Broadband Multimedia Network (BMN), offering high-speed optical communications to major cities.

To choose among these possible infrastructures for nationwide e-medicine network, the parameters to be considered include the geographical coverage, bandwidth, mode of communication, rental cost of WAN connection and capacity to add more LANs. Table 1 summarizes the data comparing among the available ICT infrastructures in Ethiopia.

Based on the data, it appears that WoredaNet is best suited to the national e-medicine network, as long as the existing infrastructures are functioning efficiently and effectively. However, as noted in Table 1, there may be a tradeoff between coverage and capacity, that is, when the coverage is acceptable the capacity may be somewhat limited. For example, BMN coverage is ideal as it represents

Table 1. Summarized comparison of existing ICT infrastructure

	Internet	DDN	SchoolNet	WoredaNet	BMN
Coverage	Telephone coverage areas only	The capital and regional Urban areas only	About 500 schools covered. There are Woredas that do not have schools	571 Woredas out of 594 are covered	The Capital city and 13 regional towns.
Bandwidth	Maximum of 56k dialup and 1Mbps in Leased line	Maximum of 1Mbps	Can be upgraded to 384k upstream	Downstream/ up-stream 45Mbps/ 256k downlink	ADSL Services: Variable bandwidth Downstream/ upstream 512k/128k and 1024k/256k
Interactivity	Two-way	Two-way	One-way broad-casting	Two-way	Two-way
Cost	0.11 birr/min dialup 1000 birr/ month leased line		Free for schools	Free For Woredas	Not yet determined, under devel-opment
Capacity to scale	Not scalable	Not scalable enough		Will have more than 10 ports free at each Woreda	Can be expanded

state-of-the-art service and higher bandwidth. However, it is centered primarily in the urban areas. It is also under development and we have thus considered it as a potential option to be used when integrated with the VSAT-based networks to enhance nationwide e-medicine network. Finally, the SchoolNet needs to be upgraded to support two-way interactivity.

Thus, one alternative approach is using a combination of VSAT networks and terrestrial BMN. VSAT-based connectivity is believed to be cost-effective and in the case of WoredaNet and SchoolNet, it enables connectivity to the public, even in the rural areas. In addition to serving the rural areas, it also covers urban areas. Together, this will provide modern, convenient as well as economical connectivity to hospitals. For improving state-of-the-art applications such as videoconferencing, connectivity via the emerging BMN is proposed to connect urban area hospitals in the capital city and in the regions where the network can be easily accessible.

Figure 2a shows the e-medicine network as a first alternative. Note that this approach requires that urban hospitals maintain two WAN connections. Having more than one WAN connection, however, may become expensive in the long run. If the two WAN infrastructures could be integrated, an improved WAN design will result with only one WAN connection to the urban hospitals through which the hospitals will be connected to BMN and the rural area clinics through the WoredaNet. Figure 2b depicts the second alternative solution of the WAN design.

CURRENT ETC INITIATIVES

The recent development in the ETC in providing multimedia network infrastructure is the integration of the VSAT-based networks (SchoolNet and WoredaNet) with the BMN (Tiruneh, 2006). In other words, these VSAT-based networks can now be used as a point of access to the BMN.

Figure 2a. Logical WAN design based on BMN and VSAT networks (1st Alternative)

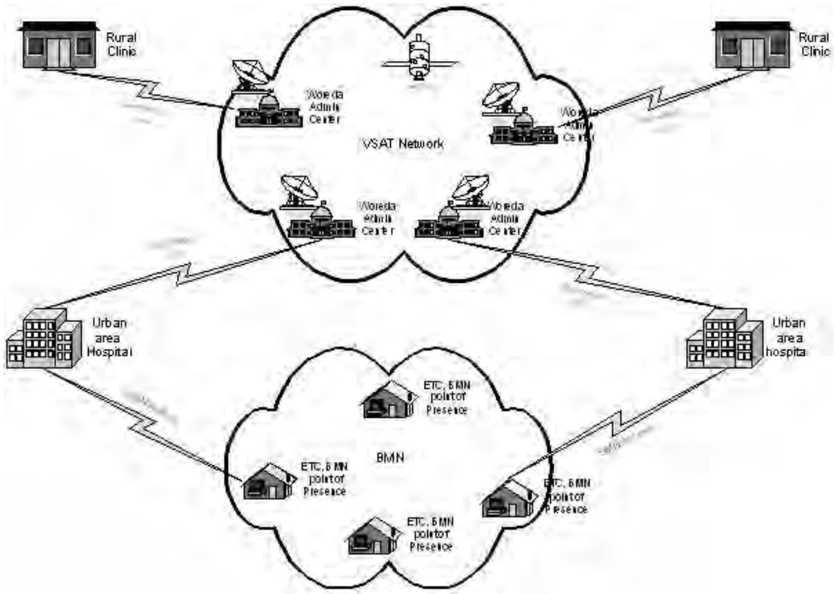


Figure 2b. Logical WAN design based on BMN and VSAT networks (2nd Alternative)

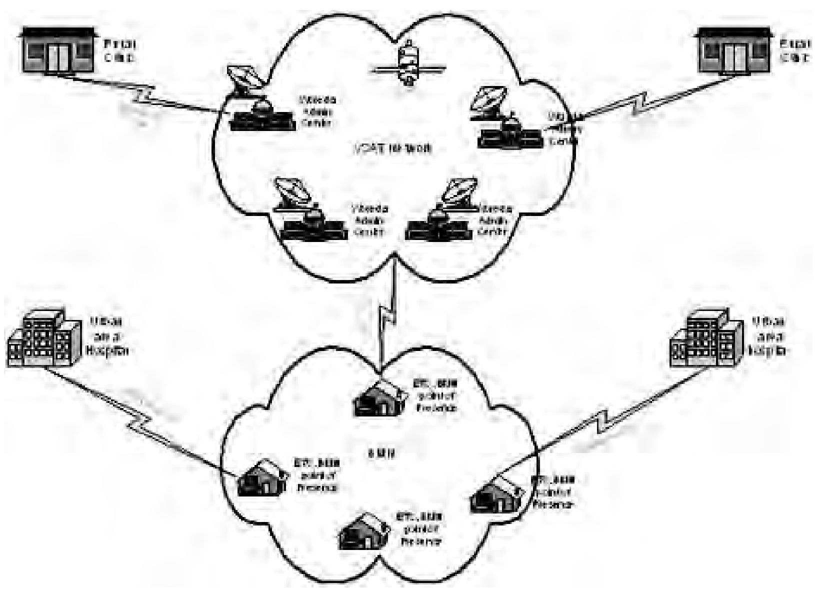


As part of a longer term vision and mission of broadband initiatives for socioeconomic development in Ethiopia, ETC has also planned an e-health setting that tries to cover rural areas, schools, clinics, hospitals, prisons, and nursing homes, including assisted living with several requirements: (a) high quality patient data, video and images to be exchanged between different medical institutions; (b) ICT infrastructure to connect geographically dispersed institutions, nationwide or worldwide; (c) infrastructure that supports data, video and voice/audio (multimedia) services; (d) high quality, secured and fast delivery of medical information; and (e) high speed (BW) connectivity or the deployment of broadband infrastructure.

Key challenges faced are the need to encompass multiple locations, to use multiple access technologies, to deliver multiple services and to address multiple user markets.

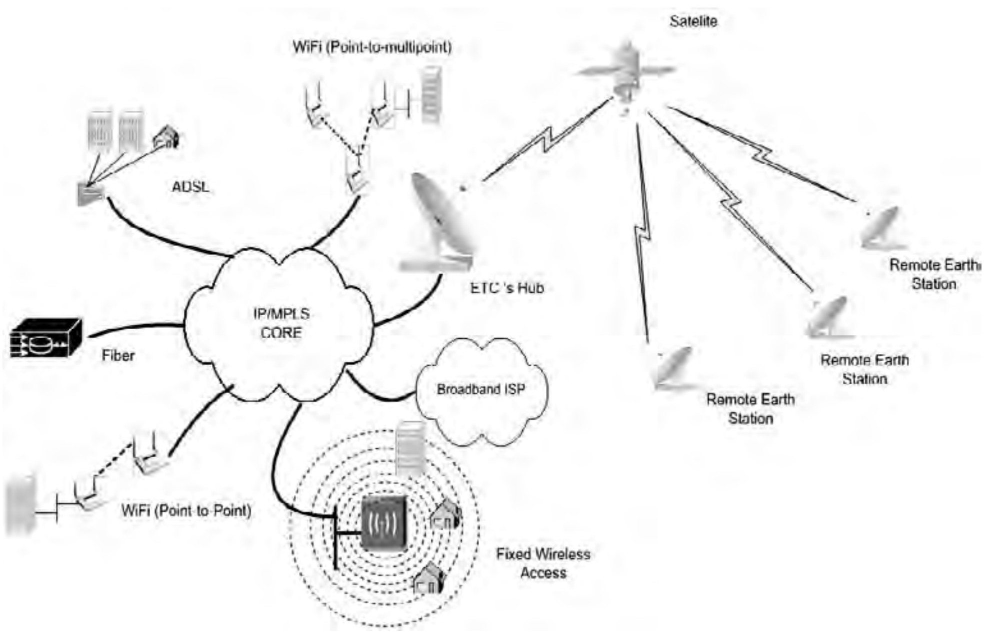
Current BMN Development

ETC has already completed building the Core Terrestrial Broadband Infrastructure, which is capable of providing data, video, and voice services with 24 Points of Presence. This infrastructure services key business sites (urban areas) and supports Multiple Broadband Access via ADSL, FWA, WIFI, and fiber networks.

Current VSAT Development

In Ethiopia, a Broadband VSAT Network platform, which supports integrated services such as video, data, Internet, and voice on a single infrastructure, is currently in place. It has countrywide coverage (450+ schools and 550+ woredas) as part of SchoolNet and WoredaNet deployments. It is integrated with the core multimedia network, also serving as broadband access means. Figure 3 shows the two recent developments.

Figure 3. ETC's broadband-integrated infrastructure for e-health applications



Apparently, the new developments in WAN infrastructure support the 2nd alternative e-medicine WAN architecture discussed here as depicted in Figure 3.

THE PROTOTYPE

Based on the specified network requirements and architecture, a working prototype for the national e-medicine network is now presented and its operations highlighted.

The prototype is a basic e-Medicine service (BEMS), which provides a Web-based graphical user interface (GUI) for health providers. BEMS facilitates the information exchange between remotely located health providers for the purpose of e-consultation, as well as for maintaining electronic patient information. The traditional paper-based forms and patient cards used in the hospitals will be digitized and reproduced electronically. Web-based technology is chosen for its ubiquity. Using Web-based technology constitutes not only a network that can be used universally, but the technology also supports system-independent platforms, thus providing access to many different computer systems at client sites (http://java.sun.com/products/jsp). Key requirements in these client sites are simply the availability of Web browser software and network connectivity.

For a secured network, password protected system ensures that user login is needed to access capabilities of the system. In addition, user types are defined so that there will be a role-based access to database and system functions in BEMS. To ensure compatibility with most legacy systems, a relational database is advocated for storing user and patient information. Beyond e-mails, this approach allows the users to mobilize structured information exchange among the communicating health providers.

Major Features of BEMS

Basically the BEMS prototype may be conceptualized as a database-driven Web site with the following main features and functions: (a) providing user management services where administrator can register users, assigning username and password, and defining user type, as well as searching and editing user information; (b) providing patient management services where health providers can register patients, search patients and view patient information on a Rolodex-like interface, as and when necessary; (c) providing, on the one hand, referral systems where physicians can write referral messages to a particular department and hospital, and, on the other, a system whereby a physician can retrieve and study the list of referrals forwarded to the department s/he is working in and allowing the physician to write feedback instantaneously after examining the referral message and patient information; (d) providing a system by which physicians can request and schedule lab test at any hospital laboratories so that patients can get tested in the clinic/hospital they are being treated; and (e) providing a list of lab test requests to laboratory technicians and allowing them to input lab test results.

BEMS Architecture

The BEMS architecture is built on three-tiered, client-server architecture. The first layer is where the client machines run Web-browser software. This layer is used to display the user interface (Web pages) of the system and send secure HTTP request to the Web server in the second layer. Along with the Web server, application server resides in the second layer. This application server manages the clinical business logic. The bottom layer contains the persistent data of the system. All data of patients, physicians and other communicated messages will be stored and maintained in this third layer. This layer runs the database management system (DBMS) software. Put simply, BEMS functions as a Web-based application connected to a Web server to provide all the interfaces of the system and that of a database server to manage all the knowledge and information elements stored in the system. Figure 4 charts the BEMS system architecture.

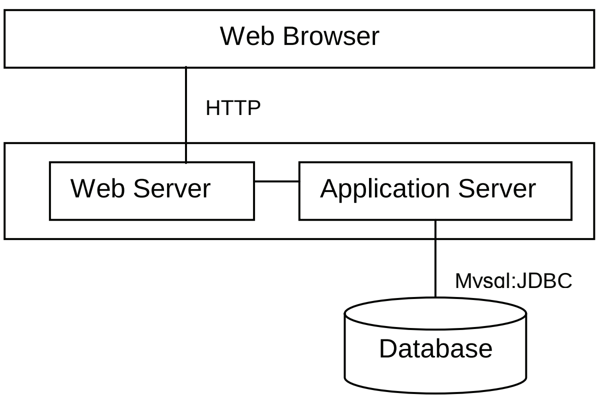
The BEMS prototype is constructed with a combination of open source products and freely available software components. The Web server suggested is the Apache Jakarta's Tomcat Web server (http://jakarta.apache.org) with the functionalities as well as the mandated business rules programmed in Java (Haile-Mariam, 2002). Java Server Pages (JSP) is used to capture the user interface and the text of Web pages (http://java.sun.com/products/jsp; http://www.coreservlets.com). Some scripting is included on the Web pages in JavaScript. JSP has a capability to import java classes and run them from the Web pages when the pages are downloaded to the client machine (http://www.coreservlets.com). Unlike other server side languages such as Active Server Pages (ASP), JSP makes the system platform independent. It also allows users to take advantage of the full power of java programming language which overcome some of the limitation of other scripting languages such as PHP (http://www.coreservlets.com).

The database conceptualized is the open source MySql to back up the database driven application. MySql works on many different operating system platforms and is known for its speed of data retrieval (http://www.mysql.com). It provides Application Program Interfaces (API) for many programming languages including Java. Passwords are secure because all password traffic is encrypted when connecting to the MySql server. For database connectivity, we use mm.mysql driver, which is a Java Database Connectivity (JDBC) driver, from MySQL AB, implemented in 100% native Java (http://www.mysql.com/products/connector-j).

Database Design Issues

BEMS needs to keep track of information about patient and related medical records, user's information, and messages for both medical referral requests and feedbacks. A well-designed minimal database is needed to manage this information. A relational database model is selected to store the persistent data of the system, as it could be easier to manage, and provides better management for complex query of such data (Amenssisa & Dabi,

Figure 4. BEMS prototype architecture



2003). This database is expected to maintain and manipulate basic entities such as users, patients, and medical records.

Each component of the medical record of a patient is an aggregation of different types of data, which are stored in the database. In the traditional paper-based system, the medical record of a patient is identified by an Out Patient Card (OPCard) Number, which is usually called patient record number. OPCard is a four-page hard-paper card, which contains patient's generic information, such as name, sex, age, address on the first page and a table of two columns for date and clinical note so as to record chronologically the compilation of health providers' notes. All other components such as laboratory test results and x-ray reports, among other pieces of information, are stored inside the hard-paper card referenced by the card number or name of the patient. The lab test results may contain zero or more test request forms along with the results for Urine, Parasitology, Blood Chemistry, Hematology, Serology, Bacteriology, Fine Needle Aspiration Cytology and Biopsy.

When a patient is admitted to the hospital, admission and social services information is stored. The admission data include identification information and name and address of next-of-kin, marital status, and number of siblings (children) information, besides occupational information and other demographics, as and when provided by the patient. Subsequently, follow-up data such as vital sign measurements, fluid balance information and other measures will be collected and recorded. Order sheet, which contains a list of treatments to be ordered following admission, is also part of the inpatient medical record. In addition to these, information about the hospitals, departments and laboratories are also stored and captured in respective entities.

To minimize connectivity cost and increase system performance, a distributed database is recommended. Horizontal partitioning that splits tables along rows, based on the location of patient and healthcare facility, is seen to be an ideal choice in the e-medicine application that tries to create nationwide connectivity. Finally, to use the database, transparent data access schemes must be defined for applications that run over the network.

BEMS Interfaces

In this part of the discussion, the design of various BEMS interfaces is presented. BEMS is accessed when opening the initial Web page where user authentication is first performed. The initial page contains a typical login screen for specifying username with authenticated password. There is no need of menu or different buttons to be submitted based on the user types. Since the user types are defined in the database when the user registered, the page corresponding to the specific user type will automatically be opened upon successful login. Currently, administrators, physicians, and lab technician user types are defined and all of these user types will have their own main pages as described below.

Administrator's Main Page

The administrator's main page is used for managing users. The functionalities accessible from this page include: *register new user* and *search user* by a combination of name, father's name, and user name. Figure 5a shows the administrator's main page whereas Figure 5b depicts the user registration page.

The other function provided to administrators is the *search user* function. It is possible to search users by keying in any combinations of name, including father's name and/or user name. Note that username is treated as "unique" in the user table with the search result being quickly displayed. Although not shown here, the full name of the search result is captured as a link. This link then leads to a page containing the relevant user information from which the administrator can edit a particular user.

Physician's Main Page

The physician's main page contains a button to open the patient manager page and has the capability of retrieving a list of referrals forwarded to the department where the physician is located. To open a new page, the physician is free to click on the *manage patients* button or link to one of the referrals. Figure 6a illustrates that the patient, Ato Andualem Lemma, is one of Dr. Aman's referrals. If Dr. Aman chooses to treat this patient in the hospital where he is privileged, he can simply open the patient manager page by clicking on the

Figure 5a. Administrator's main page within BEMS

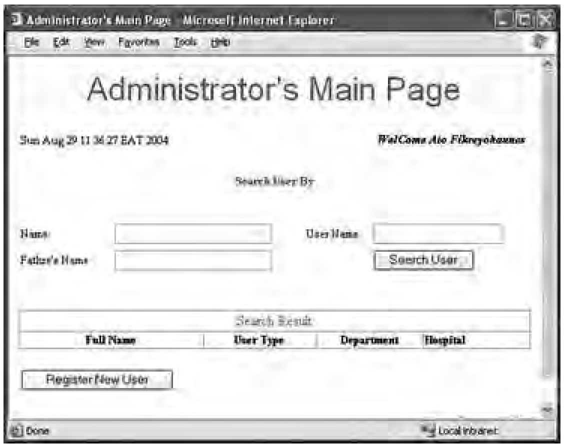


Figure 5b. User registration page

manage patients button.

Figure 6b shows that the patient manager page has two options, that is, physicians can "register new patient" or "search patient" for those who were previously registered. When selecting "register new patient," a patient registration form, similar to the user registration page, will be opened. In contrast, if the physician wants to look for a patient, s/he can input one of the search criteria such as *name* or *record number* of the patient, resulting in the display of a matching record number or name and the hospital where the patient was first registered. The patient full name is a link that leads to the patient information page similar to

Figure 6a. Physician's main page within BEMS

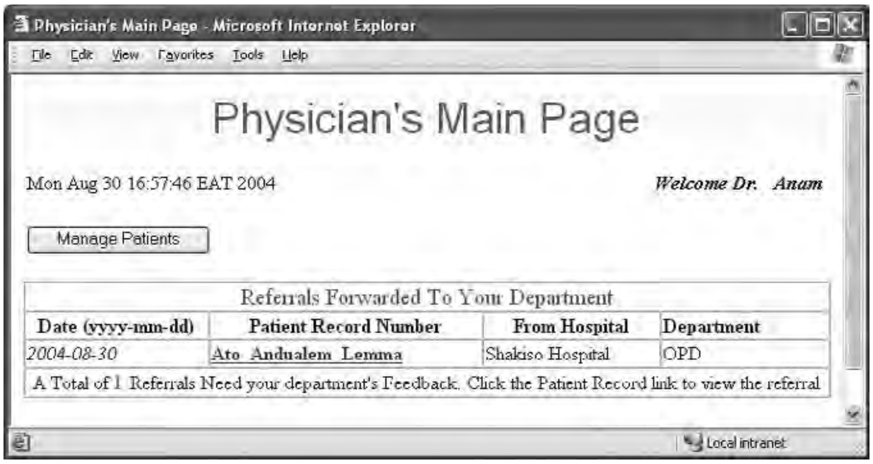

Figure 6b. Patient manager page within BEMS

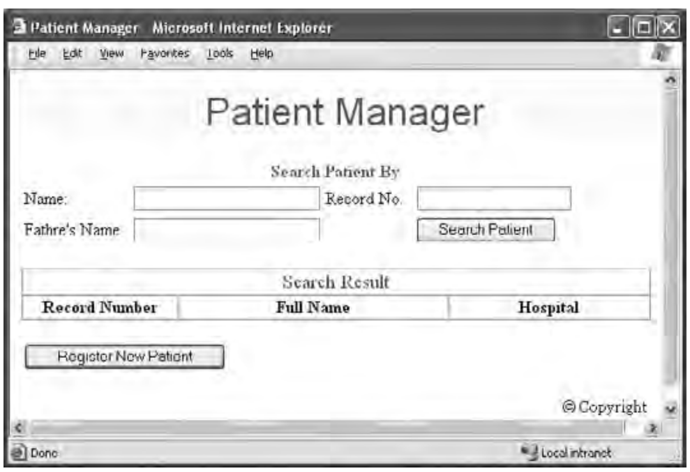

Figure 6c. Patient card page within BEMS

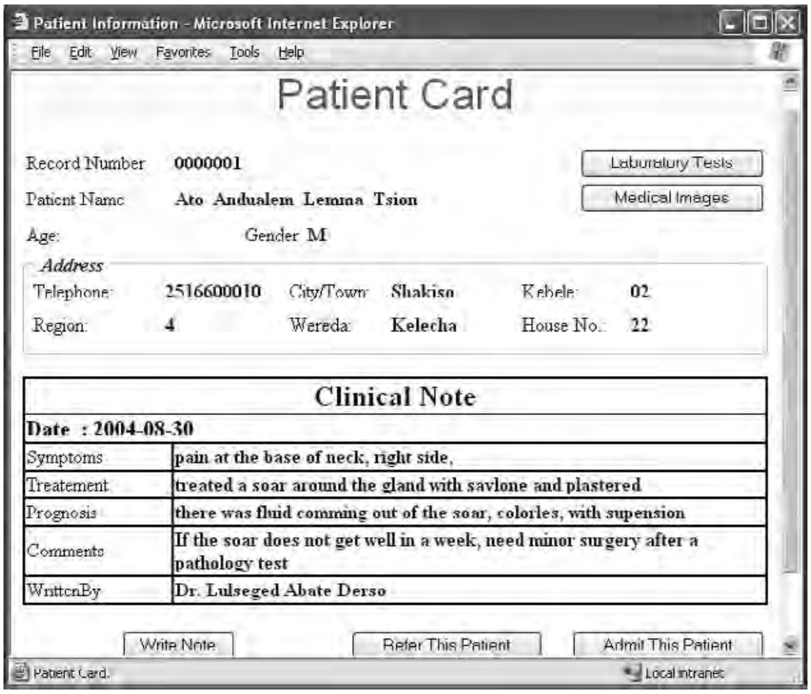


the traditional patient card used in the hospitals. An example of the patient card, which opens up when the full name link in the previous interface is selected, can be seen in Figure 6c.

The patient card contains patient's general information, address information and clinical notes that are ordered in descending order. In addition to the information displayed on the patient card, laboratory test results and medical images related to the patient are accessible by clicking corresponding buttons from the patient card interface. The physician can add clinical notes, refer, and/or admit the patient. From the physician's main page, the other option available to the physician is to see referrals forwarded to his or her department. This is possible by clicking the link that opens a referral page corresponding to the patient. The patient referral page contains the referral messages and buttons that will lead the user to patient information as well as a button that can lead to the feedback input page.

If the physician user wants to view the patient information, the *view patient card* button will support such a function. Otherwise, if the physician would like to give feedback to the referral using the feedback slip, the *open feedback slip* button will serve this purpose. Basically, the feedback slip is represented as an input form similar to a traditional form for capturing feedback information related to the current referral. Put simply, the idea here is to mimic within a virtual environment what the physicians have already become accustomed to routinely when working within a paper-based environment, which will only hasten the processing and matching of the stored computerized information for them.

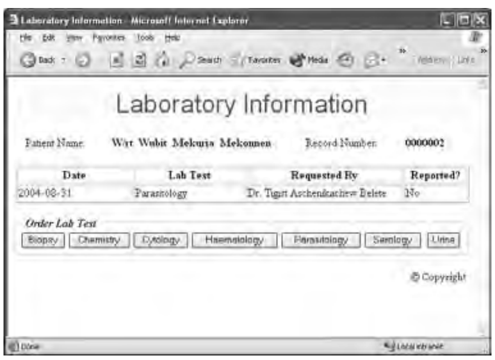
Graphical User Interface

Apparently, human computer interface (HCI) design issues are critical in determining the successful deployment and continuing use of the BEMS prototype. As indicated, the current approach attempts to optimize the interface design in mimicking more or less the traditional forms, documentation formats and paper-based patient record system that the physicians have grown accustomed to using over the years. In other words, this ensures that the BEMS supports the habits of the physician users. It will also serve to preserve physician user satisfaction and promote a high rate of acceptance among physician users with the new system implementation on the one hand while reducing disruption to the care processes on the other.

Nonetheless, new system development such as the BEMS typically provides new opportunities for revisiting the care processes that have been put in place over the years. Elimination of redundant processes as well as the need to streamline certain administrative and clinical processes may be warranted to improve quality, cost, efficiency and effectiveness of the care provided. Online requests of patient and referral information and querying of databases are expectedly translatable into more efficient, effective, appropriate and quality care. Use of GUI also permits substantial amount of data to be viewed together, improving the communication, exchange and sharing of patient data. Feedback from physician users should ultimately be channeled to an even more enhanced user interface design. In this environment, clinical test results and specialist reports can also be captured quickly and shared collaboratively among all relevant health providers.

As an example, the physician can be empowered to request laboratory test results in BEMS by viewing the patient laboratory information page, which is accessible from the patient card page by a button called "Laboratory Tests." Figure 7 provides illustrative screenshots for the laboratory information page and a parasitological test request pages. When a physician wants to request lab tests, instead of writing a prescription to the patient and having the patient wait for further scheduling information from the nursing clerk, all that is needed now is a mere click of the button corresponding to the type of "test" required from

Figure 7. Laboratory information and parasitological test request page of BEMS



the laboratory information page. The specific lab test request page can be designed such as to provide the physician user with a dropdown list from which the appropriate lab test can be immediately selected and performed as scheduled. This was found to be important in order to forward the lab test request on a real-time basis to the other user types called, the Lab technicians.

Lab Technician's Main Page

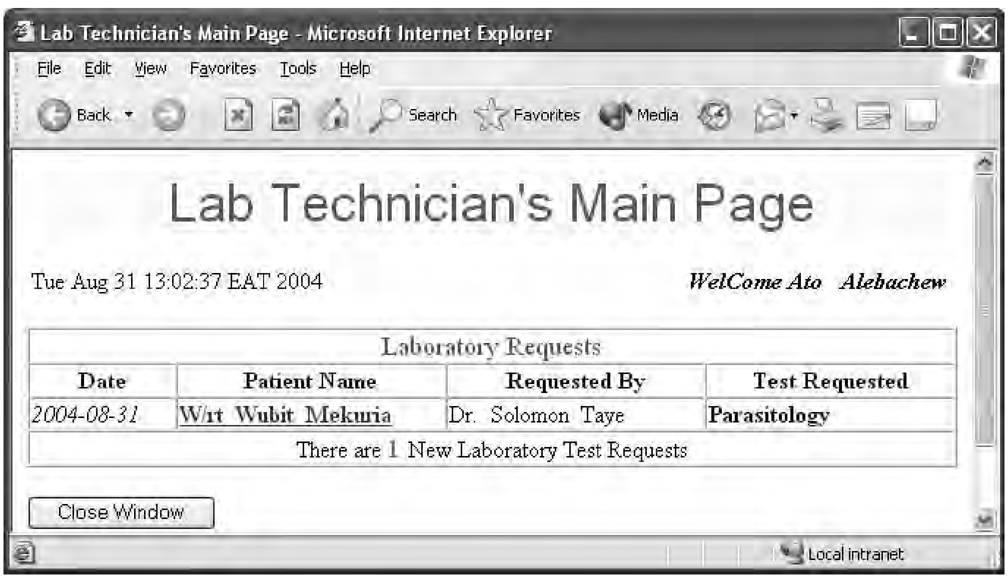
The third type of user, laboratory technician, sees a list of laboratory requests to the department s/he is practicing, on the lab technician's main page. The list contains a link to open lab test result input form where the lab technician can enter his or her report following the test as shown in Figure 8.

CONCLUSION

The key contribution of this effort lies in envisioning the planning and detailing of a Web-interface for a hierarchical model-based LAN architecture that enables the integration of the inter-network devices in layers and a WAN architecture, both fine-tuned for a developing country such as Ethiopia.

The hierarchical model adopted for the LAN is a preferred model due to its ease of expandability and improved fault isolation characteristics. The WAN design considers the existing VSAT-based WAN infrastructure in the country, the WoredaNet. Even if urban areas are relatively better equipped with adequate ICT technologies such as Internet access and digital telephone networks, the communication infrastructure is not well developed in many rural areas. These regions have to be equipped with an access to urban areas. In this context, the newly emerging state-owned, low-cost VSAT networks such as SchoolNet and

Figure 8. Lab technician's main page of BEMS



WoredaNet provide the rural areas with suitable means of communication with urban areas and beyond.

VSAT, an earthbound station used in satellite communications of data, voice and video signals, excluding broadcast television, comprises two parts: (a) a transceiver that is placed outdoors in direct line of sight to the satellite; and (b) a device that is placed indoors to interface the transceiver with the end user's communications device, such as a PC. The transceiver receives or sends a signal to a satellite transponder in the sky. The satellite sends and receives signals from a ground station computer that acts as a hub for the system. Each end user is interconnected with the hub station via the satellite, forming a star topology. The hub controls the entire network operation. For one end user to communicate with another, each transmission has to first go to the hub station that then gets retransmitted via the satellite to the other end user's VSAT. VSAT can handle up to 56 Kbps.

More importantly, the BEMS architecture discussed here is designed to integrate with a large part of the existing LAN and WAN infrastructure designs. The system can then be used to facilitate both intra- and inter-hospital communications and for all forms of information exchange. The alternative design selected will not only improve quality of healthcare services while protecting the privacy, confidentiality and integrity of sensitive patient information, but its interfaces have been set up to mimic the physician routines working in a paper-based environment. Moreover, this will also yield opportunities for further review of the paper flow and work processes to cut down on redundancies and errors while simultaneously boosting both administrative and clinical efficiencies and effectiveness of care.

As future work in the area of developing nationwide e-medicine networks, we recommend the following considerations: (a) the intended network should support real-time e-consultations via video and audio conferencing, advocate doctor-to-patient interactions, and facilitate remote training for health professionals; (b) it should also support a distributed database structure, where individual hospitals should keep their own databases, which can be further treated as one "huge" database; (c) the definition of standards is essential to facilitate information exchange among private and government hospitals as well as overseas; (d) the integration of expert systems such as case-based system where doctors can query the database to get experience from previously stored similar cases should also be considered—such a system will aid future physicians and residents working anywhere in the country to learn from past successes and/or failures of the attending specialist(s), especially for non-trivial and complex patient cases; and (e) the infrastructure should be independent of chosen platform and operating systems (e.g., Windows vs. Apple) and be able to support physicians needing to remotely monitor their patients over heterogeneous networks, including handheld devices in 2G/3G mobile networks and wirelessly.

Beyond the design of a nationwide e-medicine infrastructure, there will be a host of potential e-medicine applications that may be supported, including, but not limited to a series of healthy lifestyle promotion programs such as e-consultation and tracking of participation in smoking cessation, weight reduction, dental health, stress reduction, exercise and nutritional programs and many more. In this regard, one of the contributing authors is actively and precisely engaged with a growing network of researchers in generating such a series of educational modules intended for seniors and other population groups that will eventually be serviced on a network such as BEMS discussed in this article (Tan, 2005).

Chapter 4.18
Kaitiakitanga and Health Informatics:
Introducing Useful Indigenous Concepts of Governance in the Health Sector

Robyn Kamira
Paua Interface Ltd. & Rangatiratanga Canvases Ltd., New Zealand

ABSTRACT

Indigenous contributions to governance in health informatics can be drawn from cultural concepts such as Kaitiakitanga, which implies guardianship, stewardship, governance and responsibility roles. This chapter explores Kaitiakitanga, its potential implementation in the Aotearoa (New Zealand) health sector, and its contributions to our thinking. After decades of unsuccessful attempts to positively shift the status of health for Maori, we must ask whether more control by Maori over information about Maori will make a difference. Kaitiakitanga enables us to explore Maori perspectives and insights about health and information and calls for stronger inclusion of Maori in decisions. It acts as a guideline to address ongoing and complex issues such as collective ownership, the responsible publication of data and whether benefits in health for Maori can be explicitly declared and met.

INTRODUCTION

This chapter discusses the potential of indigenous concepts of governance within a contemporary health informatics setting. Health informatics is an evolving socio-technical and scientific discipline. It deals with the collection, storage, retrieval, communication and optimal use of health data, information and knowledge (hereafter referred to simply as "information").[1] The discipline attempts to assure quality healthcare for the community it serves.

Governance can be situated alongside health informatics, especially when considering the ethics, values and quality issues that impact on the care of people. Central to governance is decision-making and the process through which a group with delegated decision-making authority will direct their collective efforts. Governance involves multiple stakeholders to whom decision-makers are accountable: Governance in New Zealand's

(Aotearoa's) health sector deals with relationships between the Crown (Ministries, Government agencies, delegated authorities, etc.), communities, Maori and individuals. Governance also applies to guardianship over information in the best interests of stakeholders, and involves achieving both "desired results and achieving them in the right way" (IOG). Since the *right way* is largely shaped by the cultural norms and values of the stakeholders, there can be no universal template for good governance. Information technology is significantly redefining governance by providing enhanced opportunities to collaborate with and influence policy makers. Similarly, information technology changes accountabilities by opening new possibilities for the dissemination of information about the performance of government, district health boards and providers.

Indigenous contributions to governance in health informatics can be drawn from cultural concepts such as Kaitiakitanga, which implies guardianship, stewardship, governance and responsibility roles. This chapter explores Kaitiakitanga, its potential implementation in the Aotearoa health sector and its contributions to our thinking. After decades of unsuccessful attempts to positively shift the status of health for Maori, the indigenous peoples of Aotearoa, we must ask whether more control by Maori over information about Maori will make a difference. Kaitiakitanga can introduce a stronger position on ethics, values and quality when managing health data and optimize the benefits for both Maori and non-Maori alike.

Further, the inclusion of Kaitiakitanga concepts in governance structures, processes and roles in New Zealand's health sector in recent years points to a growing acceptance of indigenous input. For example, the establishment of the Cervical Screening's Kaitiaki Group as a legislated body (MOH, 2002a), and the Northern Region Hepatitis Consortium's Treaty Relationship Company model (C. Bullen, personal communication, 2003) are examples where indigenous ideas are perceived by their supporters to add value to governance.

The chapter specifically addresses collective ownership, collective privacy, responsible publishing and benefit. Kaitiakitanga implies that Maori will participate in *decisions* about health informatics and information technology, and influence policies and laws that support concepts of traditional protection, ownership and benefit that go beyond current laws and policies.

A MAORI PERSPECTIVE ON INFORMATION TECHNOLOGY

Definitions of information technology need not be limited to those found in academic or information technology industry journals. Potentially, any means of storing, analyzing and disseminating information can be included — *even our minds* (Kamira, 2002, p. 4). Maori concepts such as *Matauranga*, or intelligence, and *hinengaro*, or the mind, offer broader definitions and enhance what is generally understood about information technology. Matauranga refers to education and intuitive intelligence, and is linked to the divine. Hinengaro is the mind, the thinking, knowing, perceiving, remembering, recognizing, feeling, abstracting, generalizing, sensing, responding and reacting (Pere, 1991, p. 32). They are both vessels for knowledge.

Indeed, the broader Maori perspectives, such as those above, inform us why concepts of information technology as the information technology *industry* sees it are not only within the reach of Maori, but are also too simplistic since they do not include wider concepts of knowledge and understanding (Kamira, 2002, p. 5). It also explains why information technology is of great importance to Maori since the ancestor Tane-nui-a-rangi retrieved the *baskets of knowledge* from a celestial abode while coping with many dangers along the way (Barlow, 1991, p. 156), and that the dissemination of knowledge is thus a matter of great ritual and responsibility.

COLONIZATION, TIRITI (TREATY OF WATANGI) AND RELEVANCE FOR HEALTH INFORMATICS

It was the Maori version of the Treaty of Waitangi, "Te Tiriti O Waitangi," that was signed by chiefs at Waitangi on February 6, 1840 and subsequently in other locations. It is New Zealand's founding document. While debate is ongoing regarding its status and implementation, the legal status of the Treaty is not enforceable as there is an absence of statutory incorporation (TPK, 2001b, p. 16).[2] Therefore, governance models that are based on the Treaty are dependent on the application of moral obligations of the Crown and the recognition of principles.

The Hunn report (1961) first highlighted the failings of the Crown to meet its Treaty obligations to Maori. The government has attempted unsuccessfully since then to rectify the situation by focusing on socio-economic improvements for Maori. Yet, Maori continue to feature disproportionately in almost all of the negative statistics including unemployment, education, health, housing, domestic abuse and crime (Hunn, 1961; Williamson, 2001, p. 1; TPK, 2003). Particularly, the poor state of Maori health is well documented (MOH, 2002b, p. 2) and has sustained its negative status over many decades. Colonization clearly undermined the economic and social base of Maori society and resulted in mass dislocation and loss of land, language and spirituality: This has led to urgent calls for reclamation and protection of Maori "assets," including land, natural resources, language, belief systems, processes, etc. Active reclamation and protection of those assets are facilitated by movements such as Te Kohanga Reo (language nests), the Waitangi Tribunal and Maori authorities, etc. This call also applies to health and wider concepts of well being. As a result, Maori health provider groups aspire to become key providers for Maori and often coin the phrase "by Maori, for Maori" in the belief that other health services are not focused or responsive to the needs of Maori (Kamira, 1999-2000, p. 2).

Health informatics captures the need for technological capacity amongst all health providers, but access to that capacity for Maori providers is yet to be addressed fully. Anecdotal evidence suggests that the skills and equipment required for Maori providers to fully participate in health informatics is lacking (Kamira, 1999-2000, p. 14). Recent reports indicate that Maori are not participating in information technologies to the extent of other New Zealanders (TPK, 2001a; Infometrics, 2001).

However, there is some evidence that Maori are beginning to enter the information technology industry (Infometrics, 2001, TPK, 2001a), and that they are forming professional and interest groups.[3] These shifts towards "mastery" of information technology will eventually enable Maori to make well-informed decisions in health informatics. However, while it is an aspiration to build capacity in information technology in the broadest sense (Korowai Groups, 2002), this is some time away.

This leads us to the following questions:

1. Does the health sector enable Maori to make decisions about their health, or does it prefer to "look after" Maori?
2. What technological capacity would need to be available to Maori providers to assist aspirations to provide effective health care to Maori?
3. In the absence of technological capacity, what ways can Maori influence decisions about technology and health for their benefit?

WHAT IS KAITIAKITANGA?

Data — anonymous or not — has enormous spiritual and cultural significance for Maori, so it may require more attention and protection than generally given (MOH, 2001, p. 3). One way to provide this is to exercise the customary practices of Kaitiakitanga.

Kaitiakitanga (and the person or group who performs the Kaitiakitanga role – Kaitiaki), implies guardianship, protection, care and vigilance of data about Maori that is collected, stored and accessed. It introduces the idea of an inter-generational responsibility and obligation to protect, and enables the use of mechanisms such as *tapu*, the setting apart or restriction of knowledge or things, and *rahui*, the necessity to conserve, protect or restrict (Kamira, 2002, p. 22).

As governance decisions impact Maori and since the "right way" to govern is largely shaped by cultural norms and values of stakeholders, it is critical to extend current governance ideas if Maori are to successfully implement their Kaitiakitanga responsibilities. However, indigenous governance issues are complicated. For example (adapted from IOG):

1. What form(s) of indigenous governance are appropriate to the 21st century and suitable to the needs of indigenous peoples?
2. What is the appropriate balance between contemporary and traditional forms of governance for indigenous peoples?
3. What are appropriate strategies for creating indigenous capacity to successfully manage their governance responsibilities today?

It is important that members of governance or kaitiaki groups have an understanding of the historical, cultural and social complexities in which Kaitiakitanga perspectives are grounded.

Kaitiakitanga and Health Informatics Issues

The advantages of obtaining statistical information about health for Maori are clearly to profile groups — that will assist in developing effective policies and assist Maori to better manage their own health (MOH, 2002b, p. 23). However, decades of negative statistics indicate that gathering this information does not measurably achieve health gains for Maori.

1. Is data and information being gathered without producing *knowledge* that will generate benefits?
2. How would concepts of Kaitiakitanga in health informatics make any positive difference?

The following sub-headings provide some insights.

Data and Statistics

The publication of negative statistics over many decades undermines Maori and their health and produces few benefits. Negative statistics invoke the concept of *Takahia*, the act of trampling, often used to describe being belittled. Government databases collect abundant data about Maori: The data is analyzed and published, and Maori are profiled through statistical findings that continue to reinforce the most negative stereotypes. Currently, health informatics and statistics that are generated from databases symbolize disadvantage for Maori, who are busily curbing continuous socio-economic decline. The Maori experience of information technology that is in the control of others is the repeated reinforced perception of failure (Kamira, 2002, p. 22).

This is not to say that ethnicity data or data which identify particular Maori groups should not be collected. However, the accuracy through to the eventual publication of such data should be, ideally, constructive. Kaitiakitanga through the idea of *mana* — power or influence — can refocus the way that statistics are generated and published and demand a more productive and benefit-focused model.

Intellectual Property, Collective Ownership and Privacy

Kaitiakitanga introduces the idea of *tiaki*. Tiaki is to look after and guard and is a responsibility or an obligation rather than a right due to ownership. It enables a less exploitive relationship to exist where data about Maori are for the purpose of improvement and benefit first and foremost. Maori see the issues of intellectual property as a subset of these broader rights of ownership and include concepts of collective ownership. Collective ownership in health informatics can imply that grouped data about a collective such as a *hapu*, or an extended family tribal group, are owned by that collective. In turn, this implies their rights to make decisions about that data and benefit from that data.

In contrast, Western law defines intellectual property as outcomes of ideas or processes that are the result of human intervention — that is, knowledge created from the mind (Mead, 1997). Intellectual property laws both here and internationally tend to focus on commercial *ownership* and are inadequate as a way to protect indigenous collective knowledge. Until the fundamental ownership issues raised by Maori under the Treaty of Waitangi are mirrored in legislation, the best that can be achieved is interim recognition of Maori values and rights to participate in decision-making within the limits of the existing system (Putahi Associates, 1999).

Similarly, the Maori concept of privacy can encompass both the individual and the collective. An individual can have their privacy protected via the Privacy Act 1993. However, a *hapu*, or extended family tribal group, may feel they have a right to collective privacy that is not currently supported by legislation. Collective privacy is a means to protect data and information about groups of people rather than individuals, and is a key issue when data collection occurs on identifiable groups that wish to manage or control data about themselves.

First Beneficiaries

Kaitiakitanga introduces the idea of *awhina* — to assist or benefit. The ability to give what is truly needed without an expectation of reward means a clearer focus on more beneficial activities and responsible allocation of resources. The premise is that if Maori provide data then they should benefit from that data.

Some situations may prevent Maori from becoming the first beneficiaries. For example, limited participation by Maori providers in health informatics due to insufficient computer equipment or a lack of technological skills may be a barrier. Some Maori providers may need to rely on others to provide information, or they may only have access to information that has been collected for other purposes and does not focus on Maori, nor contain the detail required to initiate effective action (Kamira, 1999-2000, p. 14).

Mechanisms to promote Maori as first beneficiaries may include:

1. Protocols around grouped data with the input of Maori stakeholders that *require* benefits to be identified as criteria for collection and publication.
2. The development of initiative(s) when grouped data about Maori are identified to develop standards on the collection and use of data, and standards regarding real benefits that are more actively promoted and delivered.

THE STRATEGY

Mastery

While there is little *evidence* that information technology has positive and long-term impacts on the socio-economic status of people, the perception throughout the world is that information technology is a key driver for improving the world's socio-economic conditions (Riley, 1999), and that to ignore it will perpetuate or lead to even further disparities amongst the world's poorest and richest nations (UN, 2002). Maori will not be in a position to find out whether this is a *truth* for them unless they move from a passive role to mastery (Kamira, 2002, p. 17).

Apirana Ngata, a scholar and the first Maori university graduate in 1894, wrote in his grand-daughter's autograph book (Huta, 2001):

E tipu e rea mo nga ra o tou ao
To ringa ki nga rakau a te pakeha
Hei oranga mo to tinana
To ngakau ki nga taonga a o tipuna Maori
Hei tikitiki mo tou mahunga
To Wairua ki te Atua
Nana nei nga mea katoa

Grow up o tender youth in days of your life
Your hands grasp hold of the tools of the Pakeha
For your material well being
Your heart to the treasures of your Maori ancestors
As a plume for your head
Your spirit to God
The creator of all things

This well known passage captures the desire and the ability of Maori to acquire the knowledge of other cultures (of the Pakeha, or non-Maori) and is an important strategy for operating in a contemporary world, and for the uptake of information technology that would potentially improve health for Maori.

Using the Treaty / Tiriti Productively

The Ministry of Health's WAVE report (MOH, 2001, p. 3) states that the Treaty of Waitangi established a Crown obligation for Maori to enjoy a health status at least as good as that enjoyed by non-Maori. Further, it states that the government is committed to fulfilling its obligations to Maori to support self-determination for whanau (extended families) and Maori organizations. Kaitiakitanga can assist the Crown to achieve this obligation.

While Te Tiriti O Waitangi was signed and subsequently breached, attempts to bring it into a contemporary context have seen some progress. Concepts such as equity, partnership, collective ownership and protection (Treaty Articles II and III) can be expressed in relation to governance. Specifically, Maori are partners in the treaty and as such:

1. Article II guarantees Maori control and enjoyment of their valued possessions — tangible and intangible. This includes their health.
2. Article III affords Maori the attainment of equal human and social rights and privileges. The treaty implies that the *right* to good health can be exercised as per Article III regarding equity.

Validating and Promoting Maori Concepts

Health informatic projects are an opportunity to discover what gains can be made if Maori are actively involved in decisions through Kaitiakitanga. Aspirations of *tino rangatiratanga* — the ability to make decisions and control one's direction — are supported by Plumptre and Graham (1999), who conclude that three factors determine why some Native American tribes develop and some do not. They are:

1. Having the power to make decisions about their own future;
2. Exercising that power through effective institutions; and
3. Choosing the appropriate economic policies and projects.

Identifying the possible contributions from Maori through Kaitiakitanga and then incorporating them into health informatics will help to promote, protect and validate the assets (knowledge and skills) that Maori have and, importantly, may change the current negative health status that has become the norm.

HOW KAITIAKITANGA WOULD WORK TODAY

Treaty as a Framework

The Treaty of Waitangi can be implemented in current day activities as a localized and living model for Maori to apply tino rangatiratanga (decision making and control). It can act as a framework by which the appropriateness of decisions made during the development and implementation of health informatics projects can be assessed against Articles II and III of the Treaty.

Recognizing Existing Structures

Existing Maori structures also perform governance and Kaitiakitanga roles through Runanga (Maori authorities, trusts or similar organizations). These are legitimate structures often established by mandate and should not be undermined, but instead utilized where appropriate for health informatics projects. Maori governance roles will usually extend to a holistic range of areas along a continuum of well-being that extends far beyond the narrow constructs of health and all of its sub-categories.

Kaitiaki Groups

Kaitiaki groups would have overview roles to look after data, information and knowledge sourced from, or about, Maori. These groups would set ethical, value and quality guidelines. Ideally, participation of a Kaitiaki group would begin at the initiation stage of an IT project through to implementation and post-implementation.

The following points regarding establishing such a group are useful:

1. The membership and appointment of Kaitiaki groups is significant and Maori stakeholders would determine the appropriate type of Maori representation.
2. The position of Kaitiaki groups as a part of, or aside from, broader governance groups is significant as accountabilities and relationships are determined.
3. Kaitiaki group members should have decision-making powers and be informed on all issues, not just perceived Maori ones. This ensures Maori are defining what is of interest and prevents inappropriate filtering of information.
4. The issue of accountability is linked to risk. Kaitiaki groups would take into account the different levels of risk, the shared-risk and the authority it would accept or have delegated to it.

Kaitiaki Members

Kaitiaki members would represent stakeholder groups that would in turn expect them to pursue aspects of tino rangatiratanga (decision making and control). Kaitiaki members would be responsible for, and would ensure a focus on:

1. The treaty;
2. Safety and protection of Maori individuals and collectives; and
3. Benefit to Maori individuals and collectives.

CONCLUSION

Health informatics will need to include concepts of governance and Kaitiakitanga alongside its medical, technology and social discourses. Modern concepts of Kaitiakitanga can enable:

1. Maori to be explicitly identified as first beneficiaries of health informatics where relevant;
2. Recognition of collective ownership, use, access, analysis and interpretation of data; and
3. Recognition of collective privacy as a valid form of control for grouped data. (Kamira, 2002, p. 23)

Kaitiakitanga contributes useful indigenous ideas that add value to governance and potentially may result in a health gain for Maori in the long term as they make decisions about information that will be expected to return benefits. Maori can, through Kaitiakitanga, actively and effectively influence policies and laws that support the protection and ownership of data and information towards improving health benefits.

ENDNOTES

[1] While there are a multitude of definitions for data, information and knowledge, this is a favourite of the author. Data are raw and have little significance beyond itself. Information is data that have been given meaning by way of relational connection; it provides answers to "who," "what," "where" and "when" questions. Knowledge is the appropriate collection of information, such that its intent is to be useful; it answers "how" questions (Bellinger, Castro, & Mills, n.d.).

[2] A political analysis of the Treaty is not provided, as there are many appropriate and more in-depth sources of information available such as TPK (2001b) and Orange (1987).

Chapter 4.19
Effects of Knowledge Management Implementations in Hospitals:
An Exploratory Study in Taiwan

ABSTRACT

From the knowledge management point of view, the fundamental mission of hospital management is the delivery of quality medical services, utilizing highly specialized knowledge to solve healthcare problems within various resource constraints. Similar to other knowledge-intensive industries operating in highly challenging business environments, hospitals of all sizes must view the creation, organization, distribution, and application of knowledge as a critical aspect of their management activities. Knowledge management represents a viable strategy as hospitals strive simultaneously to provide quality medical services, improve operational efficiency, and conform to the government's documentation and reporting regulations. This study examines the correlation as well as the causal relationships among knowledge characteristics, knowledge acquisition strategy, implementation measures, and performance of knowledge management implementations in the context of hospital management. Using primary data collected in Taiwan, our analyses show that the characteristics of knowledge affect the ways in which knowledge management is implemented, and the implementation measures, in turn, have a significant impact on the results of knowledge management implementations.

INTRODUCTION

Hospitals of all sizes currently are faced with a multitude of management pressures, including industry competition, customer satisfaction, shortage of specialized personnel, compliance with government regulations, cost reduction, and the ever-increasing demand for more effective cures (Camilleri & O'Callaghan, 1998; Porter & Teisberg, 2004). In coping with these challenges, hospitals actively are experimenting with various management initiatives and programs, such as total quality management and knowledge management, with varying performance results. Emerging as a new multidisciplinary management field, knowledge management (KM) promises to enhance competitive advantage in the highly dynamic knowledge economy by treating valuable and scarce knowledge as a critical organizational asset and by managing it in a systematic manner (Sharkie, 2003; Ulrich & Smallwood, 2004). From the knowledge management point of view, many hospital services involve knowledge-intensive processes that are carried out to solve patient health-related problems. Because of the knowledge-intensive nature of healthcare services, much of a hospital's success depends on effective and efficient creation, organization, validation, dissemination, and application of its highly specialized medical knowledge.

Traditional knowledge management mechanisms in most hospitals typically include morning meetings, apprenticeships, internships, professional seminars, research partnerships with outside research institutions, and other forms of human interaction. Sophisticated information technologies also are being deployed in some hospitals in order to manage medical images and to capture scarce expertise (e.g., medical expert systems) (Davenport & Glaser, 2002). The addition of Internet technologies to the portfolio of information processing technologies offers a new set of powerful tools in order for hospitals to implement knowledge management programs.

In light of the strategic value of professional knowledge, hospitals increasingly recognize a need to manage more actively their intellectual capitals. The field of knowledge management provides the frameworks and techniques that are required to transform a hospital into a learning organization (Adams & Lamont, 2003; Awad & Ghaziri, 2004; Becera-Fernandes, Gonzales & Sabherwal, 2004; Gupta & Govindarajan, 2000; Hansen et al., 1999; Leonard-Barton, 1995). These frameworks and techniques emerge from the inquiries conducted and the experiences acquired in a variety of contexts, including manufacturing (Kim, Hwang & Suh, 2003), customer relationship management (Gebert, Geib, Kolbe & Brenner, 2003), consulting (Sarvary, 1999), retail chain (Tsai, Yu & Lee, 2005), and health care (Powers, 2004). Much of the literature, however, has been either case studies or conceptual discussions. Empirical studies based on the primary data collected in the field, however, are important for advancing the field of knowledge management toward maturity.

Motivated by the dearth of empirical inquiries in knowledge management that address issues in hospital management, we conduct this study to identify the relationship between some factors that play a significant role in successful knowledge management implementations in the healthcare environment. Our purpose is to understand how knowledge management is practiced and the result of implementation in this knowledge-intensive sector. We also seek to contribute to hospital management by offering empirical evidence for the value of knowledge management in coping with the multi-faceted management challenges faced by today's hospitals.

The remainder of the article is structured as follows. The next section describes an interview process conducted with hospital executives and medical doctors for the purpose of selecting the constructs for our research model. We review some of the existing knowledge management literature that relates to our research constructs. We also discuss our research hypotheses that are formulated as a result of field interviews and literature reviews. The section on research methodology describes the research framework, data collection approaches, and data analysis techniques. This is followed by the results of data analysis. The last section discusses some implications of the research findings for hospital knowledge management in particular and knowledge management in general. Suggestions for future research in knowledge management also are presented.

Identification of Research Constructs

Knowledge management increasingly has received attention as an important multidisciplinary field in both the academic and corporate arenas over the past years (Adams & Lamont, 2003; Becera-Fernandez et al., 2004; Davenport, De Long & Beers, 1998; Gloet & Berrell, 2003; Sharkie, 2003). A common denominator among knowledge management researchers is the belief that in the knowledge economy, which is characterized by rapid change and fierce competition, knowledge should be viewed as a valuable and manageable resource, just like tangible assets such as capital and factory facility (Davenport & Prusak, 2000; Leonard-Barton, 1995; Liebowitz & Wilcox, 1997; Soo, Devinney, Midgley & Deering, 2002). Various conceptual frameworks for effective implementation of knowledge management programs or projects have been proposed in order to facilitate knowledge sharing and to stimulate continuous innovation both within and across organizational boundaries (Awad & Ghaziri, 2004; Davenport & Glaser, 2002; Lee & Hong, 2002; Soo et al., 2002; Tiwana, 2000; Wang, 2002; Wiig, 1994). Due to the knowledge-intensive nature of healthcare delivery processes, there has been a call for implementation of knowledge management in the context of hospital management in the pursuit of sustainable competitive advantage (Davenport & Glaser, 2002; Powers, 2004; Van Beveren, 2003).

In order to better understand the unique features of hospital management as related to knowledge management, we conducted hour-long interviews with two hospital executives and three medical doctors in a regional medical center. A structured questionnaire was used in the interviews, supplemented by open-ended questions, to help us to identify the research constructs for our inquiry. Several points stood out to provide a direction for the study. First of all, medical services (esp. clinical care) are very context-sensitive. A specific clinical care problem may be attributed to the patient's personal condition, disease specifics, disease history, family background, treatment history, medication history, and so forth. Effective treatment collectively must consider a wide variety of factors. The complexity of clinical care knowledge, in other words, often comes from a great number of factors and the subtle relationships among these factors that need to be considered in the treatment decision. The ability to distinguish between the relevant and irrelevant factors and to identify the relationships among these factors is a core competence of a true expert. Also, although theoretical knowledge distributed by such published avenues as books and articles is valuable in developing a medical expertise, ultimately, it is the practical experience in dealing with specific cases that truly builds up a medical doctor's professional expertise and the hospital's knowledge repository. In addition, most medical knowledge accumulated over the years is practical knowledge that is not preserved in any printed media. These findings lead to the selection of knowledge characteristics as a research construct.

We also found from the field interviews that specific implementation measures, such as the availability of information infrastructure that facilitates KM activities, incentive programs, and other people-related factors, play a key role in the success (or failure) of the KM implementation program. Information technologies are used to digitize and to store knowledge content. Once kept in the systems, valuable knowledge content easily can be disseminated, integrated, and deployed. Each specialization unit in a hospital usually represents an organizational silo separated from other specialization units. A well-designed information system enables the sharing of related information and knowledge by *baking* the system capabilities in the daily business processes (Davenport & Glaser, 2002). Furthermore, the interviews identified two preferred indicators for assessing the performance of the KM implementation: improvement of internal process and overall organizational performance. Two research constructs—KM implementation measures and KM performance—are identified as a result. Finally, the research construct Knowledge Acquisition Strategy is included in the research model in order to evaluate the strategic role of knowledge source in hospital management. Based on the findings of our preliminary inquiry, the scope of this study is limited to four research constructs: the characteristics of medical knowledge, the strategy used to acquire valuable knowledge, how KM concepts are implemented, and the result of KM implementations. The following section reviews the literature relating to these four constructs.

Knowledge Characteristics

As a service-oriented and knowledge-intensive organization, a hospital typically deals with knowledge in a variety of categories: customer (patient) knowledge, service (treatment) knowledge, process knowledge, and account management, to name just a few. In generic terms, knowledge can be characterized in many ways: shallow vs. deep, procedural vs. declarative, explicit vs. tacit, domain-independent vs. domain-specific, common sense vs. professional, static vs. dynamic, and proprietary vs. nonproprietary, for example (Awad & Ghaziri, 2004; Davenport & Glaser, 2002; Gloet & Berrell, 2003; Gupta & Govindarajan, 2000; Howells, 1996; Nonaka & Takeuchi, 1995; Polanyi, 1996; Ulrich & Smallwood, 2004). A recent list of knowledge attributes proposed by Holsapple (2003) consists of 23 items. According to the healthcare practitioners that we interviewed, for the medical and healthcare service industry, four knowledge characteristics are deemed most relevant: knowledge mode (explicit vs. implicit), knowledge complexity, strength knowledge appropriability (ease of replication and transferring), and knowledge volatility (dynamic vs. static). These four characteristics were identified using a rating questions list, augmented by open-ended elaborative discussions.

Explicit knowledge is represented in the form of recorded products, such as printed documents, formulas, software, system manuals, and hardware equipment, while implicit knowledge primarily is undocumented and retained as memory (Howells, 1996; Nonaka & Takeuchi, 1995; Polanyi, 1996; Zack, 1999). Hospitals vary in their perceptions of and relative emphasis on the explicitness—implicitness continuum of their valuable healthcare knowledge. Different perceptions and preferences may lead to different strategies being adopted for knowledge acquisition and other important aspects of knowledge management implementation measures. Explicit knowledge is more amenable to technologically oriented solutions, such as a document base and a knowledge map, whereas implicit knowledge is handled primarily through social networks.

Complex knowledge is difficult for organizations to acquire. Once acquired, however, it can become a valuable source of competitive advantage (Holsapple, 2003; Teece, 1998). Knowledge complexity is determined by the abstract nature of knowledge, the number of knowledge components, and the interaction of these components (Soo et al, 2002). In the healthcare domain, both the great amount and the intricate interactive effect of professional medical knowledge pose a substantial challenge for hospitals that are striving to provide quality healthcare services.

Knowledge that is nonproprietary in nature easily can be transferred across organizational boundaries. The proprietary nature of knowledge usually is determined by the extent to which the knowledge is tightly tied to the specific organization (Teece, 2003; Soo et al., 2002). From the system development point of view, proprietary knowledge usually is domain-specific. Both domain-specific and domain-independent knowledge are important in solving complex problems. However, past successes of expert system technology applications demonstrate that domain-specific knowledge usually contributes more than domain-independent knowledge in solving difficult problems. This notion of organizational specificity associated with knowledge management is illustrated well by Gupta and Govindarajan (2000) in a case study of the Nucor Steel Corporation. The consistently superior performance of Nucor Steel demonstrates that, once knowledge creation and sharing are embedded in the management practice and the daily operational routines, the resultant proprietary knowledge can establish a solid foundation for a truly sustainable competitive advantage (Adams & Lamont, 2003). The value of proprietary knowledge is obvious in hospital management, especially in dealing with challenging healthcare problems.

Currency of knowledge can be an important issue at times when new knowledge renders old knowledge useless. In these cases, knowledge must be subject to frequent updating in order to stay valuable. The optimal updating frequency is determined by the dynamic (or static) nature of the knowledge. The issue of knowledge updating has been addressed in expert systems development (Liebowitz & Wilcox, 1997). In fact, one of the criteria in the selection of knowledge-based expert system application domains is that the domain knowledge must be relatively static. The complexity involved in knowledge updating and validation poses a significant challenge for keeping a knowledge base current and for having the system accessible at the same time. In the broader context of medical care service delivery, updating of the knowledge repository may affect the strategy for knowledge acquisition as well as knowledge management implementation measures.

Knowledge Strategy

A knowledge strategy, as defined by Zack (1999), "describes the overall approach an organization intends to take to align its knowledge resources and capabilities to the intellectual requirements of its strategy" (p. 135). Zack's (1999) knowledge strategy framework consists of two dimensions: exploitation vs. exploration and internal vs. external. While the exploitation vs. exploration dimension distinguishes a creator from a user of knowledge, the internal vs. external dimension describes the organization's primary sources of knowledge. Internal knowledge is characterized as being "resident within people's heads; embedded in behaviors, procedures, software and equipment; recorded in various documents; or stored in databases and online repositories" (Zack, 1999, p. 138). External sources of knowledge include publications, university alliances, government agencies, professional associations, personal relations, consultants, vendors, knowledge brokers, and interorganizational alliances. Using Nucor Steel's experience, Gupta and Govindarajan (2000) argued that internally created knowledge tended to contribute more to an organization's competitive advantage than did external approaches.

Another useful KM strategy framework is represented by a codification vs. personalization dichotomy. According to Hansen, et al. (1999), the codification-oriented KM strategy is suitable for explicit, recordable, formal, and replicable knowledge, and the personalization-oriented strategy works better for implicit knowledge.

Whereas information technology plays a central role within the codification strategy, it primarily provides tool support for the personalization strategy. The choice of primary knowledge acquisition strategy usually is determined by a variety of factors, among which is the characteristics of knowledge (Awad, 2004; Davenport & Prusak, 2000; Tiwana, 2000; Wiig, 1994).

Knowledge Management Implementation Measures

Knowledge management generally is viewed as a collection of management practices consisting of knowledge accumulation, knowledge organization, knowledge dissemination, and knowledge application (Awad & Ghaziri, 2004; Davenport & Prusak, 2000). The implementation of organizational KM projects typically involves technical as well as non-technical measures. A flexible and efficient information technology infrastructure is an essential requirement. The subsequent distribution and application of the organizational knowledge depends on digital representation, computerized storage, dissemination of the knowledge content, and the application context. Additionally, properly designed incentive programs must be in place in order to discourage knowledge hoarding and to promote knowledge sharing (Davenport & Prusak, 2000; Soo et al., 2002). Sufficient resources must be committed to encourage active learning and perpetual updating of the professional staff's knowledge base.

Knowledge Management Performance Measurement Issues

Measuring the results of KM projects is a challenging task. The subjective nature of the benefit measurement and the lengthy lead time required in order for the benefit to become quantitatively measurable usually are cited as the main sources of difficulty (Abeysekera, 2003; Stone & Warsono, 2003). Although the organizational benefit resulting from KM project implementation eventually must be expressible in financial terms, a significant portion of the benefit is qualitative and only can be measured subjectively. Most literature, therefore, suggests a portfolio approach to measuring the result of KM implementation, such as innovative capability, which would include both financial and non-financial data (Chourides, Longbottom & Murphy, 2002; Darroch, 2003; Soo et al., 2002). Furthermore, it is recognized increasingly that in order for KM to achieve its greatest success, KM functions must be integrated tightly with major business processes. For example, Davenport and Glaser (2002) indicate that, based on their experience at a major medical center in Boston, medication knowledge must be embedded into a doctor's prescription writing process in order to make knowledge application a natural part of daily work practice. The tight integration of knowledge management process and other business processes contributes at least partially to a straightforward measurement of the result of KM implementation (Darroch, 2003).

The input from the practitioners also suggests the following relationships to be examined in the study:

1. The primary knowledge acquisition strategy is affected significantly by knowledge characteristics (knowledge characteristics $\rightarrow$ knowledge acquisition strategy).

   Rationale: Knowledge either is created from within the organization or collected from external sources. Each knowledge acquisition strategy has its pros and cons, depending on the nature of business, the available resource, and other factors. Knowledge that is created internally tends to fit the organizational needs better and to and contributes more to the competitiveness, for example. Although both internal and external sources can be used, an organization usually has a primary knowledge acquisition strategy regarding how to build up its knowledge stock. Everything else being equal, the perceived knowledge characteristics may determine the primary knowledge acquisition strategy that is adopted by the organization.

2. Knowledge management implementation measures are affected significantly by knowledge characteristics (knowledge characteristics → KM implementation measures).

   Rationale: When valuable knowledge is perceived to be primarily tacit, it is less likely that a significant amount of resource will be invested in building sophisticated information systems to support knowledge management activities. Rather, most of the KM implementation measures will be people-oriented. Further, in an effort to cope with knowledge complexity and volatility and to encourage the development of proprietary knowledge, an organization may pay more attention to its incentive program, expertise development, and human resource planning. Therefore, it is reasonable to assume that the way a hospital chooses to implement KM programs is influenced significantly by its perception of knowledge characteristics.

3. Knowledge implementation measures are affected significantly by the primary knowledge acquisition strategy (primary knowledge acquisition strategy → KM implementation measures).

   Rationale: Creating knowledge internally often requires knowledge workers to share knowledge with the rest of the organization. Knowledge sharing usually is not a natural component of organizational culture in most Taiwanese hospitals, where high work pressure and departmental silos tend to encourage knowledge hoarding. In order to encourage internal creation of knowledge through knowledge sharing, hospitals must implement a portfolio of facilitating measures, such as incentive programs, expertise development, human resource planning, and technological infrastructure. Therefore, we postulate that KM implementation measures are affected by the primary knowledge acquisition strategy.

4. KM performance is affected significantly by the primary knowledge acquisition strategy (primary knowledge acquisition strategy → KM implementation performance).

5. KM performance is affected significantly by KM implementation measures (KM implementation measures → KM performance).

   Rationale: O'Dell, Elliott, and Hubert (2003) identified three general categories of value propositions for KM program implementation—customer intimacy, product-to-market excellence, and operational excellence—as a result of APQC's first benchmarking study on best practices in KM. Operational excellence is the most relevant to the context of hospital management. The value proposition defines the goal for KM implementation. Since the degree to which the goal is achieved can be affected significantly by the approach (strategy) and the specific actions (implementation measures) taken to pursue the goal, we set up these two hypotheses to validate our presumptions.

RESEARCH DESIGN

Research Framework, Variables, and Hypotheses

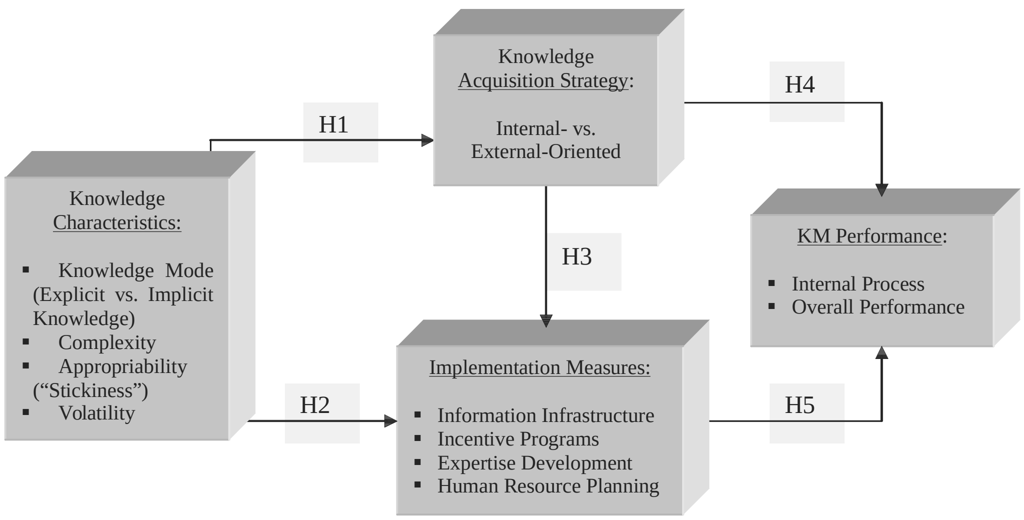
For the purpose of this research, KM was defined as a management function responsible for the acquisition, organization, evaluation, sharing, distribution, and application of both tacit and explicit knowledge for an organization. In order to gather data to analyze how KM was practiced in Taiwanese hospitals, we postulated that the hospital management professionals' perceptions of knowledge characteristics would affect the primary strategy adopted to acquire knowledge and also would affect the hospitals' KM implementation measures. We further assumed that these latter two sets of variables, in turn, would affect the result of KM implementation. These hypothesized relationships between the research variables were derived from the result of literature and our field interviews with healthcare professionals in Taiwanese hospitals. The diagrammatic depiction of our research model is shown in Figure 1. The five research hypotheses established to validate our presumption also are indicated in the diagram.

Operational Definition of Research Variables

The characteristics of knowledge were represented by four important dimensions of medical and hospital management knowledge that we identified in our preliminary interview with medical professionals: knowledge mode (explicit vs. tacit nature of knowledge), complexity, strength of knowledge appropriability, and knowledge volatility.

The primary strategy adopted to acquire knowledge in this study was dichotomized into internally oriented acquisition and externally oriented acquisition. Internal sources included apprenticeships, intranet, internal documentation, morning meetings, internal medical databases, and department meetings. External sources included collaboration with universities, external consultants, internships in other hospitals, seminars, and professional conferences.

Figure 1. Research framework



The knowledge management implementation measures were represented by activities in four areas: information infrastructure, incentive programs for knowledge sharing, expertise development, and human resource planning. The first three items corresponded to three basic entities involved in knowledge management programs: people (incentive programs), knowledge (expertise development), and technological tools (information infrastructure). The fourth item (human resource planning) corresponded to both people and knowledge.

Two categories of variables were used to represent the performance measure of knowledge management implementation in hospitals: internal process improvement and overall organizational performance enhancement. Internal process improvements consisted of communications and efficiency improvement measures, such as problem-solving time, employee participation, decision-making cycle time, and employee interaction. Overall organizational performance measures covered such items as service quality, customer focus, absenteeism, and customer (patient) satisfaction. With these definitions of the research variables, the research hypotheses were formulated as follows:

Hypothesis 1 (H1): The primary knowledge acquisition strategy is affected significantly by knowledge characteristics.

Hypothesis 2 (H2): KM implementation measures are affected significantly by knowledge characteristics.

Hypothesis 3 (H3): KM implementation measures are affected significantly by the primary strategy adopted for knowledge acquisition.

Hypothesis 4 (H4): KM implementation performance is affected significantly by the primary knowledge acquisition strategy.

Hypothesis 5 (H5): KM implementation measures affected significantly KM performance.

Questionnaire Design and Data Collection

All research variables except knowledge acquisition strategy were represented by multiple questions using five-point Likert scales, with 1 indicating very poor or highly disagree and 5 indicating very good or highly agree. A checklist was devised for knowledge acquisition strategies. A questionnaire was sent to 20 head physicians in four medical centers. This first version of the questionnaire was tested using results from the 12 respondents. Based on feedback from the pilot test, the questionnaire was revised by removing the questions with low reliability coefficients and by modifying the ones lacking semantic clarity. The revised version consisted of 44 Likert scale questions. There were 15 questions for knowledge characteristics, 18 questions for KM implementation measures, and 11 questions for performance measures. A copy of the questionnaire was mailed to the president of each of the 126 hospitals on the list that was compiled by the Department of Health of Taiwan. Hospital presidents were targeted on the assumption that they were familiar with the issues under study.

Due to the exploratory and empirical nature of the study, the questionnaire was limited in the criterion validity and the construct validity. Both the content validity and the discriminant validity were assumed to be proper, since the questions were based on the literature and the input from the practicing professionals. The reliability measures, as represented by Cronbach, if all research variables are above 0.70, an indication of acceptable reliability (Nunnally, 1978). Table 1 summarizes the reliability measures of all research variables. Note that two questions were removed from the original set of 46 questions as a result of this analysis.

Table 1. Reliability of research variables

Variables	Sub-dimensions	Question Items	Cronbach α
Knowledge Characteristics	Explicitness	1, 2, 3, 4	0.8239
	Complexity	5, 6, 7, 8	0.7605
	Appropriability	9, 10, 11, 12*	0.7187
	Volatility	13, 14, 15, 16	0.7905
Implementation Measures	Information Infrastructure	17, 18, 19, 20, 21	0.8827
	Incentive Program	22, 23, 24, 25	0.8191
	Expertise Development	26, 27, 28, 29, 30*, 31	0.8063
	Human Resource Planning	32, 33, 34, 35	0.7674
Performance Measures	Internal Process	36, 37, 38, 39, 40, 41	0.9115
	Overall Preformance	42, 43, 44, 45, 46	0.8374

*: *Questions are subsequently removed due to insufficient reliability measures.*

Data Analysis Method

In order to test the previous hypotheses, several statistical analysis techniques were employed to analyze the data. In particular, t-test was conducted to evaluate the effect of knowledge characteristics on the primary acquisition strategy and the effect of the knowledge acquisition strategy on the KM implementation measures. Canonical correlation analysis was conducted to determine the correlation relationship between knowledge characteristics and implementation measures, both of which are multiple variables. Finally, stepwise regression analysis was used to determine the impact of the KM implementation measures on both of the performance measures.

RESEARCH FINDINGS

The questionnaire was mailed to 126 hospitals in Taiwan, from which 50 questionnaires were returned. The questionnaire was addressed to the person who was most familiar with knowledge management practices in the hospital. Three questionnaires were removed due to incomplete answers. The remaining 47 accounted for an effective response rate of 37.3%. Ten questionnaires were filled out by hospital presidents, seven by vice presidents, one by a physician, and 29 by hospital management staff. The Kolmogorov-Smirnov statistics for knowledge characteristics, implementation measures, and performance measures all exhibited normal distribution at the 0.001 significance level.

Hypothesis 1 stated that the primary knowledge acquisition strategy is affected significantly by knowledge characteristics. The frequency distribution of knowledge acquisition strategies summarized in Table 2 showed that the most common internal source of knowledge was morning meetings, and the most widely used external knowledge source was outside meetings. Table 3 showed the means and standard deviations of each of the four dimensions of knowledge characteristics. The measures of knowledge characteristics were dichotomized, using averages as the thresholds, into two distinct levels: high and low. A t-test was performed to determine the correlation relationship between knowledge acquisition strategy and knowledge characteristics. Table 4 shows that the adoption of internal-oriented

Table 2. Distribution of primary knowledge acquisition strategy

Types of KA Strategy		Freq.	%	Freq. Total	%
Internal-Oriented	Manual and Instruction Management	1	2.1	20	42.6
	Morning Meeting	12	25.5		
	Group Discussion within Department	6	12.8		
	Hospital-wide Medical Database	1	2.1		
External-Oriented	Collaboration with University	3	6.4	27	57.4
	Consultant	2	4.3		
	Internship with other Hospitals	2	4.3		
	Outside Meeting	20	42.6		

Table 3. Means (μ) and standard deviations (σ) of knowledge characteristics

Knowledge Characteristics	ì	ó
Knowledge Mode	3.7872	0.5874
Complexity	2.9043	0.4056
Appropriability	3.4752	0.5462
Volatility	3.0691	0.6567

Table 4. Relationship between knowledge characteristics and KA strategy

Knowledge Characteristics	Knowledge Acquisition Strategy			
	Internal-Oriented	External-Oriented	t-value	p-value
Explicitness	3.8241	3.4825	1.152	0.012*
Complexity	3.2167	2.7621	1.224	0.000**
Appropriability	3.5667	3.4074	0.998	0.328
Volatility	3.1375	3.0185	0.610	0.545

strategy was affected significantly by the level of knowledge explicitness (t = 1.152, p-value = 0.012), and the use of external-oriented knowledge was affected significantly by knowledge complexity (t = 1.224, p-value = 0.000). In other words, the internal-oriented strategy was used more to acquire knowledge with high explicit levels, whereas the external-oriented strategy was used more for knowledge with high complexity levels. These were indications that, in general, hospitals in Taiwan tended to rely on external sources to update and upgrade their knowledge bases. The lack of resources and the competitive pressure from the environment were keeping most of them from actively investing in internal research and development in order to create valuable knowledge from within the organization. With a few exceptions (e.g., Chang-Hua Christian Hospital), only the medical centers that are affiliated with research universities had the capabilities and resources with which to carry out knowledge creation activities in a systematic manner.

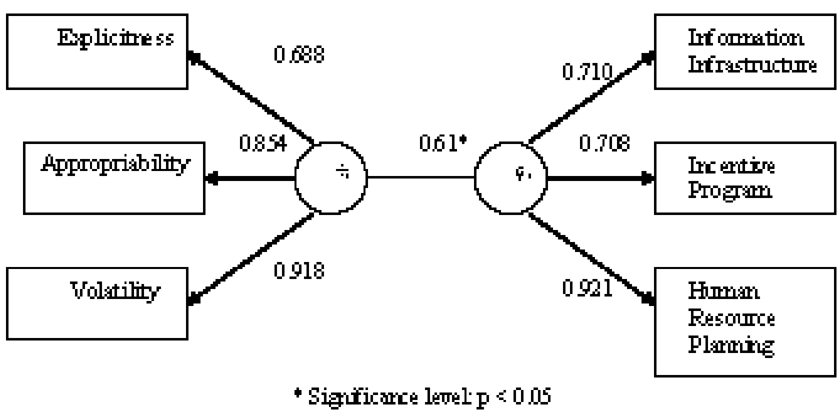
Hypothesis 2 states that KM implementation measures are affected significantly by knowledge characteristics. Since both knowledge characteristics and implementation measures consist of four variables, canonical correlation analysis was employed in order to determine the correlation relationship. As summarized in Table 5 and as graphically presented in Figure 2, the result

Table 5. Canonical correlation analysis between knowledge characteristics and implementation measures

Knowledge Characteristics	Canonical Variate	Implementation Measures	Canonical Variate
	÷		ç
Knowledge Explicitness	0.688*	Information Infrastructure	0.71*
Complexity	-0.005	Incentive Program	0.708*
Appropriability	0.854*	Expertise Development	-0.128
Volatility	0.918*	Human Resource Planning	0.921*
Extracted Variance	51.16%	Extracted Variance	46.76%
Wilks E	0.465	Redundancy	0.174
F-value	2.13	Canonical Correlation ($\hat{r}$)	0.61
p-value	0.011	$\hat{r}^2$	0.37

**:Absolute value of canonical loading > 0.6*

Figure 2. Path diagram of canonical correlation analysis between knowledge characteristics and implementation measures



of canonical analysis identified that the linear composition of three knowledge characteristics—knowledge explicitness, appropriability, and volatility—were correlated significantly with the linear composition of three implementation measures: information infrastructure, incentive program, and human resource planning. The correlation coefficient (ρ) was 0.61 at the significance level 0.05.

Hypothesis 3 states that KM implementation measures are affected significantly by the primary strategy adopted for knowledge acquisition. The result of the t-test indicated that two implementation measures were affected significantly by the knowledge acquisition strategies. Internal-oriented strategy adopters scored higher in information infrastructure than external-oriented strategy adopters, whereas external-oriented adopters scored higher in incentive measures.

Hypothesis 4 states that the performance of KM implementation is affected significantly by the primary knowledge acquisition strategy. The result of the t-test (Table 6) showed that different knowledge acquisition strategies did not cause significant differences in either dimension (internal process and overall organizational performance) of the performance of KM implementation. Hypothesis 4 was rejected. Since internally created knowledge usually is considered more likely to contribute to an organization's competitive advantage (Gupta & Govindarajan, 2000), this finding indicated that the hospitals in Taiwan still lacked a proper understanding of the strategic value of locally created knowledge.

Hypothesis 5 states that knowledge management performance is affected significantly by implementation measures. Three stepwise regression analyses were conducted to test this hypothesis. The first test was a simple regression analysis, in which both the performance measures and the implementation measures were treated as single, composite variables. The second test treated the performance measures as one variable and the four dimensions of the implementation measures as four variables. The third test treated each of the two dimensions of the performance measures as a dependent variable. The first test resulted in a regression equation:

KM Performance = 1.086 + 0.684 * KM Implementation Measures
F-value = 15.517, (p < 0.1 for the intercept and p < 0.001 for the regression coefficient), Adjusted R^2 = 0.24

This result showed that the implementation measures did exhibit significant influence on the performance measures. The second and the third regression analyses were conducted to further investigate this relationship.

In the second regression analysis, each of the four dimensions of the KM implementation measures was treated as an independent variable, with the performance measures as a single composite variable. The third regression analysis related the four dimensions of the KM implementation measures with the two dimensions of

Table 6. Effect of knowledge acquisition strategy on knowledge management performance

KM Performance	KA Strategy (i)		t-value	p-value
	Internal-Oriented	External-Oriented		
Internal Process	3.2583	3.5123	-1.028	0.310
Overall Organizational Performance	3.4500	3.5852	-0.645	0.522

the performance measures. Table 7 shows that only human resource planning and the incentive measures significantly affected the performance of KM efforts. Between the two dimensions of the performance measures, human resource planning and incentive measures contributed significantly to both the internal process and the overall performance, as shown in Table 8. The second and third regression analyses essentially confirmed the result of the first regression analysis and also provided a greater understanding of the importance of people factors in effective KM.

CONCLUSION AND DISCUSSION

This study investigated the practice and the effect of KM in hospital management. It examined the effect of knowledge characteristics on knowledge acquisition strategy and KM implementation mea-

Table 7. Impact of implementation measures on KM performance (stepwise regression analysis)

Implementation Measures	Standardized Regression Coefficient	Correlation Coefficient (R)	R^2	F-value	p-value
Human Resource Planning	0.506	0.638	0.407	30.851	0.000*
Incentive Program	0.305	0.695	0.482	20.510	0.000*

sures, the effect of knowledge acquisition strategy on implementation approaches and performance measures, and the effect of implementation approaches on KM performance. Using primary data gathered in Taiwanese hospitals, the study found that knowledge characteristics significantly affected implementation measures, and implementation measures, in turn, had a significant effect on the result of KM implementation. More specifically, the level of explicitness of knowledge (knowledge mode) was found to have a significant effect on the adoption of the internal-oriented knowledge acquisition strategy. The complexity of knowledge was related significantly to the external-oriented knowledge acquisition strategy. In general, people factors, such as incentive programs and human resource planning, appeared to have more impact on the result of KM than technology factors, confirming a popular belief regarding the importance of non-technological factors in KM, as reported in the existing literature.

The correlation relationship between knowledge characteristics and implementation measures is worth noting. In addition to incentive programs and human resource planning, information infrastructure was found to be affected significantly by three knowledge characteristics: explicitness, proprietary nature, and variation. The enabling capability of information technology for knowledge storage, dissemination, and application allows for integration of specialized knowledge with routine business processes, such as disease diagnosis and medicine prescription in the healthcare domain (Davenport & Glaser, 2002). Increasingly, hospitals are relying on technological measures as a strategic vehicle to cope with both professional and managerial challenges. The emphasis of information technology applications can be attributed to the collaboration between major hospitals and universities. Information technology development and applications have been a major thrust in Taiwan. Many universities set up research centers to function as an interface between information system researchers and the regional hospitals. Some technologies resulting from these collaborations either are adopted by or are shared with smaller hospitals. The maximal benefit of information technology deployment has yet to be realized, however. The value of technological tools is maximized when they become integral parts of truly integrated business processes.

This study contributed to the field of KM in several ways. For practicing KM professionals and business functional managers, the study demonstrates the importance of matching KM implementation measures with knowledge characteristics. Understanding characteristics of valuable knowledge in an organization is a prerequisite for effective management of its organizational knowledge. Similarly, knowledge-driven organizations consciously must evaluate and adopt their implementation measures. When properly implemented, KM programs may produce visible benefits, including those associated with operationally oriented goals and those associated with long-term financial outcomes.

For KM research, this study empirically revealed the correlation between knowledge characteristics and KM implementation measures. The performance impact of implementation measures, especially those associated with people elements, also was confirmed. The lack of the knowledge acquisition strategy's influence on performance measures suggested that hospitals may have acknowledged the value of both internal and external sources of knowledge and indiscriminately adopted both strategies in order to enrich their knowledge repositories.

Because of several limitations of the study, however, due caution must be exercised in interpreting and applying the results of this study. For example, since the data were gathered in the hospitals in Taiwan, cultural and other environmental differences may limit one's ability to generalize the research findings. Similar researches must be conducted in a variety of cultural and societal settings in order to establish the external validity in a more general fashion.

Another research limitation was that some questionnaires were filled out by the targeted respondents' delegates, including medical doctors and information technology managers. Although the delegates possessed proper understanding of knowledge characteristics or implementation measures, they might not be the best people to answer the questions about overall organizational performance resulting from KM implementation. Additionally, the subjective nature of the questionnaire responses based on the Likert scale constituted a limitation that might discount the validity of the research results.

Healthcare organizations in the United States use information technology extensively to automate important processes and support other aspects of operations. An industry expert estimated that spending in healthcare information technology will increase about 9% per year for the next three years and will reach $30 million in 2006 (Powers, 2004). In light of the important role played by healthcare organizations in our daily lives, more research is needed to provide knowledge about how to improve the quality of hospital management. Based on the findings of this research, two directions may be suggested for future research in this particular domain. First, in-depth case studies may be conducted to verify the validity of our research findings in specific contexts and to assess how contextual factors impact the linkages among knowledge characteristics, KM implementation measures, knowledge acquisition strategy, and KM performance measures. Second, our research model may be replicated in different societies to allow for cross-cultural comparison. Such comparison is necessary in order for the research model to become better established in the KM literature.

H5.6	Overall performance is significantly affected by incentive measures for KM implementations.	Accepted
H5.7	Overall performance is significantly affected by expertise development.	Rejected
H5.8	Overall performance is significantly affected by human resource planning.	Accepted

APPENDIX II: SURVEY QUESTIONNAIRE

(Measurement Scale: 1 = Highly Disagree, 5 = Highly Agree)

Questions About Knowledge Characteristics

1. Documentation has been created for all medical expertise.
2. Medical service delivery processes have formal specifications.
3. Doctor's practice experience may be documented in writing.
4. Doctors can share their professional expertise without any obstacles.
5. Major surgical operations are accomplished by task force teams.
6. Significant differences of expertise exist among the doctors in the same specialty.
7. Outside experts often are called upon to assist with major surgery operations.
8. Mutual support among doctors within the same specialty usually is difficult to come by.
9. Medical expertise is integrated tightly with hospital management and organizational culture.
10. Outsourcing often is used due to inadequacy of medical expertise.
11. Innovations of medical practices are difficult to be obtained by competition.
12. Doctors are expected to remain up-to-date with data in their expertises.
13. The frequency of rare case treatment experience is higher than the competition.
14. New and innovative medical knowledge and technology are adopted faster than competition.
15. Knowledge used around here advances fast.

Knowledge Management Implementation Measures:

16. Information systems are developed aggressively to enable organization, dissemination, and application of knowledge.
17. Doctors are strongly encouraged to access document bases and to systematically construct medical databases.
18. Operation automations through information technology are pursued actively to support doctors' work.
19. Substantial amounts of financial resources are invested in information technology.
20. Doctors are encouraged to use the Internet to enhance medical expertise exchange and diffusion.
21. Knowledge sharing is an important criterion in performance evaluation.
22. Proposals for creative ideas are rewarded, even when the ideas prove to be wrong.
23. Knowledge creation and sharing often are rewarded with salary increases and bonuses.
24. Knowledge creation and sharing are rewarded with promotions.
25. Doctors always are willing to accept training and work assignments that are tougher than the competition.
26. The hospital is not hesitant to increase head counts of supporting technical specialists.
27. Doctors are willing to accept the challenges to enhance their professional expertises.
28. Doctors often explicitly reject the idea of being evaluated by personnel from other fields.
29. Competition among doctors in the same field often hinders knowledge sharing.
30. Doctors are strongly encouraged to learn and to innovate.
31. Open and smooth channels of communication exist in the hospital.

32. Doctors frequently are encouraged to engage themselves in experience and expertise exchange.
33. One-on-one mentor and apprentice-style training of resident doctors is common here.

Knowledge Management Performance

(5 = Much Better, 3 = About the Same, and 1 = Much Worse)

34. Doctors' expertise and experience exchange
35. Handling of doctors' suggestions with regard to medical operations
36. Doctors' sense of participation
37. Decision-making speed
38. Proposal preparation cycle time
39. Overall efficiency improvement
40. Overall quality of service
41. Patient satisfaction
42. Decrease of number of administrative personnel
43. Reduction of impact caused by turnover
44. Handling of medical service improvement projects

Primary Strategy for Knowledge Acquisition

Section V
Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of medical informatics around the world. Chapters introducing this section analyze organizational factors in health informatics and patient centric health information systems, while later contributions offer an extensive analysis of the Internet's role in revolutionizing accessibility to medical-related information. The inquiries and methods presented in this section offer insight into the implications of medical informatics at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1
Organizational Factors in Health Informatics

Michelle Brear
University of New South Wales, Australia

ABSTRACT

There is a general recognition that numerous organizational factors will influence the success of an informatics intervention. This is supported by a body of evidence from multi-disciplinary and health-specific research. Organizational factors are highly interrelated and the exact nature and contribution of each to the success of an intervention is not clear. A health-specific understanding and recognition of these factors is necessary if informatics applications are to reach their potential in healthcare settings.

INTRODUCTION

The influence of organizational factors on the success of informatics interventions in healthcare has been clearly demonstrated. This health-specific research, informed by a larger body of evidence emerging from interdisciplinary organizational, psychological, and sociological research, has confirmed the view that organizational factors can be the decisive factor in the success of an intervention (Lorenzi, Riley, Blythe, Southon, & Dixon, 1997).

However, it remains rare for organizational factors to be explicitly addressed in the implementation process. As such, their contribution to the success or failure of informatics applications is not properly understood. This has implications for future interventions. Applications that were not utilized or did not perform adequately in a particular setting may be dismissed, while other less appropriate systems may be adopted because organizational factors influenced their success. Explicit study of the role of organizational factors on the implementation of health-informatics interventions is necessary to develop an understanding of their influence in the healthcare context.

Healthcare organizations tend to be highly task oriented, labor intensive, and dependent on interdisciplinary teamwork, so the influence of organizational factors within them may differ considerably from the business settings in which they have traditionally been studied (Chau, 2001). Health organizations are also increasingly underresourced due to the global downturn in government social spending, to health-sector privatization, and to aging populations. It is these characteristics that necessitate the rapid uptake of informatics applications, capable of automating aspects of healthcare provision and reducing labor intensity (Coiera, 2004).

From a technical perspective, rapid and fundamental transformation of the healthcare sector through informatics is achievable. However, without a clear understanding of, and ability to, manage organizational factors, it is unlikely that informatics applications will realize their potential in the health sector. This short review provides an overview of the key organizational factors influencing the success of informatics interventions. It begins by positioning informatics interventions in the broader context of organizational change before discussing the current understanding of selected factors.

INFORMATICS IMPLEMENTATION AS ORGANIZATIONAL CHANGE

Implementing informatics applications is essentially “a politically textured process of organizational change” (Berg, 1999, p. 87), aimed at achieving user acceptance and the utilization of informatics applications. Organizational change requires people to be aware of a need for change, to identify a particular course through which the change can occur, and to take actions to make it happen (Lorenzi, 2004). Resistance to change occurs if users are not aware of the need for change, are not convinced of the course of action set out, or are unable to carry out the necessary action. It is the users, not the technology, that should be the centre of the change process as the decision to utilize the system is ultimately theirs (Berg).

Even the best designed and well-intentioned informatics interventions are likely to lead to productivity losses in the early stages and create major changes (Lorenzi, 2004). The timely and effective training of users can reduce the disruption; however, it is not enough to ensure success as even a correctly used system can have far-reaching effects. Informaticians taking a sociotechnical approach view the application as one component of a complex system (the health organization) whose introduction will disrupt other components of the system (e.g., patients and clinicians). They advocate design approaches that aim to create technology that fits within the complex system (Kaplan, 2001).

The multidisciplinary nature of health-sector organizations makes finding the correct fit challenging (Kaplan, 2001). A range of professionals with different needs, expectations, and work norms are likely to use an application, and each will expect it to fit with his or her work practice. When an application does not fit, resistance will increase. This is often due to valid concerns about increased workload or the ability to care for patients (Timmons, 2003). When systems do not fit, the best way to overcome resistance is to change them. However, when they are essentially effective, resistance can be overcome by changing people’s opinions or work norms. Organizational culture and social networks, from which many of these norms and opinions arise, need to be understood and managed.

ORGANIZATIONAL CULTURE

Organizational culture is the set of shared norms, values, and tacit rules within which members of an organization function (Lorenzi & Riley, 2000). “Every culture supports a political and social values system” (Lorenzi et al., 1997, p. 85) that will influence the reaction to an informatics application. Healthcare settings often involve a professional hierarchy between doctors and nurses, are characterized by high levels of informal and disruptive communication, and place value on clinician-patient relationships and patient care.

It is necessary to identify and target the aspects of organizational culture presenting opportunities for and barriers to success when changing the organization through an informatics intervention. Managing change requires mediating the influence of culture on events rather than necessarily aiming to change it (Demeester, 1999). Where organizational culture and informatics applications appear incompatible, adaptation of the application should be considered.

If it is not possible to modify the system, success is dependent on changing the organizational culture to make it compatible. Cultural change directly targeted at the strongly held values of users may only increase resistance. If the organizational culture supports a belief that informatics applications undermine good clinician-patient relationships, attempting to convince clinicians that good relationships with their patients are not important is unlikely to be a successful strategy for winning acceptance of the application. However, it may be possible, through an educational process, to convince clinicians that informatics applications do not necessarily undermine good relationships and in the right conditions can even enhance them. Users may already be convinced of the need to change some aspects of organizational culture that do not threaten the values they are most passionate about. The structure of an organization, and work patterns and roles of individuals within it are influential and may be appropriate areas to encourage change.

Organizational Structure

The structure of an organization will affect the way in which decisions are made, the type of leadership that emerges, and the way resistance is dealt with in the implementation process. Flatter organizational structures tend to encourage the sharing of ideas, the emergence of innovation, and broader involvement in decision making (Leonard, Graham, & Bonacum, 2004). In these types of organizations, management tends to adopt a collaborative approach, working alongside, listening to, and involving those working on the ground rather than making decisions on their behalf and communicating orders. Management is supportive, approachable, and accountable, and shows dedication to continuous learning (Zimmerman et al., 1993). These types of organizations are more likely to include practicing clinicians in formal decision-making bodies such as management committees. They are also more likely to recognize, encourage, and legitimize the role of grassroots leaders with clinical credibility and presence, and have a commitment to involving informatics users in the implementation process.

User involvement throughout the process "leads to increased user acceptance and use by encouraging realistic expectations, facilitating the user's system ownership, decreasing resistance to change, and committing users to the system" (Lorenzi et al., 1997, p. 86). It also allows a better definition of problems and solutions from the user's perspective, and develops a better understanding amongst users of the application (Lorenzi et al.). Involving users in the design and implementation of a system is more likely to result in applications suited to the current work patterns of the intended users.

Work Patterns and Roles of Clinicians

Any informatics application must be compatible with the current work practices and values of the organization (Greenhalgh, Robert, MacFarlane, Bate, & Kyriakidou, 2004; Kaplan, 2001; Lorenzi & Riley, 2000). Compatibility will differ between organizations and cultures, so applications require the capacity to be tailored to the needs of individual organizations. Take an electronic prescribing system, for example. In one hospital, it may be used to enter prescription orders during ward rounds via a laptop computer; however, a different hospital (or even another ward within that hospital) may find it more appropriate to install the system on a computer terminal at the nurses' stations so that orders can be entered retrospectively. Bearing in mind the necessity to consider the unique context of individual organizations, it is possible to make some generalizations regarding the work patterns and roles of clinicians to broadly inform the design of informatics interventions.

Doctors have traditionally worked with a high degree of professional autonomy and status (Gagnon et al., 2003). Applications perceived to undermine their autonomy and status as professionals or "subvert the art of medical practice" (Kaplan, 2001, p. 4) are more likely to meet with resistance. In a qualitative study examining factors influencing the adoption of a CDSS (clinical decision-support system) involving automatic clinical reminders, Rousseau, McColl, Newton, Grimshaw, and Eccles (2004) found clinicians favored on-demand evidence systems to automatically generated reminders. The latter were perceived to be intrusive, often inapplicable, and not particularly useful for making patient-management decisions.

Clinicians tend to be patient focused, require an ability to maintain control of patient care, and make decisions specific to individuals, which computers are not capable of. They must be convinced that applications will not jeopardize their ability to care for patients (Timmons, 2003). Overly prescriptive systems, or those that attempt to take on the uniquely human quality of thinking, are unlikely to be successful. Rouseau et al. (2004) noted inapplicable reminders were a barrier to effective use and found that practitioners formed a habit of ignoring all reminders. In a study of adherence to electronic HIV treatment reminders, Patterson, Nguyen, Halloran, and Asch (2004) found that the inapplicability of reminders to many patients' specific situations and the time taken to document why the reminders were not adhered to were significant barriers to effective system use.

All applications will create some change to normal work patterns and roles. That is essentially what their implementation is intended to do (Berg & Toussaint, 2003). Users need to be realistically informed of and prepared for changes to normal work practice. It is inevitable that users will expect some future benefit from adapting their behaviors, and realistic communication of the likely benefits, particularly if they are indirect or not clearly visible, should form an integral part of the communication strategy.

Communication

Communication binds individuals together and is integral to the implementation process. Without effective communication, it is impossible to lead, learn, make decisions, prepare individuals for an intervention, or use the intervention effectively (Zimmerman et al., 1993). The lack of communication, or ineffective communication that lacks trust, can negatively influence the uptake of a technology (Ash, 1997). There is no magic formula for effective communication; however, there are some key principles that should be applied to enhance the effectiveness of communication.

Communication must be timely. People require time to digest information and prepare for changes (Tilley & Chambers, 2004). However, they also forget. Users who are trained to use a system months before its implementation may not remember how to use it when it finally arrives. Information must also be communicated at an appropriate time in the day. Disrupting a lunch break or patient care may not be the most appropriate way to inform users about a new application.

Communication must be sincere and truthful. Users must be offered an honest and realistic assessment of the potential negative consequences and expected benefits of an application. For example, if an electronic medical-record application is introduced, it may be realistic to expect its use to be more time consuming in the initial stages while users master the system. However, in time, its ability to provide comprehensive patient information at the click of a button may save time and provide better quality information. It is also important to acknowledge unexpected benefits and problems if they occur.

Sources of communication have an immense impact on the perceived message, its credibility, and its influence (Kaplan, 2001). A manufacturer's leaflet declaring the new system as easy to use is unlikely to carry much weight with users; however, a respected clinical peer conveying this information may be quite influential.

It is essential that the communication be recognized as multidimensional rather than a one-way channel from management to users. Mechanisms for receiving feedback must be created, and where it is not forthcoming, it should be actively elicited from users. Magrabi, Westbrook, Coiera, and Gosling (2004) incorporated two mechanisms for feedback into an online DSS. Users could volunteer feedback at any time; however, it was also actively elicited by randomly prompting users. Once received, feedback should be acted upon to adapt the application to meet user needs (Greenhalgh et al., 2004). For example, in response to clinician feedback, the patterns of automatically generated reminders in a CDSS were altered to limit the number of reminders perceived by clinicians to be inapplicable. Communication through informal structures (e.g., gossiping in the tea room) is inevitable, and the ability to manage it directly is limited. However, the less effective formal communication mechanisms are, the more likely it is that communication will take place through informal channels in the social network.

SOCIAL NETWORKS

A social network consists of the individuals, groups, and organizations with whom, and patterns of communication by which, individuals in an organization interact. It is through social networks that organizational culture and behaviors are reinforced and adapted (Lorenzi et al., 1997). The culture represented within a social network can be influential. For example, Gagnon et al. (2003) found that physicians who perceived social and professional responsibility from others in their social network to adopt telemedicine applications had a stronger intention to do so. The culture represented in each individual's social network will differ, and each individual within will interact and be influenced differently.

To properly understand a social network, it is necessary to examine the interactions, not the individuals. The frequency of interaction is important but should not be viewed in isolation from the style of communication (e.g., formal or informal), the type of communication (e.g., synchronous or asynchronous), the strength of ties between the participants in an interaction, and the power relations involved (Katz, Lazer, Arrow, Contractor, 2004). When implementing an informatics application, interactions that occur in clinical teams and with respected opinion leaders are particularly influential in relation to individuals' decisions to utilize applications.

Effective Teamwork

The clinical team has been identified as the organizational unit most influential in the diffusion of innovation (Gosling, Westbrook, & Braithwaite, 2003). Well-functioning teams facilitate effective communication, encourage continuous learning, and offer a trusting environment in which ideas and issues can be raised. Through these interactions, teams develop shared visions and common goals that support the introduction of new innovations to fulfill these goals. As work in health organizations is highly dependent on teamwork, and it is teams, not individuals, that must adopt informatics applications, well-functioning teams are a prerequisite for successful informatics implementation (Goldstein et al., 2004).

In organizations where well-functioning teams do not exist, an informatics intervention may be an opportunity to develop teams by uniting individuals around a shared vision and common goals that the application can fulfill. Doctors and nurses take on different roles and responsibilities in the process of caring for patients, so a shared vision may not be immediately apparent. However, both groups ultimately work toward the goal of providing optimal patient care, so incorporating an application into a vision of improved patient care may be a way to unite users.

Consideration should also be given to the size and composition of teams. Teams of more than 15 tend to fragment into subteams, while very small teams have a tendency to become cliquish, so ideally they should consist of 10 to 15 members (Gosling et al., 2003). The work environment may largely dictate a team's composition. In healthcare settings, teams are usually multidisciplinary. Individuals, however, are more likely to create ties with those they perceive to be similar, so identifying similarities amongst multidisciplinary teams is pertinent (Katz et al., 2004). Identifying and utilizing the influence of respected clinicians within the team can also be useful.

Clinical Champions and Opinion Leaders

Respected clinicians with influence amongst their peers and who support the intervention play an important role in convincing others of an application's worth, as do those who oppose the intervention. They are commonly referred to as clinical champions or opinion leaders. As the name champion tends to imply a positive influence and does not necessarily imply influence amongst peers (Lolock, Dopson, Chambers, & Gabbay, 2001), opinion leader will be used in this article.

Opinion leaders are individuals with the ability to influence others in the social network and who make a major personal commitment to diffusing information about an informatics application (Lorenzi & Riley, 2000). Such diffusion may have a negative or positive influence and can discourage or encourage the adoption of the application. For example, Ash (1997) identified the presence of champions as a significant factor in the diffusion of e-mail in academic health-science centres. Conversely, Timmons (2003) discusses a "strong and articulate" ward sister whose resistance to using an electronic system in the ward was successful in preventing its implementation. It is not unusual to have both negative and positive opinion leaders within a network.

Whatever their persuasion, they tend to be charismatic individuals with good interpersonal relationships based on trust and understanding. They act through clinical conviction, generally outside of the formal structures, and give applications credibility at a local level. Their role is essentially informal, and, on the proviso their colleagues respect them, they tend to be self-appointed (Lolock et al., 2001). The role is largely dependent on personal motivation and conviction, and therefore it is difficult to formalize. The potential alienating effect of being an opinion leader means that those without sufficient commitment are likely to be reluctant to take on such a role (Lolock et al.)

Despite a general consensus that successful interventions are more likely when champions are present, there is a lack of understanding about exactly what it is they do, the circumstances in which they will be influential, and how best to describe them. As with each of the factors mentioned here, opinion leaders are one small component of a large and complex system (the health organization), and it is difficult to isolate their effect. There is also considerable evidence to suggest that other factors, in particular the suitability of the application, influence the emergence of opinion leaders. Further research is needed to identify how opinion leaders influence, and how the champions amongst them can be encouraged.

CONCLUSION

There is a general recognition that numerous organizational factors will influence the success of an informatics intervention. This is supported by a body of evidence from multidisciplinary and health-specific research. In particular, research has noted the influence of organizational culture and social networks. Organizational culture, the shared norms and values within which members of an organization function, influences the organization's structure and patterns of communication. Social networks, the individuals and groups with whom one interacts and the interactions that occur between them, are the social space in which teams are formed and work, and in which individuals are influenced, particularly by those individuals known as opinion leaders or clinical champions. Organizational factors are highly interrelated, and the exact nature and contribution of each to the success of an intervention is not clear. A health-specific understanding and recognition of these factors is necessary if informatics applications are to reach their potential in healthcare settings.

KEY TERMS

Clinical Champion: Clinical champions are opinion leaders who champion or encourage the uptake of an application.

Opinion Leader: An opinion leader is an individual, respected amongst his or her peers, who acts out of clinical conviction to influence the opinions of others vis-à-vis an informatics application.

Organizational Culture: Organizational culture is the set of shared norms, values, and tacit rules within which members of an organization function.

Organizational Factors: In an informatics context, organizational factors are factors relating to the culture and functioning of an organization that, negatively or positively, influence its ability to adapt to an informatics intervention.

Social Network: A social network consists of the individuals, groups, and organizations with whom an individual interacts, and the interactions that take place between the individual and other components of his or her social network.

Sociotechnical Approach: A sociotechnical approach is one that views informatics applications as part of the broader social and political context within which they are implemented.

Teamwork: The cooperative effort of a small group to achieve a specified outcome.

Chapter 5.2
Information Imbalance in Medical Decision Making:
Upsetting the Balance

Jimmie L. Joseph

David P. Cook
Old Dominion University, USA

ABSTRACT

This chapter explores the ethical implications of a reduction in information asymmetry between health care providers and their patients. In many human interactions, asymmetry of information and experience typically raises ethical dilemmas for the party with the greater degree of information. This chapter illustrates that it is the reduction in information asymmetry that is raising ethical dilemmas in dealing with medical issues. Understanding this phenomenon may assist in identifying and managing future ethical quandaries that may occur as Internet resources provide broad access to information previously distributed only to a subset of the population.

INTRODUCTION

Information asymmetry is an imbalance in the information available to the parties in an interaction. This situation is not atypical and can be considered the basis for many of our most meaningful conversations. Human interactions would be far less interesting if everyone knew and "shared" the same thoughts, feelings, and discoveries at all times. While information asymmetry makes questions such as "How is the weather?" and "How was your day?" at least superficially interesting, in numerous human interactions, asymmetry of information and experience can raise ethical dilemmas for the party with the greater degree of information.

Significant academic research exists in the area of information asymmetry (e.g., finance and economics). The presumption of much of this research is that market efficiency can be increased by reducing the degree of asymmetry (Akerlof, 1970; Milgrom & Roberts, 2001; Payne, 2003). Furthermore, it is commonly held that information parity (or information access that moves the parties towards this point) can be the linchpin for the elimination of the ethical quandaries introduced by information asymmetry (Akerlof, 1970; Diamond, 1984; Hellwig, 2001).

In the field of medicine, for example, it is clear that the physician has historically possessed more information than the traditional patient. This disparity has created a peculiar set of ethical issues for medical providers, based on their fiduciary responsibility to their patients. As with many relationships, the relationship between caregiver and patient changes, however, as information asymmetry diminishes. Relaxing the assumption that there is a significant difference in the information available to the physician and patient causes a new set of ethical issues to arise. In the extreme case, information inversion exists: the patient knows more about his or her condition than the attending medical personnel. The anecdotes about doctors making poor patients approach the status of urban myth (Porter, 1992). This chapter focuses on these very issues: how do the physician-patient relationship and the resultant ethical issues change as the patient's information disadvantage decreases.

This chapter examines the effects of changes in technology and societal norms on the ethical posture of practitioners in the medical profession. Ethical, social, technical, and regulatory issues associated with consumers' increased access to medical information are explored. It is posited that situations exist where a reduction in information asymmetry does not lead to fewer, or less severe, ethical dilemmas — it leads to more severe ethical quandaries. This chapter illustrates a counterintuitive example to the presumption that increased information parity enhances market efficiency and diminishes the number of ethical quandaries in the provision of medical care. While the chapter seeks to illustrate a counterintuitive example and the ethical dilemmas it raises, it does not purport to provide a solution to these still evolving ethical issues.

INFORMATION ASYMMETRY AND ITS COSTS

Problems resulting from information asymmetry are generally classified as either moral hazard or adverse selection (Akerlof, 1970; Diamond, 1984; Payne, 2003). Moral hazard problems are related to the buyer's inability to observe the actions taken by the seller (Holmstrom, 1985). Adverse selection problems are related to the buyer's inability to observe either pertinent seller characteristics or the contingencies under which the seller operates (Nayyar, 1990). Adverse selection can occur in the medical environment due to the patient's inability to determine on an *ex ante* basis the competence of the physician, the value of the service, or its quality.

Given the existence of such problems, and that they arise as a result of information asymmetries, numerous strategies have arisen to attempt to remedy or mitigate the effect of these asymmetries. Several potential remedies (e.g., contingent contracts, certification, monitoring, and reputation) exist for information asymmetries (Holmstrom, 1985; Nayyar, 1990). Each of the mentioned remedies has its shortcomings. In contingent contracts, for example, the capability must exist to identify all relevant contingencies prior to the enforcement of the contract.

Certifications only indicate an entity has met some minimum standard of performance or knowledge (as established by the certifying authority). For certification to be of benefit, it is necessary for the party with the information paucity in a transaction to understand the nature or quality of the certification or certifying agency (Diamond, 1984; Hellwig, 2001). Further, some certifying authorities may not make their criteria for certification public knowledge (Diamond, 1984; Hellwig, 2001).

Monitoring introduces additional information asymmetries between the monitor and the entity being monitored. An agency problem can arise if the party depending on the monitoring organization has no way of ascertaining the diligence of the monitoring (Diamond, 1984; Hellwig, 2001). This is especially problematic in self-monitoring organizations such as bar association monitoring boards composed of lawyers and state medical boards composed of doctors (Davies & Beach, 2000; Fournier & McInnes, 1997; Marks & Cathcart, 1974). While each of these mechanisms may have been fomented with good intentions, each is fraught with difficulty.

Another mechanism to mitigate or eliminate information asymmetry is greater informational transparency and availability. The Internet is a good example of a vehicle that can facilitate these goals. The Internet presents a medium through which unprecedented volumes of data can be made available to anyone with access and interest. However, just as other forms of asymmetry mediation have unique shortcomings, the Internet may pose its own issues.

Examples of Information Asymmetry

Many of our interactions are predicated on an asymmetry in the information possessed by the parties involved. Though numerous examples of information asymmetry in interactions could be presented, along with their associated effects and resultant moral dilemmas, two situations involving information asymmetry (the sale of automobiles with known defects and insider trading) are briefly examined here. Information asymmetry involving parties to medical interactions will be examined more closely in the ensuing sections of this chapter, and so will not be discussed here.

Automobile Sales

In used car purchases, the prospective purchaser knows exactly how much she can spend on the vehicle, but the seller has no such information. Conversely, the seller may be privy to details of a vehicle's defects, accident history, and undisclosed repairs to which a prospective buyer is not (Akerlof, 1970). For the seller, knowledge of defects creates an ethical dilemma in that he must decide whether to disclose the existence of the defects and possibly nullify the interest of a prospective buyer (Akerlof, 1970).

To help address the issue of seller information advantage, governments (both Federal and state) have developed and imposed "Lemon" laws and other statutes for consumer protection (Akerlof, 1970). The intention of such laws is to facilitate commerce and to protect consumers from the problems created by information asymmetry. These laws also reduce the moral dilemma faced by the seller: it now makes moral and legal sense to disclose all known problems with the automobile (Akerlof, 1970).

Insider Trading

When a person with access to information not available to the general public wishes to trade stock, he or she is faced with a different ethical problem. Insider trading is the result of trading stock on the basis of privileged information (Anonymous, 1998, 2003b). Such trading continues because of the tremendous potential for profit that can accrue from buying or selling ahead of the disclosure of the information to the public (Anonymous, 1998, 2003b). Few would argue that trading stock on the basis of privileged information is a fair practice; as a consequence, laws exist that disallow such activities (Anonymous, 2003b). The purpose of such laws is to level the playing field so that parties without access to privileged information are not disadvantaged on that basis.

Why Medicine is Different

There is an exception to the generally accepted proportional relationship between information asymmetry and ethical concerns: the relationship between medical providers and patients. This chapter posits that as patients achieve a reduction in information asymmetry (RIA) vis-à-vis their medical care providers, the ethical dilemmas of the formerly better informed medical professionals increase in number and/or patient impact, thus inverting the generally accepted relationship between information parity and ethical dilemmas. This trend is of concern as increasing portions of the population have Internet access at work, and high-speed Internet access at home. Omnipresent Internet access allows the general public to view information available only to medical professionals or medical researchers in prior decades.

Medical Information Access

Two characteristics of medical information that have traditionally affected its dissemination are availability and readability (Majno, 1975; Marti-Ibanez, 1962). Availability is defined here as the ability of a person to discover that information about a topic exists, and then to acquire that information. Readability entails the possession of sufficient domain knowledge (assumed to be present in the target audience when writing the information) to understand and utilize available information (Aguolu, 1997).

Prior to the invention of the Guttenberg printing press in 1436, books were hand-crafted and, consequently, too expensive for (unavailable to) the average citizen (Borgman, 2000). Magazines (journals) had not even been conceptualized at that time. Most persons did not know how to read (since it was of little practical value to their daily lives), and books were unlikely to come into their possession. Even most medical practitioners could not read, and medical knowledge was typically passed from generation to generation via an apprentice-like system of medical education (Borgman, 2000; Majno, 1975; Marti-Ibanez, 1958, 1962).

A HISTORY OF MEDICAL INTERACTIONS

The practice of medicine has largely been a dyadic one between the patient and the care provider (doctor and/or nurse, midwife, witch doctor, tribal shaman, acupuncturist, etc.) (Digby, 1997; Majno, 1975; Marti-Ibanez, 1958; Summers, 1997). In the traditional doctor-patient relationship, doctors diagnosed and prescribed a course of treatment, and patients underwent treatment as directed (Majno, 1975). News of treatments available on other continents, in other nations, or in distant regions of their own land may not have reached residents of a locale until long after the discovery (Magner, 1992; Majno, 1975; Marti-Ibanez, 1962; Robinson, 1931).

Given the lack of a formal dissemination mechanism such as "continuing education" (through which medical providers could be fully trained in new techniques and procedures), even if new medical treatment ideas arrived, there was no guarantee that the local medical caregiver would understand how to implement the new regimen. While Marco Polo may have returned with information concerning the existence of acupuncture as a treatment for headaches and other ailments, this did not provide the training necessary for European doctors to perform the procedures (Majno, 1975; Marti-Ibanez, 1958).

Since there were few books prior to the widespread distribution of the printing press, availability of information was the primary limiting factor in medical innovation dissemination (Marti-Ibanez, 1962). The availability of relatively inexpensive books brought about a renaissance in reading, and public education brought reading to the masses. This change, however, did not alter the readability issue of medical texts.

In the 19th century, and through the late 20th century, the primary means of disseminating information regarding the effectiveness of various forms of medical treatment was medical journals. Current and archived volumes of these journals were available at medical libraries and hospitals. Medical professionals could also subscribe to pertinent journals, often at substantial discounts from the retail price, through their medical associations (Majno, 1975).

However, for a citizen who was not a professional in the medical field, the journals presented two familiar hurdles: availability and readability. Unless an individual lived near a medical library, the availability of medical journals was usually limited. Medical journals were (and are) prohibitively expensive for the average citizen. Along with the cost of a current subscription, there is the cost of purchasing past issues to track streams of research. Given the large number of medical journals that are/have been published and the high cost of each journal, local libraries carry a very small selection of what may be seen by the funding community to be a highly specialized item.

If the journals are available, their readability is still problematic for most nonmedical professionals. As with most publications, medical journals are targeted to a particular audience. The target audience does not typically enjoy having to wade through the same introductory and historical information for each successive article in a stream of research. It is also a waste of publication space to use excessive verbiage when there are specific terms, phrases, and acronyms widely used in the field of specialty that convey the intended meaning quickly, succinctly, and with far greater alacrity. In medical writing, authors can assume their target audience has a college education, years of medical school, and for many medical journals, specialized training in a medical sub-field. Readability for the target audience is usually not considered a problem; readability for nonmedical professionals is not a priority.

The issue of providing information concerning new treatments or medical techniques was presumed to be the purview of the medical professional. Thus, until the latter decades of the 20th century, the dissemination of medical treatments and advances had not changed significantly from the dissemination methodologies of the middle ages (Majno, 1975; Osler, 1921; Robinson, 1931). The general forms of the traditional ethical issues facing the medical profession included:

- **Traditional Dilemma 1:** How much time to spend on learning new medical techniques (since this was time that could otherwise be spent with patients); and
- **Traditional Dilemma 2:** Whether or not to discuss a medical innovation with a patient if the medical professional was not proficient with that innovation, or if that technology or innovation was not available locally.

Traditional Medical Information Access

The primary conduit of medical information to the public is the medical practitioner (Majno, 1975). From the earliest medical discoveries of tree bark for soothing aches and pains to using leeches to remove "bad humors," medical practitioners have been the repositories of knowledge on the most effective means of treating injury, regaining health, and reducing pain (Majno, 1975; Marti-Ibanez, 1961, 1962). Once medical books and journals became practical, doctors became the local repository of medical knowledge. The size of a medical provider's private medical library could dictate the breadth and depth of treatment available in a locale (Majno, 1975). New discoveries were made known to the local medical practitioner, who dispensed this information to the general populace, if needed. Otherwise, the medical practitioner simply performed the procedures as recommended.

In the 19th and 20th centuries, continuing education, conferences, seminars, and medical journals provided doctors and nurses with information on approved, state-of-the-art medical treatments (Felch & Scanlon, 1997). Information was also made available by medical device and pharmaceutical manufacturers concerning the specific implementation and formulations of their new medical treatment technologies and techniques. Patients with questions concerning the best treatments for their conditions simply queried their medical practitioners; the answers were rarely questioned (Majno, 1975).

MODERN MEDICAL INFORMATION DISSEMINATION

Television and the Late 20th Century

Mass media discussions of medical issues, techniques, and technologies added potential ethical concerns for the medical professional. These media made it feasible for patients to at least hear of new techniques and technologies through channels that were not under the control of the medical professional. However, in-depth discussion of the conditions under which a particular technique or innovation was optimal, side effects, interaction effects with other treatments or medications, and conditions that would eliminate a patient from being a candidate for the treatment were still left to the physician (Friedman, Furberg, & DeMets, 1998; Spilker & Cramer, 1992). Additionally, government control or licensing of mass media outlets meant that techniques, technologies, medications, and innovations that had not been approved by a particular nation's medical establishment or government regulatory body were unlikely to gain significant airtime for discussion in that country's media.

The proliferation of cable television channels dedicated to news, science, and medicine in the late 1980s began to change the dynamic of medical information dissemination. Shows could dedicate more time to discussing medical problems, symptoms, and treatments. Consequently, patients could ask more probing questions concerning treatment options in consultations with their physicians. The practical effect of such channels of information dissemination was to reduce the frequency of the occurrence of Traditional Dilemma 2. Interested patients of this era were rapidly reducing the information gap between patient and medical provider. Traditional Dilemma 2 became less problematic as physicians were increasingly bombarded with questions from patients referring to research studies and treatment regimens seen on television shows.

The question for physicians was not whether to broach the subject of certain treatment options, but rather, how to respond effectively to patient queries. A companion effect was that physicians were also forced to keep abreast of the types of studies and medical treatment options about which patients were asking questions, if for no other reason than to be able to adequately respond to patient inquiries (Felch & Scanlon, 1997; Pennachio, 2003; Shaneyfelt, 2001).

The Internet and the World Wide Web

The 1990s witnessed a significant change to the patient/provider dyad: widespread access to the Internet. The Internet solved the availability problem for patients by providing global access to medical information. Patients could access information on innovations without having the information limited by finances (personal or regional) or filtered by their medical provider, a media censor, or their national government.

Patients with Internet access were potentially one degree of freedom closer to the source of new medical innovations. Individuals could decide which innovations interested them and seek additional information. Individuals still faced the task of comprehending the information that they uncovered. The Internet, however, made it possible for interested parties to seek out multiple presentations of the same material with relative ease. This increased the potential for the dedicated information seeker to find a presentation of the material that was comprehendible, in accordance with the individual's level of subject and domain knowledge.

Medical Information Without Borders

Information available online is not limited by geopolitical boundaries. Patients can find information on treatments, pharmaceuticals, technologies, and innovations that have not been vetted or approved by their medical establishment or national government. E-mail, chat and PC-based video conferencing potentially allow direct access to medical professionals in other countries. These practitioners may provide an in-depth analysis of a particular medical treatment that is not available to the patient from traditional local information sources (e.g., television or radio shows). Medical providers face patients well versed in the efficacy, side effects, and potential benefits of a wide range of treatment options that may not be legally available in a particular locale, or about which the medical provider may have little knowledge or expertise.

Internet access has provided patients participating in medical experiments with an economical means to find and communicate with other experiment participants. While such actions may seem farfetched, consider the motivation many patients with serious ailments have to seek out information and develop a support network. These individuals are often in pain, scared, and desperate to find a cure for their illness. The ease with which USENET news groups (or threads within an existing group) can be created, combined with the ease of setting up IRC chats or Web-based chat rooms, makes contacting others in real time (or near real time) relatively simple.

Individuals participating in an experiment for a new drug, technique, or technology can now discuss their treatment and its results directly with other subjects in the experiment. This allows individuals to potentially discern if they are receiving the same benefit as others in an experiment. Participating patients who find that a different treatment is providing better results can go to their physicians or the experimenter and demand that other treatment. Information on experimental treatments and clinical trials is readily available. Patients interested in an experimental treatment can access CenterWatch at www.centerwatch.com, which provides access to information related to the clinical testing of drugs and recent FDA-approved drug therapies.

DOCTOR'S DILEMMA

Direct, and near global, access to medical information allows patients to petition their medical practitioners for pain-reducing or lifesaving treatments approved in other countries but not approved in their country of residence. Patients may now share and review information concerning treatment availability and costs from around the world. A doctor's local patients can compare their progress with that of patients in other nations taking different treatments or who are involved in medical experiments. Patients can compare symptoms and try to determine if their situation is the same as (or relatively close to) that of another sufferer.

Widespread information access on the part of patients has created ethical dilemmas for medical practitioners based on the fact that:

1. there may be a better (more effective or less painful) treatment available than the medical professional is currently offering;
2. regardless of the efficacy of the treatment identified by a patient, the medical professional may be prohibited from prescribing

it to, and possibly even from discussing it with, her patient;
3. there may be no clinical trials on which a medical professional can base an opinion as to the efficacy of the treatment the patient is seeking;
4. there may be no means for patients to avail themselves of the treatment they are seeking, even if the medical professional confirms that it is a better treatment than that which is currently available locally; and
5. patients involved in experiments may discover that they are receiving the placebo treatment, while ferreting out data indicating that the experimental treatment is providing relief to other participants.

The issues arising from a reduction in information asymmetry (RIA) can be generally categorized into the following ethical dilemmas for the health care provider:

- **RIA Dilemma 1:** Whether to address the patient's question;
- **RIA Dilemma 2:** Whether to provide the treatment, in possible violation of the law;
- **RIA Dilemma 3:** Whether to place the patient in contact with a medical practitioner or source for the treatment being sought;
- **RIA Dilemma 4:** Whether to petition the experimenters to provide the patient with access to the experimental treatment once the patient has made an explicit request.

Locally Unapproved Medical Treatments

National laws and approval bodies guide the approval of medical treatments, and medical practitioners are generally not permitted to prescribe treatment regimens or drug therapies that have not been approved by their governing bodies. This restriction, in part, helps to ensure that medical professionals are properly trained in the use, effects, and side effects of a particular treatment. It also helps to assure that the treatment regimens and drugs are efficacious and reasonably free of undesirable or unintended side effects.

In *RIA Dilemma 1*, the medical professional must decide if he or she will address a patient's concern. Should the medical professional address the patient's questions concerning unapproved medical treatments, the dyad may be venturing into territory proscribed by law. Refusing to answer the question leaves the patient without the knowledge to decide for him/herself whether to investigate the matter further. Indeed, not addressing the question may discourage the patient from pursuing a course of treatment that may provide him or her with relief or a cure. If the patient has the resources, he or she may travel to where the treatment is provided. If consultation with a medical professional after arrival contraindicates the sought after treatment, the patient would have wasted time and money that could have been better spent on the current treatment.

Providing an unapproved treatment to the patient may result in the medical professional being subject to censure, jail, or loss of medical license. In some rural areas, the loss of a single medical professional would deprive one or more communities of access to critical medical services (Hassinger, 1982). Thus, the medical provider is faced with the dilemma of helping one patient and possibly depriving a community of needed medical care.

Providing a patient with a treatment that is less efficacious than the best available may violate the Hippocratic philosophy of "First Do No Harm" (Majno, 1975; Marti-Ibanez, 1962; Osler, 1921). The physician's deliberations on whether to provide patients access to locally unapproved treatment options necessarily revolve around this oath. Knowingly denying a patient possible access to a treatment believed to be efficacious may constitute a violation of the Hippocratic Oath. On the other hand, governing medical bodies and governments have created protocols and procedures with the intention of protecting the populace from "snake oil" remedies (Anonymous, 2003a), with attendant penalties for willful violation. If the physician chooses to prescribe an unapproved drug therapy, for example, he or she may be unwittingly placing a patient at risk for serious medical complications while concurrently placing his or her medical license in jeopardy.

Locally Unavailable Medical Treatments

Medical treatments may be approved for distribution in a nation or region but may not necessarily be made widely available to a specific locale, leading to *RIA Dilemma 2*. This may be for commercial reasons, or it may be the result of government rationing (Morgan, 2003; Schwartz, Morrison, & Sullivan, 1999). In countries with nationalized healthcare, it may not be economically feasible or politically desirable to provide all treatments in all locations (Morgan, 2003). Thus, a treatment that is nationally approved may not be accessible in a given region (Schwartz et al., 1999).

Direct access to medical information from other regions and countries allows patients to petition for approved pain-reducing or lifesaving treatments that are not available in their area. Patients may now share and review information concerning treatments in other regions, and become aware of treatments being denied them on the basis of geography (Morgan, 2003; Schwartz et al., 1999).

Should the medical professional address the patient's questions, he or she may be venturing into territory proscribed by law, especially in the case of nationalized healthcare (Schwartz et al., 1999). To not answer the question is to leave the patient without the knowledge to decide for herself whether to investigate the matter further. Indeed, not addressing the question may discourage the patient from pursuing a course of treatment that may provide her with relief or a cure.

A patient may seek a recommendation from his or her local practitioner for a contact in another locale for a consultation, resulting in the practitioner facing *RIA Dilemma 3.* This can also have legal ramifications. Medical personnel may be prohibited from recommending persons not approved in their country to perform medical treatments.

Locally More Expensive Treatments

If a less expensive but still efficacious treatment is available, the medical practitioner is likely to inform the patient, as long as the treatment is governmentally authorized. If the less expensive alternative is not authorized for local patients, the medical practitioner is not likely to volunteer information on that treatment. However, should the patient raise the issue of the treatment, the medical provider is forced into a position of discussing an unauthorized treatment or leaving the patient in ignorance.

Prior to patient access to transnational information on treatment pricing, treatment cost differentials were not a major ethical issue for medical practitioners, since the patient was unlikely to be knowledgeable enough to broach the topic. If a less expensive alternative to the current treatment was not available in his or her country, the medical professional was under no obligation to mention the treatment, so *RIA Dilemma 1* was not an issue. With direct access to information concerning pricing worldwide, patients can now request information concerning specific alternatives to their current treatment. Patients may be able to find pricing information, but they may still have questions on efficacy, side effects, or interactions with current treatments.

An example illustrates this point. The presence of pharmaceuticals in Canada that are less expensive than their US counterparts is not an unheard of occurrence. In some cases, pharmaceuticals formulations used in Canada are identical to their US equivalents and are manufactured in the US.

Doctors and pharmacists are placed in the position of having to decide whether to respond to their patients' or customers' inquiries about the ability to purchase the same items for less via the Internet or by traveling to Canada. For patients with fixed retirement incomes facing rapidly increasing prescription drug prices on multiple prescriptions, this may be a life-or-death decision. The practitioner is faced with the same problems found in the situation of locally unavailable treatments: he or she could be subject to disciplinary action or potential loss of medical license, if he or she is found to be recommending locally unapproved pharmaceuticals.

Unaffordable Medical Treatments

Cost is a concern for many medical providers and hospitals and is often a determinant of the medical treatment made available to patients. Cost containment is an issue common to both nationalized and privatized healthcare systems (Barry & Raworth, 2002). Some countries and medical establishments simply cannot afford to provide very expensive treatments (Barry & Raworth, 2002).

The dilemma for medical practitioners is whether to inform the patient of treatments that cannot be afforded or leave the patient in ignorance (Barry & Raworth, 2002; Gert, 2002). The former option provides the patient with the information on an alternative treatment, but also the pyrrhic knowledge that his or her suffering may be in vain because it could be alleviated — if the nation or healthcare facility could afford the treatment or technology (Barry & Raworth, 2002). The latter option denies the patient the opportunity to travel to a locale where the treatment is provided, if personal resources permit (Gert, 2002).

Medical Experiments: Request for a Specific Treatment

The final situation that we will discuss concerns medical experiments and *RIA Dilemma 4*, and has been alluded to already. Traditionally, scientifically valid experiments require a control group that received a placebo (e.g., the classic "sugar pill") treatment, and an experimental group that received the treatment to be tested (Matthews, 2000; Spilker & Cramer, 1992). There may also have been a third group that received the current treatment, although in situations where removing a patient from, or denying him access to, the traditional treatment may be deemed too detrimental to the patient, the placebo is often the currently approved treatment (Barber, 1980; Cowles, 1976; Matthews, 2000; Spilker & Cramer, 1992).

Medical practitioners treating patients with a particular condition were recruited to invite their affected patients to participate in the experiment. To ensure that medical practitioners did not inadvertently influence the patient, participating medical practitioners were usually not informed whether their patient was a member of the control group or the experimental group (Barber, 1980; Cowles, 1976; Matthews, 2000; Spilker & Cramer, 1992).

Access to the Internet and chat rooms has altered this equation. Patients now have the potential to discover that an experiment is underway or planned and request that their practitioner volunteer them for the experiment. The medical practitioner must then seek out the experimenter(s) to request permission for his or her patient to be included in the experiment. This could have the effect of excluding a patient who would be a better candidate for the experiment, but who did not know to request inclusion (Barber, 1980; Spilker & Cramer, 1992).

Internet access can also provide patients with a forum to discuss their participation in experiments. Thus, it is now possible for patients to talk among themselves, compare treatment results, and determine the success of treatments using resources such as www.spinalcord.org. By comparing results, it is possible for patients to deduce whether they are in the control group and, possibly, the efficacy of the experimental treatment.

If the experimental treatment appears successful, patients in the control group can ask their physicians for the new treatment. The medical provider is placed in the position of asking the experimenter to provide the new treatment. As a consequence, the experimenter is thrust into the position of denying the experimental treatment to a subject who knows he or she is receiving the placebo. The subject who deduces that he or she is in the placebo group is no longer valid for data analysis, because the placebo effect is destroyed; continuing with the ruse serves no useful scientific purpose.

If the experimental treatment is not helping the experimental group, patients in that group may request that their medical practitioners remove them from the experiment, and return them to the existing treatments (Friedman et al., 1998; Spilker & Cramer, 1992). Since informed consent is the cornerstone of all enlightened medical research, and since that consent can be rescinded at any time, once the physician reports the patient's feelings to the experimenter, the experimenter must release him or her from the experiment (Barber, 1980; Cowles, 1976). Thus, new medical discoveries could be imperiled.

FUTURE TRENDS

An ethics discussion of the factors affecting medical professionals frees us from the constraint common to economic discussions of the topic: the need for equilibrium. As noted by Milgrom and Roberts (2001), "Almost all of economic theory is equilibrium analysis…predictions arise only once equilibrium behavior is assumed." The ethical dilemmas facing medical professionals increase as patients gain access to information, not simply once they reach information parity with their medical practitioners. Indeed, the ethical dilemmas for the medical provider continue, and may in fact increase, if a patient should surpass his or her knowledge of a specific topic, disease or treatment.

For most dyadic interactions, a reduction in the imbalance of information between parties will reduce the ethical dilemmas related to the interaction. The increasing availability and readability of information concerning new medical advances has produced the opposite effect. For medical professionals, the decrease in the traditional information imbalance between patients and medical providers has increased the number and nature of ethical dilemmas faced.

Serious illness or chronic pain provides intense motivation to pursue information on a particular affliction or condition with single-minded dedication. While a medical professional may need to track the symptoms and diseases of dozens or hundreds of patients, a particular patient can concentrate on a specific problem. Thus, a patient may be more knowledgeable about the current discoveries and findings regarding a specific problem than the medical practitioner. With the Internet providing an efficient conduit for researching a problem, a patient may be motivated to explore all available information concerning his or her affliction. Since the Internet is borderless, this research can uncover the most current medical findings worldwide.

This chapter focuses on moral dilemmas brought about through the continued spread of information access. While other chapters in this book focus on threats to privacy and intellectual property, it is important to note that there can be ethical threats engendered in the very availability of the information itself. As ever-greater volumes of information migrate online, it is possible, even likely, that other arenas of human interaction may face similar quandaries. An examination of the current issues may help prepare for a discussion of these future imbroglios.

Concomitant with such developments, the world's citizens should be prepared to deal with their governments' attempts to mitigate the effects of the ethical quandaries for which this expanded information availability is the genesis. Existing laws governing medical devices, treatments, and technologies (e.g., regulation of locally unapproved drugs) suggest that governments will likely take steps to deal with perceived problems arising from greater information flow. There is every reason to expect that regulations will be developed to counter the problems governments perceive in other arenas as well. A lively ethical debate can facilitate the development of well-reasoned laws and regulations.

CHAPTER SUMMARY

National laws are based on geography: the physical limitations of jurisdiction. As with other laws in the Internet age, laws regarding the actions of medical professionals within national borders are facing the reality of borderless information access. The Internet purchase of less expensive prescription drugs in Canada by citizens in the United States is but one example of physical laws not keeping pace with the telecommunications revolution.

This chapter is designed to illuminate the issues surrounding an interesting problem with information parity vs. asymmetry in Medicine. The changing dynamics between patient and caregiver are intricate and complex, especially with the omnipresent impact of laws governing medical treatment. The impact of RIA, combined with the presence of information sources beyond the control of a single national government, complicates the ethical decisions for medical practitioners geometrically. No easy solutions are possible to this problem, and this chapter does not purport to resolve such complex issues. As desirable as a solution to these problems is, a workable solution is not practical at this juncture due to the interplay among technology, law, and ethics.

A technological solution is not tenable since it is the technology that leads to many of the ethical dilemmas facing medical practitioners: new technology may in fact introduce additional complexity in medical relationships. A legal solution is equally fraught with difficulty. National laws currently exist in many countries that are intended to address medical issues. However, the borderless society created by modern information technologies may require an international solution that addresses the realities of physician responsibility and modern data interchange. It may be impossible, however, to un-ring the bell of borderless medical information flow. The reality is that the caregiver is ultimately responsible for the ethical quandaries posed, but that researchers, politicians, and ethicists can assist by fostering an open discussion of the moral calculus.

Finally, this inverse relationship between information parity and ethical dilemmas is of concern because it may not be a singular exception to the generally held belief that information parity decreases ethical dilemmas. As high-speed Internet access becomes more pervasive in society, other situations may develop in which information that becomes available to the general public generates an increase in ethical quandaries. Future research should explore the social impact of unfiltered information becoming available in other knowledge domains. Without awareness of this possibility, ethical training and legal debate may be unprepared to confront a potent, counterintuitive, social phenomenon. It is the nature of such issues that they do not lend themselves to formulaic solutions, but require deliberations and debate to find workable options. It is our goal to begin to foster such debate with this chapter.

Chapter 5.3
How to Start or Improve a KM System in a Hospital or Healthcare Organization

A.H. Rubenstein
IASTA Inc., USA

E. Geisler
Illinois Institute of Technology, USA

ABSTRACT

One of the key factors that distinguishes enterprises of the 21st Century is the emphasis on knowledge and information. Knowledge management is an important means by which organizations can better manage information, and more importantly, knowledge. Unlike other techniques, knowledge management is not always easy to define, because it encompasses a range of concepts, management tasks, technologies, and practices, all of which come under the umbrella of the knowledge management. This chapter deals with two aspects of knowledge management systems: (a) why KM systems are needed, and (b) how to get started on designing and rolling out a new or improved KM system. The inferences are drawn from the direct experiences the authors have had during their academic and consulting activities in many health sector organizations.

INTRODUCTION

Hospitals and other healthcare organization need bricks and mortar, human resources, medical technology, financial systems, and other infrastructure items. In addition, they need effective ways of capturing, preserving, transforming, retrieving, and applying *knowledge* about past experiences and subsequent "lessons learned" to *current* and *future* needs. These are commonly called *knowledge management (KM)* systems.

Here are some brief definitions:

1. *KM* is the management of intellectual capital (IC) in the interests of the enterprise.
2. *IC* includes knowledge, information, lessons learned, and other data held for use over time.

3. Intellectual nuggets (*nuggets*) are the units that carry knowledge, lessons learned, etc.
4. *Super-nuggets* are items tied specifically to express or implied needs of the organization.
5. The most valuable structure of a nugget (N) is a compound statement which has an "If x, ...then y" format: If you do this in a certain way, ... then you can achieve or avoid the following consequence(s).
6. Some nuggets are, in fact, *causal statements*, but many others only suggest strong *correlations* or *influence* of actions on outcomes (consequences).

QUESTIONS SURROUNDING KM SYSTEMS

Why does a hospital or healthcare organization need a new or improved KM system?

- To bridge knowledge "*silos*" in specialties and support functions.
- To learn from its own experiences and experiences of other organizations.
- To avoid repeating or duplicating major or even disastrous mistakes in, for example:
  - disease management;
  - infection control;
  - misuse or abuse of instruments;
  - duplication of expensive equipment.
- To support training at all levels.
- To support weaker or resource-poor units with experience from stronger or resource rich units.
- To share "tricks of the trade."
- To help avoid pitfalls in:
  - organizational design;
  - staffing;
  - work flow.
- To exchange methods of:
  - productivity improvement;
  - cost savings;
  - patient services.

Does everyone need a KM system?

- In general, *yes*, to help: organize, preserve, retrieve, and use lessons learned and other nuggets about his/her job, and the internal and external environment.
- However, there are vast differences among individuals and individual information needs and style — some people still pine for the all-but-obsolete card catalog in the public library. Others have gone "all electronic" and will never look back.
- There are also differences in the relevance and value of past experience or the experience of others.
- Although it is hard to imagine or accept, people in responsible positions may be completely ignoring lessons from the past.
- It is important that the organizational KM system is able to accommodate a wide range of individual differences and bring lessons learned across organizational lines.

Many areas of professional and staff practice have *common elements* where experience can be fruitfully codified and exchanged. Such commonalities can transcend narrow medical, healthcare, and administrative specialties. KM systems can also help transcend temporal and spatial distances in the organization and between organizations. Two such areas are: managing medical technology and medical and staff errors.

Managing Medical Technology

Application areas include computerized patient records, telemedicine, and improved utilization and management of equipment. These all provide opportunities for sharing knowledge and experience, but the pace of such sharing lags far behind the leading edge in industry and the evolving state of the art. Progress is slow toward achieving ease of use, standardization, and connectivity between databases and different record systems. A key challenge is to incorporate existing and new knowledge systems into integrated and comprehensive systems that can be used effectively and cooperatively by caregivers, administrators, payors, and regulators.

Medical Errors

Dealing with medical errors systematically requires improved codification, increased sharing, e.g., the "mortality and morbidity" sessions conducted in hospitals, but generally not recorded and disseminated.

How to Get Started

- Who should initiate a new or redesigned KM system — the role of "champions."
- The design and rollout teams — size, skills, experience, knowledge of the organization.
- How to keep it simple.
- How to get started in a modest way — not across the whole organization at once.
- Possible modest field experiments to test ideas and components of the system.

The champion should be a sponsor at a high enough level to provide credibility as well as material support — e.g., a CEO, other top manager, an operating division manager. The team should include three to six people with: (1) technical understanding of information and communication systems, (2) credibility and experience within the organization, and (3) good people skills.

How to Keep it Simple

- Don't start with a "greenfields" approach.
- Utilize existing components where feasible. All healthcare organizations have many existing information systems that might be adapted.
- Get something useful going quickly.
- Do not ignore possibly useful legacy systems.
- Design the size and "shape" to fit the existing organization — not an ideal one.
- Don't start on too broad a front.
- Select a functional or operating area with high success potential for KM.
- Design a fast prototype that can be readily rolled out to demonstrate the KM principle.

How to Get Started

- Identify information/knowledge needs and styles of key individuals and groups of potential users.
- Examine the current, if any, versions of KM in use or being developed.
- Develop metrics for assessing:
  - The operation of the KM system:
  - The impacts — immediate or direct, intermediate, and ultimate.
- Design and test a systematic procedure for the extraction and refinement of knowledge "nuggets."
- Design and test a monitoring and assessment procedure for system usage and effectiveness.

Some methodologies we have used for designing systems from the viewpoint of the users include:

1. Personal communication charting and communication flow matrix.
2. Individual information-seeking propensity profile.
3. Critical incident method — Effective and ineffective use of the system.

4. Black hole analysis — Where do key pieces of information disappear to?
5. Gatekeeper analysis — Who are the key intermediaries in searching for information?
6. Knowledge transfer and application mapping — What happened to a nugget or super-nugget in terms of application?
7. Individual and group risk-taking propensities.
8. Blame-placing behavior.
9. Bureaucratic analysis and the role of organizational politics.
10. Indicators for statistically out-of-control behaviors.
11. As to KM technology, adequate technology is in hand or on the way. The key problems in designing, installing, using, and management of KM systems are primarily human (user behavior) and organizational (politics, culture, and communication).

Chapter 5.4
Patient Centric Healthcare Information Systems in the U.S.

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

INTRODUCTION

Healthcare expenditure is increasing exponentially, and reducing this expenditure (i.e., offering effective and efficient quality healthcare treatment) is becoming a priority not only in the United States, but also globally (Bush, 2004; Oslo Declaration, 2003;Global Medical Forum, 2005). In the final report compiled by the Committee on the Quality of Healthcare in America (Institute of Medicine, 2001), it was noted that improving patient care is integrally linked to providing high quality healthcare. Furthermore, in order to achieve high quality healthcare, the committee has identified six key aims, that is, healthcare should be:

1. **Safe:** avoiding injuries to patients from the care that is intended to help them
2. **Effective:** providing services based on scientific knowledge to all who could benefit, and refraining from providing services to those who will not benefit (i.e., avoiding under use and overuse)
3. **Patient centered:** providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions
4. **Timely:** reducing waiting and sometimes harmful delays for both those receiving care and those who give care
5. **Efficient:** avoiding waste
6. **Equitable:** providing care that does not vary in quality based on personal characteristics

Most of the poor quality connected with healthcare—such as loss of information or incomplete information pertaining to patient medical records, allergic reactions that can be life threatening, or the ordering of wrong tests—is related to a highly fragmented delivery system that lacks even rudimentary clinical information capabilities resulting in inadequate information flows and poorly designed care processes characterized by unnecessary duplication of services, long waiting times, and delays (Institute of Medicine, 2001; Chandra, Knickrehm, & Miller, 1995). In addition, poor information quality is also a major contributor to the numerous medical errors that permeate throughout the system (Mandke, Bariff, & Nayar, 2003). The introduction of the Health Insurance Portability and Accountability Act (HIPAA, 2001) in the United States into this context only makes matters more complex, since it imposes a further level of convolution to the design and management of information and its flows throughout the healthcare system. The aims of HIPAA are indeed laudable, since they focus on establishing better governance structures and compliance so that healthcare information can be protected and secured; however, in practice, given the current platform-centric nature of healthcare organizations, this only serves to create further informational challenges.

Healthcare is noted for using leading-edge technologies and embracing new scientific discoveries to enable better cures for diseases and better means to enable early detection of most life-threatening diseases (Stegwee & Spil, 2001; McGee, 1997; Johns, 1997; Wallace, 1997). However, the healthcare industry has been extremely slow to adopt and then maximize the full potential of technologies that focus on better practice management and administrative needs (Stegwee & Spil, 2001). In the current complex healthcare environment, the development and application of sophisticated patient-centric healthcare systems and e-health initiatives are becoming strategic necessities, yet healthcare delivery has been relatively untouched by the revolution of information technology (Institute of Medicine, 2001; Wickramasinghe, 2000; Wickramasinghe & Mills, 2001; Stegwee & Spil, 2001; Wickramasinghe & Silvers, 2002). To address this dilemma, healthcare organizations globally require a systematic methodology to guide the design and management of their respective IC^2T adoptions, not only to be compliant with regulations like HIPAA but also to be able to capture, generate, and disseminate information that is of high integrity and quality, and thereby be both technically sound and meet the highest ethical and security standards. An integrative compliance framework is an appropriate solution strategy.

REGULATORY REQUIREMENTS

In the United States, HIPAA (2001) is the minimum governing regulatory compliance standard to which healthcare organizations must adhere. Essentially similar standards exist in other countries, for example, the EU Directive 46 of 1995 is currently being implemented throughout all EU countries, as well as revisions to this, including privacy law (675/96) (Inchingolo, 2003). These are developed by countries or respective governments within the EU to ensure security and privacy of sensitive patient healthcare information. Irrespective of which policy we look at (HIPAA or the EU Directive), the fundamental areas pertaining to compliance and security of health information are similar. A closer examination of HIPAA reveals three key elements: security, privacy, and standards for electronic submissions and exchange of healthcare information (HIPPA, 2001; Moore & Wesson, 2002).

Security

According to HIPAA, a number of security criteria must be met, not only by the housing of information but also by all electronic healthcare transactions that contain healthcare information. Some of these criteria directly affect how healthcare systems can be accessed as well as how the key healthcare players (governments, providers, payers, and patients) may interact with these systems. The HIPAA security requirements1 focus on:

- establishing trust partnership agreements with all business partners
- instituting formal mechanisms for accessing electronic health records
- establishing procedures and policies to control access of information
- maintaining records of authorizing access to the system
- assuring that system users receive security awareness training, and the training procedures are periodically reviewed and updated
- maintaining security configuration including complete documentation of security plans and procedures, security incident

reporting procedures, and incident recovery procedures;
- ensuring communication and network control, including maintaining message integrity, authenticity, and privacy; encryption of messages is also advocated for the open network transmission portion of the message; and
- authenticating data to ensure it is not altered or destroyed in an unauthorized manner.

The principal security tenets of HIPAA fall into three categories—administrative, physical, and technical—each subdivided into several subcategories consisting of multiple levers (Wickramasinghe & Fadlalla, 2004). Table 1 summarizes the major issues and levels under each of these categories.

Transaction Standards

The standards for electronic health information transactions cover all major transactions, including claims, enrollment, eligibility, payment, and coordination of benefits. HIPAA discusses two major categories with relation to transaction standards: practice standards and technical standards. The key practice standards are:

1. Health Care Common Procedure Coding System (HCPCS)
2. ICD-9–Diagnosis Codes
3. ICD-9–Procedure Codes

The technical standards focus on the adoption of electronic data interchange (EDI) using health care industry implementation guidelines and other standards such as XML and X12. Plans and providers can comply with these standards directly or via a healthcare clearinghouse (Wickramasinghe & Fadlalla, 2004).

Privacy

The final element of HIPAA focuses on ensuring the privacy of healthcare information. Patient healthcare data is sensitive in nature and must be protected from the potential and possibility of misuse or abuse. Specifically, the *Federal Register* (vol. 67, no. 157) details all the rules that must be adhered to with respect to privacy. The purpose of these rules is to maintain strong protection for the privacy of individually identifiable health information. Thus, these privacy requirements cover the use and disclosure of treatment and payment information, while creating a national standard to protect individuals' medical records and other personal health information. Specifically, they aim to:

- give patients more *control* over their health information;
- set *boundaries* on the use and release of health records;
- establish appropriate *safeguards* that healthcare providers and others must achieve to protect the privacy of health information;
- hold violators *accountable,* with civil and criminal penalties that can be imposed if they violate patients' privacy rights; and
- strike a balance when *public responsibility* requires disclosure of some forms of data, for example, to protect public health.

Healthcare providers and organizations must ensure that all their IC^2T initiatives are compliant with all regulatory requirements. For example, in the case of HIPAA in the U.S., non-compliance has major negative implications such as legal action and severe financial penalties. A framework that enables healthcare organizations to design and build HIPAA compliance (or other relevant regulatory compliance) into the IC^2T architecture then becomes an indispensable tool and a critical success factor for any patient-centric healthcare system.

Table 1. HIPAA security issues and key focus areas[2]

Security Issues	Key Areas of Focus
Security Management Process	• Risk Analysis • Risk Management • Sanction Policy • Information System Activity Review
Workforce Security	• Authorization and/or Supervision • Workforce Clearance Procedure • Termination Procedure
Information Access Management	• Isolating Healthcare Clearinghouse Function • Access Authorization • Access Establishment and Modification
Security Awareness and Training	• Security Reminders • Protection from Malicious Software • Log-in Monitoring • Password Management
Security Incident Procedures	• Response and Reporting
Contingency Plan	• Data Backup Plan • Disaster Recovery Plan • Emergency Mode Operation Plan • Testing and Revision Procedure • Applications and Data Criticality Analysis
Business Associate Contract and Other Arrangement	• Written Contract or Other Arrangement
Facility Access Controls	• Contingency Operations • Facility Security Plan • Access Control and Validation Procedure • Maintenance Records
Device and Media Controls	• Disposal • Media Re-Use • Accountability • Data Backup and Storage
Access Control	• Unique User Identification • Emergency Access Procedure • Automatic Logoff • Encryption and Decryption
Audit Controls	
Integrity	• Mechanism to Authenticate Electronic Protected Health Information
Transmission Security	• Integrity Controls • Encryption

Information Integrity and Quality

At the center of the information flows in current healthcare systems is the healthcare information system (HCIS). Not only does the HCIS connect the key healthcare players within the healthcare system in an efficient and effective manner, but it also forms the central repository for critical information such as patient medical records, billing, and treatment details. Hence the HCIS provides the underlying network structure for supporting the information flows which in turn support decision-making activities throughout the healthcare system. Healthcare procedures such as medical diagnostics, treatment decisions, consequences of these decisions, prevention, communication, and equipment usage can be thought of as iatric in nature since they are connected to treating patients (Perper, 1994). Integral to these iatric procedures is the generation and processing of multi-spectral data and information such as patient history, research findings on treatments, and protocols for treatment (Mandke et al., 2003). The patient provides key information at the time of a clinical visit or other interaction with his/her provider. Such a visit also generates other information including insurance information, medical history, and treatment protocols (if applicable) which must satisfy regulatory requirements, payer directives, and the healthcare organization's informational needs. Thus, from a single intervention, many forms and types of information are captured, generated, and then disseminated throughout the healthcare system. All this information and the consequent flows must, in addition to satisfying regulatory requirements such as HIPAA, satisfy some common integrity characteristics such as accuracy, consistency, reliability, completeness, usefulness, usability, and manipulability. In this way the information product will be truly useful and useable while generating a high level of trust and confidence in its content by the user or decision maker. Since the generated healthcare information flows across various departments and/or organizational boundaries, the challenge of ensuring information integrity is further compounded because any integrity problems will propagate with ripple effects following the same trajectory as the information itself. The consequences of poor quality information are multiplied as they propagate throughout the system, thus are not only significant but have far-reaching consequences.

Given the critical role information plays both within and between the many healthcare players, it is imperative that the information flowing both within the HCIS and between these key players must exhibit both the attributes and the dimensions of the information integrity construct, as well as satisfy the six healthcare quality aims (stated earlier).

Information Integrity

Information integrity is an emerging area that is "not just about engineering the right properties of information but it also includes sensitivity to the context in which information is used and the purpose for its usage" (Geisler, Lewis, Nayar, & Prabhaker, 2003, p. 5). More specifically it encompasses the accuracy, consistency, and reliability of the information content, process, and system. By focusing on the privacy, security, and standards aspects of healthcare information, it would appear that HIPAA implicitly assumes certain characteristics of this information product such as its accuracy and reliability. However, in practice this may not always be the case, and from the perspective of the healthcare organization, it is not sufficient to be HIPAA compliant, rather it must also ensure that the information product satisfies the principles of information integrity standards. Hence, the information should display the attributes of accuracy, consistency, and reliability of content and processes, as well as the dimensions of usefulness, completeness, manipulability, and usability (Mandke et al., 2003; Geisler et al., 2003).

Implicit in taking an information integrity perspective is the shift from viewing information as a byproduct to viewing it as an essential product (Huang et al., 1999). This requires following four key principles; namely that the information must (Huang et al., 1999; Mandke et al., 2003; Geisler et al., 2003):

1. meet the consumers information needs
2. be the product of a well-defined information production process
3. be managed by taking a lifecycle approach
4. be managed and continually assessed vis-à-vis the integrity of the processes and the resultant information

Healthcare Quality Aims

In the final report of the Committee on the Quality of Health Care in America (Institute of Medicine, 2001), six key quality aims were identified. They are listed again here for completeness. Healthcare should be:

1. **Safe:** Avoiding injuries to patients from the care that is intended to help them
2. **Effective:** Providing services based on scientific knowledge to all who could benefit, and refraining from providing services to those who will not benefit (i.e., avoiding under use and overuse)
3. **Patient centered:** Providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions
4. **Timely:** Reducing waiting and sometimes harmful delays for both those receiving care and those who give care
5. **Efficient:** Avoiding waste
6. **Equitable:** Providing care that does not vary in quality based on personal characteristics

These aims can only be negatively impacted by poor information quality, flow, and integrity. Conversely, a higher quality, flow, and integrity of information will positively impact these aims by helping to reduce the large number of medical errors that currently permeate the healthcare system (Mandke et al., 2003; Geisler et al., 2003). This is because more accurate data and information will be entered into the systems, and if erroneous data and/or information is entered, it will be identified quickly and corrected.

What becomes critical then is to incorporate these quality aims into the manufacturing of the information product so that the output is quality information. This requires the establishment of an information quality program which serves to (Huang et al., 1999):

1. articulate an information quality vision in healthcare business terms
2. establish central responsibilities for information quality within the information product manufacturing processes
3. educate the producers and consumers of information on information quality issues
4. institutionalize and continuously evaluate and develop new information quality skills

PROPOSED FRAMEWORK

Healthcare in the United States and globally is facing multidimensional challenges, including structuring efficient and effective healthcare systems that first and foremost deliver value to patients, enable-cost conscious healthcare treatments, and simultaneously support the statutory as well as operational information requirements. IC^2T is becoming a key enabler and strategy necessity for organizations, irrespective of their business sector (Haag, Cummings, & McCubbrey, 2004; Scott Morton, 1991; von Lubitz &

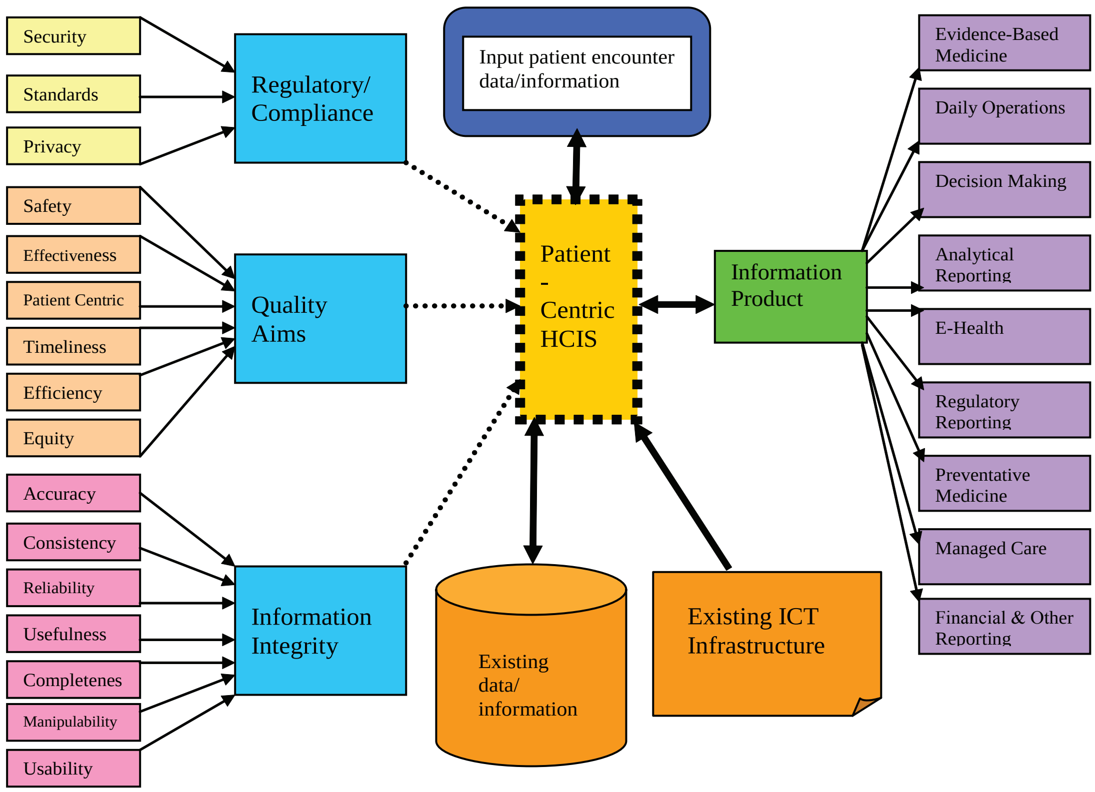
Wickramasinghe, 2005). Hence, it is reasonable to expect that HCIS in general, and e-health in particular, should be able to play a similar role for healthcare organizations; specifically these technologies should be viewed as key enablers for healthcare to meet the current challenges of escalating costs, an aging population that presents more complex treatment issues, and the need to have high-quality information and provide superior healthcare delivery. In order to systematically maximize and facilitate the full potential of such initiatives to enable healthcare organizations to cope with current challenges, it is important to have a guiding integrative framework to facilitate the design and management of robust HCIS and e-health initiatives. The following integrative compliance framework serves such a role.

The proposed framework integrates the key challenges of:

1. the three elements of regulatory compliance taken from HIPAA, including transaction standards, privacy, and security;
2. the six healthcare quality aims; and
3. the core principles of information integrity.

Further, the framework also recognizes the multifaceted nature of the key players within the healthcare system—in particular, the dynamics of their information requirements with respect to capturing, generating, and disseminating the necessary information. Moreover, the framework acknowledges the existence of other challenges such as existing IT infrastructure limitations, gathering of data/information from the patient encounter, and integrating it with (when necessary) other stored data and information. These challenges, though, are beyond the scope of this

Figure 1. An integrative compliance framework for patient-centric healthcare systems



article but are reflected in the framework for completeness. The key component of this framework is the protocols for ensuring compliance, observing the principles of information integrity, and satisfying the healthcare quality aims (Q). Figure 1 depicts the proposed framework. Finally, the framework highlights the major deliverable from the HCIS—namely, the information product and its key applications to various healthcare practices and processes.

The patient-centric healthcare information system received input of patient data at the time of the patient encounter. This information is cross-referenced with any existing data/information stored in databases and also validated using ICT infrastructure, for example, intranet capabilities. In addition the data and information are structured to satisfy regulatory and compliance standards (such as HIPAA), the six key quality aims, and the tenets of information integrity. Once this information is deemed to be correct, the resultant information product is then applied to the healthcare treatment or used to develop the evidence base. The information is input usually by a human, but is continuously corrected if required to ensure that accurate information permeates the system.

DISCUSSION

The proposed framework described above highlights the major information flows within a healthcare system. As can be seen information and data are critical to all healthcare activities, and thus the benefit of a robustly designed patient-centric HCIS that supports healthcare organizations in creating, generating, and disseminating germane data, information, and knowledge is crucial. Such a well-designed HCIS will also assist healthcare organizations as they try to address the major healthcare challenges. Ultimately, it is through having pertinent and relevant information that superior decision making can ensue, and such superior decision making is paramount if cost-effective quality healthcare delivery is to prevail (von Lubitz & Wickramasinghe, 2006). Specifically, the framework provides a useful diagnostic and monitoring tool to help healthcare organizations identify the key challenges they face regarding their healthcare data, and consequently design and/or revise the IC^2T architecture accordingly so that it takes these challenges into consideration, complies with regulatory requirements, and produces information of the highest quality and integrity. This occurs at:

1. the micro level, identifying when and how errors enter the system or if the data is in fact non-compliant with governance criteria
2. the meso level, where comparisons can occur between departments pertaining to utilization of resources and/or treatment protocols
3. the macro level, where comparisons across the healthcare organization can be made with national averages to see if, in fact, cost-effective quality healthcare delivery is occurring and where, if required, changes should be made

This will then ensure that the resultant information product will be of the highest caliber and hence support superior decision making and excellence in healthcare delivery. Given the iatric nature of healthcare procedures, the significance and need for superior information or conversely the ramifications of inferior information cannot be stressed strongly enough. It is worth noting that the framework is as relevant to existing HCIS in meeting these key challenges and refining the information product as it is to the design and subsequent management of new HCISs; hence the framework serves both as a diagnostic and prescriptive tool.

CONCLUSION

The healthcare industry is currently facing constant and relentless pressures to satisfy conflicting goals such as lower cost while maintaining and increasing the quality of service. In addition, healthcare organizations must also contend with regulatory pressures such as HIPAA compliance. In such a challenging environment, the need for well-suited and high-quality information that flows throughout the Web of the healthcare system becomes paramount. Patient-centric HCIS and e-health initiatives can be used effectively and efficiently to facilitate the information flows and consequent decision-making activities throughout this healthcare system Web. This is inevitable, given the general success of IC^2T in many business settings and the fact that healthcare is a data- and information-rich industry. What is critical, given the omnipresent and critical nature of data and information in healthcare organizations, is to take a holistic and comprehensive approach to designing a robust HCIS and subsequently effectively managing this asset.

The proposed integrative compliance framework provides a solution to the pressing problem faced by healthcare organizations of addressing the myriad of ethical, security, and informational considerations regarding their HCISs. Specifically, the framework considers the three key challenges of HIPAA compliance, the need for embracing the principles of information integrity, and the need to embrace the six healthcare quality aims. Hence, the framework provides a solid foundational step in trying to design an appropriate architecture for a patient-centric HCIS that collectively structures the key challenges facing healthcare organizations, analyzes their constituent elements, and develops protocols that attempt to ensure that not only are the data inputs into the HCIS of high quality, but also and of equal importance that the resultant information product is of a high quality and integrity. This in turn will ensure superior decision making and support excellence in healthcare delivery.

KEY TERMS

E-Health: The use of Web-based technologies, especially Internet capabilities to support healthcare delivery.

Evidence-Based Medicine: The practice of medicine where treatments and/or procedures must be justified from sound past case history or "evidence."

Health Information Portability and Accountability Act (HIPAA): Enacted by the U.S. Congress in 1996.

Healthcare Actors: All participants in the healthcare system including patients, providers, regulators, insurance companies, and healthcare organizations.

Healthcare Delivery: The process of offering treatment to patients.

ICD-9: Ninth revision of International Classification of Diseases, the classification used to code and classify mortality data from death certificates.

Information Integrity: Key tenets for ensuring that information entered or derived is accurate, correct, pertinent, and useful.

Patient-Centric HCIS: Healthcare information system centered around the patient, hence all data and information pertaining to a patient is recorded and stored together, and can be accessed and used throughout the network in a seamless fashion.

Quality Aims: There are six: healthcare should be safe, effective, patient centered, timely, efficient, and equitable.

ABSTRACT

E-learning has the potential to transform learning for healthcare and social care, supporting the aims of the NHS Plan and raising standards of care for patients and service users across health and social care. This chapter sets out a vision of healthcare and social care services in the 21st century, and a strategy for making it a reality. The authors present and discuss here the basic principles and benefits of e-learning for healthcare professionals, medical students, and patient education.

INTRODUCTION

E-learning is the use of interactive technologies to support and improve learning. It is not just about online courses. E-learning can include a range of technologies from CD-ROMs (compact disc read-only memory) to electronic whiteboards or online simulations. It should usually include some form of support, whether face to face or electronic, and can often be blended with classroom methods. It can offer learners and tutors many services, including access to resources, information, and advice. It can reduce the time spent on administration, and help with the planning, recording, and tracking of learning and development. An e-learning strategy is therefore really an aspect of a strategy for effective learning.

E-learning has the potential to transform learning for health and social care, supporting the aims of the NHS Plan and raising the standards of care for patients and service users across health and social care. This document sets out a vision of health- and social-care services in the 21st century and a strategy for making it a reality. The vision is of a health and social sector in which:

- Patients and service users have the information they need to be involved in their own care, and know that staff have the skills and expertise to give them the highest standards of care,
- All health- and social-care staff can access the learning opportunities and support they need to develop personally and professionally,
- Flexible learning is a central part of everyday work for everyone,
- The highest standards of professionalism are found throughout all occupations and communities,
- People share knowledge, resources, expertise, and good practice within and across their communities, and
- Resources are used effectively to provide lifelong learning and continuous development opportunities for all staff now and in the long term.

In the past, involvement in learning has been largely a matter of personal preference and opportunity, governed by the individual's own motivation, their seniority, the availability of suitable learning, and the support of colleagues and supervisors. Increasingly, factors such as the ones listed here mean that learning is becoming a central part of everyone's working life:

- The rapidly changing workplace
- A more competitive job market
- Increased emphasis on teamwork
- Informal learning
- Technology
- The need for professionalism

E-learning is increasingly widely used by learners in schools, colleges, and universities. It is also widely used in work-based learning and corporate education, and in industry and the public sector. E-learning is therefore a significant factor in the personal and professional development of the 1.2-million-plus people who work in the health sector, and the 1.4 million who work in social care. Clearly, e-learning is important when it comes to acquiring job-related knowledge and skills.

CAPABILITIES AND BENEFITS OF E-LEARNING

E-learning strategy sets out generic e-learning capabilities for the education sector. It is useful to look at how these could apply to health and social care.

- **Individualized Learning:** Meeting the needs of all staff, including those working in remote locations, in the home, or in small organizations, or whose work requires them to be mobile
- **Personalized Learning Support:** Exploring learning pathways and resources, finding the right courses and materials, and tracking work-based learning
- **Collaborative Learning:** Including collaboration between learners on work-based projects or action research (on, for example, national service frameworks), and supporting health informatics communities or health- and social-care interprofessional groups
- **Tools for Educators and Employees:** Support for innovation by customizing or creating learning resources or simulations
- **Virtual Learning Worlds:** Online master's classes and simulations, and access to virtual campuses or wider learning environments
- **Flexible Study:** On-demand learning, which people can access when and where they need it

- **Online Communities of Practice:** Bringing together specialist communities, practitioners, learners, community or voluntary workers, and service users and care givers
- **Quality at Scale:** Providing access to e-learning resources and services right across the sector, without variations in standards, that are linked to information, and HR (human-resource) and management systems

E-learning can offer huge practical benefits. The value of e-learning for all parties is clear:

- **For Individuals:** Freedom to develop, both personally and professionally, through accessible learning opportunities
- **For Employers:** Engaging staff and promoting a sense of ownership and involvement
- **For Managers:** Achieving business and performance targets
- **For Health Professionals:** Better collaboration and communication, and creating more development opportunities
- **For Providers:** Widening participation in learning, at work, in the community, and at home
- **For organizations:** Becoming partners in workforce-development functions and promoting knowledge management
- **For Patients and Service Users:** Getting individuals and communities involved in improving care outcomes
- **For all Staff:** Interlinking the technologies used for learning and for work

E-LEARNING FOR HEALTHCARE PROFESSIONALS

In recent years, as the demand for lectures without the limitations of time and place by those who have jobs and require lifelong education grows, there are more and more expectations on the implementation of distance learning systems (Sakai, Mashita, Yoshimitsu, Shingeno, Okada, & Matsushita, n.d.). There is a double source of demand for services: institutional and personal. Initially, the demand will basically arise from the public education system of health professionals and technicians. In this initial phase, recipients of information and courses will be of two kinds: technical staff of health divisions or institutions in every state, and managing, medical, and nursing staff of hospitals and ambulatories in individual states (Pulido & Requena, 2003).

Until now, professionals were required to take time away from their practices and personal lives to attend in-person training sessions. The introduction of an Internet-based training curriculum provides physicians with the flexibility and convenience of learning at their own pace and on their own time.

In-depth, efficient training for physicians enables them to deliver an even higher standard of care to patients. E-Learning provides physicians with the means to address their training needs immediately (Raz, 2002). The e-learning program will help participants assimilate the basic principles and practices of therapies, including patient selection, where the treatment should be positioned in the care continuum for diseases, and the significant symptoms of these diseases. The e-learning curriculum consists of modules, and some of them are free for physicians. The modules are interactive and include animation and streaming video, as well as exercises and review questions. In addition, participants receive a CD-ROM containing educational surgical or other kinds of videos, and audio programs on patient-physician communication. Finally, physicians have the option of communicating with e-learning faculty members.

E-LEARNING FOR MEDICAL STUDENTS

It is important to note that a lot of people believe that traditional training combined with a strong implementation process and coaching can create measurable results for students. E-learning can increase the retention of learned information by an additional 35% to 45% when blended with other training approaches and technologies.

Undergraduate medical students are a group of individuals who often have a list for knowledge along with the skills and opportunities to use information technology. Furthermore, as the doctors of the future, they will be increasingly involved with technology in their professional practice.

Past experience in developing e-learning packages for students learning tutorials has shown them to be powerful tools for learning as there are exciting opportunities for the use of images, video, and links to external sites or relevance. However, they are extremely labour intensive to set up and, unless created judiciously, can lead to information overload. Furthermore, whilst they are valuable for developing learning in the cognitive domain, they are less useful for improving interpersonal skills and changing attitudes (Marshall & Kirwan, 2004).

The best balance seems to be reached by providing small-group sessions with a facilitator to consolidate the subject, and to place it within the current clinical context. Furthermore, the involvement of the students in the production of e-learning packages helps to impart a sense of ownership to the students and overcome any resistance to the use of alternative teaching methods. General Medical Council (GMC) guidance on reducing the amount of information imparted to students (GMC & Tomorrow's Doctors, 2003) must be squared with ever increasing amounts of information freely available on the Internet—human contact is vital for this.

The University of Hull's School of Nursing, Social Work, and Applied Health Studies has developed an interdisciplinary, part-time module called Facilitating E-Learning in Health and Social Care Education and Practice to provide health- and social-care professionals involved in education with the opportunity of considering how they can integrate e-learning into their practice and teaching. A major step in implementing the university's e-learning strategy within the school has been to implement a virtual learning environment: an integrated set of electronic teaching tools that are available to students and teachers online, allowing information transfer, learning-material delivery, and communication through e-mail, discussion, and chat to support student learning (Santy, 2003).

The module has the potential to attract students not only nationally, but also internationally because the module can be delivered at any time to any place with an Internet connection. E-learning can make these students more independent and lifelong learners. New technology has been transforming the way we think about education in health and social care, and the increasing use of technology in practice settings.

E-LEARNING FOR PATIENT EDUCATION

GeneEd develops new e-learning systems for patient education for major pharmaceutical clients. As the leading provider of advanced e-learning solutions for the life-science industry, it announced that it has extended its e-learning curriculum to span all subject areas, from drug discovery and molecular medicine to patient education.

The GeneEd patient-education curriculum that was announced (in addition to the over-100 therapeutic courses released over the last two quarters) represents a significant expansion of GeneEd's product line. GeneEd products are extensively used in the research, development, and sales divisions of major global pharmaceutical organizations. In combination with the soon-to-be-released regulatory and compliance curriculum, the patient-education program greatly enhances the GeneEd product portfolio to address all of the mission-critical training needs of modern life-science organizations. As the role of molecular medicine broadens its reach within pharmaceutical organizations, employees, physicians, and patients alike are required to absorb the complex scientific and medical issues this new science brings. GeneEd is the only organization providing validated e-learning across the spectrum. These techniques range from genomics and proteomics, through disease states, all the way to physician and patient education. GeneEd is utilizing its award-winning, proprietary Repurposing™ and Viewing™ engine technology to offer compelling, intuitive, and effective e-learning to some of the most demanding users of information: everyday patients trying to better understand their diseases and the therapeutics that may help them (Patel, 2003).

Patient-education e-learning courses empower physicians, allied health professionals, and patients alike with the knowledge critical to the understanding of diseases and the therapeutic regimens used to treat them. E-learning courses are actively responding to the ever-changing training needs of the life-science industry, and the introduction of this new patient-education curriculum reiterates the strength of our science-focused curriculum design.

DISCUSSION

While there are clearly many benefits and advantages to e-learning, we also need to take into account the barriers, challenges, and disadvantages associated with it. These include high development costs, barriers to access for disadvantaged learners or those with disabilities, and the misconception that online learning is a solitary and unsupported activity. It is particularly important to address any barriers relating to potential users so that e-learning really does benefit all target groups. To gain full benefit, we will need to take steps to guard against a potential digital divide by addressing both access and skills. We also need to achieve the right balance between e-learning and traditional methods. While e-learning can make a powerful contribution to large-scale engagement in learning, as well as the tailoring of learning to individual needs, it should not and cannot replace all other approaches to learning. An e-learning strategy should be one aspect of a wider learning strategy.

CONCLUSION

E-learning is developing rapidly worldwide. Any strategy will therefore need to have an international dimension so that e-learning for the NHS can be genuinely world class. We may need to harness international knowledge and best practice, and use research to benchmark NHS e-learning against the very best globally. Furthermore, with the increasing pace of globalization, learning resources and opportunities that originate abroad will increasingly be available, and health and social care will require systems that are compatible and interoperable with those in use in other fields at home and abroad.

E-learning is not an end in itself, nor is it a marginal activity related only to online courses or distance learning. It will increasingly embrace all aspects of learning and will therefore form a fundamental part of how people will learn in 10 or 20 years. Although we cannot predict exactly which technologies or which models of learner support will be most widely used, existing examples of leading practice, whether in the United Kingdom or elsewhere in the world, provide some indications. These examples, as well as alternative scenarios, should inform the emerging e-learning strategy for health and social care.

KEY TERMS

CD-ROM: High-capacity optical storage medium.

Distance Learning: Learning in which students and instructors are separated by distance or time.

E-Learning: A wide set of applications and processes including Web-based training, virtual classrooms, digital collaboration, and computer-based training.

Face to Face (F2F): Students and teachers are in the same location at the same time.

Internet-Based Learning or Training: Courses delivered via Internet technologies (these were text based before the Web).

Learning Networks: Communities of learners connected via computer networks.

Learning Objects: Course materials developed according to a standard (e.g., IMS) that allows the easy sharing of materials. Materials are modular and can be used for a variety of purposes and outputs.

Online: Connected to a computer network.

Online Community: Learners who, although separated by distance and time, share a common experience.

Online Conferencing: Communications happening over a network. They can be synchronous via chat or asynchronous via discussion groups.

Web-Based Course (WBC): Distance education course materials supported by computer-mediated communications and delivered asynchronously via the World Wide Web. Ancillary materials such as print, videos, and CD-ROMs may be required.

Chapter 5.6
Fostering Meaningful Interaction in Health Education Online Courses:
Matching Pedagogy to Course Types

Richard G. Fuller
Robert Morris University, USA

Gary Kuhne
Penn State University, USA

ABSTRACT

This research study examined the best interactive practices of effective health care education faculty from six major universities that offer online health care programs. Program directors from six major universities identified effective faculty, from which twelve faculty members were interviewed to uncover effective practices and an additional thirty faculty participated in a Delphi study to identify and prioritize effective practices. The findings for this study indicate that different types of facilitation approaches are needed to generate adequate interaction in four distinct types of health care courses, i.e., foundational classes, skills classes, analysis/synthesis classes, and hybrid type courses.

INTRODUCTION

Wlodkowski (1999, 1985) suggests that effective instructors must have expertise, empathy, enthusiasm, and clarity, a conclusion that is relevant whether the teaching takes place in traditional face-to-face settings or in online formats. Interaction with the student is a central factor in demonstrating each of these elements. Effective instructors have discovered interactive practices that work well in face-to-face classrooms. The challenge for online instructors is to discover how to replicate effective interaction practices within the online, asynchronous learning environment. As with traditional face-to-face teaching, there are methods and techniques that work in some venues and not in others. Strategies that foster effective interaction in an engineering classroom may not offer the same efficacy in a healthcare program. Effective teachers are willing to explore why certain interaction techniques work and don't work in order to discover the most effective techniques for their particular educational programs.

Knowles (1999, 1980) and Rogers (1969) argue that adult education teachers serve as facilitators, providing the resources to enhance and facilitate the self-directed learning opportunities of their students. Such an understanding of the role of instructors is particularly pertinent to the online asynchronous arena of higher education systems, where educators must design a variety of courses for a variety of learners. Effective instruction requires that teachers understand the changing needs of their learners based upon the nature of the educational program. In other words, an effective instructor does not approach each learning situation with the same pedagogy and style. Different styles of course require different techniques to facilitate success learning. Knowles (1980) suggests the specific learning needs of the particular participants of a given learning activity must be diagnosed. Understanding the unique needs of different university and college programs at graduate and undergraduate levels in different disciplines will go far toward enhancing interactive teaching practices online. Regardless of the mediated nature of the communication, "It is the teacher's responsibility to precipitate and facilitate learning that has purpose and is focused on essential concepts and worthwhile goals" (Garrison & Archer, 2000, p 48.). Adults and distance-education students relate in an interactive collaborative construction of knowledge, a system that typifies many of the concepts of adult education theory (Anderson, et al., 2002). The dilemma facing online instructors is how best to accomplish the designing, facilitating, and guiding of a predominantly text-based learning arena to best foster the different levels of interaction required for learning success.

BACKGROUND

In conducting online teaching, interaction needs to be planned to facilitate learning. Vrasidas and McIsaac (1999) found that structure can affect interaction, and concluded that educators need to design courses to foster learner-to-learner interaction and dialogue. Kozma (1991) agrees with the need for less structure and more dialogue and suggests that learners should actively collaborate in order to construct knowledge rather than relying solely on knowledge gained from direct instruction. For such collaboration to occur, learners must feel a sense of connectedness with the group (Gibb, 1995).

Howland and Moore (2002) found that when students initiated interaction with instructors and other students, knowledge was often built spontaneously, such as through students guiding the direction of discussion-board threads. Such student leadership then led to positive results for others. One student said, "Several times, I have seen questions asked by others that had not even occurred to me to ask and the answers benefited me" (p. 188). Swan (2001) found that students with higher levels of interaction with their classmates through online discussion also reported higher levels of learning and satisfaction from courses. Rovai and Barnum (2003) also found evidence that student perception of learning from online courses was positively related to course interaction, lending further support to the need to provide opportunities for online students to learn by active interaction with each other and with instructors. Effective online instructors develop highly interactive material and facilitate participation in online discussions. Rovai and Barnum also suggested that passive interaction, analogous to listening to,but not participating in, discussions, was not a significant predictor of perceived learning in the present study. Consequently, using strategies that promote active interaction leads to a greater perception of learning and higher levels of learner satisfaction.

Beaubien's research (2002) described instructor characteristics that contribute to effective online courses. Students need to feel that the instructor is online regularly. The instructor does not need to be intrusive to the online dialogue but his/her presence needs to be known. Short postings are good for the most part but the teachable moment should be capitalized upon to provide sufficient information and clarification as is necessary. Sometimes the instructor can pose questions that will stimulate or lead the discussion in a direction. Instructor modeling of a high level of presence sets a positive norm for the class and encourages students to do the same. Moore (2001) suggests that instructor interaction should have the goal of establishing a culture of independent learning and peer participation. Positive instructor feedback tends to bring out the best in people and motivate them to invest discretionary effort (Braksick, 2000; Daniels, 2000). Positive instructor feedback can energize the learning system and increase interaction frequency.

Vrasidas (1999) examined the conceptual framework of interaction in online courses and found that the factors influencing interaction were learner control, social presence, structure, feedback, and dialogue. In a follow-up study, Vrasidas and McIsaac (1999) found that each of these factors has specific implications for teaching practice. For example, activities can be structured to increase interaction with the instructor, other students, and the course content. Discussing a paper outline with an instructor; collaborating activities with peers, and participating in required online discussions were found to increase interaction among participants. This study, not unexpectedly, found that higher-than-expected workloads contributed to decreased interaction. Thus, the appropriateness and on-task time of course requirements must be suitable to facilitate online interaction.

PURPOSE OF THE STUDY, HYPOTHESES, AND QUESTIONS

The purpose of this study was to investigate the interactive practices of effective online health care graduate and undergraduate instructors as gleaned from the experience of successful faculty. This study focused on understanding how the online teaching technologies in the courseware of an Internet portal system were being employed to promote interaction. The goals of this research study were: (a) to better understand the phenomenon of successful online computer-based education in graduate and undergraduate healthcare education through the identification and description of online educational constructs that exemplify effective interactive practice, (b) to better understand how effective distance educators in health-care education utilize the innate capabilities of online courseware to support interactive constructs, and (c) to better understand what techniques and strategies faculty employ to foster and facilitate the sense of interaction. It was hypothesized that effective faculty employ certain methodologies, practices, and mindsets in planning and active teaching phases to promote interaction when utilizing online courseware. The research asked what successful online distance education faculties do to make their teaching more interactive, and do they use different approaches to generate interactivity in different situations.

The Study or Methodology

The research design for this study involved a triangulated three-tiered process. The first phase was to identify graduate and undergraduate health-care faculty from major university schools of nursing and health professions who provide effective interactive education that fosters learning. Potential faculty were identified by program directors from six university health education programs (The University of Pittsburgh, George Washington University, West Virginia State

University, West Chester University, University of Maryland, Baltimore County (UMBC), and Drexel University), who based their identification on the criteria that the instructor, (a) promotes a high level of student-to-student interaction through threaded e-mail and discussion-board activities as well as other activities that allow learners to construct or formulate an idea in a deeper sense, and raises the interest and motivation of the students, (b) the instructor promotes a high level of student-to-instructor interaction through both quantity and quality of assignments that maximize the impact of interactions, and (c) the instructor promotes a high level of student-to-content interactions through offering a variety of activities and resources that offer students a variety of alternatives for learning.

The second phase, utilizing the program director's listings, involved interviews with twelve (12) selected faculty from the list developed in phase one. These instructors were requested to participate in phenomenological interviews, either face-to-face or by telephone to establish trends and common themes in effective online instruction.

The third phase of the research involved taking the 12 phenomenological interviews and synthesizing the results to create a Delphi questionnaire for use with an experienced group of 30 faculty members drawn from the list developed in phase one. Trends and common threads were identified to assist in categorizing the data. To assure that all common themes and trends were identified, a second evaluator was utilized to assure inter-rater reliability. The questionnaire was operationalized following the Delphi Technique with the 30 additional faculty. This tool allowed a group of defined experts to come to a consensus of opinion when the decisive factors were subjective, and not knowledge-based. Through a series of questionnaire exchanges, the experience group identified additional ideas through individual brainstorming and communicating ideas with the investigator to clarify and validate the findings from the previous questionnaire. Questionnaires were exchanged through e-mail to maximize efficiency and minimize time associated with conventional mail. A series of three exchanges with progressive fleshing out of ideas as well as generation of new ideas beyond those attained through the phenomenological interviews was facilitated. It was determination after the third questionnaires that no new ideas had emerged.

Limitations

The attempt of this research was to capture interactive fundamentals of practice among health care online educators. It is acknowledged that in the context of the interview, that some may have issued their espoused theory and not their actual theories in use (Argyris, 1999). Argyris suggests that people consistently act inconsistently, unaware of a contradiction existing between their espoused theory and their theory-in-use (what they actually do in the practice setting). Despite this possibility, participants offered what they envisioned as the most effective pedagogies to maximize interactivity in online health care programs.

It is further recognized that one of the limitations of this study is that the definition of effective practice is based upon the single lens, or perspective, of the identified instructors. This research did not take into consideration student perspectives of effective practice. This research also relied upon the identification of effective faculty from the perspective of program directors who based their recommendations upon a provided set of criteria.

Interview Findings

The 12 faculty members interviewed suggested that different types of courses require different types of facilitation to generate effective interaction. As one instructor for this study stated:

There are different types of courses, such as the hard sciences classes versus the social science classes. There may be classes such as skills classes, such as a clinical class, or a research class where students need to leave with a skill. There may be social science or discussion/opinion classes that take information and apply it in different situations. This is both online and in the traditional courses. There is a big difference. At times the conceptual pieces in putting things together as opposed to the nitty-gritty facts and research and data collection are trickier to do. The relating this in the everyday life can be more difficult and more challenging.

Four types of courses were distinguished, including foundational classes, skills classes, analysis/synthesis classes, and hybrid type courses.

- **Foundational or rote memorization courses:** Such courses provide the foundation or knowledge that will be used to build upon in other courses. The prioritized interactions in such courses focus on helping the student make more "student-to-content" connections. As one instructor from this study stated, "In the foundational course, you either get it or you don't." Foundational courses include courses like anatomy and physiology, pathophysiology, medical economics, and the business of health care. Many of the assignments in such courses are e-mailed weekly based upon module content to assure interaction with the content and understanding of key concepts. Some "student-to-student" is fostered, primarily through having assignments shared and discussed on discussion boards, something that does not routinely happen in a face-to-face classroom. As one instructor stated:

Health Care economics is a foundational course (not all economics courses are this way). In this course it is more of the memorization and regurgitation that is important. I can't ask them to compare and contrast John Maynard Keyes to Karl Marx because they are not there yet. I facilitate this differently than an upper level class. I use more discussions based upon the facts. They come into their first class and think that they understand this stuff. They think that they have all the answers. But they give what I call, "man on the street" answers. I have to remember that what I am doing here is building a "foundation." This type of course and a rote memorization course is foundational for other courses.

Such interactions are not generally open-ended and are designed primarily to reinforce the memorizing of basic concepts that will be applied later in their professional studies and practice. For example, an online nursing student may not understand all the reasons for memorizing anatomy and physiology, but will come to understand better the value of such memorization as the anatomy and physiology facts are applied in future courses.

The faculty interviewed believed that while foundational courses do not innately lend themselves to great online discussions, providing interactive e-mailed assignments, more instructor presence for Q & A, and instructor interaction in discussion boards helps to foster meaningful learning interactions with such courses.

- **Skills based courses:** Such courses require students to gain a particular skill(s) set that is applicable to a specific environment. The prioritized interactions in such courses focus on content, however, and expand beyond "student-to-content" connection, requiring instructor facilitation and presence to promote dialogue specific to the skill and the application of the skill. Instructors facilitate critical thinking and understanding of the concepts through the skillful use of questioning, such as "if we did this what would happen" or "how could we do this if…?" or "Great idea. Does anyone have any other directions?" Examples of such skill-based courses would include Nursing Research, Medical Informatics, and Patient Assessment. Skills classes such as Nursing Research or Health Education Research should be project-based, as students need to flesh out ideas and application of concepts. Interaction focuses on how and where to perform the skills as well as facilitating students toward a finite answer and how they get that answer (example: Identifying research questions). As one instructor stated:

Part of my goal is that I want them to understand the complexities of research and how you work with other people, so I do include a group project into the course. I believe that you learn from your peers. There is a skill set in how do you develop a proposal, how do you interpret statistics, how do you design research. The goal isn't to make them an expert when they are finished but to give them a set of skills that they can apply.

Another example drawn from an instructor teaching a Physical Assessment course:

I found teaching Physical Assessment online a difficult course to teach online because there is, or should be, so much hands on, and if you teach it in the classroom there is. So it is very difficult to deliver the physical assessment content Web-based because there has to be a video portion. The student has to be able to see how you percuss (thumping of the different body areas to determine if air or fluid is present), what the assessment of the abdomen looks like, and one of the big issues that we have is not bandwidth on our end at the university but among the receiving students. So I can decide to send them this fabulous thirty-minute clip, the best I've ever seen, and they are not going to be able to download it if they don't have the technical capabilities. I have to make a decision about how much information I can chunk into a block.

Assignments that facilitate student-to-content interaction in a skills-based class are weekly assignments that are e-mailed back to the instructor to assure that they are interacting with content and understanding it. Interaction with students and instructor focuses on the processes that they are going through in learning the content.

- **Synthesis/Analysis Courses:** Such discussion-based courses are used to teach students to analyze a situation and engage in problem solving. Instructors find that authoritative postings tend to shut down dialogue or that students simply parrot instructor ideas or postings (most students do not want to challenge instructors and risk receiving a lower grade). Dialogue among participants provides regular opportunities for reflection and inquiry and requires the least intervention in the discussion boards of all the course types. Simulated interaction in this manner through subject matter presentation can subsume part of the interaction by causing students to consider different views, approaches, and solutions and generally to interact with a course.

These are courses where core information is presented but there is not necessarily a right or wrong view. An example may be an Issues in Health Care, Health Care Policy, or Nursing Practice course where a module or lesson would focus on "Compare the value of the Canadian versus the USA health systems." This is the type of course or topic that will prompt many opinions and views. The key is to flesh out all angles of the subject and have the students explore and support the differing viewpoints with the facts. For the instructor in this type of class, the key was not to intervene too much. As one instructor stated:

I've found that if I post my particular opinions about a topic, then I change the discussion in that students stop posting or they just restate *my opinions. I think you have to be very careful. What I do is post more personal experience than personal thoughts and beliefs. You have to control that and it can be very difficult. You have to post more with "what I've found is." Any time you give them a clue on which direction you lean the majority of the class is going to lean that way too because they want a good grade too. So you need to be very careful how you do that. I think that if you come down with a very dogmatic statement then you shut them down as people don't want to be wrong. They are still learning and fleshing out their own thought processes and if you post too much you shut down their thought processes or they may not agree but are not willing to take this instructor on.*

There is a need to establish the culture of independent collaborative learning. Instructors do not respond to the majority of postings in this type of course but read them all and respond to key ideas and elements and, through additional questions, guide the learning process. If the discussion is getting one sided or negative, the instructor can, through a posted thought, direct the dialogue to view all sides. "That is true but what would 'so and so' say regarding this and why?" One technique in this type of course is to create an online debate where students don't get to pick but defend an assigned point of view, which forces them to see all sides. In a Nurse Practice course, one technique reported was that students were facilitated to choose a topic, interview someone, and then write a paper and discuss their issue and what they have found by leading a discussion-board thread.

- **Hybrid Courses:** Such courses have a combination of the above three and require a mixing of techniques to facilitate interaction. An example of this may be a Health Care Management or Leadership course where there is specific theory to understand and employ but also where you want students applying and understanding their own personal leadership style in different situations.

THE DELPHI FINDINGS

The Delphi process suggested that interaction strategies vary according to the type of course. Those participating in the Delphi component agreed with the majority of the interview findings, and in many cases further elaborated on the four types of course offerings.

Foundational or Rote Memorization Courses

It was agreed that while these types of courses don't generally lend themselves to great online discussions of the material, the interaction generated was centered on assisting students with learning the content material. It was also believed that a greater instructor presence was necessary so that some students don't have the feeling of learning alone or in a vacuum.

Skills-Based Courses

It was agreed that the interaction in a skills-based course is centered on the content, and that interaction was again used to make connections between content and skill application. This type of course was again found to require more instructor presence for students to gain the skill, and that the instructor's role was to generate thinking and a better understanding of the concepts. A majority of the Delphi participants utilize the weekly assignments format for a skills class. The concept of forcing a student-to-student interaction just for the sake of having one was not described to be effective. One instructor stated: "Certain topics don't lend themselves to meaningful discussion. Having a discussion assignment because there should be student-student interaction is not effective, does not facilitate mastery of the material, and frustrates the students." Another articulated that: "Instructor interaction in this type of course takes a lot of instructor facilitation and takes on a greater role with telephone follow-up when they are having difficulty in understanding concepts."

Synthesis/Analysis or Discussion-Based Courses

It was agreed that in these types of courses, the free flow of ideas monitored and facilitated by the instructor is the best technique. This requires that the instructor monitor carefully, and he or she must be diligent in fostering good online dialogue about the topics at hand. In this type of course, a majority of instructors reported using a "search and report" technique, where students go out and research a topic and then report back as a catalyst for generating good discussion boards. Additionally, instructors reported using weekly discussion board topic questions based upon the readings and students' own research to generate discussions. The instructor would monitor and then post as was appropriate to guide, stimulate, and assure good dialogue. As one instructor stated: "In my nurse practice course they will choose a topic and go interview someone and then write a paper and discuss their issue and what they have found by leading a discussion board thread."

Hybrid Courses

It was agreed that there are these types of courses but not all agreed on which type of course was in which category. Some reported that a research course was felt to be a skills class while others felt that it was a hybrid class where multiple techniques are employed. It becomes less of an interest to this research to categorize courses as it is to understand that there are different courses that may need facilitation using different techniques differently to maximize the online learning.

CONCLUSION AND DISCUSSION

One of the more significant findings in this research is the identification and confirmation that different types of courses require different types of facilitation to generate interaction. The four types of courses in the health-care educational systems (foundational classes, skills classes, analysis/synthesis classes, and hybrid type courses) require the employment of specific facilitation techniques on the part of online instructors. This finding has implications for interactive design and online teaching.

Foundational or Rote Memorization Courses

The interaction in this type of course is more focused on providing a greater understanding of material to serve as the basis for future learning. The central focus here is on student-to-content interaction. Health care programs have innately established a framework of knowledge and skill that serves as a foundation for future learning. The information learned in a Medical Terminology course is the building block for an Anatomy and Physiology course. The knowledge gained in these courses serves as the universal knowledge for the rest of the health care clinical education, whether in nursing or any other allied health field. These courses are typically very structured in nature and require the instructor to clearly articulate the material for ease of consumption by the learner. The learner of online foundational material must be independent in learning the material but, as with a face-to-face class, the interaction is designed to assist the learner to that end. Carnwell's (1999) concept of developing internal dialogue is supported here. His research indicated that the students in this situation desire more highly structured materials. Design of text materials is also important since the level of structure within the text may create either independence or dependence in students. Jones and Kemper (1994) suggested that independence can be fostered by requiring students to use self-study packages in an unsupervised manner.

Instructors need to design interaction that is more finite in assisting participants to understand the material. This interaction takes its form in assisting students to learn and memorize the material, to see how it all fits together. The design of the interaction is seen through e-mailing assignments to the instructor for feedback and assistance in learning the key objective elements of the foundational course. While this type of course does not lend itself to great online discussions, but is more focused on learning the concepts, it is also paramount for the instructor to practice a greater presence that provides the student with a sense of contact with the instructor (Townsend, 2002; Kanuka, Collett, & Caswell, 2002; Beaubien, 2002).

Skills-Based Courses

The implications of the research suggest that instructors need to design their interaction in this type of online course to assist students to gain the skills necessary to function in the particular health-care environment. Effective interaction requires designing discussion board activities to present applications and allow students to see other's work and learn from each other toward the final goal of attaining the skill, whether it is learning the physical skills of chest percussion, or lung sounds (where there are significant limitations), or the mental skills of designing and conducting medical research, or the skill of learning database construction and manipulation in a medical informatics class. The ability to demonstrate competence for the physical skills innate to health-care practice is one that has significant limitations in the current online environment within the present available technological structures, and assessment of competency often requires a face-to-face environment with credentialed professionals. The implications for the design of interaction are for the instructor to use a more facilitative role to assure that student-to-student interaction is being assisted here toward applying the information from the class to the field. Kennedy (2002) supported this premise as he suggested that learner-to-learner interaction is a valuable part of the online learning experience and that the distance education format is particularly well suited to engaging students in this type of interaction. These discussions can be deeper and more reflective, covering a broader range of issues that assists students to gain the skills taught in the course. Encouraging greater interaction among learners not only enhances student learning and application of the new skill set, but also places the instructor in a more supportive, facilitative role, which results in more efficient use of instructor time (Udod & Care, 2002). Instructor interaction in this type of course needs to take on greater monitoring of the learning, and the utilization of personal e-mail contact and telephone conversation may assist with students having difficulty in understanding concepts.

The interaction to facilitate these skills in online teaching needs to be planned to include learner-to-learner contact to assist students to learn from each other in how they design and apply the skills discussed above. Vrasidas and McIsaac (1999) supported this finding, as a need for educators to structure for dialogue including learner-to-learner interactions was found important. Kozma (1991) supported this premise seeing the need for more dialogue by visualizing learners actively collaborating with the medium to construct knowledge and skill.

Synthesis/Analysis Courses

The implications for these courses are for the instructor to understand that there may be multiple views of a situation that require exploration by the participants to fully realize the depth and breadth of the concepts. The obvious nature of these types of courses is for students to explore all aspects of the topic and then draw conclusions based upon the information presented and explored. The online instructor in this type of course must take care not to be too authoritative, as stated above, otherwise he or she will shut down the exploration and the insights that can be gleaned from students interacting and dialoguing about opposing viewpoints. Instructors will find that taking an authoritative stance and letting participants see their opinions on an issue will close dialogue, or they will find that students will simply repeat or "parrot" the instructor's view on the issue. This is in direct conflict of what the instructor may wish to accomplish by allowing students to analyze and synthesize all views of the problem or issue. Dialogue among participants provides regular opportunities for reflection and inquiry (Wesley & Buysse, 2001) and requires the least intervention in the discussion boards of all the course types. Simulated interaction through subject matter presentation in pre-produced courses can subsume part of the interaction by causing students to consider different views, approaches, and solutions and generally to interact with a course (Holmberg, 1999, 1989).

Hybrid Courses

Courses that reflect a combination of the above three forms require a mixing or blending of techniques to facilitate interaction. The advantage for an online instructor is to be aware of the first three types of courses and the methodologies that are effective in facilitating those types of courses, and then applying that on the micro-application level for the hybrid course.

If we frame the curriculum in the context of the four different types of courses, then we provide a better opportunity in the planning phases to maximize the learnings, as we are focused on the goals and best structure for interaction given the different types of course limitations and opportunities available in the online courseware. Knowlton (2000) believed that learning and teaching are reconceptualized in the online course to allow maximum independence among students by framing the curriculum and student interactions through the providing of resources and opportunities. Framing is used to facilitate students' desire to develop and implement shared goals in making connections with the curriculum. Students must be able to find space for their own inquires and needs within the assurance of a well-planned, content-rich, and flexible learning environment with adequate navigational tools and support systems (Vandergrift, 2002). This type of in-depth planning is more demanding and time consuming than the traditional classroom planning. A classroom teacher can draw upon his/her innate knowledge and platform skills to provide an impromptu lesson structure that cannot be duplicated in the online text-based arena. Vandergrift demonstrated the need for a deeper understanding of the dynamics that online teachers apply to the deliberate acts of design and interaction that facilitate successful courses.

Visor (2000) supported this as faculty serve to design and conduct a course, which is positive for student learning outcomes and serves to maximize the learning opportunities the same way that faculty foster learning in the traditional setting. They prepare and organize content according to well-established and communicated objectives, consider methodologies, which will assist the student to achieve the objectives in an online format, and be cognizant of time that the student will need to spend on the course. Wright and Thompson (2002) support this, as faculty establish a pedagogical strategy and begin to understand how online activities will occur in their discipline for maximum learning, and that faculty create templates in which they can insert their specific academic content. The four types of courses identified in this study have different goals and objectives for learning outcomes. Instructors need to facilitate interaction specific to the needs of the students in the confines of these course types.

The innate properties of the course shell portal allow options for organizing the pedagogy of an interactive course. This also becomes part of the consistency described to establish a "think-forward" type of lesson. The shell portals have innate properties built in that provide a "think forward" consistency of structure that becomes a comfort for students if interaction is designed consistently by the instructor. If the online course facilitates interactions in the nature described in this study, the constructivist and andragogical models of learning predict that successful learning is likely to result. These models require students to create their own meaning to knowledge in a self-directed manner and take more responsibility for their own learning (Knowles, 1999, 1980). This is not to say that the courseware becomes limiting but, as with the traditional classroom, there are confines of what can and cannot be done successfully. The innate properties of the course shell portal allow options for organizing the pedagogy of an interactive course and provide a level of flexibility to allow instructors and designers freedom to explore a number of pedagogies. Instructors need to be open to exploring new pedagogies that require different thinking.

FUTURE DIRECTIONS

Insight into establishing some of the best methodologies utilized in each of these types of courses would assist online instructors to establish the interaction that is employed and how best to maximize the competencies attained by students. Applying the practices used in the four types of courses would further establish a number of pedagogies that would work in different online health-care educational settings and may open the door for more nontraditional online courses to be offered. Brooks (1999) suggested that curriculum should be examined to determine how technology fits. Using technology, we should identify content that is technology neutral, technology driven, and technology enhanced. Salmon (2000) identified the teacher in the role of e-moderator as the key ingredient for effective teaching and learning online. It is the instructor who is the driver of the technology, given the differing nature of the four types of courses found in this research. Providing online educators with greater insights as to the application of pedagogies in different courses will assist them to create more effective online learning environments and help their students learn the true benefits of online learning communities as established from interactive practice priorities. Until now, there are those who would only see certain types of courses being taught online. With the identification of these four types, and the methodologies that can be employed, additional insights will assist the less traditional online course (clinical-based skills courses) to be opened to this technology.

Applying Holmberg's (2003) conversational theory to the four types of online health-care courses taught will assist in further understanding the dynamics of the interaction required to facilitate learning. This application will aid in offering insights to the pedagogies which promote learning in each of the four course types and the dialogue necessary to promote the interaction. Carnwell's (1999) dialogue is much more than merely transmitting messages to students about requirements of courses. Curriculum planners of distance education programmers and materials designers need to devise a balance of internal and external dialogue which allow students with different learning style preferences and approaches to gain the maximum from their learning experiences. MacDonald (2001) suggests that there may be particular times when extra formative feedback is of particular importance to students. Additional research is necessary to understand the balance of internal and external dialogue and the feedback necessary to maximize the learning opportunities in the four different types of courses.

ABSTRACT

Computer-based learning has been developed for the beginning medical student and the experienced practitioner, for the lay person and the medical expert. There are many advantages to online and computer-based learning when compared to traditional face-to-face courses and lectures. Information technologies are providing new opportunities for linking medical schools around the world for sharing computer-based learning materials. In this chapter, the authors present examples of actual programs that are being used to support medical education for each of these categories of learners.

INTRODUCTION

Information technology is an increasingly important tool for accessing and managing medical information: both patient-specific knowledge and more general scientific knowledge. Medical educators are aware of the need for all medical students to learn to use information technology effectively. Computers can play a direct role in the education process; students may interact with educational computer programs to acquire factual information and to learn and practice medical problem-solving techniques. In addition, practicing physicians may use computers to expand and reinforce their professional skills throughout their careers (Shortliffe & Perreault, 2001).

The application of computer technology to education is often referred to as computer-assisted learning (CAL), computer-based education (CBE), or computer-aided instruction (CAI).

Computer-based learning has been developed for the beginning medical student and the experienced practitioner, for the lay person and the medical expert. In this article, we present examples of actual programs that are being used to support medical education for each of these categories of learners.

TYPES OF COMPUTER-BASED TRAINING

There are four levels of computer-based training (CBT), each based on the application's complexity and its level of interactivity with the user (Dulworth & Carney, 1996):

- **Level I. Customized Linear Presentation:** Training similar to a standard PowerPoint overhead presentation with little interactivity
- **Level II. Instructor-Led, Nonlinear Presentation:** Training by a facilitator accompanied by navigation through the information on a computer without the use of multimedia
- **Level III. Facilitator-Led Training:** A multimedia presentation accompanied by classroom-based training
- **Level IV. Self-Paced Training:** A multimedia presentation that trainees use independently with minimal assistance (also known as stand-alone training). Individuals can train at their own pace, either at an outside lab or on their own desktop computer, and complete the exam provided in the program.

Levels I, II, III, and IV are the types of computer-based training that would be most effective in addressing performance gaps among international health workers. To qualify for these levels, a computer-based training program must meet the following commonly accepted criteria (Dickelman, 1994).

- Be easy to enter and exit
- Provide a simple way to move forward and backward (i.e., from screen to screen)
- Be consistent in its key conventions
- Offer context-sensitive prompts and helps
- Provide tracking feedback (e.g., where have I been? Where am I now? How much more is there to go?)
- Offer bookmarks (i.e., quit now, resume later)
- Always offer a way out

COMPUTER-BASED TRAINING IN HEALTHCARE

In the health setting, CBT can be delivered in a preservice or in-service mode, as follows:

- **Preservice Training:** Computerized training delivered in health-education, nursing, and medical-school curricula through the use of software tutorials with or without professor facilitation, followed by examinations programmed in the computer program or given by an instructor
- **In-Service Training:** Health workers use CD-ROMs independently on their own computers for stand-alone training, meet at a computer lab where facilitator-led courses are coupled with the computer program, or attend the lab according to their own schedules and review the materials at their own pace

Research has shown that computer training is particularly well suited to visually intensive, detail-oriented subjects, such as anatomy and kinesiology. This is because it allows text to be combined with still and moving graphics, with the display of this information controlled by the learner (Toth-Cohen, 1995). For example, computers can be particularly effective in presenting the following (Phillips, 1996):

- Subjects that are difficult to conceptualize, such as microscopic processes
- Material that is three dimensional and difficult to visualize on traditional two-dimensional media such as books or whiteboards
- Simulations of expensive or complex processes, where the mechanical details of performing the process or the impossibility of using the real equipment may hinder understanding

BENEFITS OF COMPUTER-BASED LEARNING

Students may be learning more from using their computers than from attending lectures, according to a study published in July 2004 at studentbmj.com (http://www.studentbmj.com/back_issues/0800/news/265a.html).

Research psychiatrists at the School of Medicine, University of Leeds, compared students' use of a computer-based multimedia package with lecture-based teaching on the subject of anxiety. They found that even though students felt they learned more in the lecture theatre, they gained more from using a computer package.

There are many advantages to online and computer-based learning when compared to traditional face-to-face courses and lectures. There are a few disadvantages as well.

Main Advantages of Online or Computer-Based Learning

- Class work can be scheduled around work and family.
- It reduces the travel time and travel costs for off-campus students.
- Students may have the option to select learning materials that meet their level of knowledge and interest.
- Students can study anywhere they have access to a computer and an Internet connection.
- Self-paced learning modules allow students to work at their own pace.
- There is the flexibility to join discussions on the bulletin-board threaded discussion areas at any hour, or visit with classmates and instructors remotely in chat rooms.
- Instructors and students both report that e-learning fosters more interaction among students and instructors than in large lecture courses.
- E-learning can accommodate different learning styles and facilitate learning through a variety of activities.
- It develops knowledge of the Internet and computers skills that will help learners throughout their lives and careers.
- Successfully completing online or computer-based courses builds self-knowledge and self-confidence, and encourages students to take responsibility for their learning.
- Learners can test out of or skim over materials already mastered and concentrate their efforts on mastering areas containing new information and/or skills.

Main Disadvantages of Online or Computer-Based Learning

- Learners with low motivation or bad study habits may fall behind.
- Without the routine structures of a traditional class, students may get lost or confused about course activities and deadlines.
- Students may feel isolated from the instructor and classmates.
- The instructor may not always be available when students are studying or need help.

- Slow Internet connections or older computers may make accessing course materials frustrating.
- Managing computer files and online learning software can sometimes seem complex for students with beginner-level computer skills.
- Hands-on or lab work is difficult to simulate in a virtual classroom.

THE INTERNATIONAL VIRTUAL MEDICAL SCHOOL

The International Virtual Medical School (IVIMEDS, http://www.ivimeds.org) is a major international collaboration created to meet the challenge facing medical education through innovative approaches that exploit developments in educational thinking and information and communication technologies. Currently, 37 leading medical schools located in 14 countries have committed financial and human resources, and have agreed to share learning resources to make a reality of the IVIMEDS vision.

The International Virtual Medical School provides the following:

- A comprehensive medical-education resource, the Medical Education Service, available to teachers and learners worldwide. It will provide users with educationally and technologically state-of-the-art medical-education resources and services at low cost.
- A cost-effective alternative-track curriculum for undergraduate medical students for the early years of the undergraduate program, and the right to complete the clinical stages of their training in a partner medical school.
- Customized postgraduate and continuing professional development (CPD) programs that can be taken at the time and place of choosing of the learner, thereby facilitating convenient and cost-effective lifelong learning.
- Customised medical and multiprofessional health education through the IVIMEDS Foundation appropriate to the needs and circumstances of developing countries in regard to curriculum, localization, language, and mode of delivery.

Benefits to Partner Institutions

IVIMEDS offers membership to an international network of partner institutions sharing resources to enrich individual member curriculums and to enhance the ability to deliver cost effectively high-quality medical-education programs. Benefits include the following:

- Improved finances and assets by providing the means to develop an enhanced curriculum with additional topics and approaches to learning, open access to medical training for students of different backgrounds, and a global market for homegrown educational resources and strategies.
- Rapid, effective execution of new approaches that may be beyond the budget and scope of any one institution, drawing upon a global body of expertise in subject matter, educational theory, and technology.
- Reduced risk associated with curriculum changes by sharing innovative thinking and benefiting from other schools' experiences in curriculum planning and their use of learning technologies and learning-management systems.
- Quality resources and innovative approaches to medical education, which can contribute to the creation of a curriculum that is coherent, integrated, student centered, and authentic.

Benefits to Students, Trainees, and Practicing Doctors

IVIMEDS will provide an innovative curriculum and/or curriculum elements tailored to the changing educational needs of students, trainees, and medical professionals. Benefits include the following:

- A learner-centered approach with students exposed to just-in-time learning with theory closely linked to practice.
- Adaptive learning or "just-for-you" learning catering to individual learning styles and interests.
- Curriculum frameworks provided by established learning outcomes, a broad curriculum map, and a bank of virtual patients.
- Blended learning including anytime, anywhere electronic study guides, face-to-face and online tutors, and peer-to-peer learning.
- Flexible learning based in a variety of settings (e.g., a university teaching hospital, a local health centre, or home-based study), best suited to the financial, personal, and educational circumstances of individual students.

Benefits to Society

IVIMEDS offers an approach to medical education and training that is both adaptable and cost effective. Benefits to society include the following:

- Flexibility to expand and contract numbers of learners to meet changing circumstances.
- Wider access to medical education for students, including disadvantaged and mature students.
- Training doctors to focus on the needs of particular communities, with the potential that qualified doctors will return to work in these communities.
- Training doctors with an appropriate high level of competence in information handling and an aptitude for self-directed learning and continuing professional development.
- Cost-effective training with schools working together to blend e-learning with face-to-face learning in a variety of educational and clinical settings.

CONCLUSION

We recognize that technology impacts health-care-education, research, and science educators in the areas of research, classroom teaching, and distance education. While the overall effect is not yet fully assessable, the presence of technology in so many different aspects of the profession makes it important to more clearly recognize and appreciate its current and potential role.

Information technologies can be educators' tools in finding creative ways that encourage students to self-test, self-question, and self-regulate learning and in helping them to create solutions to complex problems. Information technologies are providing new opportunities for linking medical schools around the world for sharing computer-based learning materials. They open a wide horizon for acquiring and expending medical knowledge originated in any part of the world without the limitations of time, space, or distance.

The use of computers and information technology in medical education should be regarded as an additional tool and must never be a goal in itself but part of flexible learning. On the contrary, clinical medical education should always be centered on direct patient contact and bedside education. While we urge for direct patient contact, we believe that using stimulations would also benefit the student in training.

KEY TERMS

Computer-Aided Instruction (CAI): The application of computer technology to education (also called computer-assisted learning and computer-based education).

Computer-Assisted Learning (CAL): The application of computer technology to education (also called computer-aided instruction and computer-based education).

Computer-Based Education (CBE): The application of computer technology to education (also called computer-assisted learning and computer-aided instruction).

Multimedia Content: Information sources that encompass all common computer-based forms of information, including texts, graphics, images, video, and sound.

Simulation: A system that behaves according to a model of a process or another system; for example, a simulation of a patient's response to therapeutic interventions allows a medical or nursing student to learn which techniques are effective without risking human life.

Tutoring System: A computer program designed to provide self-directed education to a student or trainee.

Julian M. Jenkins
University of Bristol, UK

INTRODUCTION

The potential for computers to assist learning has been recognised for many years (Jenkins, 1997), with reproductive medicine benefiting greatly from Internet technology (Jenkins, 1999). Following a detailed survey of information technology facilities and skills for postgraduate education (Draycott, 1999), a pilot Internet training programme in reproductive medicine demonstrated effective methods to deliver online teaching (Jenkins, 2001). Based on this experience, in 2001 the Obstetrics and Gynaecology in the University of Bristol, U.K. launched a postgraduate masters course in human reproduction and development, delivered principally over the Internet (Jenkins, 2002). This course has been under continuous evaluation and development since its launch, refining the application of learning technology to most appropriately meet students' needs (Cahill, 2003). A particularly challenging module of the course considers research methods and statistics. This module was independently evaluated from both a student and tutor perspective, with the objective of identifying learning priorities and optimal educational methodology. This article presents strengths and weaknesses of delivering statistics education online, considering how best to develop this in the future.

BACKGROUND

Teaching statistics to medical and allied healthcare undergraduates and post-graduates has been a challenging area in higher education (Marantz, 2003). Traditionally taught early in the medical course by colleagues from the mathematics department, basic statistical principles are not retained by many medical graduates. A number of reasons have been postulated for this, including the timing of the teaching and lack of practical implications at this stage of training, and lack of motivation among the students (Marantz, 2003; Romero, 2000; Astin, 2002).

As medical students progress through undergraduate education to post-graduate education, the requirement for medical statistics knowledge increases and ranges from day-to-day needs to critique published literature to the ability to design and evaluate research proposals. The knowledge from undergraduate courses is often inadequate to deal with the increased responsibility, and statistics update courses are difficult to attend while working full time as a clinician (Astin, 2002). Many medical statistics textbooks are available; however, they cannot be individually tailored to meet each student's needs. Many candidates report medical statistics as a difficult subject to learn, and the students notoriously lack motivation with regards studying (Romero, 2000). The practical aspects are not always relevant to the clinical aspects of medicine being studied; thus, retention of knowledge is poor (Astin, 2002). Evaluations of the current methods of teaching medical statistics in undergraduate curriculum have focused upon the need for clinical relevance when teaching at earlier levels. Courses based around data analysis have been criticised, while a greater emphasis upon critical appraisal and data presentation has been recommended (Romero, 2000; Astin, 2002; Bruce, 2002). One course reported improved student preparation and participation when a case discussion method was employed to teach epidemiology and bio-statistics (Marantz, 2003).

The Internet provides a comprehensive range of statistics resources that could be used to support an Internet biomedical statistics training programme. Table 2 contains many of the more popular resources, but is by no means an exhaustive list. To highlight several of the Web sites: Statistics at Square One is an online version of a statistics text available via the British Medical Journal Web site. This is an easy-to-read text regarding basic statistics, and has clinical examples at the end of each chapter. Clara is a Web-based computer statistics program that enables the user to perform basic statistical calculations. This assumes some knowledge with regard to the most appropriate test for the data set. Although the scope of this article does not permit discussion of the many other Internet statistics resources, Table 2 provides a guide to many Web sites that may be of interest.

BRISTOL APPROACH

The University of Bristol course aimed to address some of the above challenges of delivering biomedical statistics by providing more student-centered learning delivered over the Internet, with emphasis on clinically relevant practical exercises. This section presents a course evaluation of the Bristol approach to date, identifying the problems that need to be considered with suggestions for future research and possible solutions for Web-based training.

Methods

In 2003, during the second year of the Reproduction & Development MSc in the University of Bristol, an online survey was completed by 18 of the 20 registered students who had completed the statistics and research methods module. Prior to starting the course, students had been sent a copy of the statistical computer programme Stats Direct (wwww.Statsdirect.com) with explanatory

Figure 1. Student responses regarding online teaching in general (n =18)

Student characteristics	Total respondents N=18 n (%)	Part-time subgroup N=14	Clinician subgroup N=12
Full time	4 (22%)	-	2 (17%)
Part time	14 (78%)	-	10 (83%)
Clinicians	12 (67%)	10 (71%)	-
Scientists	6 (33%)	4 (29%)	-
Male	5 (28%)	5 (36%)	5 (42%)
Female	13 (72%)	9 (64%)	7 (58%)
UK based	11 (61%)	9 (64%)	6 (50%)
Overseas based	7 (39%)	5 (36%)	6 (50%)

reference material, and were advised to complete simple tasks to familiarise themselves with statistics prior to a workshop. During the workshop, students were taught by lectures in small groups and completed specific exercises. Following the workshops, further information was delivered online, with interactive questions provided to allow reflection on workshop learning and to develop and test their understanding of statistics. Assessed practical exercises provided an opportunity to apply their knowledge to relevant tasks. Following the period of Internet teaching, students returned for a formal examination by computer-marked assessments, short answers and data analysis exercises.

The online student survey evaluated the distance education component of the course, with particular emphasis on the teaching of the statistics and research methodology module. The students were presented with statements about online learning and asked to respond by grading their views using: strongly agree, agree, neutral, disagree and strongly disagree. Statements specifically targeting the statistics module were

Figure 1. Student responses regarding online teaching in general (n =18)

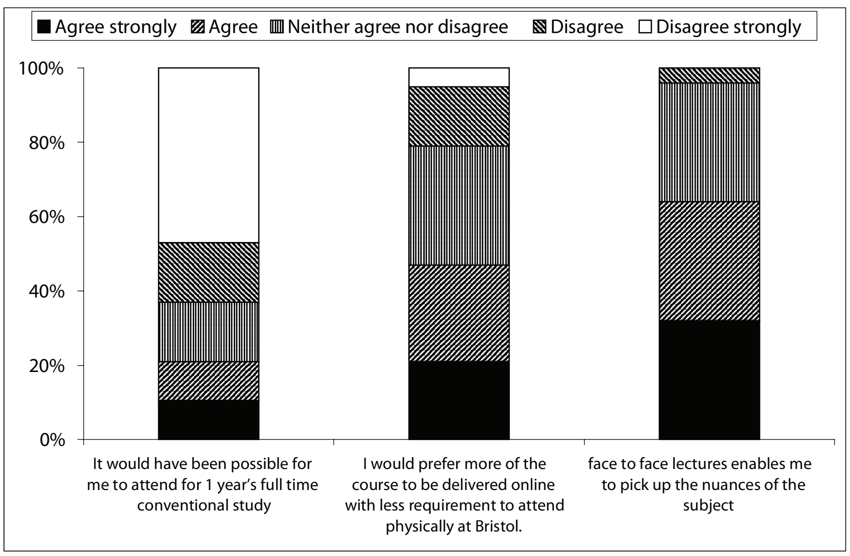

Figure 2. Student responses regarding Internet-based teaching of statistics (n=18)

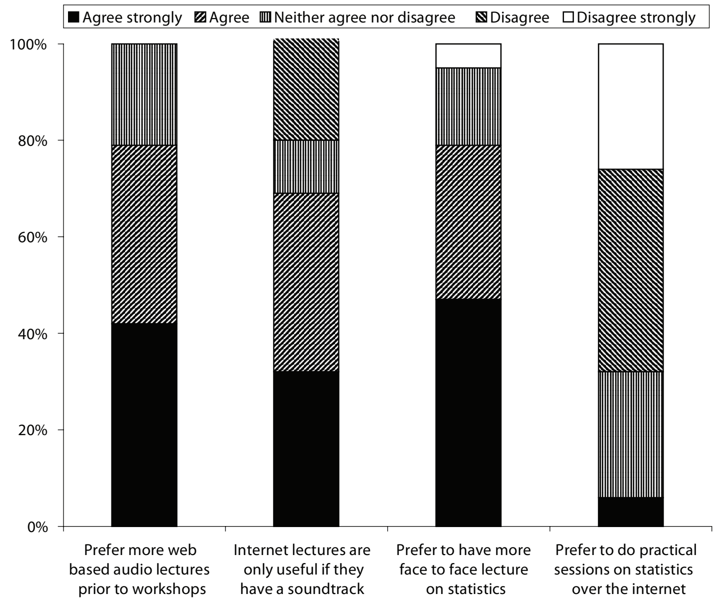

included, and students were asked to prioritise the statistics lectures and tutorials.

Results from a course appraisal of a distance learning statistics module for medical and paramedical postgraduates

The demographics of the students on the course are indicated in Table 1. When appraising Internet-based vs. traditional face-to-face learning, students reported that it was not possible in the majority of cases to attend a conventional lecture-based university course. Seventy-nine percent of part-time students felt they would not have been able to attend the course if it was arranged as a conventional one-year campus-based study (see Figure 1). Most students reported they could learn efficiently from audio-Web-based lectures and would prefer more audio-Web lectures to be delivered prior to the attending workshops. In contrast, when students were specifically asked about Internet-based learning of statistics, they reported that they would prefer more face-to-face lectures and less Internet-based practical sessions (see Figure 2). They reported that face-to-face lectures allowed them to pick up the nuances of the subject and thus improve their understanding.

Students preferred to have lectures on basic statistical concepts; design of clinical trials; calculating means, medians and confidence intervals; and which statistical test to apply (see Figure 3). Lectures on survival analysis, regression, correlation and advanced statistics were found to be least useful. The overall preference was to have face-to-face lectures for basic statistical principles and common statistical calculations, with less emphasis on more advanced statistics such as regression analysis. Students also appreciated lectures and tutorials on practical aspects of statistics that would be useful for their career and ongoing medical education, such as the design of clinical research, determining which statistical test is most appropriate for a given data set and how to use a computer-based statistics program.

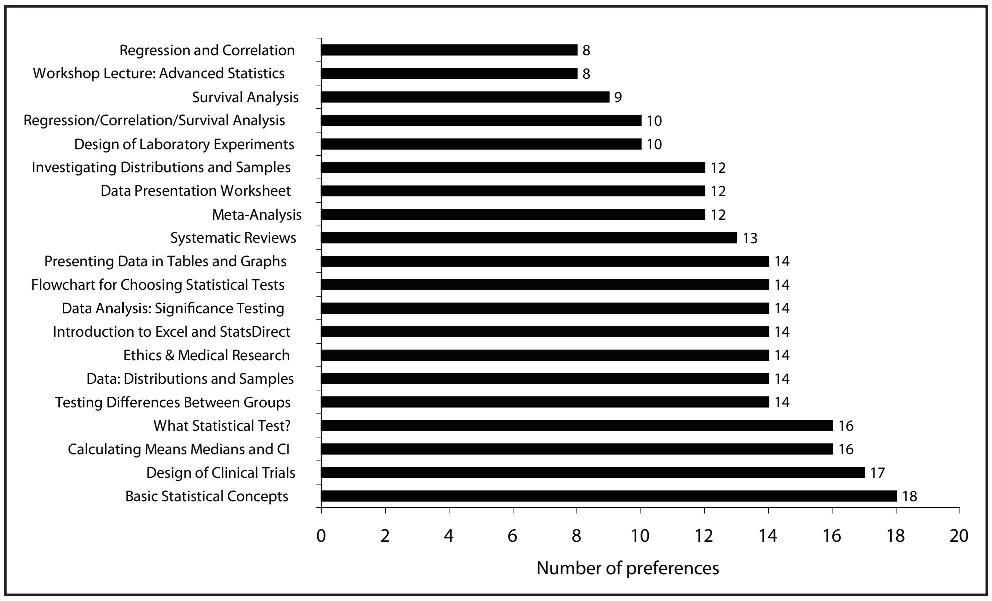
FUTURE TRENDS

This survey demonstrates students' desires for more Internet teaching to allow a larger proportion to participate in additional education, but illustrates both the need to support this with workshops and the particular challenges of teaching statistical concepts online. From the recent survey, the Internet approach initially adopted in Bristol did not overcome the problems associated with teaching statistics, as students felt they preferred more face-to-face lectures and more supervision of practical sessions. This highlights that teaching difficult concepts using a Web-based approach can be challenging. This may be explained by students' needs to attend lectures for difficult concepts to pick up the finer points of the subject and to ask questions of the lecturer. Students may also perceive the need for increased assistance in what is traditionally a difficult area, and they may have a lack of self-motivation with respect to this topic, which Internet-based lectures do not overcome.

Figure 3. Summation of lectures included by individual student preferences for top 10 most useful lectures in statistics



In part, this assistance may be addressed through structured online discussion bulletin boards, providing the opportunity to explore the concepts with views from both tutors and fellow students. The use of online discussion bulletin boards requires further research. The preference for lectures that cover basic statistical concepts; design of clinical trials; calculating means, medians and confidence interval; and learning which statistical test to apply indicates that students are looking for a course with more day-to-day, practical emphasis. They want techniques to use when appraising the medical literature and reviewing and designing audit and research. More complicated medical statistics were less popular, such as advanced statistics, correlation and regression, and survival analysis. It may be prudent to design a course emphasising the skills needed on a day-to-day basis, with more advanced concepts defined but not discussed in great detail. A second level of the course could be designed around the teaching of advanced statistical concepts, if this was required.

CONCLUSION

Current postgraduate students are demanding courses adaptable to their lifestyle and more clinically relevant. Geographical location and work commitments involving long hours combined with an increased knowledge and skill of Internet and computer technology, particularly among younger students, places increased challenges for course providers. Thus, courses that place more emphasis on distance learning are becoming increasingly popular, and the Reproduction and Development MSc course at the University of Bristol is now extremely popular, attracting an international student group (Whittington, 2004). Statistics has always been a difficult subject area to teach, and the results of our survey may be explained by students' needs for a practical-based statistics course with emphasis on basic concepts and skills needed for literature appraisal. From the results presented above, we conclude that for postgraduate students distance learning packages are very popular and useful; however, teaching difficult concepts online is more challenging for course organisers and requires careful development.

KEY TERMS

Biomedical: Relating to biomedicine, the application of natural sciences, especially biology and physiology, to clinical medicine.

Cognitive Learning Theory: This provides a framework to understand learning, suggesting that although learning is not directly observable it occurs through active mental processes where knowledge is progressively assimilated, making a change in behaviour possible.

Distance Education: Students learning remotely from their educational establishment, supported by a variety of methods.

Reproductive Medicine: Speciality of medicine dealing with the reproductive system and related medical issues such as infertility, contraception, menopausal problems and menstrual dysfunction.

Statistics: Branch of mathematics concerned with the collation, analysis and interpretation of quantitative data.

Self-Directed Learning: Students are empowered to learn at their own pace, catering to the different learning speeds and styles of individuals.

Web-Based Training: Use of material delivered via Web browser to support education. This may support distance learning or can be used within an educational establishment.

INTRODUCTION

Educational goals have generally shifted from knowing everything in a specific domain to knowing how to deal with complex problems. Reasoning and information-processing skills have become more important than the sheer amount of information memorized. In medical education, the same evolution has occurred. Diagnostic reasoning processes get more strongly emphasized. Whereas previously knowing all symptoms and diseases was stressed, reasoning skills have now become educationally more important. They must enable professionals to distinguish between differential diagnoses and to recognize patterns of illnesses (e.g., Myers & Dorsey, 1994).

BACKGROUND

Authentic or realistic tasks have been advocated to foster the acquisition of complex problem-solving processes (Jacobson & Spiro, 1995; Jonassen, 1997). In medical education, this has led to the use of expert systems. Such systems were initially developed to assist practitioners in their practice (NEOMYCIN, in Cormie, 1988; PATHMASTER in Frohlich, Miller & Morrow, 1990; LIED in Console, Molino, Ripa di Meana & Torasso, 1992) and simulate real situations. These systems were expected to provoke or develop students' diagnostic reasoning processes. However, the implementation of such expert systems in regular educational settings has not been successful.

Instead of developing reasoning processes, these systems assume them to be available. They focus on quickly getting to a solution rather than reflecting on possible alternatives. Consequently, it was concluded that students need more guidance in the development of diagnostic reasoning skills (Console et al., 1992, Cromie, 1988; Friedman, France & Drossman, 1991), and that instructional support was lacking.

KABISA is one of the computer programs purposely designed to help students in the development of their diagnostic reasoning skills (Van den Ende, Blot, Kesten, Van Gompel & Van den Enden, 1997). It is a dedicated computer-based training program for acquiring and optimizing diagnostic reasoning skills in tropical medicine.

DESCRIPTION OF THE PROGRAM[2]

KABISA confronts the user with cases, or 'virtual patients'. The virtual patient is initially presented by three 'characteristics'[3] randomly selected by the program. After the presentation of the patient (three characteristics), students can ask for additional characteristics gathered through anamnesis, physical examination, laboratory and imaging. If students click on a particular characteristic, such as a physical examination test, they receive feedback. Students are informed about the presence of a certain disease characteristic, or whether a test is positive or negative. If students ask a 'non-considered' characteristic; that is, a characteristic that is not relevant or useful in relation to the virtual patient, they are informed of this and asked whether they want to reveal the diagnosis they were thinking about. When they do so, students receive an overview of the characteristics that were explained by their selection and which ones are not, as well as the place of the selected diagnosis on a list that ranks diagnoses according to their probability given the characteristics at hand. If students do not want to show the diagnosis they were thinking about they can just continue asking for characteristics. A session is ended with students giving a final diagnosis. KABISA informs them about the correctness. If the diagnosis is correct, students are congratulated. If the diagnosis is not correct, students may be informed that it is a very plausible diagnosis but that they do not have enough evidence, or they may get a ranking of their diagnosis and an overview of the disease characteristics that can and cannot be explained by their answer. Additionally, different non-embedded support devices – that is, tools are made available to support learners. These tools allow students to look for information about certain symptoms or diseases, to compare different diagnoses or to see how much a certain characteristic contributes to the certainty for a specific diagnosis. Students decide when and how they use these devices (for a more detailed description, see Clarebout, Elen, Lowyck, Van den Ende & Van den Enden, 2004).

FUTURE TRENDS AND CRITICAL ISSUES

KABISA is designed as an open learning environment (Hannafin, Hall, Land & Hill, 1994); that is, students are confronted with a realistic and authentic problem, there is a large amount of learner control and tools are provided to guide students' learning. However, the evaluation study performed revealed some interesting issues. A first revelation was that students do not follow a criterion path when working on KABISA. Prior to the evaluation, two domain experts in collaboration with three instructional designers constructed a criterion path. This path represented the ideal paths students should go through to optimally benefit from KABISA (following the "normative approach" of Elstein & Rabinowitz, 1993), including when to use a specific tool. Only 5 out of 44 students followed this path.

A second issue relates to the use of the tools. KABISA offers different tools to support students. These tools can help students in their problem-solving process. Results suggest that students consult some help functions more than others. However, overall they do not consult them frequently, and if they use them, they do not use them adequately. Students also tend to not use the feedback that can be obtained when asking for a 'non-considered' characteristic.

Although this environment can be described as an open learning environment, it seems that students do not perceive it as a learning environment. Thinking aloud protocols reveal that students think they are cheating or failing when consulting a tool. Giving the limited use of the tools, their impact on the learning process cannot be but limited.

However, in spite of the observation that in only a small number of consultations the criterion path was followed, students do find the right diagnosis in 80% of the consultations. It seems that by trial and error students can also obtain the right diagnosis.

The results of this evaluation suggest that KABISA is currently not used by students to foster their diagnostic reasoning skills. Rather, it enables them to train readily available skills. The results are an example of a well-designed learning environment used by learners as a performance environment. With the use of more open and online learning environments, this raises the issue of how to realize that students see such environments as learning environments with learning opportunities, rather than a performance environment.

In the design and development of KABISA, a lot of time and effort was spent in developing the tools. However, results show that students do not (adequately) use these tools. Other authors have found similar results with other programs (e.g., see Crooks, Klein, Jones & Dwyer, 1996; Land, 2000). This raises questions about the amount of learner control in open learning environments. Should the environment be made less open and provide embedded support devices instead of tools, so that students cannot but use these devices? Or should students receive some additional advice towards the use of these tools? In the first case, support might not be adapted to the learners' needs. This might cause problems, given that either too much or too little support can be detrimental (Clark, 1991). The second option leaves the environment open. But here also, it can be questioned whether this advice should not be adapted to the learners' needs. A possible solution might come out of the animated pedagogical agent-research. These agents are animated figures that aim at helping learners in their learning process and adapt their support based on the paths learners follow (Shaw, Johnson & Ganeshan, 1999). Certainly in online learning environments where there is by definition a large extent of learner control, such agents might provide a solution, and act even as a personal coach for learners.

Another aspect revealed by the analysis is the importance of an evaluation phase in the development of computer-based training programs. For instance, a more thorough analysis of student characteristics could have provided a means to adapt the difficulty level to the level of the students or to identify what guidance students actually need. Apparently, the feedback given to students does not encourage them to adapt their problem-solving process. Being product- rather than process-oriented, feedback may not be adapted to students' actual needs. Likewise, students' instructional conceptions about computer-based learning environments or their perceptions about KABISA (game vs. educational application) may influence the use of the program. Students' instructional conceptions should be taken into account through the design process of the program. One possible way to influence these conceptions might be through an introduction of the program. In the introduction, the aims of the program, the different functionalities and the relationship with the different courses should be clearly defined (see Kennedy, Petrovi & Keppell, 1998).

Given the difficulty of anticipating potential problems and difficulties students might encounter in open learning environments, the introduction of a formative evaluation during the design and development of this program seems warranted. This would enable the redirection of the program while developing it, rather than after implementation. Rather than only evaluating a final product, the development process should be taken into consideration, as well. Rapid prototyping would allow for testing the program at different phases of the development. This leads to a more spiral cycle rather than a linear design process.

CONCLUSION

The evaluation of KABISA addressed some general issues important to consider in the design, development and implementation of open learning environments. Although these environments are advocated to foster the acquisition of complex problem-solving skills, there seems to be a gap between the intention of the designers and the use by the learners. This relates to the issue addressed by Winne and Marx (1982) about calibration. For an instructional intervention to be effective, calibration is needed between the conceptions of the various people involved. The introduction of a pedagogical agent might help to calibrate the conceptions of students towards those of the designers. Moreover, these agents might help in encouraging students to adequately use tools without reducing the openness of the learning environment.

KEY TERMS

Animated Pedagogical Agents: Animated figures operating in a learning environment and aiming at supporting learners in their learning process and capable of adapting their support to the learners' paths.

Criterion Path: This a representation of an 'ideal path' to go through a specific learning environment. It specifies for each possible step in the program the most ideal subsequent steps.

Embedded Support Devices: These are support devices integrated in the learning environment. Learners cannot but use these devices (e.g., structure in a text).

Instructional Conceptions: These are conceptions about the functionalities (elements) of a learning environment. These conceptions can relate to the effectiveness or efficiency of specific features in a learning environment (e.g., tools) or to the environment as a whole (e.g., KABISA as a learning environment).

Non-Embedded Support Devices (Tools): These are support devices put to the disposal of learners. Learners decide when and how to use these tools.

Open-Ended Learning Environments: Aim at fostering complex problem-solving skills by confronting learning with a realistic or authentic problem in a learning environment with a large amount of learner control and different tools.

Perceptions: Students' perceptions relate to how they perceive a specific environment (KABISA). They are the results of an interaction between students' instructional conceptions and a specific learning environment.

END NOTES

[1] A more extended version of this manuscript with more background information was published in Armstrong, A. (Ed.). (2004). *Instructional design in the real world. A view from the trenches.* Hershey: Information Science Publishing.

[2] The authors are grateful to Stefano Laganà, who invested a lot of effort to adapt KABISA and to develop a log file system.

[3] The term 'characteristic' refers to either a symptom or disease characteristics, either a request for results of a physical examination,

Chapter 5.10
Gastrointestinal Motility Online Educational Endeavor

Shiu-chung Au
State University of New York Upstate Medical University, USA

Amar Gupta
University of Arizona, USA

ABSTRACT

Medical information has been traditionally maintained in books, journals, and specialty periodicals. A growing subset of patients and caregivers are now turning to diverse sources on the internet to retrieve healthcare related information. The next area of growth will be sites that serve specialty fields of medicine, characterized by high quality of data culled from scholarly publications and operated by eminent domain specialists. One such site being developed for the field of Gastrointestinal Motility provides authoritative and current information to a diverse user base that includes patients and student doctors. Gastrointestinal Motility Online leverages the strengths of online textbooks, which have a high degree of organization, in conjunction with the strengths of online journal collections, which are more comprehensive and focused. Gastrointestinal Motility Online also utilizes existing Web technologies such as Wiki-editing and Amazon-style commenting, to automatically assemble information from heterogeneous data sources.

INTRODUCTION

For the last several decades, Harrison's Principles of Internal Medicine, published by McGraw Hill, has served as a major source of information in the field of Gastrointestinal Motility. This book and its online presentation have been, and continue to be, used by many medical colleges to train the next generation of medical doctors; practitioners in this field also frequently refer to them.

Traditionally, papers and articles in specialty medical journals supplemented the material in textbooks like Harrison. The latter book would itself be updated periodically to reflect the state of the art in medicine and the various specialties, providing a consensus opinion of the standard of care.

The advent of computers and Internet has given rise to online sources of information such as UpToDate (http://www.uptodate.com/) and WebMD (http://www.webmd.com/). While gaining tremendous following and being updated frequently, these sources of online information relate to the medical field as a whole and not to particular specialties. Furthermore, the information on these sites is generally maintained by personnel of the respective organizations, not by specialists in specific disciplines of medical science. These organizations are usually set up as commercial entities, rather than not-for-profit ones.

The progressive transformation of information has seen many journals that were previously in paper format opting to use new electronic technologies; most of them now come out both in paper and electronic formats. Searchable electronic archives, such as PubMed (http://www.pubmedcentral.nih.gov/), now place a plethora of information into the hands of researchers and physicians. However, such searches are very time consuming and often produce irrelevant or poorly supported articles. Sites like Harrison's Online (http://www.accessmedicine.com/) serve as information directories that can be searched, hoping to place the most suitable information on a medical topic in a user's hand.

Students have gradually come to expect information in quick and readily available forms without having to bother about inter-library loans or even hardcopy versions at all.

The goal of the endeavor described in this article was to adapt emerging technologies to improve methods of teaching gastrointestinal material to students and to serve as a more effective source of relevant and accurate information for medical practitioners and specialists.

Evidence-Based Medicine

A study from the School of Information Management and Systems at UC Berkeley estimates that, in 2003, the World Wide Web contained about 170 terabytes of information on its surface alone, equivalent to seventeen times the size of the information in the Library of Congress (Lyman & Varian, 2003). With this increasingly information-rich society, the most precious ability for students and learners is no longer to find the information, but to discern the most relevant pieces of information and to integrate them into practice. The American Library Association describes "information literacy" as the ability of individuals to "recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information" (American Library Association, 1989).

The medical domain version of information literacy is evidence-based medicine.

Evidence-based medicine (EBM) is the integration of best research evidence with clinical expertise and patient values (Guyatt et al., 1992). The Centre For Evidence-Based Medicine in Toronto, Canada, states that the origins of evidence-based medicine date back to post-revolution Paris (CEBM, 2007), but that the current growth is most closely attributed to the work of a group lead by Gordon Guyatt at McMaster University in Canada in 1992. EBM publications, reflecting interest in this field, have grown from a lone publication in 1992 to thousands in 2007.

Studies have become increasingly critical of the value of textbook sources (Antman et al., 1992). Didactic continuing medical information may be ineffective at changing physician performance (Davis et al., 1997), and clinical journals may lack practical application (Haynes, 1993). In addition, physicians are faced with an increasing burden on their time, forced to diagnose patient findings within a matter of minutes (Sackett & Straus, 1998), and can only afford to set aside half an hour or less per week for general medical reading (Sackett, 1997). The staggering mass of information being discovered is also daunting: 500,000 articles are added to the commonly used Medline medical journal database every year, and "if a physician read 2 articles each day, every day for a year, (s)he would still find herself or himself 648 years behind" (Lindberg, 2003). As research increases the quantity of information available, medical practitioners are compelled to find efficient methods to educate themselves.

The Centre for Evidence Based Medicine has cited several examples of strategic, educational, and technical improvements in medicine that have enabled the current explosion in interest in this field. These include the emergence of new strategies for evaluating information; the creation of systematic reviews; the growing emphasis on continuing medical education and lifetime learning; and the advent of online journals, meta analysis of multiple studies, and ready access to such resources through electronic archives. Rapid dissemination of accurate and comprehensive compilations of research results enables medical practitioners to make informed decisions that are supported by the latest research results, and not by outdated trials.

In light of the increasing number of medical journals, especially journals that focus on specialties, the sheer quantity of information threatens to overwhelm medical practitioners. The concept of information mastery has been coined to describe the set of skills that physicians must nurture in approaching, analyzing and incorporating or rejecting new information. The issues mentioned above are not limited to the medical arena alone: Former Vice-President Al Gore described the state of information management as "*resembling the worst aspects of our agricultural policy, which left grain rotting in thousands of storage files while people were starving*" (Gore, 1992).

The Center for Information Mastery at the University of Virginia asserts that the usefulness of medical information is dependent upon its relevance, validity, and the work required to obtain it, as specified in Equation 1 (Slawson et al., 2007).

Further, the increasing quantity of research being performed by commercial enterprises, as well as other organizations with potential conflicts of interest, requires information be filtered for validity before incorporation into medical the canon. Finally, increased effort involved in accessing the relevant pieces of information reduces the accessibility of such information. In addition, healthcare organizations are siloed, gaining the advantage of sub-optimizing local departments, possibly at the cost of the whole (Senge, 1980); this complicates the problem further.

Information Retrieval and Decision-Making

As Stephen Hawking observes in *The Universe in a Nutshell*, the rate of growth of new knowledge is exponential. While 9,000 articles were published annually in 1900 and around 90,000 in 1950, there were 900,000 scientific articles published per annum in 2000 (Hawking, 2001). The explosive growth of information is challenging both the information repositories designed to hold it, and the ability of users to access relevant information.

At the time of this writing, Wikipedia serves as the de-facto standard for online general encyclopedias, and is among the top ten most-visited Web sites (Alexa Internet, 2007a). Its open-source, volunteer-without-accountability approach led to initial concerns about information validity, but these concerns have been largely addressed. Nature magazine studied Wikipedia and Encyclopedia Brittanica and found that the two of them were largely similar in accuracy (Giles, 2005). The growth of Wikipedia's information base further enhances the quality and breadth of coverage, and supports the possible future use of Wikipedia or Wiki-style architecture as an academically respectable source of reference.

Equation 1. Usefulness (Slawson et al., 2007)

$$\text{Usefulness of Medical Information} = \frac{(\text{Relevance})(\text{Validity})}{\text{Work}}$$

In contrast to the indexed and contributed semi-structured format of Wikipedia, Google relies on search-keyword phrases. The usefulness of Internet-crawling indexers, like Google, is based upon the ability to retrieve and capture information from many sites, and to retrieve relevant pages on query. Google's initial strength and rise to stardom was achieved through its superior PageRank algorithm, which still remains a carefully guarded trade secret; this algorithm provides an uncannily relevant list of matches to any user query, ranging from commonplace query phrases to obscure esoteric trivia and even misspellings.

In a small supermarket today, shoppers are bombarded with a selection of 285 varieties of cookies and 95 varieties of chips, leading the consumer to a state of decision overload (Schwartz, 2004). There is a growing need to restructure data to meet the informational and management requirements of an organization or group of people (Carlson, 2003).

Medical Information Repositories

For the medical arena, PubMed is the most widely used information database in the world, accounting for 1.3 million daily queries by 220,000 unique users (Lindberg, 2003). It is a free access search engine, provided by the U.S. National Library of Medicine as the main access point to the Medline database, a cataloged repository of medical literature classified using the descriptors known as Medical Subject Headings (MeSH). A broad range of search features are offered, including combined searches, exclusions, classification by type of article (original research versus review) and related articles. Another feature of the Medline database, known as MedlinePLUS, provides generalized information on health topics, and is aimed at the public or at practitioners outside their specialty domain. At the current time, PubMed serves as the gold standard in comprehensive medical information, despite its dated interface.

HighWire Press, a Stanford-originated endeavor, distributes thousands of journals, and provides its own search engine. In a recent study, the relevance of articles retrieved from HighWire was found to be greater than that of PubMed, but with the disadvantage of a slower retrieval Speed (Vanhecke et al., 2006).

In order to make a comparative evaluation between different approaches, it is appropriate to characterize the information recall ability using three parameters: precision, recall, and fall-out.

Precision (Equation 2) can be defined as the proportion of all retrieved documents that are relevant.

Recall (Equation 3) captures the concept of complete retrieval of all relevant documents.

Fall-out (Equation 4) is a measure of the number of documents that are retrieved but are unrelated to the issue being searched.

Medical research, while generally emphasizing maximal precision and minimal fall-out, occasionally requires increased recall, in the case of obscure diseases, or unusual side effects of medications. Medline serves as a canonical list for such purposes, but at the cost of significantly lower precision.

Medical practitioners using Google for their searches will often find themselves frustrated at the large quantity of articles on obscure and irrelevant topics. A researcher searching for a pharmacologic treatment of a syndrome will turn up with thousands of articles dealing with vari-

Equation 2. Precision (Wikipedia, 2007)

$$\text{precision} = \frac{|\{\text{relevant documents}\} \cap \{\text{retrieved documents}\}|}{|\{\text{retrieved documents}\}|}$$

Equation 3. Recall (Wikipedia, 2007)

$$\text{recall} = \frac{\left| \text{relevant documents}\} \cap \text{retrieved documents}\} \right|}{\left| \text{relevant documents}\} \right|}$$

Equation 4. Fall-out (Wikipedia, 2007)

$$\text{fall-out} = \frac{\left| \{\text{non-relevant documents}\} \cap \{\text{retrieved documents}\} \right|}{\left| \{\text{non-relevant documents}\} \right|}$$

ous sub-types, biochemical-signaling processes involved, and even support groups, before finding a therapeutic treatment. Due to the nature of the search engine and the storage methods, there are concerns about Google's or any search engine's ability to maintain a collection of such information. Carlson (2003) showed that due to the relatively small collection of documents indexed by an average search engine, a significant amount of relevant information would not be returned even in the presence of a perfectly formulated search phrase.

In order to accommodate domain-specific areas, Google has introduced the concept of "Refine Your Search" (http://www.google.com/coop). Without altering its main core search methodology, Google allows users to more quickly locate the type of information desired (i.e., treatment or symptoms). These refinement tools, provided by vendors and other private individuals or agencies that are deemed authoritative, subsequently label Web sites with appropriate descriptor tags. The potential conflict of interest created by these corporate associations is a matter of concern, due to omissions or maliciousness of the labeling.

The range of challenges and issues that characterize the medical domain include:

- The presence of an extensive array of synonyms for various drugs and diseases that require semantic knowledge to be encoded into the search engine in order to link concepts that are not lexically related;
- The naming of disease subtypes (often after a major contributor or discoverer), requires that hierarchies be constructed to allow users looking for the subclasses of disease to find information on the main umbrella disease, and vice versa;
- The growth in the understanding of generalized syndromes results in a corresponding need for reclassification based on new etiologies of disease, thereby suggesting a dynamic organizational structure for the online medical information systems.

In view of the growing difficulty in locating desired pieces of information, individuals performing research are in increasing danger of information overload. As such, the next generation of medical information access tools must aim to improve the ability to retrieve the right chunks of information quickly, with zero or minimal extraneous information; this concept is termed as increasing the signal to noise ratio in the field of electrical engineering.

VISION AND GOALS FOR GASTROINTESTINAL MOTILITY ONLINE

Gastrointestinal (GI) Motility Online is an example of a medical information system that seeks to provide access to high quality medical information online related to a particular medical specialty by centralizing the information and presenting relevant information that is customized to the user's information requirements.

The field of Gastrointestinal Motility is complex and interdisciplinary, involving a variety of experts. The possible user base includes laypersons, patients, medical students, biomedical scientists, physiologists, pathologists, pharmacologists, biomedical students, researchers, pharmaceutical staff, house staff, specialty fellows, internists, surgeons, and gastroenterologists. Each role requires a different approach to depth, scholastic relevance, and clinical direction in terms of information presentation. For example, students are interested in innovative research or review papers; researchers would like to know the most recent developments, and practitioners might be more interested in using the information for differential diagnosis purposes. GI Motility aims to serve as a collaboration of medical professionals, approaching diseases and patients from different angles.

In a library, a user interacts with the data in books very differently from the way that she or he interacts with data in an online presentation. The user expects the book to be focused and to address the topic in a linear fashion. Online, the same user navigates quickly, using hyperlinks, to explore secondary topics. In fact, the user *expects* a different presentation and a different style of information; as a result, the nature of the interactions will differ even with the same content. One of the aims of Gastrointestinal Motility Online is to address these different styles and to present the desired subset of information in the manner that the user might expect. For example, a user might be interested in viewing articles from the perspective of case-based, symptom-based, or test result-based diagnosis in order to apply the information to a particular problem at hand. In essence, the vision of Gastrointestinal Motility Online is to present information as framed by the interaction with the particular user at the particular point in time.

The first step in the vision of Gastrointestinal Motility Online was to collect the information in a manner consistent with the goal to acquire the reputation for the highest quality of knowledge. The information base is assembled entirely from material provided by internationally acknowledged experts. All chapters including synopses, articles, and reviews are written by reputed authorities. The pool of information is envisaged to be shared between different types of users and for different purposes. The design of the system emphasizes a one-stop information approach that enables the users to derive information at various depths. This applies to onsite information, as well as to information at offsite locations.

Details of Effort

A two-phase approach is being utilized for the creation of the information system: the first involves full leveraging of commercial technology as it exists today, and the second involves further research on aspects that can be incorporated in future versions of our system. In the absence of a better term, the term gastrointestinal knowledge repository is used for the final system, as well as for the initial concept-demonstration prototype system.

For the first phase, the acquisition of knowledge proceeded with the establishment of titles and themes for chapters, as determined through discussions involving the concerned authors and the editors for this project (Dr. Raj Goyal of Harvard Medical School and Dr. Reza Shaker of the Medical College of Wisconsin). The creation of the gastrointestinal motility knowledge repository began with calls to key gastrointestinal experts inviting them to submit a chapter, in electronic form, for inclusion in this knowledge repository. The inputs from the contributing authors were reviewed by these two editors and by others, on an anonymous peer review basis. Under the aegis of an unrestricted grant from Novartis Corporation, the two editors worked closely with the staff of

Nature Publishing Group on a number of tasks that ultimately led to the creation of the following Web site: http://gimotilityonline.com.

The creation of the site involved an automated conversion process to adapt MS-Word and rich text documents into a Web presentable format, with special emphasis placed on images, tables, and video. The majority of the investment for development lay in formatting and typesetting; the design itself was of less concern as it followed existing Web branding and style guidelines of Nature Publishing Group. Rights for images needed to be obtained; further, images, tables and video needed to be edited to fit a standard look and feel. After receiving author contributions, the project required approximately 18-24 months to complete, with 9-12 months required for the editorial process itself. The current site consists of 1,000 HTML pages, 1,000 images, 500 Powerpoint presentations and 40 videos. Articles are cross-linked by topics, and the current volume is equivalent of about 700 pages of text. This volume is increasing as this endeavor continues to progress.

Site Purpose

The ostensible purpose of the site is to disseminate information on the specialty of gastrointestinal medicine, primarily to gastrointestinal medical practitioners and to other interested parties. The ambition for the site is for it to become the central hub of information on this specialty, aggregating information from many sources, authors, and journals into one central location with the objective of becoming a de facto standard for online gastrointestinal information.

A secondary role is the development of a community of gastrointestinal specialists and other interested parties, who can form an online collaborative, expand upon the information repository, and facilitate peer communications and discussions. In addition, the site aims to explore and to expand the concept of online information repositories, especially the optimal integration of the current generation of electronic journals and online textbooks.

Site Audience

The primary site audience is the set of gastrointestinal specialists, associated medical staff, and staff under training. Members of this primary user base would initially visit the site because of a recommendation from a colleague or because another site (search or advertisement) directed the user to it. Occasional patients are expected, but are unlikely to become the primary users of this site.

Initially, the core attractions for users to this site are the quality and depth of information coupled with the ease of access and the low cost; these same factors will also help to retain the user base. Most physicians and healthcare specialists spend relatively little time online (six hours per week on average); in order to impress the user base, the signal to noise ratio of the site must be high, along with the ease of locating a desired piece of information (through the information architecture) (Friedman, 2000). The primary user of the site is unlikely to demand high interactivity; instead, the interest will be on locating and extracting the information as quickly as possible. As such, the site must be efficiently organized, streamlined, and equipped with powerful search and index functions.

After drawing a user initially, repeat visitors would use the site to browse new topics of interest, as well as to entrust the editorial staff to select articles that represent innovative research in the relevant field. An interacting community base would evolve over time and eventually cause a change in the workflow. Specialists would then visit the site to explore the comments from their colleagues on the topics expressed and to leave their own authoritative inputs on different articles, eventually contributing entire articles as much as a good electronic journal aspires to do today.

While relatively low in terms of being technically savvy, a typical user of Gastrointestinal Motility is likely to be very comfortable with using the Internet for retrieval of scholarly information through PubMed, online textbooks, and ready references such as UpToDate. A sleek, uncluttered design is likely to be the most attractive, even though it may not support applications involving high load times, such as Flash or embedded videos. Users are comfortable reading large articles online, but they also expect printable versions to be available, on an as-needed basis.

The user base, while highly intelligent, is relatively small in numeric terms, and is characterized by a small presence on the Web. The process of attracting a critical mass to build and to maintain a user community is a high priority task; this involves contacting a high percentage of all members of this specialist community.

Site Content

Gastrointestinal Motility Online is a site that provides information on both medical practice and the fundamentals of the gastrointestinal tract. The information must provide both breadth and depth on the topic, and should ultimately serve as an encyclopedia of the domain-specific knowledge.

Information Architecture: As in a library, information must be properly accessible in order to have value. The architecture of the information is partly determined by the methods that the users will use to query the evolving knowledge base. In a library, the name of the author and the title of the book are important. In a journal, the age of the article or the issue in which it was published may be essential. In Gastrointestinal Motility Online, the most likely user scenarios involve searching for information by anatomical section or syndrome. The timing is also important; recent material is favored over older material. Since relevance of the article is also important, the name of the journal and the name of the author are also used prominently in searches.

Furthermore, classification schemes or hierarchies to group-related topics are essential to narrow the branching process used by the search technique. The determination of related information is a complex topic. In order to address the latter issue, medical organizations are creating medical ontologies, such as unified medical language system (UMLS), to quantify and to impose structure on conceptual relationships. With this classification, the selection criteria can be hierarchically built up or finely specified to obtain desired results. A lengthier discussion of this topic appears later in this article.

Look and Feel: The look and feel of the site needs to convey the sense of scholarly authority, but with a sleek technological approach. Medical personnel have high standards concerning the accuracy of articles, and a professional presentation aids in supporting this perception. A site that is gaudy or shows too many bells and whistles, or involves a long load time, reflects poorly on the content, as do garish colors or lack of color.

Images and video must be consistent and should be available to download as needed for reference and for closer examination. The level of interactivity available should be low, as most gastrointestinal specialists have small online presence. Natural language queries, such as those used with AskJeeves (http://www.ask.com/), are unnecessary, as long as the search and browse features are precise and efficient. Pages may be presented as either textbook or journal articles, based on the preference of the user.

Extracting Content, Metadata, and Cross Referencing: One of the most powerful functions of the Internet is the ability for Web users to span several related articles quickly because of cross-referenced links. A user interested in the preparation of a particular chicken recipe can quickly reference how to sauté and with what form of pan, moving quickly to sources to buy the appropriate cast-iron skillet or wok to benefits and comparisons of different brands and retailers. A Wiki of only gastrointestinal specialists, with limited control from an editor, would be appropriate for the collection and dissemination of information: Gastrointestinal Motility Online is striving towards that goal.

A particularly useful feature in Gastrointestinal Motility Online, not available in online journals, is its cross-referencing tool. Articles that are closely related or broach a topic in greater depth can be quickly accessed by a cross reference within the Gastrointestinal Motility Online domain. These links are established by content extraction tools that create metadata and relate that data between different documents. Footnotes are available at the bottom and allow for a broader topical search; however, the inline linking of articles is particularly appealing for tracking particular items or syndromes of interest.

Auxiliary Technologies

Search features are incorporated in Gastrointestinal Motility Online, but are considered secondary to the organization of the information. A dynamic keyword search for anatomical sections of the gastrointestinal tract is less likely to reveal useful information on general function than a manual perusal of the literature through the prepared subject browse option. The efficient organization of the information, based on the anticipated needs and access patterns of users, is an essential feature for building a knowledge repository. By acknowledging that specialists would be more likely to query by anatomy or syndrome, one needs mechanisms for structured order, as compared to mechanisms that order by article size, author name, or recent usage. An additional feature, incorporated within the community-building module, is a user rating system that allows users to rank the importance of articles so that users browsing information can be directed to the most useful and informative articles.

One difficulty with searches is the likelihood that a particular phrase will appear in nearly all documents unless the search is very specific. In cases where the gastrointestinal tract is analyzed as an interactive system, the phrases for anatomical locations may occur multiple times as reference points, but the central theme of the article may not be easy to determine by word frequency. As a result, a number of semantic tools, described later in this article, are used to analyze articles and to classify them appropriately.

Experts of the Nature Publishing Group (NPG), who possess prior experience in online information presentation, based on the online version of Nature magazine, helped to develop the initial vision of the online knowledge repository. The base site is hosted by Nature Publishing Group. While the site was being developed, commercial tools were available to handle both the production of electronic journals and static textbook efforts like AccessMedicine/Harrison's Online (http://www.accessmedicine.com/) and WebMD. However, the gastrointestinal knowledge repository falls somewhere in between these two cases; accordingly, few over-the-shelf tools and algorithms were available for immediate use. As such, a significant fraction of the interface and architecture had to be innovated and refined, through experimentation.

Many of the existing tools for creating electronic journals are geared towards collation of articles, graphics, and layout work. These tools reduce the time needed by the authors and editors for the processes of uploading, formatting, and editing. In the development of Gastrointestinal Motility Online, the use of a software suite facilitated handling of images and consistency of look and feel. One area where tools are lacking is the ability to organize information into a coherent topical fashion, as in a textbook. Searching by keyword is especially difficult on a physician specialty site, where the dialect is limited and the concepts are reused multiple times. As such, editorial staff must impose additional control to prevent the site from becoming a write-only knowledge repository.

Collections of electronic journals, such as Ovid (http://www.ovid.com/site/index.jsp), have been primarily targeted for libraries and research centers. The primary purpose of Ovid is to serve as a warehouse of information, albeit uncategorized. Gastrointestinal Motility Online's current state differs from that of Ovid in terms of the presentation of the material: the former system is specifically formatted to provide an online view as well as a hardcopy output. The long-term goal of Gastrointestinal Motility Online is to collect a comprehensive knowledge on subjects (as Ovid does), as well as to add more intelligent search tools or information utilities. While Ovid does not organize information except into broad categories, Gastrointestinal Motility Online refines classifications, provides responses to search queries that are more accurate, and supports tools that use the knowledge in compelling ways, such as for differential diagnosis.

The advantages of sites built in a textbook style, such as AccessMedicine, is the hierarchical organization and ready access to information. The evolution of online textbooks has generated significant activity on the sites, as teaching tools. Gastrointestinal Motility Online uses over 40 illustrative videos, which are not typical of a journal, but fit the online textbook paradigm. Online textbooks are excellent repositories of information, except that updating the sites to incorporate new information is generally cumbersome because of the level of interactivity involved.

"Gastrointestinal Motility Online" is a hybrid, adopting the best qualities of online textbooks, such as Harrison's Online, and journal collections, such as PubMed. Organized, Well Edited, Frequently Updated and Comprehensive Information are self-explanatory. Search features specifically refer to the ability to search for a keyword or phrase. Differential diagnosis refers to the ability to integrate clinical patient presentations and create a list of possible problem diagnoses.

At a broader technological level, eBooks represent a technology that has been adapted to deliver information electronically. Medical eBooks can be argued to be a natural outgrowth of the eBook movement to electronic media: volume and space requirements are reduced, key phrase searching can be performed, and portability is enhanced. Nevertheless, few medical texts are adapted as eBooks.

Although eBooks have grown in popularity, they have not grown as rapidly as projected by consultants; this could be because of the following reasons:

1. Most readers see no need to replace print books.
2. Due to the limited screen size, limited battery life, and navigation interface issues with eBooks, many people still find paper books easier to handle.
3. Digital rights management causes compatibility and portability problems when attempting to move the eBook from desktop to PDA or laptop.
4. Current pricing of eBooks does not account for the reduced value relative to paper books. When readers finish reading a paper book, they can give it to a friend or sell it to a used bookstore; neither is possible with most eBooks. (Crawford, 2006)

Additionally, delivery of information may not be simply online, but online and to a mobile user using a PDA or other portable device. The constraints involved in transmitting and displaying information on a limited display panel create a new set of challenges. In most markets other than healthcare, the primary applications for PDAs are for scheduling and contact management (as a busy executive might use in lieu of a pen-and-paper daily planner), or as a portable browser or e-mail client (as in the case of technologists and engineers). In such cases, the application of the PDA works within the bounds of the limited display and the modern constraint of minimal bandwidth, often serving as a surrogate cell phone of sorts.

Table 1. The online endeavor

	Online Textbook	Journal Collections	Hybrid – GI Motility Online
Organized	X		X
Well Edited	X		X
Frequently Updated		X	X
Comprehensive Information		X	X
Search Features	X	X	X
Differential Diagnosis			X

However, in medicine, the PDA is often stretched beyond its limits. The current trend is the delivery of detailed information pages into a portable format, downloadable to PDA. Since medical practitioners can no longer maintain a complete mental catalog of all drugs and particularly obscure clinical symptoms or diseases, PDAs assist physicians in their duties without requiring a quick trip to a computer terminal or a large paper binder archive. Harrisons and UpToDate have both moved rapidly in this area, and the list of available drug databases is already large. PDAs fill the role of drug lookup very well, as well as serve as a primer for obscure diseases. The difficulty lies with more graphically intense data that may not display properly, or may need to be downloaded on the fly. In such cases, medical information systems are pushing the technological limits of PDAs.

PDA sales as a whole, however, are in decline, except as a niche application. Analysts at organizations such as IDC and Gartner have predicted downtrend trend in sales of PDA. Dell has withdrawn its PDA line from production (Mechaca, 2007). In the long term, the PDA may carefully constrain its niche to feature more of the portable planner features and less multimedia and display power, rendering it less useful to medical practitioners. Until the advent of revolutionary new display technologies, such as holographic displays or direct-to-eye projection technologies, the ability for PDAs to contribute to medical reference appears to be technologically limited.

As shown in Table 1, Gastrointestinal Motility Online is a hybrid that lies between the two models of electronic journals and online textbooks, exclusively focused on providing authoritative information in an organized fashion within a specific domain. Using this system, a gastrointestinal researcher can find the most recent journal articles because of the frequent updates, and a gastrointestinal clinician can easily locate a detailed diagram of the lower esophageal sphincter. In addition, topical information can be cross-linked between papers—a typical feature of textbooks and very pertinent for teaching and presentations.

CONCEPTS AND INNOVATIONS

The exploration of the technological space between electronic journals and online textbooks is a relatively new idea. All new ideas face challenges in terms of deployment and adoption. Consider the fax number. As the number of fax machines increases, the value of the fax increases—this illustrates the fact that networks attain greater value with larger number of users. The difficulty faced by Gastrointestinal Motility Online and other specialty interest sites is in terms of initial growth and development of specific communities of interest. These sites must be aesthetically attractive, informative, efficient, and up-to-date.

The case of Gastrointestinal Motility Online illustrates one form of evolution of online journals and textbooks into an active online scientific community. Site loyalty is achieved and maintained by the reputation of the authors and contributors. Gastrointestinal Motility Online needs only to achieve a critical user mass before gaining the benefits of Web sites like e-Bay (http://www.ebay.com/) or Amazon (http://www.amazon.com/) in terms of de facto authority and brand recognition. For sites which are less commercially oriented, the loyalty of the user base is perhaps even more heavily emphasized. Two notable sites, which have grown rapidly without such a strong commercial bias, are Wikipedia and Imdb.

Wikipedia has been both maligned and praised for its loyal community and efforts to create a free encyclopedia that is accurate and up to date without any commercial affiliations. Wikipedia began in 2000 as a complementary project for Nupedia, in which articles were written by experts and reviewed by a formal process (Wikipedia, 2007). In 2001, Larry Sanger proposed on the Nupedia mailing list to create a wiki as a “feeder” project for Nupedia (Sanger, 2001); this spawned rapid growth. By 2001, Wikipedia contained approximately 20,000 articles and 18 language editions. As of 2007, English Wikipedia contains over 1.7 million articles, making it the largest en¬cyclopedia ever assembled. The site relies on the goodwill of its members to write, update and contest articles, and has thus far proven that the Internet community as a whole is willing to contribute towards the database, albeit haphazardly (recent events are more likely to be covered in detail, while significant historical figures languish). Given the size and relatively stable growth of the project, the prospect of a peer-reviewed and written information repository might not be so cynically doomed.

The International Movie Database (IMDB), a site in the top 20 (Alexa Internet, 2007b) U.S. Web sites visited, is the largest Internet compilation of movie information (approximately 900,000 titles and 2.3 million names) (IMDB, 2007). IMDB draws a significant portion of its information from the participation of its user base. Beyond subjective reviews, users are also asked to supply cast and crew lists, production details, and actor biographies. IMDB grew from two lists that started as independent projects in early 1989 by participants in the Usenet newsgroup rec.arts.movies. Each list was maintained by a single person, recording items e-mailed by newsgroup readers, and posting updated versions of his list from time to time. The lists were eventually combined, and by late 1990, the lists included almost 10,000 movies and television series. As the contributions continued to grow rapidly, the IMDB formed as an independent company in 1995 and was later purchased by Amazon Inc. (Wikipedia, 2007b).

The approach of the IMDB system closely resembles the envisioned system for GI Motility Online, with the user population submitting proposed changes, followed by an editorial process. Database content is generally provided and updated by a vast collection of volunteer contributors. There are only 17 members of the IMDB who are dedicated to monitoring received data, although 70% of IMDB’s staff serve as editors (IMDB, 2007), reviewing changes, verifying the information before posting the changes, and policing the forums.

Peer review is considered to be one of the most even-handed and least biased methods of scrutinizing articles for publication. The development of a community, as well as the ability for members of that community to voice their opinions about professional papers is pivotal to the dissemination of accurate information. The model of Amazon or eBay is to allow users to comment, and thereby to signify reliability and approval. Gastrointestinal Motility Online allows users to provide feedback, both critical and supportive, in order to enhance the relevance of articles.

According to Harris Interactive poll, only one-fourth of physicians use the Internet to communicate with their patients (Computing in the Physician’s Practice, 2000). In the same poll, although 89% of physicians use the Internet in their practice in search of information, they spend only six hours per week to browse medical developments. Accordingly, Gastrointestinal Motility Online has been configured to serve as an encyclopedic source, as well as a high-value news feed. AccessMedicine uses a Podcast update model, with 10-minute broadcasts generated daily for use in family practice. Gastrointestinal Motility Online caters to a smaller specialty group with correspondingly less frequent pace of developments, and is therefore less time sensitive.

Automation

Automated content generation or extraction from other publications is not feasible, due to the stringent need to maintain relevance and quality. Thus, deployment of a pure peer-reviewed wiki-style community is precluded by the need to maintain quality. If membership of the wiki is restricted to those users whose credentials are accepted, or if changes must be approved at an editorial level, then a wiki would facilitate the rapid exchange of information as well. In the second part of the endeavor, the goal is to enable machine-assisted updating of the material in the gastrointestinal knowledge repository. Currently, all updates must be initiated manually. The pressure to update, but to update accurately applies to many situations: addition of new material, editing of existing material, and deletion of parts of existing material as new study results become available. Initial thoughts and test results are documented in Sharma (2005).

As the site evolves, the need to keep the site relevant to a particular group of specialist physicians may conflict with the preferences of another significant category of users: the researchers. Gastrointestinal Motility Online intends to use user-based customized layout, as presented by Sarnikar et al. (2005). The filtering of details from the main knowledge repository is not intended to block or hide information, but to provide a more relevant source. Classification and weighting are accomplished by a rules-based system that can assess whether an article is clinical- or basic science-related. Login will also provide both the ability to contribute and comment on articles, and to obtain a specialized view depending on the type of user. The application of user-based site layouts is not innovative, but is important to the domain of medical informatics because physicians attach such a high priority on relevance.

Given the large number of articles published weekly and the difficulty in ascertaining relevance and quality, a number of automated tools will be used to optimize the updating process. Sarnikar et al. (2005) present one technique that will assist in filtering journal results and maintaining and updating the site. Their method selects articles ranked by relevance using a combination of both rule-based and content-based methods, using the following principles:

1. Profiles are modeled in the form of rules.
2. The purpose of the rule-based profile is to identify a sub-set of documents of interest to a user.
3. Each role has a set of predefined rules associated with it.
4. Rules specify knowledge sources to access (e.g., nursing journals for Nurses).
5. Rules can specify knowledge depth and knowledge breadth.
6. Rules can specify semantic types of primary importance to roles.

Profiles are used in the gastrointestinal motility context to separate information into categories: for example, new clinical findings versus basic science. Articles may be assigned a category and a relevance weight, given categorization rules based on Unified Medical Language System (UMLS) synonym lists and the categories *sign or symptom, diagnostic procedure therapeutic or preventive procedure and disease or syndrome semantic types.* In addition to a text search in the abstract, Sarnikar and Gupta (2007) also assign weights to the type of journal. These tools can select and filter relevant articles for presentation as an RSS XML news feed to editors or automatically assemble relevant articles for use by the editors or Web site administrators. While these tools will aid the editor, there is no replacement for the role of humans in decisively selecting and classifying information.

Ontologies and semantic networks are prerequisites to the development and classification of information repositories. Ontologies serve many purposes (Kumar, 2005) including:

- Reuse and sharing domain knowledge
- Establishing classification schemes and structure
- Making assumptions explicit

They further enable analysis of information and complement the stricter terminology that is used in straightforward text searches. Examples of ontologies in use today include the National Library of Medicine's Medical Subject Heading (MeSH), disease specific terminologies such as the National Cancer Institute's PDQ vocabulary, drug terminologies such as the national drug data file, and medical sociality vocabularies such as the classification of nursing diagnoses and the current dental terminology. In Gastrointestinal Motility Online, the ontological hierarchy will be used to distinguish between sections of the gastrointestinal tract, from the stomach and esophagus to the large intestine and colon (Kumar, 2005).

A key enabler for development of automatic information processing is the set of ontologies presented in the UMLS semantic network that rely upon the concepts built in the UMLS concept hierarchy. Hierarchical and clustered ontologies allow software to construct knowledge trees, conglomerating relevant knowledge. An overview of the UMLS is available at the unified medical language system: What is it and how to use it? (http://www.nlm.nih.gov/research/umls/presentations/2004-medinfo_tut.pdf).

UMLS is an aggregate of over 134 source vocabularies, including the classifications from such lists as ICD-10 and DSM: IIIR-IV. It represents a hierarchy of medical phrases that can be used to classify most medical articles and textbook entries. For example, using UMLS, the following phrases are grouped similarly: *Deglutition Disorders, Difficulty in swallowing, Difficulty in swallowing (context-dependent category), Dysphagia NOS, Dysphagia NOS (context-dependent category), Can't get food down, Cannot get food down, Difficulty swallowing, Difficulty swallowing (finding), Dysphagia, Dysphagia (Disorder), Swallowing difficult, Swallowing Disorders* (Aronson, 2001).

The system described in Sharma (2005) uses techniques of Natural Language Processing (NLP) to construct a semantic understanding that surpasses text searching. Using the automated integration of text documents in the medical domain (ATIMED) system, the content and order of phrases are related lexically using a concept called Word-Net. Word-Net operates on the verbs, subjects and objects of the sentences, comparing sets and subsets of subject-verb-objects collections in order to determine topic relatedness.

Word-Net further uses a lexical dictionary to determine similarity in all verb pairs and then subject-verb-action pairs. Sharma (2005) uses the following two sentences as examples: **Dysphagia is a disease and defined as a sensation of sticking or obstruction of the passage of food. Dysphagia is related to obstruction of passage of food.** Since both sentences contain similar objects and subjects, and use the verb "is", the sentences are deemed similar. However, within the current mechanism, the phrase, **"Dysphagia relates to obstruction of passage of food"** would result in a poorly scored correlation or low match because the action verb is not similar (Sharma, 2005).

Finally, the same technique allows the creation of new documents by collating sentences and paragraphs from various documents. An initial method of grouping sentences uses the quantity of concepts expressed. This method is further refined by evaluating the sentences based on the following criteria: *similar-subjects, similar-objects, similar-subjects-objects,* and *similar-objects-subjects.* Based on the structure of English grammar, these techniques have been reliably shown to collate relevant data into a readable format.

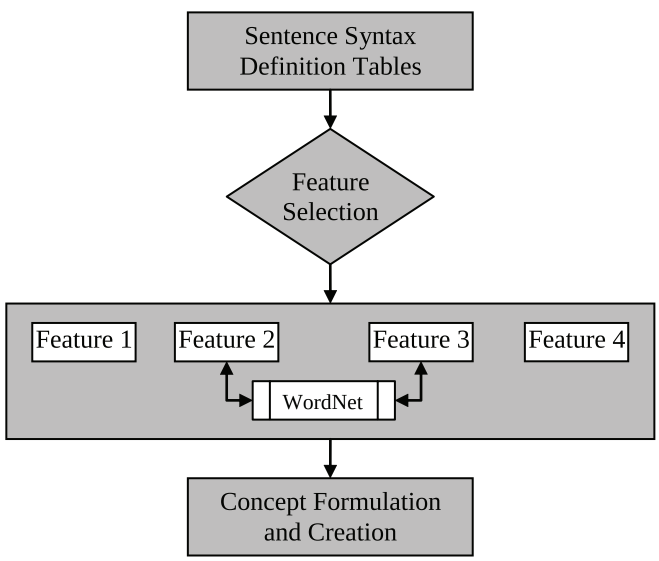
A diagram of the method is shown in Figure 1.

A sample output, based on the use of this technique, is provided below:

REGURGITATION is defined as the spontaneous appearance of gastric or esophageal contents in the back of the throat or in the mouth. In distal esophageal obstruction and stasis, as in achalasia or the presence of a large diverticulum, the regurgitated material consists of tasteless mucoid fluid or undigested food (Sharma, 2005).

The context interchange of heterogeneous sources of information being collated for different classes of users leverages tools from an additional branch of information technology. One level of development is the creation of maps between inputs and outputs, in much the same way that a dictionary might map between languages. The conversion of *n* sources to *m* outputs can grow to be an exponentially difficult problem; this can be addressed with the use of intelligent heuristics and protocols to selectively prune the data. Difficulties become particularly apparent with changes in any client schema that cause a cascade of changes in the mappings (Sarnikar, 2005). Using an independently developed predefined mediating schema would restrict the amount of information that could be exchanged. Apart from relational schema, a client schema could also be specified as a hierarchical schema or as an XML-based message (Sarnikar & Gupta, 2007). In the context of Gastrointestinal Motility Online, the specific source contexts are innovative journal papers, reviews, and textbook articles. The output contexts are specialist clinicians, researchers, students, and other health professionals. Developing a schema to accurately represent journal abstracts and determine the relevance of those abstracts is another method of exchanging contexts. Innovation in this domain will allow Gastrointestinal Motility Online to maintain updated, consistent-quality

Figure 1. Integration of semantic understanding to generate new information (Adapted from Sharma, 2005)



references without requiring an editor to read every journal article published immediately.

LESSONS LEARNED

The GI Motility Online site benefited from a mature development environment for Web-based information retrieval.

Interface: In the case of GI Motility Online, the user base is a readily identifiable group, trained in a similar fashion, with specific needs and expectations of organization and formatting. The following two aspects influenced the design process:

- Pagination is a critical issue for online didactic materials. As people do not like the interface to online books (Crawford, 2006), the development of the site must reflect the reading style and needs of its users. In the case of GI Motility Online, there are currently no page delimiters; this is encouraging users to print the material to be used as a reference. A solution of delivering a formatted print-ready PDF could be applied, but the cost begins to climb with the number of different formats and delivery options supported.
- Tables must be handled intelligently. Tables are used in many medical publications to rapidly and clearly present information. The trend in the mid-1990s for netiquette was to inline the tables with the text, but this can create awkward gaps or poor formatting choices. GI Motility Online chooses the path of Harrison's Online, in linking to the tables outside the main document to preserve readability.

Based on their respective training, many physicians expect a particular language and layout of medical information. The highest-value information for each physician may vary based on specialty, and user-customization of graphical widgets may enhance information value. Since GI Motility Online aims to support a broad base of users with many different roles and information needs, reusable widgets, of the type available in customizable Web-portals, may potentially solve these varying needs.

Workflow: As stated previously, over nine months was required for simply editing the site information, moving documents back and forth between editors, experts and developers. The method involved several inefficient technologies, such as mailing CDs and sending large files through mail servers. The advantage of such hands on interaction and communication is the result: the authors of the site are particularly pleased by the polished appearance of the delivered product.

Electronic collaboration between different sites was difficult due to the nature of document formats, which does not produce a consistent print layout on different computers, and layout formats, which do not allow easy markup or revision to the document.

The use of a standardized input format and efficient conversion of the RTF-formatted documents into Web viewable formats was crucial to the development of the Web site. Though conversion of documents is a minimally complex task, the production of a site that allows conversation on the fly to support concurrent editing and proofing between multiple users is a challenge. Online publishing companies, such as Atypon, offer suites of software to facilitate publishing workflow, allowing multiple authors to upload articles, multiple editors to revise articles, and art editors to manage graphics, all in an organized fashion.

Metainformation: The World Wide Web provides a tremendous asset in connecting related articles seamlessly. In determining related pages, an active agent—a human, machine or some combination thereof—who must isolate the crucial elements of a page and capture that as meta-information, preferably categorized. Organized meta-information allows automated tools to develop connections and links to potentially relevant information.

Extracting crucial elements of a page is best handled by encouraging authors to define keywords, as with scientific articles. Although many automated agents have historically been unsuccessful in information extraction, the medical domain provides some assistance with standardized ontologies, which allow agents to categorize information in a framework, reducing some identification errors.

Maintenance: Many articles in mainstream sites, such as ESPN.com, offer the opportunity for users to comment and leave feedback. This increases user participation and value to the site, but raises additional issues that need to be addressed, such as:

- Profanity or other inappropriate comments must be censored
- Sites are more open to attack and security leaks due to their increased functionality
- Bandwidth usage increases, and may debilitate the site

In addition, a version control framework must be established for sites that allow updates, in order to rollback unwanted changes. Furthermore, hardware resources must be allocated to store site changes.

CURRENT USAGE AND FUTURE DIRECTIONS

Anecdotal evidence provided by the lead creator of GI Motility Online, Dr. Raj Goyal, highlights that the representatives of Nature Publishing Group describe the site as being popular, and that site visits to GI Motility Online are increasing. Due to the delicate nature of conversation with his peers in gastroenterology, Dr. Goyal cannot be certain, but he states that initial impressions are unanimously positive and enthusiastic. Dr. Goyal notes that the majority of the traffic to GI Motility Online currently arrives from Google, and indeed, Google's first returned site in response to "GI Motility" is GI Motility Online (Google, 2007). GI Motility Online does not currently permit any advertising; if this policy is revised, the usage patterns may change. Further, the numbers for site visits are expected to increase if the site were to be more supported by Nature Publishing Group.

The stakeholders are satisfied with the quality of the product, and are ambitiously pursuing an extension of the product to broaden coverage to other parts of the GI tract.

Dr. Goyal has received inquiries to publish the material in a hardcopy format. Custom-built books or full-page colored slides offer additional utility to medical educators, specialists, nurses, and students, and may also offer a revenue stream. These custom-built printable books are a logical extension of the current "print what you want" photo fulfillment services that are popular on photo sharing sites or album hosting services. Given that Harrison's Principles of Internal Medicine contains over 2,000 colored pages in book form, there may be a future for customized books in medicine.

Retrieval: New algorithms for search and ranking are not merely lexically-based, but also combine closely related concepts and relationships between ideas. This facilitates the creation of a richer search language that can account for relationships, such as causation, consequence, association, treatment, or opposite. For example, hypothermia is directly opposite hyperthermia, and may be caused by thalamic alterations. Such basic chains of relationships could be easily captured if the language and storage of meta-information about articles could contain the necessary underlying details.

Presentation: Using Tufte's principles (Tufte, 2001), the real estate of a screen needs to be more efficiently used. Currently, most search-engine results do not often give the sense of the relevance of the article, of the correct sections, or the tone of the article. The information density of the return pages is low, causing users to scroll through potentially hundreds of articles to find relevant information. Graphical interfaces are likely to be a solution, as the ability of the Internet to handle higher bandwidth applications grows. In medical research in particular, an interface, that allows users to quickly see search results of the primary concept and even related concepts, may dramatically affect usability.

Online Sharing: Bulletin board systems, which flourished during pre-Internet days, have re-emerged on the Internet as forums, and are a popular source of information. Corporations with significant Internet presence, and especially gaming companies like Nintendo (http://forums.nintendo.com/nintendo/), have begun adding and using these forums as a method of improving public relations and offering support.

Intranet and Internet file sharing systems have also flourished, as bandwidth rates increase. The rise of Youtube is one phenomenon, but the comfort of using the Internet to disseminate multimedia (such as GI endoscope video) appears to be more solidified. These high bandwidth applications have grown in acceptance, and despite the threat of viruses in downloaded files, file-sharing traffic is increasing daily.

Megaupload and Rapidshare, two prominent file sharing services, are now ranked #18 and #27 in the reliable Alexa ranking (Alexa Internet, 2007b) of most visited Internet sites in the U.S. However, these services are predominantly used by non-commercial entities. Commercial enterprises may be hesitant due to slow adoption, security issues, bandwidth maximums, or unprofessional presentation. Such file sharing sites will certainly cater in the future to commercial entities, perhaps by providing specially developed sites, or providing branded services. The future of the Internet, and especially the ability to deliver high bandwidth, will increasingly rely upon specialized sites with high-capacity and high-bandwidth connections close to Internet backbones.

Collaboration: Collaboration in the domain of GI motility will drive improvements in language tools, with many GI specialists throughout the world who may need to collaborate via the Internet or phone services. Currently, Altavista and Google offer Web-based text translation, but more intelligence or domain-specific knowledge may be required. One common example in GI translation is translating the world "oral" to mean "verbal", when in fact, the correct reference is to the mouth cavity. Overall, however, text translation between languages is generally adequate for initial communication.

Oral translation is a high value direction to pursue, but at the same time, is a very difficult task. Psycholinguistics research is still unraveling the complexities of language parsing, and the ability of current artificial intelligence to understand language is severely limited. Nevertheless, translators in this area will prove essential and highly desirable for the next generation of online collaborators.

Similarly, one of the holy grails of artificial intelligence development is the creation of an artificial system capable of interpreting human language. Within specialized domains with limited vocabularies, artificial readers become more feasible, but the medical domain is particularly difficult, due to its large specialized vocabulary. Development in this area would provide rewards for medical researchers, allowing the creation of agents, which would allow researchers to process more information by selecting and even summarizing articles.

Organizationally, scientific research in domains such as medicine would benefit tremendously from the creation of a centralized authority to monitor, synthesize and rate research. The current system of research funding in America places research at the whim of special-interest private funding and sometimes misdirected public funding in overly popular or extremely esoteric areas. Regulating and directing research might also help avoid repeating inconclusive research, which does not get published (and thus may be repeated).

CONCLUSION

Gastrointestinal Motility Online is an evolving knowledge base related to Gastrointestinal Motility disorders. The current phase of the endeavor focuses on the collection and organization of knowledge from many different sources. Knowledge-mining tools are being developed to utilize this information as it becomes available to add fast, relevant access and other utilities to the information repository.

The continuous change in standards of care and knowledge due to rapid discoveries in the basic and clinical sciences prompts for a system that is more flexible than a textbook, while demanding thoroughness and accuracy. Knowledge mining tools and other advanced technologies to aid in the conversion and integration of articles and research into the mainstream science are being integrated into Gastrointestinal Motility Online, and look to impact the breadth and speed of knowledge-base upgrades. Gastrointestinal Motility Online serves to balance the needs of its user base while embracing the academic rigor in a novel application of technology to the science of medicine.

ACKNOWLEDGMENT

The authors would like to thank Dr. Raj Goyal for his invaluable input and contribution to GI Motility Online and this article. The authors also thank Richard Martin for his helpful comments and proofreading of the text.

Chapter 5.11
Web Services in National Healthcare:
The Impact of Public and Private Collaboration

Matthew W. Guah
University of Warwick, UK

Wendy L. Currie
University of Warwick, UK

ABSTRACT

The implementation of a national programme for information technology into the complex environment of the UK's National Health Service (NHS) system is only the first step in a system modernisation journey for this multifaceted organisation. This article reports the findings of a two-year research study on the decline of the ASP (application service provision) industry, from which the current move to Web services was born. It combines the case of the NHS with existing literature on disparate research perspectives to explore the effects of the 'Not Invented Here' syndrome on an IS implementation journey. The article also suggests ways that project leaders can redirect such strong feelings about a new system to increase the chances for a successful outcome. Information systems (IS) is "an instantiation of information technology (IT), where the same information technology is instantiated in different ways" (Lee, 1999). A rich organizational and political process is required for a given set of IT to be instantiated, relying greatly upon the continual managing, maintaining, and changing of technology to sustain the instantiation. Within a rather diverse NHS environment, IS may include relational aspects like the effectiveness of system design, the timely delivery of such systems, an appropriately obtained usability training by all users, and future impact of IT in the organisational and entire society.

BACKGROUND

The National Health Service for the United Kingdom (NHS) has been responsible for the provision of health care and services in the UK for the past 56 years, on a "free for all, at the point of delivery" basis. The traditional perception of the NHS is one of a healthcare system organised as a professional guild, with unlimited finance from the government. This type of NHS is experiencing an irrevocable change, as taxpayers are no longer complaisant, and paternalistic employers are reacting against inflating costs and escalating complaints from the patients. The employer is reacting to the continuous massive flow of subsidies for inefficient physician practices, fragmented delivery systems, and cost-unconscious consumer demand. The patients are increasingly assertive as to their preferences, and few have expressed their willingness to make additional contributions for particular health benefits and medical interventions.

Web services (WS) are technologies with roots in the application service provision (ASP) business model which are used mostly to automate linkages among applications (Hagel, 2002). They are generally anticipated to make critical systems connections not only possible, but also easy and cheap (Kreger, 2003; Sleeper & Robins, 2001). One of the perceived benefits of WS is that organisations would be able to concentrate on their core competencies (Perseid, 2003). Service providers argued that the remote delivery of software applications would release managers from the perennial problems of running in-house IT departments, allowing more time to develop IT and e-business strategy rather than the day-to-day operations (Currie, Desai, & Kahn, 2004). This justification has been used in traditional forms of outsourcing over many years (Willcocks & Lacity, 1998).

The NHS is experiencing massive changes in the structure of information systems provision markets and organisations. The local service provision (LSP) and national service provision/provider (NSP) models, in use by the National Programme for Information Technology (NPfIT), are in a state of ferment. The payment methods borrow from both capitation and 'fee-for-service', and methods of utilisation management that compromise between arm's-length review and full delegation. LSP and NSP consist of large and more complex entities. These are the result of merger, acquisition, and product diversification. The service providers involved have had to take on a visible feature of ceaseless acquisition and divestiture, integration and outsourcing, and combination and recombination. Providers of medical systems, hospital administration systems, and health plans are coming together and then coming apart. They are substituting contract for joint ownership, creating diversified conglomerates and refocused facilities, and experimenting with ever-new structures of ownership, finance, governance, and management (Robinson, 2000). These would give the NHSIA the benefits not only of a middle ground between the extremes of vertical integration and spot contracting, but also a balance of coordinated and autonomous adaptation in the face of its ever-new challenges.

The general assumption is that expenditures in the nation's health will outpace the overall growth in the economy (Collins, 2003; Pencheon, 1998). This is reflected in the percentage of gross domestic products (GDPs) of the U.S. (13%), Germany (10.7%), France (9.6%), and the UK (7.6%) being devoted to the total cost of healthcare resources (Brown, 2002). Unlike the UK, however, some of these countries are faced with limitations in social willingness to pay. It has been documented that millions of U.S. residents currently lack the most basic insurance coverage (Institute of Medicine, 2002).

Response to Emerging Technologies in the NHS

Over the years, non-technologists in the NHS have managed to muddle through one powerful new system after another. 'Generational strategy' is one continuously being used to deal with some of the pressures induced by IS. Adopting such innovations as PCs and the Internet requires the personal and organizational costs of "unfreezing" deeply ingrained old habits. Many workforces ignore, deny, or deal awkwardly with such technologies.

A common response to new systems is the 'Not Invented Here' (NIH) syndrome (Collins, 2003; Haines, 2002; Guah & Currie, 2002). This often leads to certain organisations rejecting a perfectly useful system based on an implicit assumption that the system does not fully recognise or accommodate their own needs and idiosyncrasies (Brown & Venkatesh, 2003; Davis, 1989). Davis (1989) sees this as a likely result of a decline in communication with external sources. NIH syndrome could also result from competences that can be proven to be outdated and inefficient in comparison to an existing technology. One Trust, which plays a central role in the direction of regional IS strategy, had to reject a Department of Health-promoted system because the system was not as familiar as another bespoke system (Haines, 2002).

The common characteristics of new systems in the NHS are uniformity in products and prices in the face of great variability in consumer preferences and the actual costs of providing service (Collins, 2003). This one-size-fits-all approach usually leads to services that are of excessive costs for some users and insufficient quality for others, impeding the use of price flexibility to enhance capacity utilization (Robinson, 2000). Also of concern is a combination of over-capacity and low load factors in some regional trusts with under-capacity and shortages elsewhere. Concerns are growing in the NHS that this may generate cross-subsidies from trusts for which the cost of service will be low to trusts for which the cost of service will be high (McGauran, 2002). Additionally, deregulation of healthcare costs has spurred an outpouring of new services. Consequently, several of these services are the following (Collins, 2003; Pencheon, 1998):

- A different cost structure
- An impact on IS budgets
- A better match between supply and demand

Incomplete information has been a fascinating attribute of the NHS unusual systems organisational and normative characteristics. The asymmetry of NHS information between patients and medical practitioners has changed in an exogenous fashion over its 56 years. The amount of healthcare information available to patients is usually the result rather than the cause of changes in the economic and political environment (Robinson, 2000).

PROJECT DESCRIPTION: NATIONAL PROGRAMME FOR INFORMATION TECHNOLOGY (NPFIT)

The NPfIT is an initiative by the National Health Service Information Authority (NHSIA), born as a result of several plans to devise a workable IS strategy for the NHS (NHSIA, 2003; Wanless, 2002). The NPfIT was designed to connect the capabilities of modern IT to the delivery of the 'NHS Plan' devised in 1998. The core of this strategy is to take greater control of the specification, procurement, resource management, performance management, and delivery of the information and IT agenda (NHSIA, 2003).

The NPfIT is an essential element in delivering the NHS Plan. It has created £6 billion budget for information infrastructure, which could improve patient care by increasing the efficiency and effectiveness of clinicians and other NHS staff. The intention of the plan is to address the following (www.npfit.nhs.uk):

- Create an NHS Care Records Service to improve the sharing of consenting patients' records across the NHS

- Make it easier and faster for GPs and other primary care staff to book hospital appointments for patients
- Provide a system for electronic transmission of prescriptions
- Ensure that the IT infrastructure can meet NHS needs now and in the future

The decision to implement a national programme for IT into the NHS system complexity is only the first step in an IS modernisation journey for a multifaceted organisation. There are many examples of new technologies disrupting organizational routines and relationships in the NHS (Majeed, 2003; Atkinson & Peel, 1998; Metters et al., 1997). These usually require both medical professionals and NHS Regional Trusts Managers to re-learn how to work together. Orlikowski (1994) and Edmondson (2003) suggest that one technology can be seen differently by two groups of people in an organisation. Findings from Barney and Griffin (1992) and Orlikowski (1994) have showed how this could result in the elicitation of different responses for members of that organisation.

SCOPE OF PROJECT WORK

This article takes a more in-depth look at the role of the NHSIA (seen as the project leader for the NPfIT), currently the most visible spokesperson and translator for the potential implications of the resulting new technologies. Research has shown NHS IS staff to pay particular attention to what the NHSIA says and does in regards to information systems (Collins, 2003; Ferlie & Shortell, 2001). This research builds on a framework that identifies the key dimensions of the NHSIA tactic that is situation-specific for NPfIT as assumptions. The work looks at the NHSIA goal and roles for the NPfIT, as well as the role of the private sector service providers in the implementation of NPfIT.

Here are a few objectives the NPfIT hopes to accomplish:

- To have a series of tightly specified and priced framework contracts on a short list (of about five) primary service providers (PSPs) who can work at the regional/local Strategic Health Authority (StHA) level. This should enforce the integration and implementation partnership — at a national level — during all aspects of the NPfIT project. Each PSP will have an aligned consortium of service providers and vendors for the integrated care resource service element of the NPfIT, and will be mandated to work with the domain PSP for electronic booking the infrastructure providers and healthcare providers. StHA PSPs may not make their products exclusive or mandatory to their StHA.
- To create priced packages of national services and applications that the PSPs and StHAs can together implement locally. This activity will include managing the creation of a single HRIS and other national services, to access and move health record information as required.
- To create Service-Level Agreements for the national services and other services out of the scope of the PSP consortium which the PSPs can work towards in providing an integrated service to the StHA.
- To develop and maintain the national standards and specifications that all vendors must use. It is also anticipated to create the national business cases required for the Department of Health governance (required by the National Treasury), and to support the local decision-making business cases required at the StHA level.
- To procure, under national contracts, a backbone network infrastructure.

Such an arrangement provides the greatest clarity in respect to the appropriate allocation of responsibilities, and should be well understood in the public and private sectors (see Table 1). Services will be procured on a long-term basis so the combination of local and central funding will be required for at least five, and preferably 10, years at guaranteed levels.

THE RESEARCH STUDY

The findings reported in this article are part of a larger, five-year research study that was developed to investigate the deployment, hosting, and integration of the ASP and WS technologies from both a supply-side and demand-side perspective. The overall research was in two phases. The first phase, comprising a pilot study, was conducted in the U.S. and UK (Currie & Seltsikas, 2001). An exploratory-descriptive case study methodology (Yin, 1994) was used to investigate 28 ASP vendors and seven customer sites in the UK. The dual focus upon supply-side and demand-side was critical for obtaining a balanced view between vendor aspirations about the value of their business models, and customer experiences, which may suggest a less optimistic picture. The unit of analysis was the business model (Amit & Zott, 2001), not the firm or industry level, so a case study methodology was anticipated to provide a rich data set for analysing firm activities and behaviour (Currie, Desai, & Kahn, 2004).

The result from the pilot study led to the funding of two additional research studies by the Engineering and Physical Sciences Research Council (EPSRC) and the Economic and Social Research Council (ESRC), respectively. Industrial collaborators were selected for the roles of technology partner, service providers, and potential or existing customers. These studies were concerned with identifying sources of value creation from the ASP business model and WS technologies in different vertical sectors (including health).

Research Methodology

The research followed a number of stages involving the use of both qualitative and quantitative data collection techniques and approaches (Walsham, 1993). A questionnaire survey was distributed by e-mail to businesses and healthcare organisations all over the UK. These organisations were listed on a national database maintained by the NHSIA,

Table 1. PSP implementation timetable (as of July 2002)

Activity / output	***Target Date***
Agree Procurement Strategy (DoH & local health authorities)	End Jul 2002
Service requirement finalized and approved	End Sep 2002
Outline Business Case developed and approved	End Sep 2002
OJEC Advert	Oct 2002
Procurement of systems and implementation services for electronic booking begins	Oct 2002
National long list PSPs created	Dec 2002
Invitation to Negotiate Issued	Jan 2003
National shortlist PSPs created	Apr 2003
First local health authorities begin detailed planning with PSPs	Aug 2003
PSP Framework Contract finalized	Oct 2003
Infrastructure provider(s) contract agreed	Oct 2003
First local health authorities begin implementation	Nov 2003
Infrastructure migration begins	Mar 2004

plus those maintained by the university. To ensure relevant managers and practitioners responded, the cover letter clearly stated the purpose of the questionnaire and requested that it be passed on to the person(s) with responsibility for managing healthcare e-business strategy.

The Questionnaire

Scales to address the research questions were not available from the literature, so the questionnaire was developed based on the theory of strategic value (Banker & Kauffman, 1988). It included a checklist, open-ended questions, and a section seeking organisational data. Research questions under Part I required respondents to answer yes/no if the application of Internet technologies in healthcare was bringing value to patients. Data in Part II of the questionnaire was collected by open-ended questions seeking respondents' views on the best approach to healthcare performance improvement and WS value creation. This line of questioning was used to increase the reliability of data, since all respondents were asked the same questions, but some added additional information. The purpose was to impose uniformity across the sample of representation, rather than to replicate the data obtained from each participant (Yin, 1994).

ANALYSIS

As a result of the first phase of the research carried out in the U.S. and UK, a database was developed of 700 international firms, all of which had developed an ASP business model. The data served to build-up a 'data-bank' of market intelligence on a variety of ASP firms and their offerings. Many of these firms were tracked over a four-year period to identify changes in their business models. From this sample of 700 ASPs, about 55% continued in application provisioning (excluding infrastructure) by the time Phase II of the research began. A good number of the original sample had ceased to exist (about 24%), and some had been taken over by other firms (about 6%). The remaining (about 15%) had changed their business model, moving away from software-as-a-service (Kakabadse & Kakabadse, 2002) into data storage and managed services provisioning. The ASP database proved to be a very useful source of market intelligence for the research study since it helped to develop a questionnaire survey targeted at the healthcare sector.

In Phase II of the research, a total of 350 questionnaires were distributed to NHSIA directors, current and prospective suppliers of IS to the NHS, and medical practitioners from general practices in major cities as well as rural towns, in an effort to avoid bias. The vendors were drawn from a list of businesses negotiating for contract under a PSP scheme (Guah & Currie, 2004). After persistent follow-up (telephone calls), 225 questionnaires were completed and returned, representing a 64% total return rate. As this study was exploratory in nature and was designed to develop a framework to inform practice and guide future research, rather than testing hypotheses (Avison & Fitzgerald, 2003), the 225 organisations' situations on which it is based provided useful preliminary data.

Respondents were mainly middle-level business managers (60%) offering various Internet-related services in WS to the global healthcare industry, while the rest (40%) consisted of medical practitioners working in the NHS. The 40% included IT coordinators at different institutions nationwide, some already implementing WS architecture locally. The vendor organisations were predominantly American and British, consistent with the business structure in the UK. Seventy-eight percent of the companies were large ones with an annual turnover of over £1 billion, while 13% had between £25 million to £1 billion, and 9% were considered small with an annual turnover of less than £25 million.

Technology for gathering information is not a new thing in the NHS. Nevertheless, a few questions remain such as:

- Has IS accelerated to a point at which long-practiced denial is no longer possible?
- Has IS become so important to the NHS that a single project (NPfIT) implementation can no longer be ignored by any part of the NHS?

Nearly all our interviewees (79%) believed the cacophony of IS is approaching a critical threshold and they don't know how to prevent the volume from becoming even more deafening, let alone how to turn it off.

DISCUSSION

Earlier findings suggest that most of the software applications offered by vendors were loosely defined as horizontal business applications (i.e., accounting, human resources, fixed asset management software, etc.). Even where the NHS was deploying the Web services for more complex applications, there was little evidence that the scale and scope of usage amounted to extra time for managers to engage in other activities. Other benefits to the NHS were defined in terms of cost savings from total costs of operation (TCO). Many vendors used TCO models to show how IT costs would be reduced using a remote software delivery model. Our findings pointed to a lack of relevance in TCO models, particularly for the NHS with increasing demands on low IT budgets. One NHS IT manager said:

"Our overall IT spending is only about £150 k per annum. I don't think using a Web service solution will necessarily save us much money. But if it means fewer headaches with physicians using IT, then I would be prepared to pay more for Web services! "

Integrating Healthcare Applications with WS

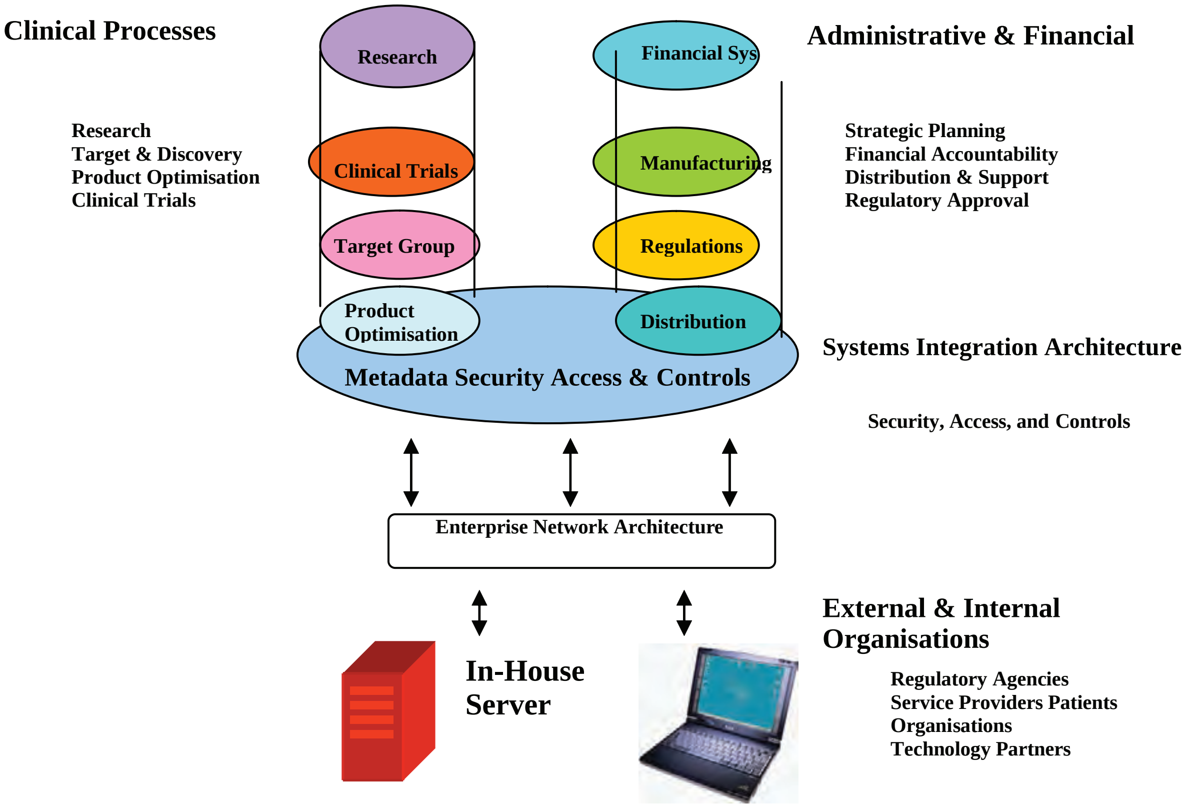
Medical practitioners among our interviewees failed to see the integration of software applications as an immediate priority. Some didn't see it as a priority they were prepared to pay for. What then is the NHS interest in WS? Many organisations in the NHS were deploying WS solutions that were non-mission-critical (e.g., e-mail, rather than patient records). One medical consultant, using an electronic diary application, commented:

We were not particularly looking for a WS solution to organise our time management. However, when a vendor approached us with a product for diary scheduling, we thought to give it a trial. The main advantage of this is that you can make changes to patient appointments from a remote location and submit the data to the surgery. It is particularly useful for staff working away from the surgery for long periods, but the current shortage of GPs in the NHS does not encourage that.

Such comments show the complexity of the outsourcing relationship between supplier and customer. It is largely effected by the number and scope of such partnerships, the sophistication of the products/services, and the type of outsourcing contract. Differentiation in products/services further suggests a more complex procedure for benchmarking service providers' performance, with measures designed to evaluate outcomes at every stage of the system development and implementation process (Ahn, Leem, & Yang, 2001).

One area where WS could potentially make a significant difference is the integration of software applications across multiple platforms, sites, and departments of healthcare organizations (Laroia, 2002). A commonly cited benefit from service providers was that software applications across business and IT functions could be integrated to fulfil the goal of enterprise application integration. Many service providers planned to develop a wide portfolio of business applications (including ERP, CRM, accounting and financials, logistics, etc.), which could eventually be integrated to provide the customer with a comprehensive enterprise solution.

Figure 1. Complex data generated by healthcare enterprises value chain



Majeed (2003) questioned if the employment of such features is sufficient to successfully deploy and manage IS in healthcare, where patient data and processes must be integrated, managed, and deployed strategically. To manage such real-time procedure requires the integration of complex enterprise information (see Figure 1) including the following:

- **Research:** Molecular, genetic, proteomic, and pharmacological data
- **Manufacturing:** Integrated global pharmaceutical information on drugs manufacturing process
- **Metadata:** Information about what is contained in these phases of development
- **Clinical:** Clinical trial, side effect, outcomes, and "real-life" effects of drugs
- *Validation*: Strategic planning data on the validation of the drug for the target patients
- **Administrative:** Healthcare claims, membership, diagnostic, and treatment data
- **Financial:** Design, development, pricing, deployment, and patient intelligence data

These have been articulated in two "stacks" of data presented in Figure 1:

1. **Clinical:** The data and information supporting medical and research and development (R&D) of new drug entities
2. **Administrative and Financial:** The data and information supporting the processes of drug approval, production, distribution, and patient care monitoring

Figure 1 describes the data model for the integration of information across the value chain of a healthcare organization that is multi-vendor and multi-source. Such an organization encourages the definition and sharing of data — within the organization and among partners and regulators.

Eisenhardt and Martin (2000) highlighted that credibility in identifying benefits from an IS is the top constraint, followed by cost justification. The NHS is aware of the potential benefits private service providers can bring to healthcare. On the other hand, it is unable to quantify those benefits and is therefore being sceptical of the scale. This scepticism may be strengthened by a degree of distrainment engendered with past experiences with IT projects.

The following are some of the factors that will promote implementation success:

- Support from trust managers
- Availability of sufficient resources
- Prime users' prior experience with similar technology
- Technology introductory procedure
- Reputation of technology in other industries (preferably other government departments)

Expressing concern about IT's great leaps forward is more than politically incorrect when a national IT project is being fully deployed (Williams, Dobson, & Walters, 1990). Most of the documentations on current discussions of the future of emerging technologies in the NHS come from insiders (scientists and technologists on scientific and technological grounds). The intention of this article is to present a view from outside the technological world, and on social and psychological grounds. The argument in this article is based on this unsettling proposition:

Information technology in the NHS has accelerated, is accelerating, and must continue to accelerate, but both medical staff and patients must become key players in that process.

The above proposition is both inevitable and scary. However, several authors have given a moderately rational basis for the position that information technology in the NHS has accelerated (Eccles et al., 2002; Jacklin et al., 2003; Keen, 1994) and must continue to accelerate (Doherty, King, & Marples, 2000; Majeed, 2003). Such basis extends well beyond the now familiar truth that more knowledge has been accumulated in the past 15 years than in the previous four decades of the NHS existence.

New systems are usually integrated into particular sub-cultures by different routes. In most medical systems, technological change is often mediated through opinion leaders, often respected doctors (Doherty, King, & Marples, 2000). Although some systems (i.e., diabetes monitoring systems) are initially adopted out of necessity, sometimes systems are adapted over time without conscious awareness that they are doing so.

On the other hand, IS — which the NHSIA seeks to promote and control — has also ensnared the NHS. Unless they keep up with global healthcare technological development, the NHSIA cannot hope to survive the violent, ever-changing mix of inter-organisational warfare and collaboration that has become their normal milieu (Leavitt, 2002). Some of our non-technologist interviewees saw the situation with IT in the NHS this way:

Between IS and the NHS, it is now no longer clear which is master and which is servant. What is clear is that both have spiralled up to positions of enormous social power.

IS's rising status and budgetary allocations signals much more than a mere shift in the NHS hierarchy. It also signals a shift in the thought-to-action ratio. IS becomes a drive shaft that turns the wheels of change in an organisation (Leavitt, 2002; Scott et al., 2003).

Few in the NHSIA hide their irritation at the frequent requests for real deliverables from past national IS initiatives. But is this enough justification for a huge project, like NPfIT, which stands to really change procedure for delivering health to the NHS users. One executive claimed that the identification of problems is the first step toward its solution. This project could presently deliver one modest deliverable that might help dampen users' resistance based on past projects. The NHSIA should learn to look further ahead at the possible effects of new technologies that would emerge from this project. Research findings haven't done a very good job of such forecasting (Gerowitz et al, 1996).

To deal with such an important part of the NPfIT, the NHSIA needs dialogue, not just among the IS departments, but among other staff and prospective users of IS in the NHS. This approach would handle the project's possible long-term social impact on its end-users. As most of the phase implementation goes ahead, the users await the transition from this achievement to its forthcoming implementation. The fact that this is one of those issues being debated vigorously sends a positive but inchoate signal to the staff and patients of the NHS (Marshall, 2003; McGauran, 2002; Robinson, 2002). However, a nationwide project costing £6 billion has become far too important to be left to one NHS agency and their private sector collaborators. There ought to be something more formal pushing the look-ahead idea further. Users are impatiently awaiting news of real actions being taken to avoid problems in the future and the consequences of things that may go wrong within the patient care process as a result of a failed NPfIT. The NHSIA should identify, at an early stage of the developmental process, the most likely social, educational, psychological, moral, and other probable fallouts of emerging technologies of the NPfIT, and propose ways of coping with them.

The Treasury sees economic rewards in promoting cost-decreasing healthcare services, given the government's own pressure to restrain inflation (Wanless, 2002). This affects the NHSIA emphasis on making each process in the NPfIT face continued pressure towards evolution or extinction. However, similar projects in the past have exemplified the process of organisational experimentation that has been unleashed by the transition to unmanaged internal competition in a NHS (Keen, 1994; Robinson, 2002). One anticipated benefit of the NPfIT is the nationwide integration of patient information, expected to moderate cost inflation. This must be an improvement on the traditional system of professional dominance and partially implemented systems of utility regulation and internally managed competition.

CONCLUSION

The original demand placed on IS in the NHS was to reduce the cost of healthcare, and not necessarily to improve quality and service. To this cause, most existing systems have responded accordingly. Patients, however, are now increasingly worried about the quality of care they receive from the NHS as a result of such cost-control measures. The NHSIA needs to shift its IS strategic emphasis to developing methods for measuring rather than improving service in a manner analogous to the process pursued in the NHS after deregulation. NPfIT should provide the NHS with a system that is subjected to systematic monitoring of quality and service levels. The intent should be of promoting clinical comparisons and quality-conscious patient choice. NHSIA is in no position to expect that a salient feature of the NPfIT will be reliance on unmonitored trust and opposition to quantitative, validated measures of performance. LSPs and NSPs should ensure satisfaction surveys as indicators of preventive services utilization. There must also be a means of tracking appropriate clinical processes and risk-adjusted measures of patient outcomes. If these are taken seriously by the NHSIA, the NPfIT will prove to hold great potential to enhance as well as simply measure the quality of care, since statistical and epidemiological methods always outperform the pick-and-choose approaches to quality improvement (Robinson, 2000).

The emerging technologies from NPfIT are expected to pioneer new methods for the collection, dissemination, and comparison of data on patients and clinical quality. While the progress to date has been frustratingly slow, it has laid the foundation for more specific, severity-adjusted, and outcomes-oriented measures in the future.

Some are afraid that the NPfIT, like other IS innovations in the NHS, it will not progress smoothly, nor always at full throttle. The message that seems to be coming from the NHSIA is that this project will surely go forward.

Despite some pessimistic views in this article, it is clear that the NHSIA strategy of private partnership has brought some benefiting systems to the NHS, which have outweighed its costs (NHSIA, 2003; Robinson, 2002). While some users look upon further IS acceleration quite positively, others have visualised an enormous technology-driven economic expansion ahead for the NHS. Most staff continues to envision a technological paradise awaiting the NHS at the end of the NPfIT. Some may even dismiss this article as just another illusion.

Chapter 5.12
Using Hospital Web Sites to Enhance Communication

Sherrie D. Cannoy
The University of North Carolina at Greensboro, USA

Lakshmi Iyer
The University of North Carolina at Greensboro, USA

INTRODUCTION

A large number of patients currently utilize the Internet to access healthcare-related information (Tobin, 2002). Many physician and health-related Web sites have been information portals lacking interactive services that could benefit healthcare partners through decreased costs, increased convenience, and communication. Patients typically visit Web portals to learn more about medical topics, often discussing this information with physicians.

Emerging Internet technologies can be a strategic asset for hospitals to impact physician bonding, patient self-service, and overall enterprise performance efforts. We conducted an investigation of Web sites of 10 hospitals listed in *U.S. News and World Report*'s Best Hospitals of 2004 Honor Roll, as well as a random selection of seven other hospital sites. An examination of each hospital's site was performed to determine what features were provided to enhance communication between the partners in healthcare. Partners are defined as patients and their families, referring physicians, insurance companies, vendors, pharmacies, job seekers, and the media. Communication-enhancing features are any features that have the potential to increase communication between the hospital and its partners. We focused on patient communication-enhancing features, since patients are the primary partners of healthcare entities.

BACKGROUND

Healthcare Basis

A medical Internet Usage Survey conducted by the Health on the Net Foundation (2002) found that 57.95% of the respondents had used the Internet for more than four years. Of the patients who responded, 21.62% correspond with their providers through e-mail and 75.52% have used online medical consultation services; 69.47% of physicians that responded stated that patients discuss information they found on the Internet with them, while 62.75% of those providers recommend specific information-based sites to their patients.

Healthcare can be improved through e-health services such as online patient pre-registration for admission, access to test results and medical records, insurance referrals and eligibility, access to reputable links for accurate healthcare information, patient forms and brochures, online support groups, access to clinical trial information, appointment scheduling and reminders, refill requests and authorizations, and e-mail capabilities. In implementing e-health "there is an urgent need for healthcare organizations to re-engineer their processes" (Wickramasinghe, Fadlalla, Geisler, & Schaffer, 2004), and physicians face obstacles such as "technologic barriers, resource priorities, and privacy issues" (Zingmond, Weilim, Ettner, & Carslile, 2001) that are secondary to providing excellent healthcare. Hospital and medical office sites can be enhanced to offer patient-centered services, while informing patients of their strongest services/specialties, convincing the patients that their organization is better than any general Web portal for accessing health-related information (Anonymous, 2001).

The drive for e-health initiatives can be patient driven, physician driven, or government mandated. "What is less clear is whether or not the services offered by healthcare organizations and the services that patients desire are the same" (Wilson & Gustafson, 2003). Government-driven initiatives include electronic health record implementation within the next 10 years which serves a dual-purpose: to allow hospitals and healthcare providers to access patient records in a standard format, and to decrease medical care errors. Veterans Affairs Secretary Anthony Principi stated that "one in every seven hospital admissions and 20% of lab tests occur because health records are not available to the clinician. More than one of every seven hospitalizations is complicated by medical prescription errors" (CNN, 2004). Thus, comprehensive electronic medical records which the patient, physician, or pharmacist can access are critical to reducing such errors. Access to these records may also be offered online so that patients can access them and check for accuracy or take them to a physician's office to which they have been referred for further tests.

In a related initiative, the National Quality Forum (NFQ) sponsored a National Summit on Information Technology and Healthcare Quality in March, 2002, to examine a national healthcare infrastructure. The design principles stated by NFQ to aid in the infrastructure development (NFQ, 2002) are:

1. Care based on continuous health relationships
2. Customization based on patient needs and values
3. The patient as the source of control—encourage shared decision making
4. Shared knowledge and free flow of information
5. Anticipation of patient needs

Theoretical Basis

The Internet can be considered a mass medium, and therefore, communications theories have been applied most frequently in this area (Merrill et al., 1996). Such theories applied include the learner-as-a-bucket theory in which the user searches for information and information is "poured" into the brain via a Web portal (Morris & Ogan, 1996). Another theory applied frequently is the critical mass theory, which states that the diffusion of innovation and adoption by about 20% of the population results in critical mass being achieved (Morris et al., 1996). Because use of the Internet, as well as other forms of electronic communication, is widespread now, it can be assumed that these are forms of media utilized by a critical mass.

In an article regarding physician communication skills, Kurtz (2002) outlines the domain of physician communication with patients. This could be expanded to any healthcare partners, and involves goals and approaches. Goals promote collaboration and partnership, and ensure increased accuracy of medical information, supportiveness, improving patient and physician satisfaction, and quality of healthcare. Approaches depend on the type of communication and can involve a well-conceived and delivered message versus communication for interaction, feedback, confirmation, and relationship. Kurtz (2002) also states that effective communication requires planning and should reduce unnecessary uncertainty—a critical factor in healthcare communication. Examples of Internet communication include e-mail, listserv, discussion forums/support groups, chat, and interactive site features (December, 1996). Features that enhance the communication between the doctor and the patient have not been explored. Prior studies analyzed sites of specialty practices (Smith-Barbaro, Licciardone, Clarke, & Coleridge, 2001), one specific type of communication such as e-mail (Moyer, Stern, Dobias, Cox, & Katz, 2002), Web portal information (Zhang, Zambrowicz, Zhou, & Roderer, 2004), or healthcare support groups or forums (Zrebiec & Jacobson, 2001). Our study specifically examines communication features offered on hospital Web sites.

WEB SITE ANALYSIS

Seventeen hospitals were chosen, with 10 of the Top Honor Roll hospitals (Group 1) selected from *U.S. News and World Report's* Best of Hospitals 2004 Report. Our premise was that the top 10 hospitals will be more likely to utilize technology to communicate better with patients, vendors, and insurance companies. Seven additional hospitals (Group 2) were randomly chosen from the *American Hospital Directory* (2004) for comparison of size and specialty, and site technology. Tables 1 and 2 display the selected hospitals.

Background information regarding bed sizes, hospital type, specialty areas, and accreditation were verified through the *American Hospital Directory*, the individual hospital sites, and the Directory of America's Hospitals (*U.S. News*, 2004b). Web site addresses listed in the *Directory of America's Hospitals* were selected as the URL locations to be examined.

Sites were examined in August 2004. Criteria chosen were adopted from related surveys by Zingmond et al. (2001) and Kind, Wheeler, Robinson, and Cabana (2004), and supplemented with features determined to be communication enhancing. The Zingmond et al. (2001) and Kind et al. (2004) studies examined only the type of content and quality of information in the sites, not specific features offered.

The criteria for Web site communications are listed in Table 3. Weighted features are noted by * in the descriptions of pertinent features discussed as follows.

1. **HIPAA* (Health Insurance Portability and Accountability Act):** Coding: 1 if there was a HIPAA statement only on the homepage, and 2 if the HIPAA statement was found on more than one page.
2. **International Patient Information/Languages*:** Some hospitals have an international presence and include such information as traveling, hotel information, specialty information, and so forth, as well as offering Web pages or forms in different languages. Coding: 1 if international patient information page was offered in different languages, 2 if additional pages or forms were offered in different languages.
3. **Support Groups*:** 56.34% of doctors that responded to the Medical Internet Usage HON survey recommend support groups

Table 1.

TABLE 1		
	Top 10 from Best Hospitals 2004 Honor Roll List (GROUP 1)	**Bed Size**
1	Johns Hopkins Hospital, Baltimore, MD	886
2	Mayo Clinic/St. Mary's Hospital, Rochester, MN	797
3	Massachusetts General Hospital, Boston, MA	875
4	Cleveland Clinic, OH	999
5	UCLA Medical Center, Los Angeles, CA	552
6 TIED	Duke University Medical Center, Durham, NC	758
	University of California, San Francisco Medical, CA	544
8	Barnes-Jewish Hospital, St. Louis, MO	906
9 TIED	New York-Presbyterian Hospital, NY	2,163
	University of Washington Medical Center, Seattle, WA	410

to their patients (Health on the Net, 2004). Coding: 1 if support groups were listed and phone numbers given for a contact, and 2 if a support group was offered online, even if through a linked affiliated site.

4. **External Web Sites:** The availability of links to external sites, further information, or discussion groups was analyzed.
5. **Insurance Accepted:** Physicians' offices are frequently asked about the insurance companies with which they participate. Having this information available online could enhance communication by giving patients a list to refer to if their insurance companies change.
6. **Appointment Scheduling*/Fill Out Patient Information Online*:** These features would allow for great efficiencies in the check-in process for patients. If an appointment has been scheduled online or patient information has been filled out online, the check-in process for a patient is more efficient. Patients may be allowed to fill in their information online (Code 2) or they may be able to download a form to print (Code 1), fill out, and take to the physician's office at the appointment time. Appointments were coded as 1 if only requests for appointments were offered, and 2 if appointments could be made online.
7. **Patient Access to Records:** With mandates for Electronic Medical Records evolving, accessing patient records online will be important for partners. Often, patient records and lab test results are copied and/or faxed to a physician, and this may be more

time consuming than allowing appropriate partners access.

8. **E-Mail Doctor:** Disadvantages of offering the physician's e-mail are privacy issues, timeliness of the response, liability issues, filing insurance on e-consults, and volume of e-mail that could be received, especially for large hospitals with international presence. Advantages are that the doctor can answer at his convenience and provide patients an avenue to ask embarrassing questions or clarify instructions. The limitations are most likely from the disadvantages of offering widespread access to physicians, including a patient's inappropriate use of e-mail (in lieu of office visits), security issues, and that physicians may be inundated with e-mails from not only their patients, but others seeking advice (Mandl, Kohane, & Brandt, 1998).
9. **Referring Physician Online Access*:** Allowing physicians to fill out a form online for patients who have been referred for tests, x-rays, or admission would save time and money, as well as decrease medical errors and medication interactions. Coding: 1 if contact information was given for the referring physician to call, and 2 if the referring physician could fill the patient information online.
10. **Intranets:** These serve the purpose of communicating between internal partners of the hospital. Policies, procedures, and other hospital information can be available through the intranet. Intranets may possibly include the capability for physicians to enter prescriptions directly to the hospital pharmacy.
11. **Interactive Content:** This includes features such as virtual tours, interactive maps, and videos.

One issue to be considered was that hospitals often operate underneath an umbrella of a parent organization, which also includes other medical centers and often educational organizations. Generally, there is a seamless navigation between hospital entities, therefore the extensiveness of sites was an advantage to the user, and no differentiation between the parent organization and its entities was made. All sites examined had search features which would search anywhere within the site for requested information.

Findings

Results of the site evaluation are in Table 4. All sites included general information and features such as a search feature, information about the organization, mission, services, privacy policy, parking and directions, news, employment, support groups, and general phone contacts. The following is a summary of the findings:

1. **HIPAA (Health Insurance Portability and Accountability Act):** It was expected

that the sites would offer a main link, probably in the privacy policy, that explained HIPAA and its regulations regarding patient confidentiality. However, only five offered a direct link to HIPAA information through a HIPAA link or through the privacy policy. Searches of some sites found no results of "HIPAA."

2. **International Patient Information/Languages:** Group 1 offered more information in different languages. This is understandable, since hospitals on the Honor Roll list are larger and have an international presence. The top four of the Honor Roll list (Johns Hopkins, Mayo Clinic, Massachusetts General, and Cleveland Clinic) allowed a user to select a language in which to view the International Patient Information page.
3. **Support Groups:** Of the Honor Roll hospitals, 40% provided a main link for access to support group information, while 85.71% of the Group 2 hospitals provided a main link. However, all sites provided at least a link to support groups in each specialty area (cancer, etc.).
4. **External Web Sites:** 82% of the sites provided external links. Links to outside sites were generally to government or health organization sites. Sometimes the information given by hospital sites was generated by a purchased knowledge database, and it was difficult to determine if the information was generated by an outside site or a knowledge database. Knowledge database information was considered as internal information and not as a hyperlink to an external site. Only one hospital, New York Presbyterian, required the user to read a disclaimer and click to accept before accessing external health information.
5. **Insurance Accepted:** 70% in Group 1 provided insurance participation information as compared to 28.57% in Group 2. Many sites allowed searching for a doctor according to the insurance with which they participated.
6. **Appointment Scheduling:** Since the intricacies of appointment scheduling are vast, and result from specialty variations as well as individual physician preferences, some hospitals allowed requests for appointments in which someone would contact the patient to set up the appointment. Hospitals from Group 1 were more likely to offer appointment requests online, with 80% providing the service, as compared to 28.5% in Group 2.
7. **Patient Access to Records:** Only three hospitals (Cleveland Clinic, Duke University Medical Center, and Barnes-Jewish Hospital) allowed some type of access to the patient's records, including prescription refill requests, appointment requests, patient information updates, appointment reminders, online payments of balances, and self-assessments of healthcare.
8. **E-Mail Doctor:** None of the hospitals in Group 1 and only three in Group 2 had the capability to e-mail physicians directly.
9. **Referring Physician Online Access:** 71% of all sites allow referring physicians to fill out patient information online. This would allow the hospital time to verify insurance information and send materials and brochures to patients before being admitted.
10. **Intranets:** The presence of an intranet was difficult to determine, since the intranet may be a different URL than the hospital URL. Of all hospitals, 41% had some type of intranet available. The intranet at Cleveland Clinic was confirmed to have physician access to medical records online.
11. **Interactive Content:** The two groups had equal participation in offering interactive content, which was in the form of audio, video, or Web tours of facilities.

Table 5 shows some of the interesting interactive and weighted features.

FUTURE TRENDS

Availability of comprehensive patient information and other hospital services will improve the efficiency and effectiveness of patient care through better communication among healthcare partners. Some hospitals which were contacted regarding intranet availability were in the process of electronic record conversion. EMRs (electronic medical records) would provide a concise map of a patient's medical history, and, if accessible by various healthcare partners, including the patient, could offer a means of communication by clarifying questions or documenting previous medical problems and medications.

Blogs such as those offered on the Cleveland Clinic and High Point Regional sites are being tested as a type of forum for patients to support one another. Blogs allow personal expression and diary-type entries for those who want to share health-related experiences. Ideally, communication could be customized by allowing the user to enter a username and password which will allow specific access to that person's information and personal preferences—a patient portal. Messages and reminders from physicians may appear, as well as charts showing, for example, one's diabetic sugar level readings for the past few months. Very few hospital Web sites offer the capability to pay bills online, and access to one's medical bill history online may decrease calls to the billing department regarding balances owed. Patients may opt to receive automatic e-mails from physicians and healthcare partners for appointment reminders, test results, prescriptions, or to inform the patient if the pharmacy has the medication in

Hospital	Features
Massachusetts General	Live surgery webcasts and e-consults for second opinions
Cleveland Clinic	e-clinic for second opinions
University of California, SF Medical	Sample bills available online
Loma Linda	e-cards and radio shows
Moses Cone Health System	Excellent library sources
High Point Regional Health System	Request callback; Extensive search feature--can search for a physician by name, specialty, gender, insurance accepted
University of Maryland Medical Center	Webcasts
St. Vincent Hospital	MyStVincent--access to personal information; can update insurance information online
Yale-New Haven	Call Me Later feature

stock. Telemedicine and videoconferencing are popular in other countries such as Australia and New Zealand, and could provide healthcare to those patients in remote areas, if the technology were provided.

CONCLUSION

Communication between physicians and healthcare partners, specifically patients, is critical to the quality of care provided. Forms of online communication need to be identified and researched further so that efficiencies and effectiveness can be gained for healthcare organizations' quality of care goals. Because patients are active in their medical care, healthcare organizations need to be aware of patient needs and preferences in their communications. What needs to be determined is how users decide to search for information on a specific hospital site. Which features are preferred by both physician and patient? As Bohn (1999) stated, "As sites grow ever more central to successful healthcare business, analysis of the way they are used becomes a fundamental issue." In this respect, the functionality of sites needs to be addressed—is it enough to offer such interactive features and anticipate that they will be found and utilized, or does this interactive functionality become part of emerging culture of healthcare? The opportunity to utilize Web technology to communicate with partners allows hospitals to become more strategically competitive while also increasing efficiency and effectiveness, and ultimately improving patient care.

KEY TERMS

Blog: A Web log which allows for a diary-style forum for posting one's personal thoughts and experiences.

E-Health: A concept in which Internet-based technologies are used to enhance access, delivery, quality, and effectiveness of health services, as well as information utilized by patients, physicians, healthcare organizations, and related partners such as pharmacies, vendors, and insurance providers.

Extranet: Allowing an organization's external partners (i.e., pharmacies, insurance companies, vendors) to access a computer system via a username and password.

HIPAA: The Health Insurance Portability and Accountability Act (1996) regulates the electronic exchange, privacy, and security of one's health information.

Intranet: Allowing access to a hospital's computer system to internal users via a username and password.

Privacy Policy: A disclaimer placed on Web sites informing users about how the organization handles one's personal information.

Telemedicine: The delivery of healthcare through the Internet or other computerized means such as videoconferencing.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 1139-1145, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 5.13
The Internet, Health Information, and Managing Health:
An Examination of Boomers and Seniors

Christopher G. Reddick
The University of Texas at San Antonio, USA

ABSTRACT

This article examines the use of the Internet for gathering health information by boomers and seniors. This study attempts to determine whether online health seekers (individuals that have Internet access and have searched for health information online) have changed their behaviors from the information they found online. Essentially, has online health information helped them to manage their health more effectively? This research analyzes the Kaiser Family Foundation e-Health and the Elderly public opinion dataset of access by boomers and seniors to online health information. The major results indicate that boomers marginally use online health information more than seniors for the management of their health. The most significant results indicated that boomers and seniors who are more aware and have positive feelings toward online health information would use it more to manage their health.

INTRODUCTION AND BACKGROUND

For baby boomers, the Internet has become the most important source of health information other than consultation with their family doctor (Kaiser Family Foundation, 2005). The focus of this article is on both baby boomers, those in the age range of 50 to 64, and seniors, or those 65 and older.[1] This study examines the use of online health information by baby boomers and seniors and how they use the information for managing their health. The primary objectives of this article are to examine the differences in behavior between boomers and seniors and to test for the presence of a variety of associations among their characteristics and a number of management of health variables.

This study explores five specific questions. First, are there any differences between boomers and seniors and their access to health information for managing health? Second, will healthier boomers and seniors rely less on online health information in order to manage their health because they would have less need? Third, will the presence of boomers and seniors that have more experience and familiarity with the Internet lead to greater use of online health information to manage health? Fourth, will individuals who are in a lower sociodemographic status rely less on online health information because of lack of resources to access this information? Finally, will avid Internet users use online health information more often to manage their health because they would have greater access to and familiarity with the Internet?

The American health care system is different from many Western countries, since it is administered primarily by the private marketplace. The majority of the United States population contracts with a private provider for his or her health insurance coverage. Medicare is a federal health insurance program for people age 65 and older. In addition, Medicaid, a program sponsored by the federal government and administered by states, is intended to provide health care and health-related services to low-income individuals. However, there are millions of Americans who do not fit into either the Medicare or Medicaid plans and, essentially, remain uninsured. Online health information is especially important, given the millions of uninsured Americans trying to get information on their health situation. Individuals can use this online health information to make informed choices on their health care needs. They potentially can use information on the Internet to better manage their health.

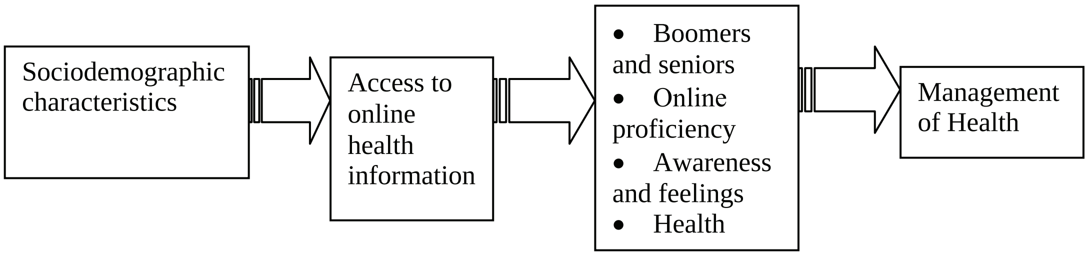
Essentially, has online health information influenced the behaviors of boomers and seniors with respect to their health care needs? This influence could be as extensive as visiting a doctor or simply talking to family or friends about health information that a boomer or senior found online.

Access to timely and reliable information on health and health care long has been a goal for seniors, who face a greater number of health conditions and use prescription drugs and health care services at a higher rate than younger adults (Kaiser Family Foundation, 2005). However, the online behavior of seniors has not been studied as closely as that of health information searches of adolescents (Gray, Klein, Noyce, Sesselberg, & Cantrill, 2005), women (Pandey, Hart, & Tiwary, 2003), cancer patients (Eysenbach, 2003; Ziebland, 2004), those affected by the digital divide (Skinner, Biscope, & Poland, 2003), and those that compare online and off-line behavior (Cotton & Gupta, 2004). There is little empirical research that examines whether online health searches affect the management of health (Lueg, Moore, & Warkentin, 2003; Nicholas, Huntington, Williams, & Blackburn, 2001), one of the two objectives of this study. This study measures whether Internet health information changed the self-reporting behavior of boomers and seniors and does not specifically address change in health outcomes.

There are two reasons why this study does a comparison of both boomers and seniors. First, baby boomers represent future seniors, and by examining this age group, this study can provide some indication about what the future holds for the Internet and health information. Second, both boomers and seniors are in the greatest need of health information, since they are more prone to have health problems than other age groups.

This study is different from existing works of Nicholas et al. (2001), Lueg et al. (2003), and Huntington et al. (2004), since it focuses on the use of online health information in the management of health. This study focuses especially on comparing two groups, boomers and seniors, while the existing empirical work examines the entire Internet population. This study is different from studies that conduct a meta-analysis, which combine published results from different sources

Figure 1. Conceptual framework of access to online health information by boomers and seniors



(Eysenbach, 2003). This research performs a statistical analysis that leads to conclusions that are different from the original dataset (Kaiser Family Foundation, 2005). The aim of this study is not just to learn about the differences between boomers and seniors and access to online health information; it is to discern the magnitude of differences between these groups and the impact of factors such as awareness and feelings on health management.

In order to accomplish the goal of examining online health information and the management of boomers' and seniors' health, this article is divided into several sections. First, this research examines the literature on the use of the Internet as a health information source. Second, this article outlines how the literature can be summarized into hypotheses that model the most probable impacts on management of boomers' and seniors' health. Third, this research provides details of the Kaiser Family Foundation's e-Health and the Elderly dataset that is used to model public opinion data of online health information (Kaiser Family Foundation, 2005). The fourth and fifth sections discuss the models and results of tests on the use of online health information for health care management. The sixth section provides a discussion that outlines how the test results confirm or deny the specified hypotheses and shows the broader significance of this work. The last section provides avenues for future research and presents limitations of this study.

LITERATURE REVIEW

The following section outlines the common themes found in the literature on the Internet and health information and the management of health. They can be divided into the factors of differences between age groups, the health of the individual, online proficiency, sociodemographic characteristics, and awareness and feelings about online health information. Existing research shows that little is known about how Internet usage, health status, and sociodemographic characteristics affect health information seeking (Cotton & Gupta, 2004).

Eysenbach (2003) provides a conceptual framework of the possible link between Internet use and cancer. Some of the important factors, according to that author's meta-analysis, indicate that Internet use is related to communication, community, and content, leading to an impact on cancer outcomes. In a similar line of inquiry, a study by Lueg et al. (2003) provided a conceptual framework of Internet searches for online health information. These authors examine the situations with which individuals find themselves confronted in terms of health needs and frequency of use, predicting access to health information. Eysenbach's (2003) conceptual framework is different from Lueg et al. (2003), in that the former examines the social aspects of Internet use and health information, while the latter study focuses on the situation involvement and the frequency of Internet use. The conceptual framework of this study is similar to Eysenbach (2003) and Lueg et al. (2003) but differs, in that it examines boomers and seniors and factors such as frequency and satisfaction having an influence on the management of health (Figure 1).

Online Health Information and Managing Boomers' and Seniors' Health

If the Internet can be used to change the behavior of individuals, this is one assessment of the long-term utility of this information resource. If individuals just look at information online and do not use it in any substantial way, it does not make much sense to invest in Internet health resources. The Internet suggests a remarkable change from the traditional doctor-knows-best approach (Eysenbach & Jadad, 2001). The Internet can be seen as challenging hierarchical models of information sharing, in which the provider of the information decides how the information should be delivered (Ziebland, 2004).

For example, existing research in a 2001 survey showed that 44% of online health information seekers said that the information they found online affected a decision about how to treat an illness or to cope with a medical condition (Fox & Rainie, 2002). A majority of respondents to a survey of adolescents and use of Internet health information reported that it helped them to start a conversation with a lay or professional medical person (Gray et al., 2005). Online health information seekers mostly are going online to look for specific answers to targeted questions (Fox & Rainie, 2000). In addition, four out of 10 young people say that they have changed their personal behaviors because of health information that they obtained online (Rideout, 2002). In an Internet survey, more than one-third of the respondents said that their conditions had improved after having visited a Web site, and more than one in four said that the Web information had resulted in a deferred visit or had actually replaced a visit to the doctor (Nicholas et al., 2001). Therefore, the existing research has examined adolescents' and all age groups' behavioral changes but has not focused on seniors and their use of the Internet for managing health. There are five factors outlined in the literature, which are differences between boomers and seniors, the health of boomers and seniors, their online proficiency, their sociodemographic characteristics, and awareness and feelings toward online health information that are predicted to have an impact on whether online health information is used.

Boomers' and Seniors' Differences

Existing empirical evidence shows that health seekers are proportionately more middle-aged than very young or old, with the highest proportion of usage witnessed in those between the ages of 30 and 64 (Fox & Rainie, 2000). A more recent survey indicates that 70% of baby boomers has gone online in 2004, while only 31% of seniors has gone online (Kaiser Family Foundation, 2005). Boomers will retire shortly, and the amount of online health information for which they will search should increase dramatically compared to what seniors are currently consuming. In order to explore both the present and what the future will hold for online health information and seniors, it is important to compare both age groups. In addition, individuals over the age of 50 may have a greater need for more information on health care than someone much younger because of the greater chance of facing health problems (Brodie et al., 2000).

Health of Boomers and Seniors

The literature also mentions that individuals who are in worse health will want to search more for online health information. The Internet becomes an additional tool in order for them to search for health information. Empirical evidence shows that there is a link between an individual's health and his or her need for online health information. Less healthy individuals are more likely to explore different aspects of a Web site and to use more health-related interactive features and, in doing so, improve their well being (Lueg et al., 2003). Individuals who were suffering with an illness were two and half times as likely, compared to respondents without a standing illness, to say that they had used information from the Internet as an alternative to seeing their general practitioner (Nicholas et al., 2001). In many cases, information seekers were acting on behalf of others, such as family and friends. However, access to online health information also should be related to the consumer's ability to use the Internet, not just on whether they are healthy.

Online Proficiency

The ability to use the Internet also should have an impact on whether boomers and seniors use online health information to manage their health. Individuals who use Internet information more to manage their health have broadband Internet access, are frequently online, spend many hours online, and search for information on many different topics. Research shows that individuals using a Web site regularly were more likely to have said that the information was helpful (Nicholas et al., 2001). A survey of adolescents shows that there are issues of the disparity of Internet access and quality of Internet access such as dial-up vs. broadband connection (Skinner et al., 2003).

Sociodemographic Characteristics of Online Health Seekers

Another factor explored in the literature that should have an impact on access to online health information is the sociodemographic characteristics of the individual. There is research on the digital divide, between the haves and the have-nots of Internet access. This research predicts that those who have greater access to the Internet would have more resources in society. For instance, those groups of individuals who are more disadvantaged economically in the United States would have less access to the Internet and online health resources. Hispanics, the largest minority group in the United States, traditionally have had less Internet access (Fox & Rainie, 2000). Those with medium to high family incomes should be able to access the Internet more for health information because of greater resources.

Existing research shows that individuals who are older, have lower incomes, are minorities, are less educated, and are males will be less likely to use the Internet for health information seeking (Cotton & Gupta, 2004; Anderson, 2004). In contrast, women increasingly rely on the Internet to supplement health information received from traditional sources (Pandey et al., 2003) and are more likely than men to seek online health information (Fox & Rainie, 2000; Nicholas et al., 2001). Awareness and feelings toward online health information also should have an impact on using this information to manage consumers' health.

Awareness and Feelings Toward Online Health Resources

A final factor that should explain access to Internet health information is the awareness and feelings of the individual toward online health information. If boomers and seniors have more positive feelings about the Internet as a health information resource, they will utilize it more often than someone who harbors more negative feelings toward the Internet. In addition, individuals who go online for health information frequently should use it more to manage their health. If a boomer's or senior's doctor or medical professional recommends or uses the Internet as a communication device, the patient is more likely to use it to manage his or her health. In summary, the prediction is that boomers and seniors who are more aware of online health resources should use these resources more to manage their health. In addition, boomers and seniors who have positive feelings about the benefits of online health information will use this resource more to manage their health.

Empirical evidence shows that there is a relationship between using the Internet more often and accessing health information (Lueg et al., 2003). Those using the Web once a day were twice as likely to report that it helped a lot in terms of being better informed from health information found on the Web (Nicholas et al., 2001). E-mail is still a new medium for obtaining access to consumer health information and also is explored in the research as a way to manage a consumer's health (Huntington et al., 2004). The literature just outlined can be formally specified with the following hypotheses that demonstrate the relationship between boomers and seniors, the Internet, and the management of health.

HYPOTHESES

In order to examine whether online health information has affected the choices that individuals make in managing their health and the differences between boomers and seniors, several hypotheses are tested in this article. These hypotheses are derived from the literature mentioned in the previous section and are divided into five areas:

Boomers' and Seniors' Differences

Hypothesis 1: Online health seekers who are baby boomers are more likely to believe that online health information has helped them to manage their health better compared with seniors.

Health of Boomers and Seniors

Hypothesis 2: Online health seekers who are healthy or who have family and friends that are healthy will rely less on online health information because of lack of need.

Online Proficiency

Hypothesis 3: Online health seekers who have broadband Internet access will go online more for health information to manage their health.

Hypothesis 4: Online health seekers who go online more often and conduct many online activities will use Internet health information more to manage their health.

Sociodemographic Status

Hypothesis 5: Boomers and seniors who are females will rely more on online health information.

Hypothesis 6: Boomers and seniors who are college educated will rely more on online health information.

Hypothesis 7: Boomers and seniors who are Hispanics will go online less for health information.

Hypothesis 8: Boomers and seniors who have family income above $75,000 will go online more for health information.

Awareness and Feelings Toward Online Health Resources

Hypothesis 9: Online health seekers who most of the time and always look to see who provides medical information on the Internet will use online health information more to manage their health.

Hypothesis 10: Online health seekers who access health information online once or twice a month will have a greater likelihood of using online health information to manage their health.

Hypothesis 11: If a doctor has recommended a Web site to an online health seeker, he or she is more likely to use health information to manage his or her health.

Hypothesis 12: If an online health seeker has communicated with his or her doctor via e-mail, he or she is more likely to use online health information to manage his or her health.

Hypothesis 13: Online health seekers that have more positive feelings about looking for health information on the Internet are more likely to use this information to manage their health.

These hypotheses are examined with a dataset that surveyed public opinion of both baby boomers and seniors on their use and acceptance of online health information.

DATASET AND METHODS

The e-Health and the Elderly dataset is a nationally representative random digit dial telephone survey of 1,450 adults age 50 and older.[2] Included in this sample were 583 respondents age 65 and older. The survey was designed by Kaiser Family Foundation (KFF) (2005) in consultation with Princeton Survey Research Associates (PSRA), and the survey was administered in the field by PSRA. The survey interviews were conducted between March 5 and April 8, 2004. The entire dataset of 1,450 respondents was first examined to determine the characteristics of boomers and seniors and access to online health information.

Out of the 1,450 responses to the survey, this study also has taken a subsample of 628 respondents, of which there were 464 boomers and 164 seniors surveyed. Therefore, the original dataset was split, and the sample sizes differ for both age groups. The 628 boomers and seniors represent those individuals who are called online health seekers. They both have Internet access and have looked for online health information. This group is of interest, since in this study, there is a comparison of the characteristics of those that actually look up online health information.

Table 1. Boomers and seniors who go online for health information

Go online for health information (Yes or No)	Age group	Frequency	Percent
No	50-64	335	42.5
	65+	454	57.5
	Total	789	100
Yes	50-64	464	78.2
	65+	129	21.8
	Total	593	100

In this study, we use a consumer survey to explore the differences between boomers and seniors and their use of online health information to manage health. This research uses both descriptive statistics and logistic regression to explore differences in access to online health information between boomers and seniors.[3]

DESCRIPTIVE STATISTICS OF BOOMERS AND SENIORS AND ONLINE HEALTH INFORMATION

In order to model the relationship between seniors and boomers, online health information, and its impact on managing health care needs, this study has specified the following variables that will comprise the models tested.

Table 1 provides information on boomers and seniors who go online for health information. Boomers that go online for health information represent 78.2%, while seniors that go online for health information represent just over 21% of those surveyed in this category. This table generally supports the notion that boomers tend to go online more for health information than seniors. Boomers that do not go online for health information represent 43%, and seniors that do not go online represent 58% of those surveyed in this category.

Table 2. Demographic information of boomers and seniors and going online for health information

Go online for health information (Yes or No)		N	Mean	Standard Deviations
No	College educated	822	0.15	0.36
	Gender is female	822	0.65	0.48
	Race is Hispanic	822	0.03	0.18
	Family income 2003 above $75,000	822	0.07	0.25
	Age	822	68.79	12.41
Yes	College educated	628	0.43	0.50
	Gender is female	628	0.61	0.49
	Race is Hispanic	628	0.03	0.17
	Family income 2003 above $75,000	628	0.27	0.45

Table 2 outlines demographic information of boomers and seniors that go online and do not go online for health information. The digital divide is very evident with the data presented in this table. For instance, 43% of college-educated individuals go online for health information compared with only 15% who are college-educated that do not go online for health information. Among females and Hispanics, there is not much of a difference in the percentage who go online and do not go online for health information. However, boomers and seniors that have a family income above $75,000 in 2003 were more likely to go online for health information. Finally, age seems to have an impact on accessing online health information. The mean age was 61 years for individuals that go online and 69 years for consumers who do not go online for health information. Higher income implies greater use of online health information, and having a college education means a greater likelihood of going online for health information. This finding also indicates that boomers are more likely to go online for health information, since the average age range was just over 61 years old.

Logistic regression is used to test whether sociodemographic variables predict whether boomers or seniors go online for health information. Logistic regression was used, since this study models dependent variables that are binary, represented by either a 1 or 0 (Nicholas et al., 2001; Lueg et al., 2003). The odds ratio can be used to interpret the relative impact of the observance of a 1 in the dependent variable. Table 3 shows that almost all of the sociodemographic variables help to explain whether someone goes online for health information, with the only exception being Hispanic. For instance, having a college education means that a boomer or senior is four times more likely to go online for health information. Having a higher income indicates that boomers and seniors are two times more likely to go online for health information. However, as the age of the respondent increases, this marginally decreases the likelihood of someone going online for health information.

Dependent Variables

Table 4 provides a list of the dependent and predictor variables and also demonstrates whether there were differences between boomers and seniors in these variables. Perhaps the most important dependent variable is whether "somewhat" or "a lot" of information on the Internet has helped to take care of a senior's or a boomer's health. The mean score indicates that 59% of boomers and 46% of

Table 3. Logistic regression results of sociodemographic variables predicting going online for health information

Dependent Variable	Go Online for Health Information		
Predictor Variables	Odds Ratio	Wald Statistic	Prob. Sig.
Age	0.95	(301.47)***	0.00
College educated	4.05	(300.72)***	0.00
Gender is female	1.25	(11.49)***	0.00
Race is Hispanic	1.06	0.26	0.61
Family income 2003 above $75,000	2.25	(63.38)***	0.00

Nagelkerke R-Square	0.25		

Note: significant at the 0.01 level

seniors believed that the Internet has helped them to take care of their health, demonstrating some impact on the management of their health.

The second dependent variable measures whether online health seekers had a conversation with family or friends about health information that they found online (Table 4). Family and friends who go online for health information may guide someone else as to whether they should see a doctor because of this information (Eysenbach, 2003). The results indicate that 66% of boomers said that they had a conversation with family members or friends, and only 48% of seniors said that they had this conversation about the information they saw online. There were statistically significant differences between seniors and boomers for this question with the reported F-statistic being significant at the 0.01 level, meaning that boomers were more likely to have a conversation with family and friends about health information that they found online.

The third dependent variable measures whether online health information changed the behavior of boomers and seniors (Table 4). Thirty-six percent of boomers' behaviors changed as a result of online health information, compared with 25% of seniors. This result also was shown to have a statistically significant difference between boomers and seniors at the 0.01 level. Around one-third of boomers changed their behaviors, which is a good indication that the information that they are finding is affecting their health.

A fourth management of health issue was whether boomers or seniors made a decision on treatment of an illness as a result of the information they found online (Table 4). The results showed that 34% of boomers believed that they made a decision about how to treat an illness because of information they found online, while only 26% of seniors made a decision on treatment. This result also showed a statistically significant difference between the two age groups at the 0.01 level.

Another dependent variable was visiting a doctor as a result of the health information found online (Table 4). Only 16% of boomers visited a doctor as a result of health information they found online, while 13% of seniors visited a doctor. Visiting a doctor was the least utilized change in behavior as a result of online health information.

Referring back to Hypothesis 1 on whether online health information has been used to manage a boomer's or a senior's health, this study has found that overall, there were differences between both groups of online health seekers (Table 4). The mean values for all five dependent variables were higher for boomers compared with seniors. In addition, three out of the five dependent

Table 4. Difference of means tests of dependent and predictor variables for online health seekers; boomers are significantly different from seniors

Variable Name	Mean of Boomers	Standard Deviations Boomers	Mean of Seniors	Standard Deviations Seniors	Probability Significantly Different Boomers and Seniors

Notes: The number of observations are 464 for boomers and 164 for seniors.

variables showed statistically significant differences between boomers and seniors at the 0.01 level. With these dependent variables outlined, this research also should describe the predictor variables and their characteristics.

Predictor Variables

The predictor variables used to explain how the Internet has managed the health care of boomers and seniors also are presented in Table 4. Many of the predictor variables are represented in terms of binary numbers in order to capture the specific impacts on the dependent variables. As previously noted, this study has divided the hypotheses into the differences between boomers and seniors, the relative health of the individual, his or her online proficiency, and how active he or she is at seeking online health information. This study discerns the impact that these factors have on the management of the health care of boomers and seniors.

To see all of the predictor variables, refer to Table 4. We will only mention a few of them in this section. For instance, an index was created of the health problems that boomers and seniors or someone they know have faced in the past year. An individual who has more health problems or is concerned with someone else's health problems would score higher on the index. The health problems index indicates less than four issues that they or someone they know faced, indicated by online health seekers (out of nine possible health problems). The nine possible health problems listed were cancer, heart disease, obesity and weight loss, arthritis, diabetes, Alzheimer's, high cholesterol, osteoporosis, and mental health.

The online activities index measures the amount of activities that boomers and seniors conduct online, and the average is around two activities (Table 4). The prediction is that health seekers who conduct more online activities have a greater likelihood of using health information to manage their health because of their familiarity and comfort with the Internet. The four online activities that comprised the index were using instant messaging, reading news, buying a product, and checking the weather.

The online health information predictor variables also show the capacity of the individual to look up health information on the Internet (Table 4). Seniors are more trusting of the health information that they read online, with only 24% of seniors "most of the time" and "always" looking to see who provides medical information on the Internet. On the other hand, 40% of boomers are looking to see who provides the online health information. This difference was also statistically significant at the 0.01 level. In addition, boomers are more frequent consumers of online health information, using it at least once or twice a month, as represented by 38% of the sample. Seniors consume online health information marginally less frequently with 34% doing so.

With regard to overall positive feelings toward the Internet, there was an average score of two on an index scaled from zero to three, indicating that boomers and seniors have overall positive feelings toward the Internet as a source of health information. The index was calculated by adding up the specific responses to whether the online health seeker agreed that online health information gave them information quickly, whether it helped them feel more informed when they go to the doctor, and whether it allows them to get information from a lot of different sources.

On an index of zero being the lowest and two being the highest, less than one was found, indicating that very few online health seekers harbor negative feelings toward the Internet as a source of health information. Having positive feelings about online health information also showed a statistically significant difference between boomers and seniors at the 0.01 significance level. Similarly, this negative feelings index was calculated by adding the individual responses, if they agreed that online health information was frustrating because it is hard to find what they were searching for and if it is confusing because there is too much information. The following section tests the relationship between accessing online health information and managing a boomer's and a senior's health.

RESULTS OF LOGISTIC REGRESSION MODELS OF ONLINE HEALTH INFORMATION MANAGING HEALTH

This study uses logistic regression with five separate management-of-health dependent vari-

Table 5. Logistic regression of factors predicting whether online health information has managed a boomer's or a senior's health

Dependent Variables	Somewhat and a lot of information on Internet helped take care health		Had a conversation family or friend about online health information		Online health information changed behavior		Made a decision about how to treat an illness because of online health information		Visited a doctor because of information found online

ables. A "1" was recorded for each of the five dependent variables if (1) the online health seeker said "somewhat" or "a lot" of information on the Internet helped them to take care of their health; (2) they had a conversation with family or friend about online health information; (3) online health information changed their behavior; (4) they made a decision about how to treat an illness because of online health information; and (5) they visited a doctor because of information found online. A "0" was recorded for each of the five dependent variables if this was not the case.

The results in Table 5 indicate that for four of the five dependent variables, boomers were slightly more likely to use the Internet to manage their health. For instance, an odds ratio of 1.31 for the dependent variable of "somewhat" or "a lot" of information on the Internet has helped to take care of the online health seekers' problems implies that consumers are around one and one-third times more likely to say that this is the case, if they are a boomer rather than a senior.

Changing behavior for boomers because of information found online registered an odds ratio of 1.71, having a conversation with family or friend about online health information had an odds ratio of 1.49, and making a decision about how to treat an illness had an odds ratio of 1.66 (Table 5). Overall, the results showed that boomers are around one and one-half times more likely than seniors to change their behavior and to use online health information to manage their health, which is not that high, given the attention placed on the differences between these age groups (Kaiser Family Foundation, 2005).

In terms of online proficiency, those who had broadband Internet access were less likely to have a conversation with a family member or a friend about what they saw online and less likely to make a decision about how to treat an illness. However, for those online health seekers who are online every day, this had a consistent impact across all five dependent variables, if they used online health information to manage their health. For instance, there was a 1.82 times greater chance that daily online users changed their behavior because of online health information. In addition, individuals who go online every day were 1.41 times more likely to visit a doctor because of information that they found online. In terms of being online more than 10 hours a week, this had a negative likelihood for the dependent variables "somewhat" or "a lot" of information on the Internet helped to take care of their health, but had a positive impact with an odds ratio of 1.46 for making a decision on how to treat an illness. Overall, there was no overwhelming support that being more proficient with the Internet had a substantial impact on using health information to manage an online health seeker's health. The only consistently significant variable that had an impact on managing health was being online every day.

Boomers and seniors who had excellent or very good health were 1.64 times more likely to have a conversation with a family member or a friend about online health information. In addition, the boomer or senior who had more health problems or who knew someone who was experiencing health problems was 1.14 times more likely to have a conversation with family or friends about online health information. Individuals who were in excellent and very good health were 1.36 times more likely to use online health information to make a decision about how to treat an illness because of online health information. Generally, the health of the individual was not a strong predictor of using health information to manage a boomers' or seniors' health.

The strongest predictors of using health information to manage health were for the online health information awareness and feelings variables. Frequent consumers of online health information were 3.51 times more likely to use the Internet to take care of their health. It has become a valuable tool for their health care management needs. There was also a 3.11 greater likelihood of someone making a decision about treating an illness to use the Internet more than once a month for health information. In fact, frequently accessing health information registered an impact for all of the dependent variables.

Individuals who had positive feelings about online health information were more likely to use online health information to manage their health. Boomers and seniors who had more negative feelings toward online health information were less likely to use it for health management. This finding was consistently found across all five of the dependent variables. Online health seekers who usually looked to see who provided the health information were more likely to use this to manage their health. For instance, individuals who looked to see who provided the health information were 2.80 times more likely to have a conversation with family or friends about the information that they saw online. If a doctor recommended a health or medical Web site, online health seekers were 2.13 times more likely to make a decision about how to treat an illness because of online health information, and they were 3.68 times more likely to visit a doctor because of information they found online. In addition, individuals who communicated with a doctor or a health care provider via e-mail were 1.95 times more likely to have a conversation with a family member or a friend about health information that they found online. Overall, the logistic regression results indicate the most consistent and highest support for increased awareness and positive feelings toward online health information as a driver for helping to manage boomers' and seniors' health.

CLASSIFICATION TREES ANALYSIS OF TAKING CARE OF BOOMERS' AND SENIORS' HEALTH

Another way to examine the relationship between boomers and seniors and online health information is a classification tree analysis. Classification trees are used to predict membership of cases or objects in the classes of a categorical dependent variable from their measurements on one or more predictor variables. Classification tree analysis is a common data mining technique. Figure 2 shows that the taking care of health variable is related to boomers and seniors having positive feelings toward looking for online health information. In addition, having positive feelings about online health information is related to accessing health information online once or twice a month or more. These findings reinforce the logistic regression results that awareness and feeling toward online health information helps in the management of a boomer's or a senior's health. How do these findings relate to the hypotheses outlined in the beginning of this article?

DISCUSSION OF RESULTS AND HYPOTHESES

This section will discuss how the empirical results of this study confirm or deny the hypotheses (see Table 6). First, the evidence shows through the difference of means tests that boomers and seniors are different in terms of their use of online health information in the management of their health. The mean values scored higher for boomers in using online health information to take care of their health, having a conversation with a family or a friend about the health information found online, changing their behavior because of online health information, and making a decision about treating an illness because of online health information. There is some evidence that boomers will use more online health information to manage their health, supporting Hypothesis 1. However, there is no overwhelming support for differences between boomers and seniors and using health information to manage their health, with boomers only utilizing this information one and one-half times more than seniors.

The health of the individual, or Hypotheses 2, only predicted the use of online health information to manage a boomer's and a senior's health when

Figure 2. Classification tree of impact of online health information taking care of a boomer's and a senior's health

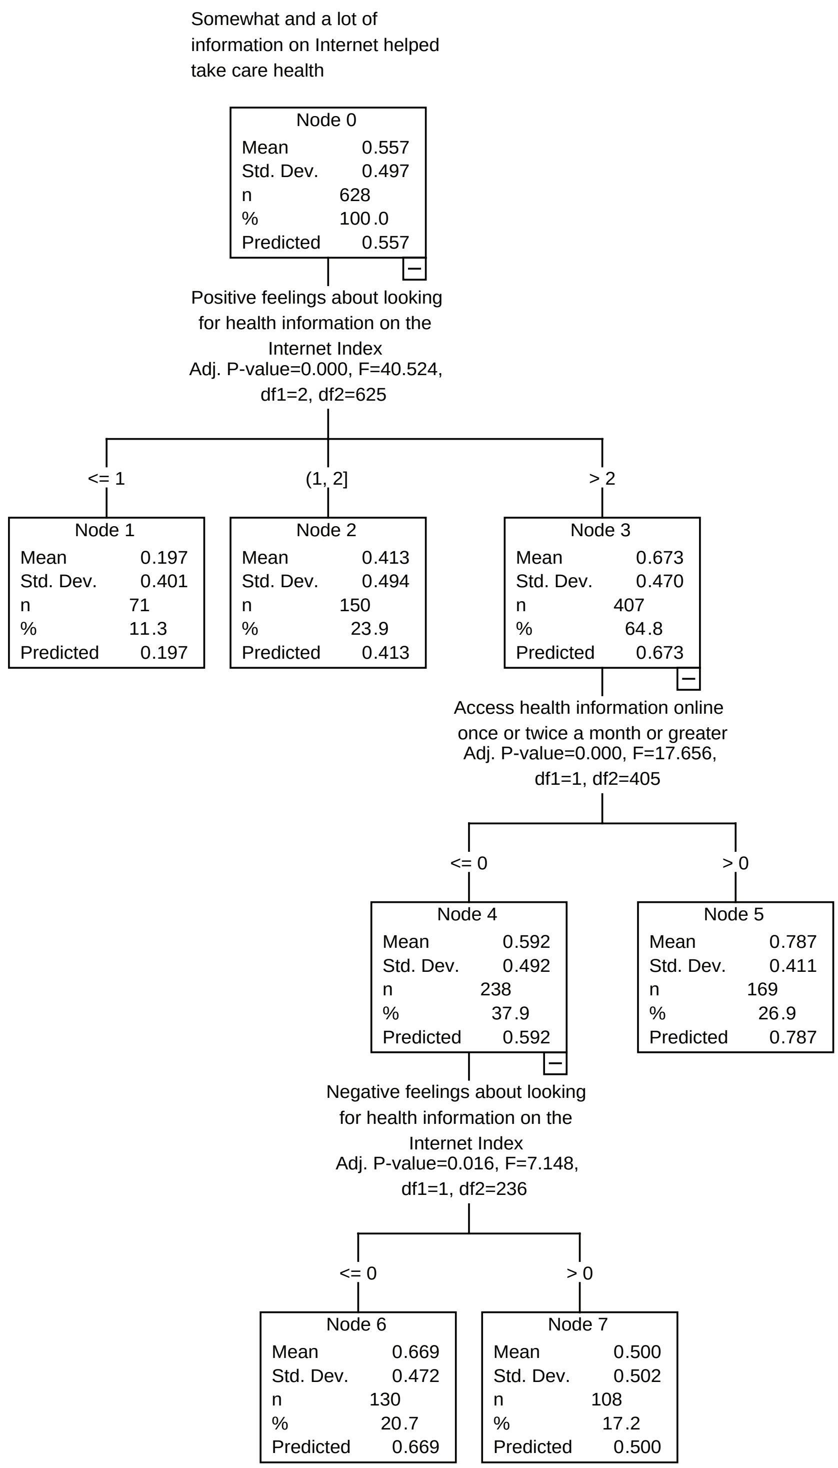

Table 6. Support for hypotheses of boomers and seniors and online health information

Hypotheses	Supported? (Yes, No, or Partially)	Major Test(s) Performed
Hypothesis 1: Online health seekers who are baby boomers are more likely to believe that online health information has helped them manage their health better compared with seniors.	Yes	Descriptive statistics, difference of means tests, and logistic regression
Hypothesis 2: Online health seekers who are healthy or who have family and friends that are healthy will rely less on online health information because of lack of need.	Partially	Logistic regression
Hypothesis 3: Online health seekers who have broadband Internet access will go online more for health information to manage their health	No	Logistic regression - Evidence found in the opposite direction
Hypothesis 4: Online health seekers who go online more often and conduct many online activities will use Internet health information more to manage their health.	Yes	Logistic regression
Hypothesis 5: Boomers and seniors who are females will rely more on online health information.	Yes	Logistic regression
Hypothesis 6: Boomers and seniors who are college educated will rely more on online health information.	Yes	Logistic regression
Hypothesis 7: Boomers and seniors who are Hispanics will go online less for health information.	No	Logistic regression -No support found in logistic regression
Hypothesis 8: Boomers and seniors who have family income above $75,000 will go online more for health information.	Yes	Logistic regression
Hypothesis 9: Online health seekers who most of the time and always look to see who provides medical information on the Internet would use online health information more to manage their health.	Yes	Logistic regression
Hypothesis 10: Online health seekers who access health information online once or twice a month would have a greater likelihood of using online health information to manage their health.	Yes	Logistic regression
Hypothesis 11: If a doctor has recommended a Website to an online health seeker he or she is more likely to use health information to manage their health.	Partially	Logistic regression
Hypothesis 12: If an online health seeker has communicated with his or her doctor via email he or she is more likely to use online health information to manage their health.	Yes	Logistic regression
Hypothesis 13: Online health seekers that have more positive feelings about looking for health information on the Internet are more likely to use this information to manage their health.	Yes	Logistic regression

they had a conversation with a family member or a friend about online health information and when they made a decision about how to treat an illness. In addition, the health variable predicted a boomer's and a senior's behavior when he or she talked to his or her doctor about information that he or she found online. Overall, there was not overwhelming support that the health of the boomer or senior had an impact on use of online health information to manage his or her health.

Hypotheses 3 and 4 examine whether being more proficient online means that the online health seeker will use the Internet more to manage his or her health. The results consistently showed that those who go online every day were more likely to use the Internet to manage their health. There was not much support that being more proficient with the Internet meant that boomers and seniors would use it more often for health information, since many of the other independent variables in this category were not statistically significant. This is most likely explained by what these online health seekers are doing on the Internet; they are looking for information, which does not require, for instance, broadband Internet access, since a standard dial-up connection will suffice. Therefore, this research cannot confirm that being more proficient with the Internet means that online health seekers will use this communication media to manage their health more than those who are not as proficient. However, this could change with greater availability of streaming video health information, which is much more suited to a broadband Internet connection.

Boomers and seniors of higher sociodemographic status use the Internet for health information much more than lower sociodemographic status individuals (Hypotheses 5-8). Therefore, this research confirms that there is a digital divide in access to online health information, and public policy should attempt to address this issue. It should be noted that one-third of the United States adult population has not gone online and, therefore, would not be able to benefit from online health information (Pew Internet & American Life, 2005).

Hypothesis 10 was confirmed in the logistic regression results that those who are frequent patrons of online health information actually will use it more often to manage their health. The results showed that health seekers who are accessing health information online once or twice a month or more will be more likely to actually use this information to manage their health. Therefore, these individuals are not just searching for information; they actually are using some of what they find online. Individuals who have positive feelings about online health information also will use it more often to manage their health, and individuals that harbor more negative feelings will use it less often (Hypothesis 13). Online health seekers who are very aware of who provides the medical information on the Internet are more likely to use this information to manage their health (Hypothesis 9). Finally, where there is communication with their doctor via e-mail or at the doctor's office about online health information, boomers and seniors are more likely to use online health information to manage their health (Hypothesis 12). Awareness and feelings toward online health information generally were well-supported predictor variables (Hypotheses 9-13), having an impact on a boomer's or a senior's use of this information to manage his or her health care needs.

RECOMMENDATIONS, LIMITATIONS, AND FUTURE RESEARCH

This article examined the use of the Internet for accessing health information by boomers (age 50 to 64) and seniors (age 65 and over). Boomers generally use Internet health information to manage their health more than seniors. However, there was no overwhelming differences between boomers and seniors, which is the main difference in the finding from another study (Kaiser Family Foundation, 2005). For instance, boomers are much more likely to talk to a doctor about health information that they saw online. Boomers are around one and one-half times more likely than seniors to use online health information to manage their health. This study found that awareness and feelings toward online health information provided the best explanation of health information for management of boomers' and seniors' health.

Since boomers were found to use online health information marginally more than seniors, what are the implications of this observation? Will seniors of tomorrow be similar to seniors of today? Perhaps boomers will continue to seek online health information as they get older. The implication that boomers and seniors may be in the greatest need of health information may not be true in the future with the growing obesity epidemic in the United States, which affects all age groups.

Some policy recommendations should be noted in order to bring more seniors online and to enhance the quality of Internet health resources. Health care professionals should recommend Web sites, promote more effective search and evaluation techniques, and be more involved in developing and promoting uniform standards for health Web sites (Morahan-Martin, 2004). Since only a minority of seniors has ever gone online, this represents a significant digital divide. These findings confirm that for the foreseeable future, the Internet is less likely to be a primary source of information for most seniors, which suggests a need to invest more heavily in education and outreach strategies. This is especially the case for seniors with low or modest incomes, who are least likely to go online for this information. These recommendations could make seniors more aware and could create a positive experience when going online for health information.

In the near future, the Internet will become a decision-making tool for seniors, who will need to make choices about the Medicare prescription drug benefits. They will need to decide which plan has the most attractive premium and to determine whether it will cover the medications they take and will work with the pharmacy they use. Seniors also will need to manage the Internet to make these important decisions. Web site design is part of the solution, since seniors have problems scrolling on Web sites and remembering Web pages (Voelker, 2005).

There are some limitations of this research. With any type of public opinion data, especially when asking subjective questions about sensitive topics of consumers' health, respondents may not be as forthcoming with information. Another limitation is that of the general applicability of the results, given that the proportion of the sample is different for seniors and boomers. In addition, there is no question that specifically addressed whether there was an improvement in the health outcome, just that people felt better informed. Future research could do a longitudinal follow up of this dataset, which might reveal shifts in the use of Internet health information for managing health with boomers and seniors, looking at other measures to see if there is an impact on change in the person's health.

Chapter 5.14
The Role of Internet Self-Efficacy in the Acceptance of Web-Based Electronic Medical Records

Qingxiong Ma

Liping Liu
University of Akron, USA

ABSTRACT

The technology acceptance model (TAM) stipulates that both perceived ease of use (PEOU) and perceived usefulness (PU) directly influence the end user's behavioral intention (BI) to accept a technology. Studies have found that self-efficacy is an important determinant of PEOU. However, there has been no research examining the relationship between self-efficacy and BI. The studies on the effect of self-efficacy on PU are also rare, and findings are inconsistent. In this study, we incorporate Internet self-efficacy (ISE) into the TAM as an antecedent to PU, PEOU, and BI. We conducted a controlled experiment involving a Web-based medical record system and 86 health care participants. We analyzed both direct and indirect effects of ISE on PEOU, PU, and BI using hierarchical regressions. We found that ISE explained 48% of the variation in PEOU. We also found that ISE and PEOU together explained 50% of the variation in PU, and the full model explained 80% of the variance in BI.

INTRODUCTION

Application service provision (ASP) — a model of distributing software services over the Internet — has shown its advantages over the traditional model of information technology (IT) deployment. The expected benefits include the reduced cost of technology ownership, the reduced time to market, and the reduced risks with software deployment.

Nevertheless, the growth of the ASP business has been comparatively slow. In response to the situation, many researchers (Jayatilaka, Schwarz, & Hirschheim, 2002; Peterson & Fairchild, 2003; Susarla, Barua, & Whinston, 2003) examined its ensuring factors. Along the same line of inquires, this study attempts to understand the acceptance issue from the end-user perspective and searches for guidance on methods and effective interventions to promote the adoption of the ASP model.

Understanding user acceptance behavior is important for several reasons. First, it is the end users who use the technology in their work on a daily basis. Any decision that changes their work behavior should consider their willingness to adopt the change. Empirical evidence has shown that the technology adoptions involving end users were more successful than those without (Chau & Hu, 2002; Lederer, Maupin, Sena, & Zhuang, 2000). Second, only the end-user acceptance can ensure a potential long-term continuous adoption (Bhattacherjee, 2001). This is particularly crucial to the ASP adoption since most ASPs are operated on short-term renewable contracts.

In the technology adoption literature, the technology acceptance model (TAM) by Davis (1989) is one of the most widely applied models (see Ma & Liu, 2004, for a meta-analytical survey). It has received extensive empirical support through validations, applications, and replications. Compared with competing models, the TAM is believed to be more parsimonious, predicative, and robust (Venkatesh, 2000). However, the TAM has been criticized for being less informative in understanding usage behavior (Taylor & Todd, 1995). Accordingly, researchers have attempted to extend the TAM by embedding it into a nomological network of other antecedents and consequences. To this end, a few researchers appeal to cognition theories and emphasize the importance of self-efficacy.

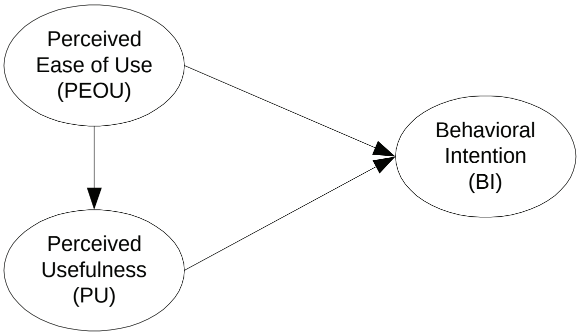
The notion of self-efficacy refers to beliefs about individuals' capabilities of performing a certain task (Bandura, 1977). Numerous studies have found that self-efficacy is an important determinant of perceived ease of use. For example, Venkatesh (2000) found that computer self-efficacy was one of the main factors that affect ease of use. Agarwal, Sambamurthy, and Stair (2000) defined software-specific self-efficacy and had a similar finding. However, currently there is no research, to the best of our knowledge, testing the relationship between self-efficacy and behavioral intention (to use an information technology). The impact of self-efficacy on perceived usefulness is also less known, and findings are inconsistent. The goal of this paper is to fill in this gap. In particular, we extend the TAM by considering Internet self-efficacy (ISE) as an antecedent to perceived ease of use, usefulness, as well as behavioral intention in the context of accepting Web-based electronic medical records, and investigate how such an extension affects our understanding about end-user acceptance behavior.

The rest of this paper is outlined as follows. In the next section, we review the literature related to the TAM. In "Research Hypotheses," we present our research model and develop research hypotheses. In the section after that, we describe our research design, including research methodology, experiment procedure, and instrument validation. In "Data Analysis," we perform data analysis and show test results. Finally, we discuss the results and draw conclusions.

TECHNOLOGY ACCEPTANCE MODEL

There are numerous perspectives from which one studies user acceptance and usage behavior of information technologies. Among them, the TAM by Davis (1989) is a more popular one. The TAM is grounded in the theory of reasoned action (Fisherbein & Ajzen, 1975). It stipulates a nomological network of three constructs (Figure 1) — perceived usefulness (PU), perceived ease

Figure 1. Technology acceptance model



of use (PEOU), and behavioral intention (BI) — connected by the causal links that both PEOU and PU directly influence BI, and PEOU influences BI indirectly through PU.

The TAM has been applied to a wide range of technologies, including e-mail, fax, word processors, spreadsheets, and workgroup applications. It has been recently applied to the adoption of e-commerce and Internet technologies (Gefen & Straub, 1997, 2000; Lederer et al., 2000). According to Ma and Liu (2004), there have been over 100 studies applying or validating the TAM. Most of these studies confirmed the reliability and validity of PU and PEOU in predicting BI or technology usage, although conflicting evidence exists.

Compared with other competing models, the TAM is believed to be more accurate and parsimonious when it is used to predict adoption. However, its parsimony results in being less informative in understanding usage behavior (Taylor & Todd, 1995) or providing usable results. What IT managers desire to have are implementable prescriptions (Benbasat & Zmud, 1999). It is imperative that researchers equip them with some useful guidance on methods and effective interventions, for example, by augmenting PU and PEOU through manipulating their causal antecedents to achieve greater technology acceptance or usage. As Gefen and Keil (1998) noted, without a better understanding of the antecedents to PU and PEOU, managers and developers are unable to know which levers to pull in order to affect these beliefs and, through them, technology usage.

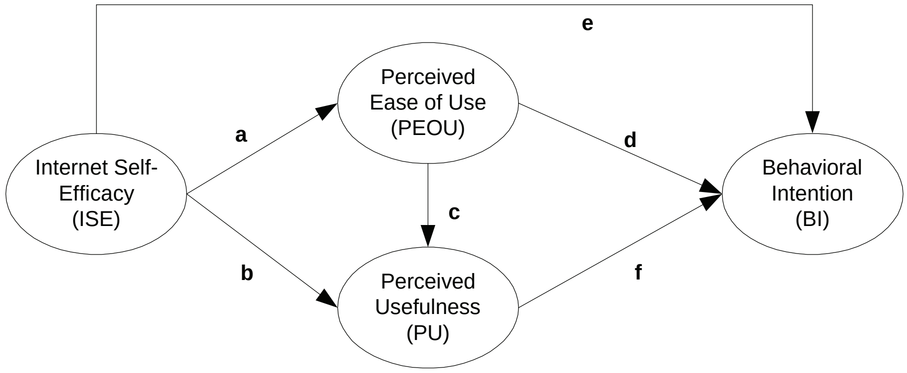
Recognizing the necessity of identifying the antecedents to user acceptance, researchers have attempted to extend the TAM by encompassing various constructs such as gender, culture, trust, experience, and social influence (Chircu, Davis, & Kauffman, 2000; Gefen & Straub, 1997; Straub, 1994). Among the constructs, self-efficacy is recognized to be a more important one.

Self-efficacy has been documented to be an important determinant of PEOU (Agarwal et al., 2000; Venkatesh, 2000; Venkatesh & Davis, 1996). However, there is no research examining the relationship between self-efficacy and BI. Also, very few studies have been done to understand the impact of self-efficacy on PU, and their findings are inconsistent. In a study with a sample of 58 participants from the California Network Engineering Center, Lopez and Manson (1997) found that computer self-efficacy was positively related to the PU of the Empowered Desktop Information System. Using 288 junior business students, Agarwal et al. (2000) conducted a similar test within the context of Web technologies. They found a positive effect of self-efficacy on both PU and PEOU, and a stronger effect on PEOU than on PU. In contrast, Igbaria, Iivari, and Maragahh (1995) found that self-efficacy had an insignificant direct effect on PU. Chau (2000) also found that computer self-efficacy had a relatively small, but negative, impact on PU. Therefore, to understand the exact effect of self-efficacy on PU, additional evidence seems necessary.

RESEARCH HYPOTHESES

The aim of this study is to examine the role of ISE in accepting Web-based electronic medical records. In addition, we want to validate existing findings in the new context. To this end, we extend the TAM by including ISE as an antecedent to the three theoretical constructs: PEOU, PU, as well

Figure 2. Research model



as BI. We hypothesize that ISE directly influences PEOU and PU, which in turn influence BI (Figure 2). We also hypothesize that ISE directly influences BI. We justify these hypotheses based on existing theories and findings.

The notion of self-efficacy is due to Bandura (1977). It refers to beliefs about individuals' capabilities to produce designated levels of performance that exercise influence over events that affect their lives. Since its inception, the construct has been widely tested in organizational behavior, education, and human resource management.

In the context of end-user computing, Compeau and Higgins (1995) proposed the concept of computer self-efficacy to refer to the judgment of one's capability of using the computer. Marakas, Yi, and Johnson (1998) made a further distinction between computer self-efficacy and task-specific self-efficacy. Following the same distinction, in this study we define ISE as the estimate of one's capability to perform Internet tasks.

ISE is different from general computer self-efficacy in that ISE focuses on what an individual believes he or she can accomplish online now or in the future — the belief that one can establish, maintain, and utilize the Internet effectively over and above basic personal computer (Eastin & LaRose, 2000). It is the judgment of one's capability of applying Internet skills rather than the measure of his or her specific skills in using an Internet browser. People who have little confidence in their ability to use the Internet or who are uncomfortable using the Internet may be said to have weak self-efficacy beliefs.

Venkatesh (2000) studied factors that affected PEOU and classified them into two categories: anchors and adjustments. Anchors include computer self-efficacy, perception of external control, computer anxiety, and computer playfulness. Adjustments include perceived enjoyment and objective usability. The general computer self-efficacy turns out to be a strong determinant of PEOU before hands-on experience (Venkatesh & Davis, 1996). Based on this evidence, we expect that ISE has a positive effect on the PEOU of Web-based applications.

Hypothesis 1 (path a): Internet self-efficacy has a positive effect on the perceived ease of use of Web-based electronic medical records.

Self-efficacy is significantly related to end-user competence. Munro, Huff, Marcolin, and Compeau (1997) suggested that the construct of user competence is multifaceted, composed of both *breadth* and *depth* of knowledge on end-user technologies, and one's ability to creatively apply these technologies (*finesse*). Thus, it is reasonable to infer that self-efficacy is also a multidimensional construct, with some capability beliefs coming from the breadth of knowledge, some from the depth of knowledge, and some from the finesse of knowledge. Based on this logic, we assume that some aspects of competence or knowledge give a user confidence in using a technology, which contributes to the perception of its ease of use, whereas others give the user confidence in understanding the design logic or objectives of the technology, which contributes to the perception of its usefulness. Therefore, we anticipate that ISE has a direct positive effect on PU.

Hypothesis 2 (path b): Internet self-efficacy has a positive effect on the perceived usefulness of Web-based electronic medical records.

Research has found that self-efficacy is an important determinant of user perception besides PEOU and PU. For example, Levine and Donitsa-Schmidt (1998) found that as individuals expressed stronger computer confidence, they demonstrated more positive attitudes toward computers and higher levels of computer-related knowledge. According to Bandura (2001), self-efficacy is also a major determinant of intention. Although there is no IT research testing the relationship, studies in other areas confirm its significance. For example, Armitage and Conner (2001) conducted a study testing a model based on the theory of planned behavior in blood donation. They found that self-efficacy accounted for unique variance in behavioral intention. In another extended study with a sample of 172 participants, they also found that self-efficacy and several other factors were all important independent predictors of behavioral intention. Based on this body of theoretical and empirical evidence, we propose the following.

Hypothesis 3 (path e): Internet self-efficacy has a positive effect on behavioral intention to use Web-based electronic medical records.

In addition to Hypotheses 1 to 3, we present the original three hypotheses stipulated by the TAM as Hypotheses 4 to 6 as follows.

Hypothesis 4 (path c): Perceived ease of use has a positive impact on the perceived usefulness of Web-based electronic medical records.

Hypothesis 5 (path d): Perceived ease of use has a positive impact on behavioral intention to use Web-based electronic medical records.

Hypothesis 6 (path f): Perceived usefulness has a positive impact on behavioral intention to use Web-based electronic medical records.

RESEARCH DESIGN

We conducted a controlled experiment using senior clinic trainees and staff members who are responsible for managing patient records. We collected data by means of a survey instrument. We distributed a questionnaire and a cover letter with instructions to selected participants. In the cover letter, we informed the participants that the experiment was volunteer-based and they could refuse to participate or quit at any time. In the instruction sheet, we provided a URL to the target system under testing, a test account for using the system, and a link to a quick user guide that details the functionalities of the system.

Target System

According to our research objective, we used a commercial Web-based electronic medical records (EMR) system. We used two criteria in selecting the system. First, the system should be truly Web-based; a participant merely needs a Web browser to load the system and perform record management tasks. Second, the system must be a full-fledged EMR system. It must allow a participant to create, update, delete, and retrieve patient records from anywhere at anytime. It must support electronic communication with labs, pharmacies, hospitals, and other service providers. For example, participants could create and retrieve prescriptions or add and modify medications and pharmacies. The system must support multiple file types including sounds and videos so that a participant can add quick notes to a document, and store and maintain dictation files on the server.

Literally there were 100s of application service providers who claimed to provide EMR applications. Among them, a few delivered applications that truly worked within a Web browser. Many others employ client-server architecture, that is, a user has to download and install a Windows client in order to work with a remote server. After a long process of searching, eliminating, pondering, and many runs of back-and-forth communications with application providers, we decided that HyperCharts™ was the most appropriate for this study.

Subjects

The goal of this study is to understand the end-user behavior in accepting Web-based medical record systems. Thus, the ideal target population should be those health care workers who are responsible for managing patient records using the computer. Since these people are typically supportive staff members in clinics, their contact information is often not accessible to outsiders. We assessed that a mail survey was going to be difficult to find its way to a target audience and the overall response rate would be low. Therefore, in this study, we identified 90 senior health care trainees in a large mid-west university as surrogates. These students were majoring in dental hygiene, physician assistant, and radiology. These four-year programs were designed to prepare the graduates to successfully enter health care organizations such as hospitals and clinics. Their program curricula include intense problem-based learning modules combined with clinical experience such as internships and externships. All the selected participants had training and experience in managing patient records and were familiar with the daily operations in hospitals and clinics.

We also obtained 85 clinic e-mail addresses through a medical worker association. We sent e-mails to the candidates requesting their participation. We provided a link to the HyperCharts™ system in the message. We assumed they agreed to participate if they did not indicate otherwise. In the following week, we did a Web-based survey. Eventually, we received 11 completed responses; two candidates refused to participate and 13 messages were undeliverable.

In total, 86 participants completed the experiment and returned usable responses. Among them, 75 were senior health care trainees and 11 were staff workers in clinics. The overall response rate was 49%. We did t-tests on gender, experience with Web-based medical records, and attitudes toward the Internet, and there was no evidence showing any difference between these two groups. Among all the subjects, almost all of them were female and over 85% of them were at the age of 20 to 25. Of the participants, 13% reported awareness of some EMR systems and only 8% of them had hands-on experience with Web-based medical records. The rest of them had used traditional paper-based systems. Based on the five-point Likert scale from very negative to very positive, 69% of them had reported neutral attitudes to their current paper-based systems. With regard to Internet experience, 84% of them had over three years of using the Internet and 69% of them had positive feelings toward surfing the Internet.

Instrument

All constructs are measured using multiple scale items. The items underlying each construct were carefully developed according to its respective definition. Each item is measured using a five-point Likert scale ranging from *low* to *high*.

Internet self-efficacy. Research on self-efficacy prescribes that self-efficacy assessment should reflect different facets of the task domain, types of capabilities required, and situational circumstances in which those capabilities are exercised

Table 1. Scale reliability

Construct	Number of items	Cronbach's Alpha
Perceived Usefulness (PU)	5	0.94
Perceived ease of Use (PEOU)	5	0.91
Behavior Intention (BI)	5	0.89
Internet Self-efficacy (ISE)	6	0.93

(Bandura, 1997). However, the original computer self-efficacy scales were developed prior to the rise of ubiquitous Internet computing. They do not capture many important skills unique to the Internet (Torkzadeh & Van Dyke, 2002). Existing studies on ISE (Nahl, 1996; Nahl & Meer, 1997) focused on the operations of specific tasks such as entering a Web address (URL), creating folders, adding and removing bookmarks, mailing Web pages, and using file transfer protocol. Accordingly, Joo, Bong, and Choi (2000) measured ISE based on specific tasks in Internet search such as navigation, printing, and closing the browser. On the other hand, Eastin and LaRose (2000) proposed an instrument based on overall performance of Internet users. In the current study, we took a balanced stand in between these two positions and adapted most of the items from the studies (Dinev & Koufteros, 2002; Eastin & LaRose; Joo et al.; Torkzadeh & Van Dyke). We created an additional item for an important skill, which was not addressed in previous studies. Finally we had eight items based on the skills that are required to run Web-based applications (see Appendix A).

Other Constructs. Items for measuring PEOU and PU were originally proposed by Davis (1989) and successively tested and validated in many other studies (Chau, 1996; Gefen & Straub, 1997; Hendrickson, Massey, & Cronan, 1993; Mathieson, 1991; Ridings & Gefen, 2000). We tailored the items so that they are applicable to Web-based technologies. The items for measuring BI were adapted from the studies of Chau (1996) and Venkatesh and Davis (1996).

Task

Due to time limitation, we did not require the participants to test all functionalities available in HyperCharts™. Instead, we focused on the primary EMR functions as suggested by Waegemann (2002) and required participants to accomplish the following tasks: (a) Log into the system with the provided user name and password; (b) create, update, and delete a patient record, search for a patient record, and add quick notes to a patient record; (c) search for prescriptions for a patient, add and sign off a new prescription, and add and modify medications on a prescription; and (d) upload and download a dictation audio file. These primary functions were also described in the introduction to the system on the HyperCharts™ Web site. All test data are similar to what the subjects are dealing with in their everyday work.

DATA ANALYSIS

Analytical Techniques

When deciding on analytical techniques, we considered hierarchical multiple regressions versus structural equation modeling (SEM) techniques like LISREL. SEM has its advantages in assessing both the efficacy of a measurement model and the significance of a structural model in one test, and is becoming popular in IT research in recent years. However, one is advised that SEM has some limitations compared with other more traditional techniques such as multiple regressions. First, SEM has a stringent requirement on sample sizes. Ding, Velicer, and Harlow (1995) noted that 100 to 150 participants is the minimum sample size for SEM while Hu, Bentler, and Kano (1992) indicated that sometimes 5,000 participants is insufficient. Second, the goodness-of-fit indices for SEM have no single statistical test of significance that identifies a correct model (Schumacker & Lomax, 1996). The widely cited criteria often falsely accept bad models (Liu, Li, & Karau, 2003). The problem compounds when the sample is too small or too large.

Therefore, in this study we choose hierarchical multiple regressions as the primary technique for data analysis. The use of hierarchical regression allows us to test recursive models, where a predictor in one model may become the dependent variable in another, and therefore an antecedent variable may have impacts on a consequent variable in multiple distinct ways, with some direct and some indirect. Our research model is a case in point; each hypothesis stipulates the total effect of a predictor on a dependent variable, including both direct and indirect effects. For example, according to Figure 2, ISE can affect behavioral intention in four distinct ways, and the total effect of ISE on BI is the sum of all these direct and indirect effects.

1. ISE → BI (path e)
2. ISE → PU → BI (path b + path f)
3. ISE → PEOU → BI (path a + path d)
4. ISE → PEOU → PU → BI (path a + path c + path f)

Following the guideline proposed by Hair, Anderson, Tatham, and Black (1998), we assessed the assumptions of hierarchical regressions: the linearity of a phenomenon, the constant variance of the error term, and the normality of the error term distribution. We chose studentized residuals as the measure of the prediction error of each dependent variable. We examined residual scatter plots and partial regression plots. We did not detect any violations of these assumptions.

Scale Assessment

Before the survey was conducted, three PhD students and two faculty members reviewed the survey questions regarding their clarity and face and content validity. Two scale items for ISE were dropped because they were not directly related to Web-based medical record systems. As a result, six items are used to measure the construct of ISE while the scales for other constructs remain unchanged (Appendix B).

Since all research constructs are latent, each one is reflected by a group of measurable items and indirectly measured as the average of their scores. Therefore, before we conduct data analysis on the constructs, we need to ensure the reliabil-

ity of their scales, which are usually measured by Cronbach's alpha coefficients. The reliability coefficient of each construct is reported in Table 1. In general, a coefficient value of 0.70 or higher is considered acceptable (Hair et al., 1998). As per this standard, the reliabilities of our constructs are very high and comparable to or even better than those in other similar studies (Appendix A).

To ensure that the items for the same construct measure a single trait while items for different constructs measure distinct traits, we conducted a principal factor analysis with varimax rotation on 16 items for all independent constructs: ISE, PEOU, and PU. Using the Kaiser eigenvalues criterion, we extracted three factors that collectively explained 77.28% of the variance in all items. Statistically, to obtain a power level of 80% at significance level 0.05, the significant value of factor loadings with a sample size of 100 is 0.50 (Hair et al., 1998). The rotated factor matrix in Table 2 shows that all the items cleanly load on the correct latent constructs, supporting the factorial validity of the measurement instrument.

Results

In hierarchical multiple regressions, the researcher decides on not only how many predictors to enter, but also the order in which they enter. Usually, the order of entry is based on logical or theoretical considerations. We enter the most exogenous predictors first and the most endogenous predictor last. In our case, because ISE is modeled as having a direct influence on PEOU, it is important to statistically control the direct influence of ISE on BI before evaluating the independent contribution of PEOU to BI. Failing to control the direct influence of ISE could result in the relationship between PEOU and BI being artificially inflated due to the indirect influences through the perceptual variable. In the same vein, it is important to control the direct influence of PEOU on BI before evaluating the independent contribution of PU. Thus, ISE was entered into the regression model first, followed by PEOU and PU in the second and third step. In this way, we are able to tease out the influence of ISE before considering that of PEOU and PU. The regression results are presented in Table 3. We did similar regressions when PU and PEOU are dependent variables, and the results are shown in Table 4 and 5, respectively.

R^2 value — the coefficient of determination — represents the percentage of the variance that can be explained by the predictors in a relationship. According to the guideline provided by Hair et al. (1998), the threshold of R^2, for example, with a power of .80 at significance level 0.01, is about 15% for a sample of 100 participants with four independent variables. In other words, if the R^2 value for a relationship is greater than 15%, we will be confident that the effect of the independent variables on the dependent variable is statistically significant. According to this standard, all R^2 values are statistically significant.

An R^2 change is probably more important than an R^2 value itself. A significant R^2 change, say at level $\alpha \leq 0.01$, means that an additional predictor can explain a significant amount of the variance in the dependent variable and hence add additional explanation power to the model. For example, according to Table 3, about 80% of the total variance in BI is explained by three predictors: ISE, PEOU, and PU. Besides, all R^2 changes are significant, meaning all three predictors exhibited significant positive influences on BI. The three predictors explained respectively about 55% (ISE), 15% (PEOU), and 10% (PU) of the variance in BI. Similarly, according to Table 4, about 50% of the variance in PU was explained by ISE (45%) and PEOU (5%).

In order to test our research hypotheses, we need to calculate the coefficient of each path, called direct effect, as well as the total effect of each predictor. A direct effect represents the change in the dependent variable directly attributable to a standard deviation change in a predictor. A total effect represents the total change in the dependent variable attributable to the direct

Table 3. Hierarchical regressions for dependent variable BI

Model	Coefficients			Model Summary

Table 5. Hierarchical regressions for dependent variable PEOU

Model	Coefficients			Model Summary		
	Beta	T	Sig.	R^2	R^2 Change	Sig.
1				.478	.478	.000
ISE	.691	8.770	.000			

effect of the predictor, as well as its effects that are mediated through other predictors. Thus, we need to accumulate both direct and indirect effects to compute a total effect. Direct effects are the standardized beta coefficients in the full model. For example, according to Table 3, the beta coefficients in the full model are respectively 0.16 for ISE, 0.41 for PEOU, and 0.44 for PU. Thus, the direct effect of ISE on BI is 0.16. Similarly, the direct effect of PEOU on BI is 0.41 and that of PU is 0.44. Figure 3 shows all direct effects taken from Tables 3 to 5.

To compute the total effect, we consider all the paths that link a predictor to the dependent variable with or without mediators in between. If a path has no mediator, it carries a direct effect. If a path consists of one or more mediators, it carries an indirect effect, which is the product of all direct effects on the path. For example, the indirect effect of ISE on BI through the path ISE $\rightarrow$ PEOU $\rightarrow$ PU $\rightarrow$ BI is $0.69 \times 0.31 \times 0.44 = 0.09$. The total effect is simply the sum of the direct and indirect effects carried by all the paths. In Table 6, we summarized the total effect for each pair of a

Figure 3. Direct effects of predictors

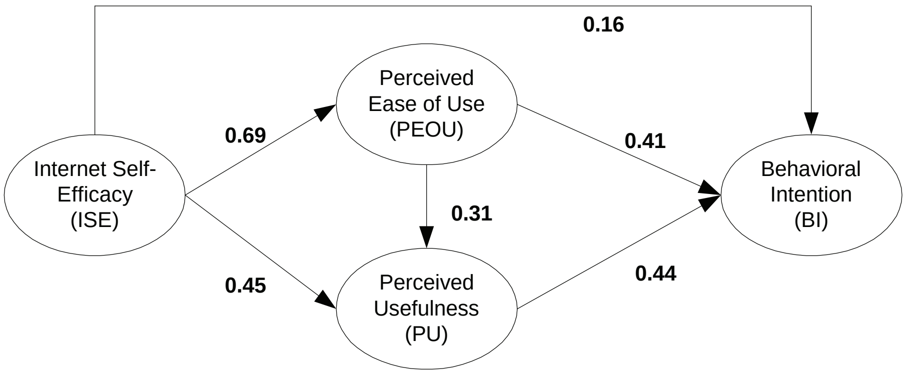

Table 6. Total effects summary

Hypothesis	Relationship	Total Effect	Supported?
H1	ISE → BI	.741	Yes (p<.001)
H2	ISE → PEOU	.691	Yes (p<.001)
H3	PEOU → PU	.313	Yes (p=.004)
H4	PU → BI	.441	Yes (p<.001)
H5	PEOU → BI	.546	Yes (p<.001)

predictor and a dependent variable, and the level of support for each research hypothesis. As shown, all hypotheses are strongly supported by the data at the significance level 0.005 or higher.

DISCUSSION AND CONCLUSION

The results of this study indicated that Internet self-efficacy has a significant impact on perceived ease of use, perceived usefulness, as well as behavioral intention to use Web-based electronic medical records. The total effect of Internet self-efficacy on perceived usefulness is slightly weaker than that on perceived ease of use. It indicates that users perceived the system to be both easier to use and more useful when their Internet self-efficacies are higher. This finding is consistent with that of previous studies (Agarwal et al., 2000; Lopez & Manson, 1997). By synthesizing this and other self-efficacy studies (Agarwal et al.; Igbaria et al., 1995; Lopez & Manson), we found that the impact of self-efficacy on usefulness is significant in Internet- or Web-related settings, but not significant in traditional non-Web-based contexts. Of course, this finding needs further investigation before jumping to a firm conclusion.

Perceived ease of use influences both usefulness and intention. However, its total effect on behavioral intention is stronger than that on usefulness. This finding is interesting because the role of ease of use has been found unstable and controversial (Ma & Liu, 2004). Most studies indicated that the impact of ease of use on usefulness is stronger than that of ease of use on behavioral intention, although few other researchers found a much larger effect of ease of use on intention than usefulness (Lim, 2001). In a study with the Internet technology, Gefen and Straub (2000) found that PEOU influences BI when a Web site involves inquiries, but does not influence BI when a Web site is used for a purchasing task.

Implications

Theoretically, this study helps understand the antecedents to the key constructs in the technology acceptance model. It confirms the existing findings on the role of self-efficacy in perceiving the usability of an information technology. It adds additional evidence to the conflicting findings on the role of self-efficacy in determining perceived usefulness. Most importantly, it does all these in the context of accepting Web-based electronic medical records, which has not been done yet. Since the software industry is currently undergoing a revolutionary transition from software as products to software as services, a study of how end users respond to such a transition is very important. This paper represents a first attempt in applying the technology acceptance model to the adoption of application services. The result may be generalizable to other emerging e-business technologies such as Web and grid services (Liu & Ma, 2004).

The findings of this study have some important managerial implications in practice. First, cognitive factors have been recognized to be the biggest obstacle for the widespread adoption of electronic medical records (Waegemann, 2002). In fact, the medical informatics community blames physicians for not being ready for a change to the computer. Among others, three critical cognitive factors are recognized (Voelker, 2003): (a) confidence in computers amongst their users, and especially in the availability, privacy, and security of data made of the electronic medical records; (b) adoption of a positive attitude towards computers in the workplace; and (c) adequate skills and proficiency in the use of the computer application. Our study confirms these general beliefs and addresses these factors using three constructs: self-efficacy, perceived ease of use, and perceived usefulness. Further research is needed to address other aspects of these cognitive factors. Second, our findings imply that, as for other technologies, enhanced usability and usefulness are a very important step toward the acceptance of Web-based electronic medical records. Third, to achieve end-user acceptance of electronic medical records, health care organizations can introduce interventions aiming at improving usability and utility perceptions as well as the end-user's Internet self-efficacy. However, as Table 6 shows, the total effect of self-efficacy on behavior intention is much stronger than that of perceived ease of use and usefulness. The significance of Internet self-efficacy suggests that enhancing self-efficacy may be a more effective option toward technology acceptance than enhancing usability and utility perceptions. After all, enhancing perceived ease of use and usefulness often requires significant effort in modifying the services being provided and is thus more difficult to do.

Note that self-efficacy is not a measure of skills. Rather, it reflects what individuals believe they can do with the skills they possess. As such, it is easy to be manipulated. For example, optimistic outlook, self-deception, heuristics judgments, and excessive wishful thinking can all induce overconfidence (Metcalfe, 1998). Then, will overconfidence bias our findings? In metacognition, underestimation was found to be detrimental to learning outcomes while overconfidence was found to be beneficial, although individuals with overconfidence tend to overestimate their knowledge (Gravill, Compeau, & Marcolin, 2002). However, its impact on perceptual and attitudinal variables is not known yet. More research seems necessary to study this phenomenon and examine whether overconfidence enhances one's willingness to accept a technology.

4	I feel confident to visit a web site if I am given a web address (URL).			
5	I feel confident to log on to a website if I have the account information.			
6	Overall, I feel comfortable when I am using Internet.			
7	I feel it is easy for me to learn to use an Internet feature.	Dinev & Koufteros	.96	.82
8	I feel confident to perform data transactions (e.g., buy a book) on the web.	Dinev & Koufteros	.96	.58

APPENDIX B

Survey Instrument

PU1	Using this system in my job would enable me to accomplish tasks more quickly
PU2	Using this system would improve my job performance
PU3	Using this system would enhance my effectiveness on the job
PU4	Using this system would make it easier to do my job
PU5	This system is useful in my job
PEOU1	I found it was easy to do whatever I want
PEOU2	The navigation on the site is easy
PEOU3	Learning to operate this system is easy for me.
PEOU4	This web site provides information content that is easy to understand
PEOU5	I found this system was flexible to interact with
ISE1	I feel confident to use search engines like Yahoo, Google, and AltaVista.
ISE2	I feel confident to log on to a website if I have the account information.
ISE3	I feel confident to download necessary material from Internet.
ISE4	I feel confident to search for information on the Internet.
ISE5	I feel confident to visit a web site if I am given a web address (URL).
ISE6	Overall, I feel comfortable when I am using Internet.
BI1	I will support it if my clinic decides to use this system.
BI2	I would like to come back to this site for a second look
BI3	I do not mind spending some time to learn how to use this system for my work
BI4	I am willing to use the system for my work
BI5	It would be efficient if we were going to adopt this system.

Chapter 5.15
Intelligent Portals for Supporting Medical Information Needs

Jane Moon
Monash University, Australia

Frada Burstein
Monash University, Australia

ABSTRACT

The aim of this chapter is to review the way portal technology can assist users seeking medical information. There has been an increase in health Internet usage, and better health-care delivery outcomes are predicted as users are better informed when making medical decisions. At the same time, there is much concern about the need for medical portals to meet community information needs. This chapter discusses what constitutes an intelligent portal, discusses desirable portal components and attributes of intelligent portal features, and how these can be implemented to meet the needs of diverse users. Seven Australian medical Web sites have been analysed according to intelligence features. The results and analysis are presented and discussed, in particular, with respect to their functionality as defined for intelligent portals. The discussion is focused on the extent to which these attributes help users with their information seeking and therefore support their decision-making processes.

INTRODUCTION

Internet technology provides a useful and easy information channel, which enables various content materials to be streamlined to users on request. The amount of information that is now available electronically is as large as that produced in non-electronic form since the development of print media. With the global proliferation of Internet use, obtaining information in this way has become the norm for many. This presents opportunities for providing the most relevant and current content to users when they need it. Information relating to health is no exception; more and more people are relying on the Internet as a way of accessing information relating to health. Research shows that one in four of 80 million users of the World Wide Web in 2000 visited at least one medical Web site, and the number of visitors to such sites grew faster than with other sites in general (Murray, 2002).

However, studies show that many Internet users looking for information are often frustrated by a large amount of irrelevant information retrieved by search engines and by the time it takes to obtain truly relevant information. Personalization and customization of the interface through portal technology are a timely response to these problems (Finkelstein & Aiken, 2000).

There are many definitions of portals. Merrill Lynch in November 1998 described portals as "applications that enable companies to … provide users with a single gateway to personalized information needed to make informed business decisions" (Quirk, 2001, p. 2). A very generic definition of a portal is as a single gateway connected by a server that connects people with information (Harvard Computing Group, 2002).

The limitations in portal technology and specific human behaviour are factors affecting the efficiency of information retrieval. Consequently, modern portals are built with the intent of implementing some intelligent ways of catering for different needs. Improving in portal technology and understanding the dynamics of human nature can improve information retrieval.

The aim of this chapter is to review the way portal technology can assist users in broader community contexts. In particular, we look at how portals are employed for meeting community medical information needs and ways to improve these medical portals.

Specifically, we explore the extent to which these portals behave "intelligently" in addressing users' needs. The analyses of medical portal intelligence issues are discussed in terms of search engines, spell checking, "sounds like" indexing, parsing, ontology, use of thesaurus, personalization, and decision facilities or expert system functionality. Finally, Australian medical portals are analysed in order to illustrate the problems and opportunities of intelligent community portals.

HEALTH INTERNET USAGE

Increasingly people are seeking medical information on the Internet. In America, Ehrenberger in 1991 predicted that by 2005, 88.5 million Americans will be using the Internet to seek health information (Ehrenberger, 2001). The current survey exceeds his prediction. According to the Harris Interactive consulting firm, health Internet users grew exponentially from 50 million in 1998 to 69 million in 1999, 97 million by year 2001, and reached 110 million in year 2002. The research concluded that:

The Internet continues to be used by huge, and growing, numbers of the public interested in getting information about particular diseases or treatments or about staying healthy. The results also demonstrate the critical importance to health care websites of the need to be quickly and easily accessible through search engines and portals. (Taylor, 2002, p. 1)

Brodie et al. report (2000) there is no significant difference in information-seeking habits due to age, and there is a direct correlation between computer usage and access to health information:

Once people gain access to the Internet, its use at home to get health information is similar across income, education, race and age. Therefore the number of persons using the Internet to access health information should rise along with computer use. (Brodie et al, 2000, p. 262)

A report by the Australian Bureau of Statistics in 2002 on Internet usage shows that there has been a gradual increase in the use of computers and the Internet at home. In 2000, 53% of households (3.8 million) had a computer, an 11% increase over 1999. About one-third had Internet access, a 49% increase over 1999. The Australian Government is taking a proactive role in developing medical portals to encourage general use of the Web for the dissemination of medical information (National Health Information Management Advisory Council, 2001). Australian government portals such as Health*Insite* and HealthFinder argue that the better informed the users are, the better their health outlook (National Health Information Management Advisory Council).

Because there is an increased usage of the Internet and because medical information is one of its most valuable resources, the control of this content is very important. Research shows that the degree of trust people have in the content of the information from medical portals is increasing (Ho & Tang, 2001). Anecdotal evidence suggests that some users prefer information from the Internet over advice from their consultants. For example, a woman who was recommended to have a splenectomy (removal of spleen) by her consultant refused surgery twice. However, she changed her mind after she read the same information on the Internet. She put more trust in the information she read from the Internet than her consultant. Ho and Tang showed that of their 1,232 respondents more than 60% believed that the Internet contained more in-depth information than either TV or newspapers. Whilst Ho and Tang's research reveals trust shown by the users, there are conflicting reports, however, suggesting that users are still confused about the material they read from medical sites (Wilson, 2002).

There is also an issue of retrieving vast, complex, and widely distributed medical information. How do you retrieve correct, relevant, and reliable information in a timely manner? How do you know when you have searched enough? It is extremely difficult for users to access the exact type of medical information they need (Shepherd, Zitner, & Watters, 2000). Whilst there is a growing number of Internet users and reliance on information from these sources, many users looking for information are often frustrated by the amount of irrelevant information retrieved via search engines, the time it takes to retrieve this information (Finkelstein & Aiken, 2000), and its perceived quality (Wilson, 2002).

CURRENT PORTAL TECHNOLOGY

In Latin, the word *porta* means a door, gate or gateway, entrance, or opening. A portal can be defined as a gateway to information (Clarke & Flaherty, 2002; Quirk, 2002; Rao, 2001). It is Web-based and connects a set of commonly used information or services via a link from a single page (Notes, 2002; O'Leary, 1999).

There are many types of portals. In general portals can largely be classified into four categories:

- Corporate or enterprise (intranet) portals;
- E-business portals;
- Personal portals; and
- Public portals. The public portals include general public portals such as Yahoo, AOL, AltaVista, and community portals.

The types of medical portals we will be looking at are community portals. Some of the functionalities that can be implemented into medical portals are as follows (Collins, 2001; Millen, 2000; Tushkar, 2000):

- **Browse/Navigate documents**—this allows users to search for and locate information manually by navigating through a directory structure.
- **Collaboration**—represents an important aspect of a portal and is a powerful tool. It

includes instant messages such as "chat," document sharing, videoconferencing, virtual conferencing, and discussion forums.

- **Content management**—a process of approving, authoring, delivering, maintaining, and publishing content integrated with or accessed from a portal or other Web site. This can be implemented as a separate component with a common database accessible through the portal.
- **Directory**—a directory within the portal's enterprise taxonomy. It is a collection of data structured into a hierarchy of categories.
- **Document management**—similar to content management but mainly dealing with control and management of an enterprise's documents. It involves managing electronic files, including scanned images of pictures and documents.
- **Personalization**—portal personalization can be achieved at different levels. An individual can have a personal setting; a group of people sharing the same function can have group settings. An organization can set up its own setting. This feature allows a portal to be customized according to needs.
- **Search engine**—the ability to search is the fundamental component of a portal. It allows users to browse the content, retrieve information on the content basis, and link to other repositories for information.
- **Subscribe/What's new**—allows users to register an interest in a particular aspect of a portal. Portals then notify the user when changes in content occur.
- **Taxonomy**—a classification scheme to organize information. Additional functionalities, such as metadata added to the taxonomy, could help to organize documents into different categories that could make the information easy to browse, search, or navigate.
- **Online community**—provides the opportunity for users with similar interests to share their medical conditions and experiences. This could range from sharing experiences of treatment to discussing medical conditions and alternative medicine.

For the purpose of this chapter, we assume that a portal is an Internet-based information system providing uniform access to different sources of information in an enterprise and maintaining dynamic links to information resources. A portal supports communication within the enterprise and connects people with information and applications they need for performing tasks. Unlike a conventional Web site, portals should support both push (subscription) and pull (search) functions in assisting users to gain access to essential contextual information (Probst, Raub, & Romhardt, 2002).

INTELLIGENT MEDICAL PORTALS

The term "intelligent medical portal" refers to a Web gateway environment that allows users with varied medical interests and diverse backgrounds to access medical resources and information to support their decision-making processes, which often involve critical medical problems.

Current portal technology fails to deliver the types of medical information needed by users (McKemmish, Burstein, Manaszewicz, & Fisher, 2002). In the following paragraph, some of the users' experiences are included to illustrate this deficiency of portal technology.

A 44-year-old female who wants to go on a Pap smear registry so that she can be notified automatically every two years could not get a satisfactory answer from the Australian government medical Web site, Health*Insite*. It provided her with hyperlinks but these were not operational—not much use to the user. She was inundated with general information on Pap smears instead. In another medical Web site, Health Network, users were encouraged to write to the consultants.

An enquirer's e-mail did not get an answer for 3 weeks, and in that time she had already found the answers through other channels.

A quality search engine with built-in intelligence features such as a thesaurus, sounds-like index, ontology, and parsing could assist users with difficult medical jargon, treatments, and the spelling of difficult drug names. However, current portal technology does not have many of these intelligence features. If a person looking for medical information on rheumatoid arthritis types phonetically *rumatoid arthritis*, he would not get any returns in current medical portals. Ideally some assistance should be provided as in Google: "Did you mean: …" This could help the users.

Current medical portals do not have provisions for differentiating users with different educational background, age, ethnicity, location (urban or rural), and stage of disease. For example, there is no distinct information for a 63-year-old female with early breast cancer or for a 35-year-old mother experiencing advanced breast cancer living in a rural area. Hyperlinks to the actual breast cancer information seem to be provided with a "one size fits all" category, which does not suit everyone (McKemmish et al., 2002).

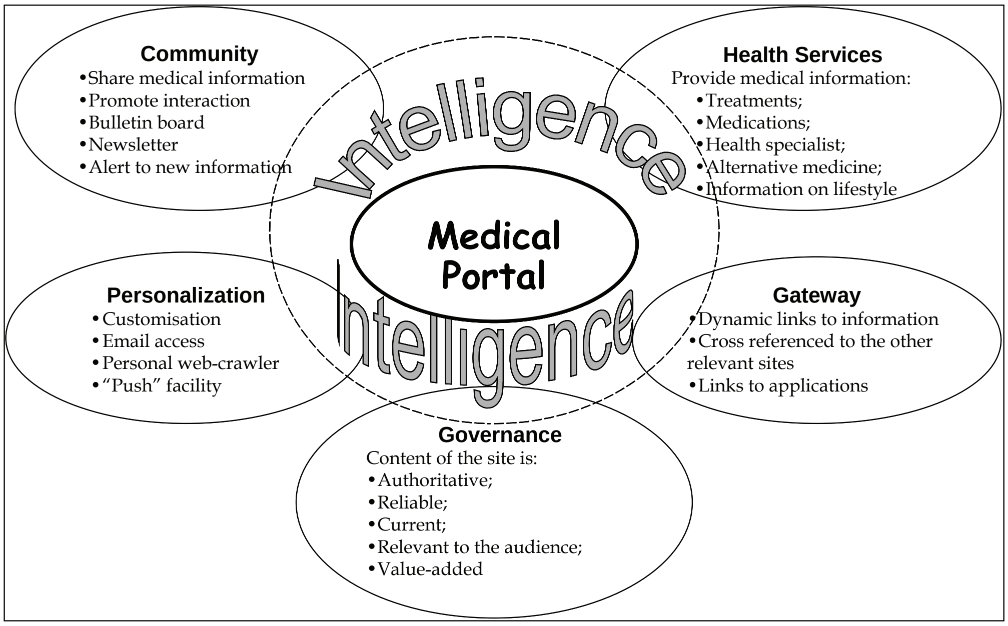
The problems lie in the limited portal technology, which is inflexible, and inadequate search engines, which do not allow for sophisticated searching facilities.

How can a portal be made to behave intelligently so that users can get access to vastly distributed medical information easily? McKemmish et al. (2002) describe how an intelligent portal "will improve the structure and manage the quantity of information presented" (p. 5). Indeed an intelligent portal should provide information that is of high-quality, relevant, and timely. It should address the needs of users by helping them to solve issues that are often critical. With the use of intelligent portal technology, combining knowledge management issues of personalization and decision support, the needs of the Internet users of medical portals could be better served.

Components of Medical Portals

The following diagram shows the components of medical portals which should be implemented

Figure 1. Proposed components of medical portals



to ensure their efficient information retrieval capabilities. Figure 1 depicts the major components expected from the medical portal. These components are:

- **Health services**—medical portals should provide foremost medical information pertinent to that site, i.e., if it is breast cancer, provide medical facts on treatments, as well as associated and often sought-for information on lifestyle and complementary medicine.
- **Gateway functionality**—should provide dynamic links to other sites, facilities for cross-referencing, and links to other applications.
- **Community support**—involves a space to share medical information and treatments, share personal experiences, offer a bulletin board to provide information about the latest technologies and medications; it could also be a forum for medical professionals to share their knowledge and peer reviews on aspects relevant to the medical portal.
- **Personalization**—should provide facilities to customize sites so users can get to them with ease and e-mail systems to receive the latest news and to send any queries or share any information at a personal level.
- **Governance**—the contents of the information can have significant influence on the livelihood of users. Some users could make important decisions about their treatments on the basis of what they read from the Internet. Thus it is paramount to ensure the quality, authority, currency, and relevance of the information.

Intelligence Features of Medical Portals

Intelligence is the necessary interface between the users and those components that make the portal a useful and unique information system to satisfy the potential dynamic needs of a user. As pointed out by Shepherd et al. (2000), medical information is vast and distributed. To retrieve these items of information effectively, there needs to be a quality search engine that "understands" the user's needs.

The following intelligence features can be incorporated into medical portals to improve information retrieval:

- **Search engine**—the ability to search is fundamental for the implementation of a portal. It allows users to browse the content and retrieve information on a content basis, and assists users by providing links to other relevant information repositories. Use of artifical agents such as artificial neural network (pattern matching) and fuzzy logic can be applied to specify the search (Negnevitsky, 2002).
- **Spell checking**—often medical terms and the drugs that are used for treatments are hard to spell, and there are both English and American variants. Current portal technology does not have provisions for misspelt words. A list of possibilities should be shown if the word entered is spelt incorrectly.
- **Sounds-like indexing**—this is to search for "sounds like" terms. Fuzzy logic can assist in refining the search. Medical jargon is extremely difficult to spell; thus, sounds-like indexing could add value to the portal.
- **Parsing** sentences or phrases to identify key words and then searching for the content. In general, search engines are based on key words and often inadequate. For example one could be searching for "evening primrose" for either dermatitis or menopausal symptoms. Parsing allows the user to enter more than one search option, and this could be a powerful tool if implemented.
- **Metadata**—a mechanism used for resource description and specification. It can be used for marking or tagging the repository content

for locating the resource according to parameters specified in the metadata. For example, the Australian Government Locator Service (AGLS) was introduced in 2002 for use by government departments and agencies to improve the visibility and accessibility of their services and information provision over the Internet. It uses a standard set of 19 descriptive elements (National Archives of Australia, 2000).

- **Ontology**—representing a domain discourse in a way that terms specific to this domain can be identified from synonyms. For example, the word *drug* can be expressed in many different ways (medicine, medication, tablets, pills, prescription). So the word retrieved should have relevance to the search. That is, if *drug* is typed into a breast cancer portal, the portal should return Tamoxifen, for example, a common anti-estrogen drug.
- **Thesaurus**—can be used together with ontology to describe a structure of the problem domain. In our context, it can be too broad if it includes outside knowledge not relevant to medicine. However, if complemented by a metadata repository, it can be narrowed.
- **Personalization**—special service to the specific users, which can be set up at various levels. The users can have personal settings in the portal (profile) such that they can share information and receive notifications when there is a change to the content. The user can set up a Web spider to collect information of interest and push it to the user as soon as it is collected. Users can tailor the "look and feel" of the portal interface to suit their preferences. They can also select personal services such as news, e-mail, and relevant service sites to be available within a portal page.
- **Decision-making facilities**—some analytical tools can be provided with the portal to help users with decision-making processes (loan calculators, for example). These can be more sophisticated if built on the basis of decision analysis algorithms, or implement if/then/else rule reasoning engines. The users' profile information can be utilised here to assist them with their enquiries.
- **Quality-rated information**—the information retrieved is presented to the user with some indicators relating to generally accepted criteria of quality, such as author, publisher, currency, purpose, etc. This should help the user to be in a position to make an informed choice.
- **Content management**—a process of approving, authoring, delivering, maintaining, and publishing content integrated within or accessed from a portal or other Web site. It can be implemented as a separate component with a common database accessible through the portal.
- **Document management**—similar to content management but deals with control and management of the enterprise documents. It involves managing electronic files, including scanned images of pictures and documents. It can also incorporate workflow facilities for supporting organizational processes. In medical portals this can be a facility to access insurance forms and claims.
- **Knowledge management**—this can be seen as a mechanism for capturing know-how and know-why in a knowledge repository.
- **Use of artificial intelligence**—such as artificial neural networks, fuzzy logic, expert systems for implementing learning capabilities, adaptation, and dynamic reasoning.
- **Other intelligent agents**—intelligent agents can assist in searching through the data to support "push" facilities of the portal (Probst et al., 2000). They can save users time by sifting the data, retrieving relevant information, and pushing it to the user on request.

The intelligence features listed above can be incorporated within portal components as shown in Figure 1. The following sections present the analysis done against the intelligence features identified above to see to what extent existing medical portals comprise those features.

MEDICAL PORTALS ANALYSIS

In this section, we will analyse Australian medical portals to assess the extent to which identified intelligence features are present. The features that will be investigated are as follows:

- Search engine;
- Spell check;
- Sounds-like index;
- Parsing;
- Ontology;
- Personalization; and
- Thesaurus.

The Australian medical Web sites were specifically chosen to assess to what extent medical information needs are met. The problems and types of information the users were seeking were pertinent to Australians. For example, recent user needs analysis regarding availability of breast-cancer-related information online showed that one third of the users live in rural areas. For those users, availability of medical specialists, treatments, and travelling and accommodation during the treatments are issues (Manaszewicz, Fisher, Williamson, & McKemmish, 2002). The current medical portals should address those needs.

The seven most popular Australian medical Web sites have been chosen and analysed according to intelligence features. We have analysed how these features are implemented in medical portals. The portals analyzed are listed in Table 1.

The next section provides an analysis of each intelligence feature with screen shots.

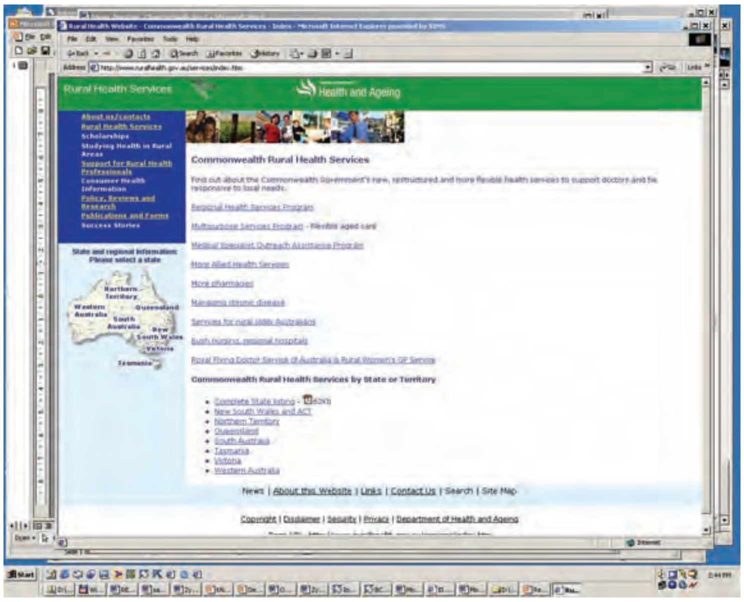
Search Engine

The first analysis was to look for the presence or absence of search engines in those seven medical Web sites. Not all of these Web sites were provided with search engines. For example, Rural Health does not provide a search capability, either internal or external. In fact, it operates as a gateway to the various resources available from other medical or health Web sites and draws heavily on content from Health*Insite* (see Figure 2). This Web site provides access to a knowledge repository selected mostly from a review of existing resources, "personalizing" them to a specific audience—the Australian rural population.

Table 1. Medical portals analyzed in this study

Australian Medical Portal	Web address	Managing organisation
BetterHealthChannel	www.betterhealth.vic.gov.au	Victorian Government's Department of Human Services
Health*Insite*	www.healthinsite.gov.au	Commonwealth Government of Australia
RuralHealth	www.ruralhealth.gov.au	Office of Rural Health (ORH), Australian Commonwealth (Federal) Department of Health and Ageing
Australian Indigenous Health-*InfoNet*	www.healthinfonet.ecu.edu.au	School of Nursing and Public Health, Edith Cowan University
HealthConnect Department of Health and Ageing's website	www.health.gov.au/	Australian Government Department of Health and Ageing
Medicine Australia (MedAu)	www.medineau.net.au	Northern Rivers Division of General Practice (NSW) Ltd
HealthNetwork	www.healthnetwork.com.au	General health information site run by Editorial Committee of medical practitioners for educational purposes

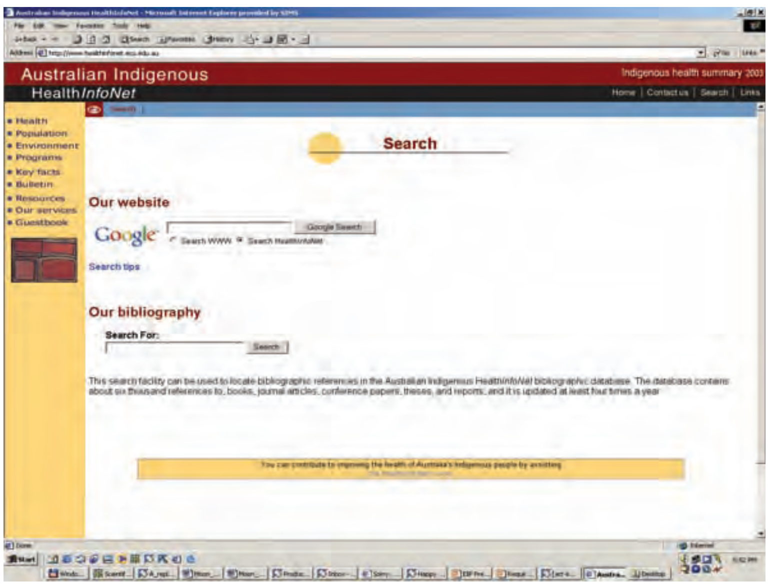
Figure 2. Rural Health gateway



Better Health Channel used an internal search engine to search the site content and used Google as an external search engine. Health*Insite* used Yahoo externally and had its own internal search engine. Health Network also offered search engines for selective links.

Figure 3 shows an example of a search facility for the Australian Indigenous Health*InfoNet* portal (http://www.healthinfonet.ecu.edu.au). It is a resource that provides medical information for Indigenous Australians. It contains literature reviews on various topics listed on the site map.

Figure 3. Search facility in Australian Indigenous HealthInfoNet



It also uses Google for external search (see Figure 3).

Spell Checking or Sounds-Like Search

None of the medical Web sites provided spell checking or sounds-like indexes. The following is an example from Better Health. When the common anti-estrogen drug for breast cancer, tamoxifen, was misspelt as *Tomoxifen*, there were no results returned, as can be seen in Figure 4a.

However, it provided links to the Google search engine. When the drug tamoxifen was misspelt as *tomoxifen*, Google provided the correct drug name, as shown in Figure 4b.

Other medical portals such as Health Network offered partial matching of spelling (sounds-like) in that you could type the first three letters of a word and still recognize the full word. For instance, if one was searching for the country Vietnam, typing *Vie* would return the country Vietnam if the first three letters were spelt **correctly**. However, it did not offer the facilities of thesaurus, spell check or sounds-like index (see Figures 5a and 5b). This feature provides some help to the users, but it could also retrieve many drugs or chemicals with the first three letters that are relevant to the query.

However, if *Vie* is mistyped as *Bie* or *betnam*, it will not recognize it.

Parsing

Parsing is the ability to separate a sentence into meaningful words. For example, if the sentence "Where can I find Tamoxifen?" is entered, a search engine should look for the key word in the sentence, "Tamoxifen," in this case, and retrieve the requested information.

Medicine Australia (MedAu), a general medical portal, was the only Web site that had the ability to show parsing. For example, the following: To the question "Where is Lithium?" the search result was the same as when the word "Lithium" was typed. The portal was able to extract the word from the sentence and retrieved information relevant to the sentence. It retrieved two articles that had information on lithium (see Figure 6).

Figure 4a. Better Health Channel sounds-like search facility

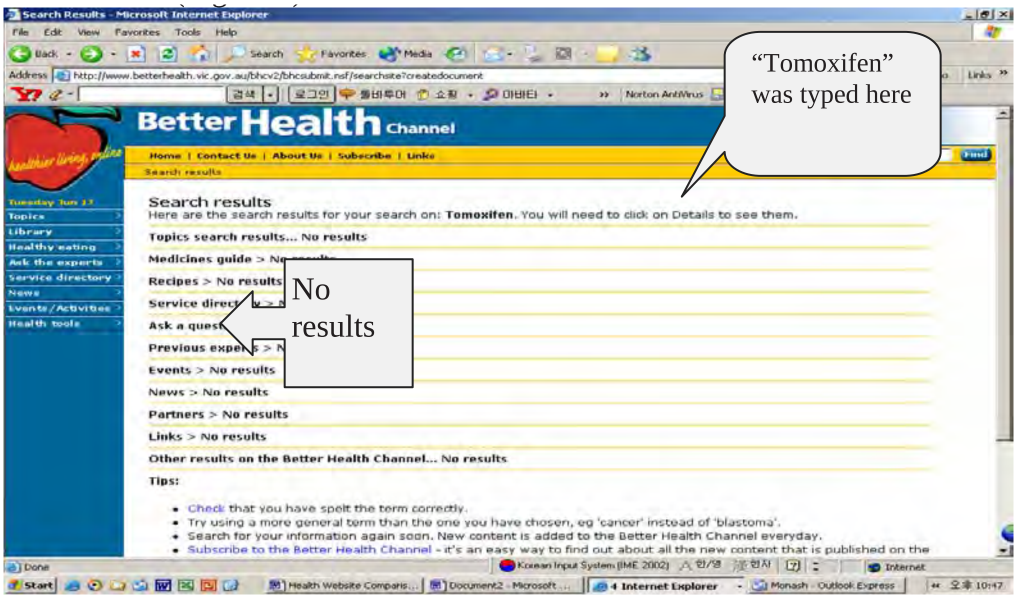


Figure 4b. Better Health Channel search facility through Google

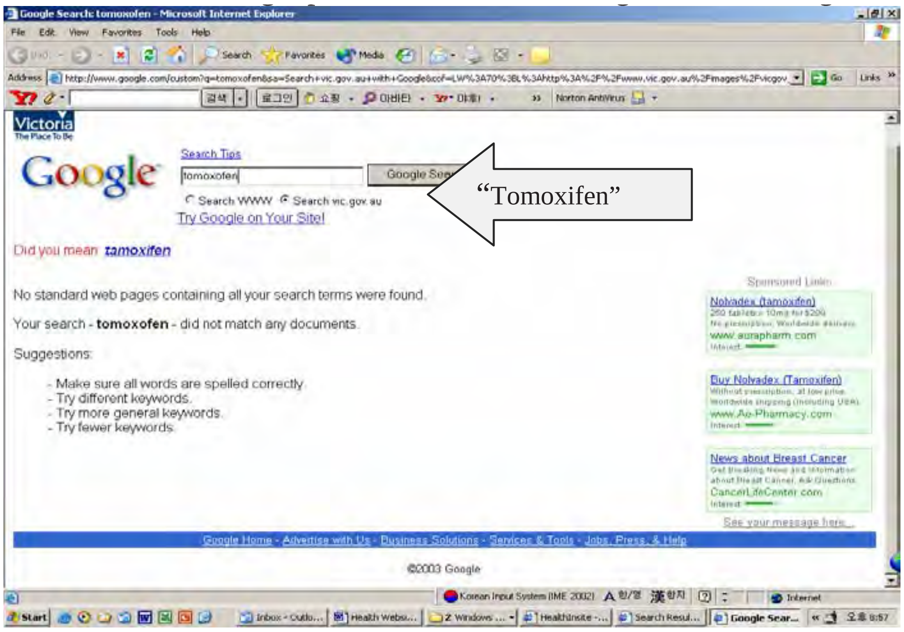

Figure 5a. Health Network sounds-like search

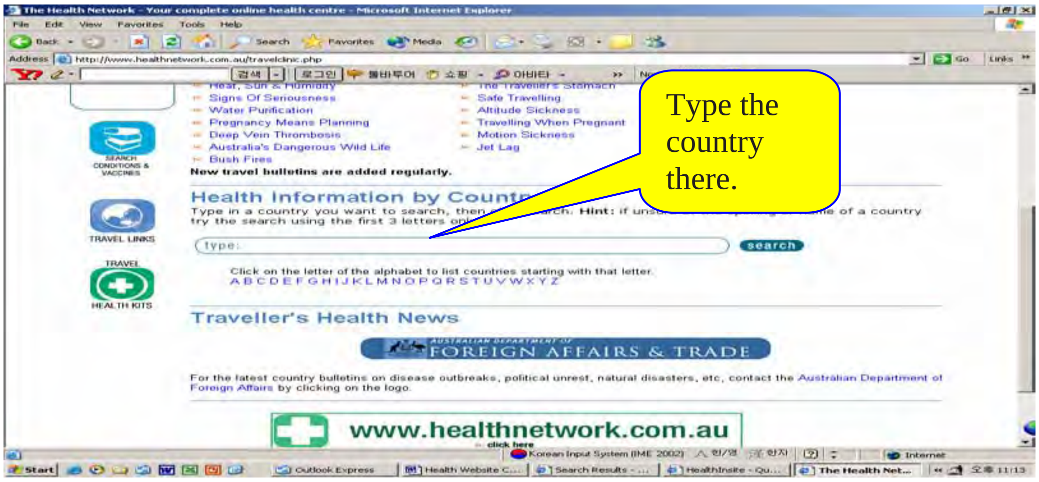
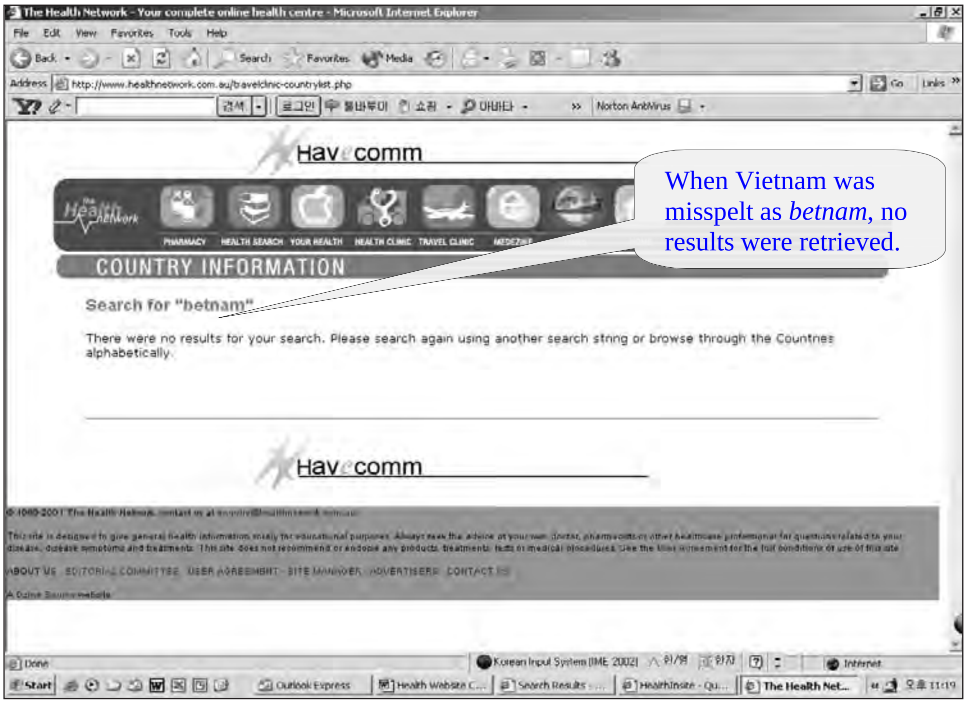


However, none of the other medical Web sites tested showed the ability to parse. In Figure 7 we present an example of the search with Better Health for the answer to the question "Where can I find tamoxifen?" As can be seen, this search found no results.

Another example was from Health*Connect* in response to "Where can I find tamoxifen?" (Figure 8).

The same question was entered into the Better Health portal through its link to Google search. When the sentence "Where can I find tamoxifen?"

Figure 5b. Health network sounds-like search



was entered, it was able to extract tamoxifen and returned the information shown in Figure 9.

Personalization

Personalization is one of the intelligence features of the portal by which users can:

- Receive an e-mail from the Web site if there is a major change to the Web site.
- Personalize the site interface—select the types of information they want to view.
- Have personal selection lists that can be placed where users can find them easily.
- Have automatic search items that match interests of users through "My interest link."

Figure 10 shows an example of how Health-*Insite* provides personalization features.

Health Network provides personalized contacts where the users can write to medical experts, who will promptly answer their questions (see Figure 11).

This provides the possibility for an added intelligence that offers the users personalized service, in addition to searching facilities. However, it is entirely manual, the questions being answered by people who are also logged on to that Web site.

Ontology and Thesaurus

No medical portal we have analysed had an ontology linked to it. Only one medical portal, Health-*Insite*, showed some presence of a thesaurus. But it was not exactly what would be expected when the full thesaurus is implemented and accessible through the portal. For example, when the drug tamoxifen was misspelt as *tomoxifen*, the search could not find it. It offered links to the Thesaurus Navigator instead (see Figure 12).

Figure 6. Example of Medicine Australia (MedAu) parsing ability

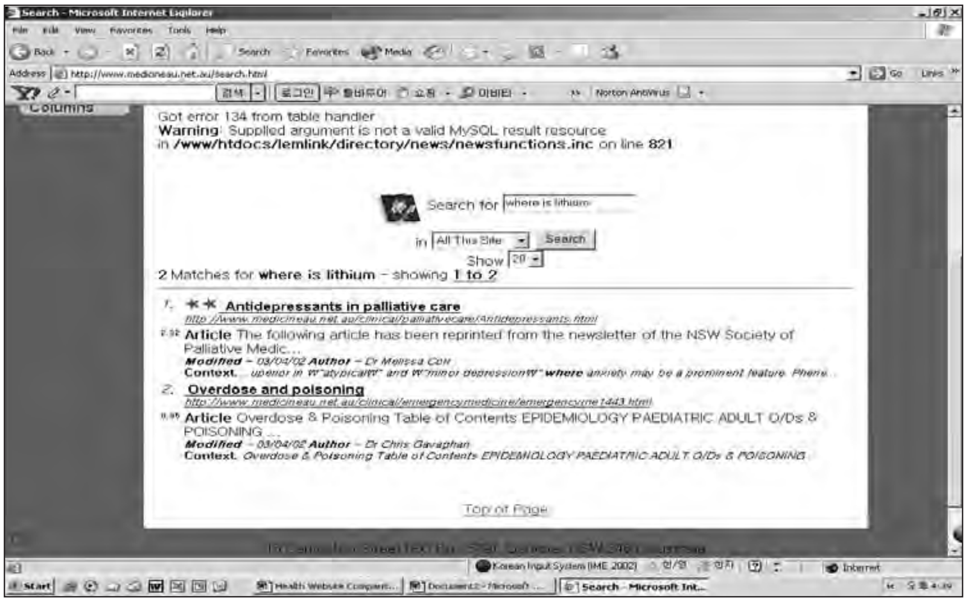


Figure 7. Example of Better Health Channel search without parsing

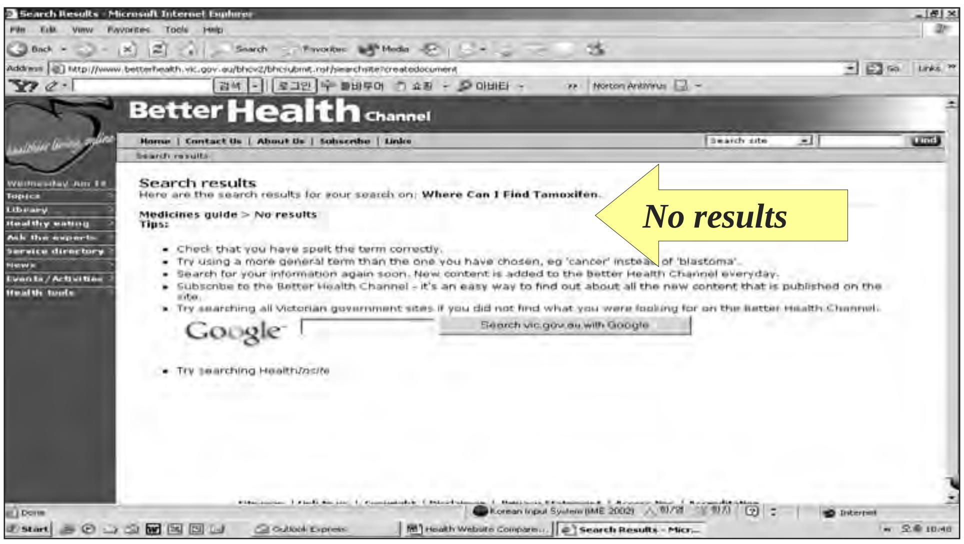

Figure 8. Example of HealthConnect search without parsing

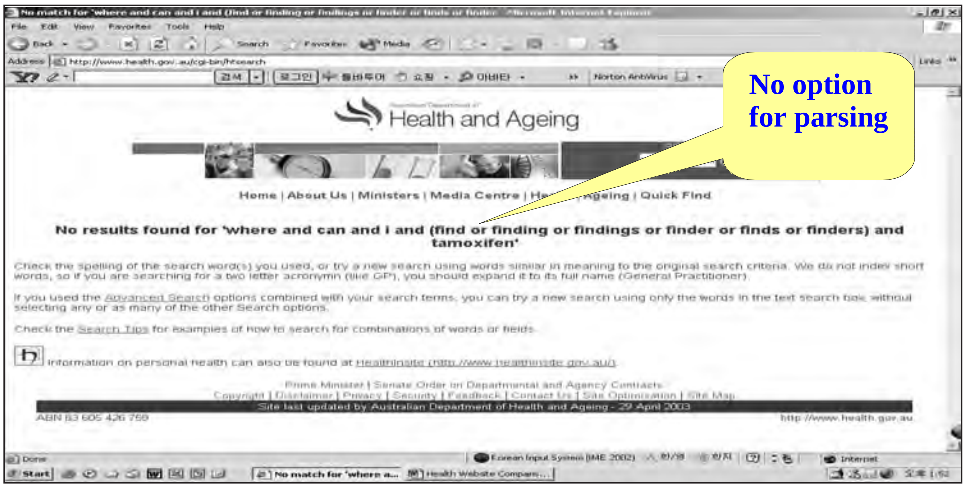

Figure 9. Improved search in Better Health Channel with Google parsing

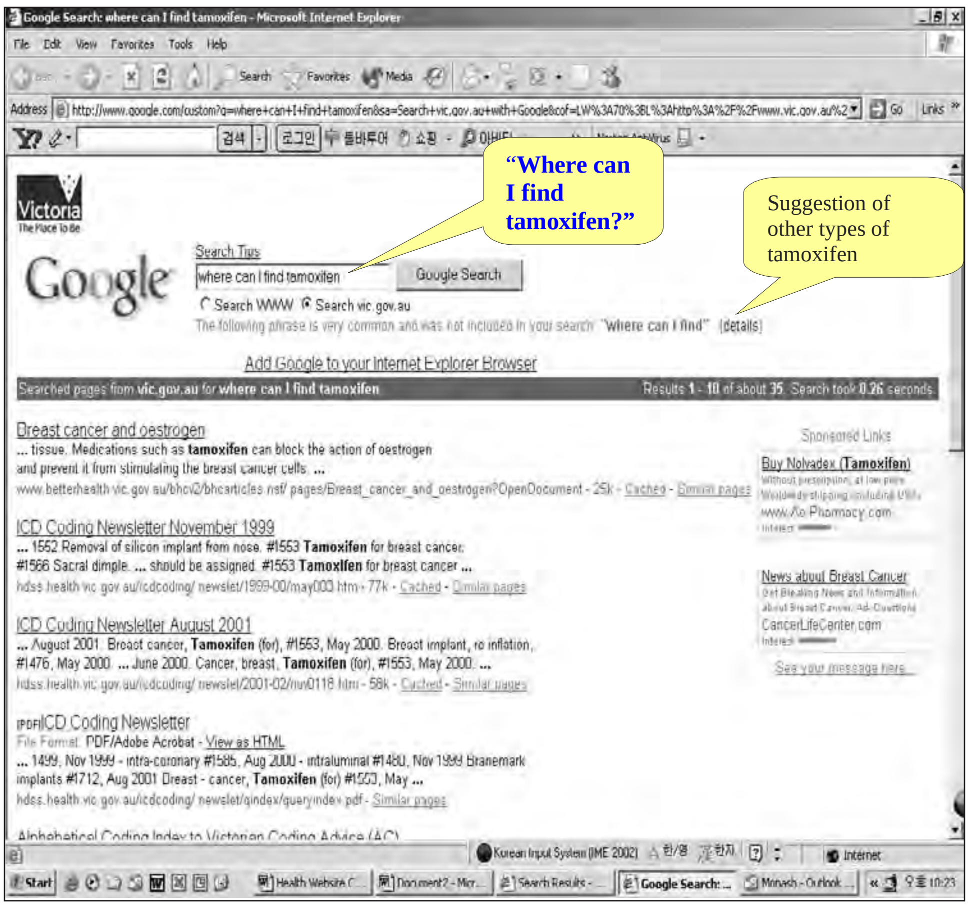

Figure 10. HealthInsite personalization facility

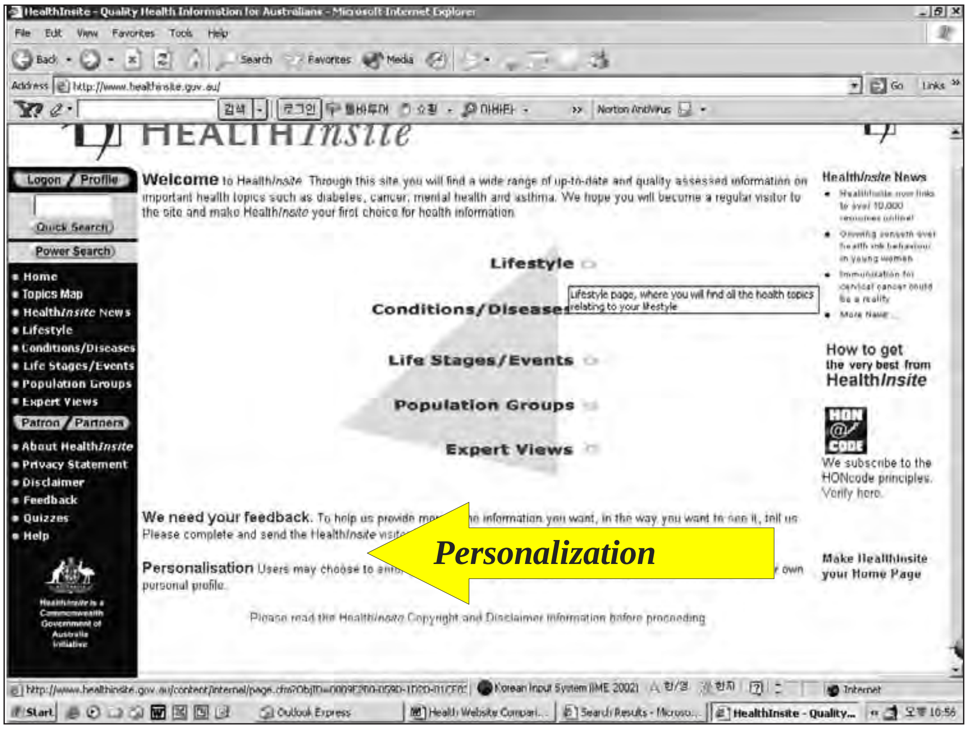

Figure 11. Health Network personalization facility

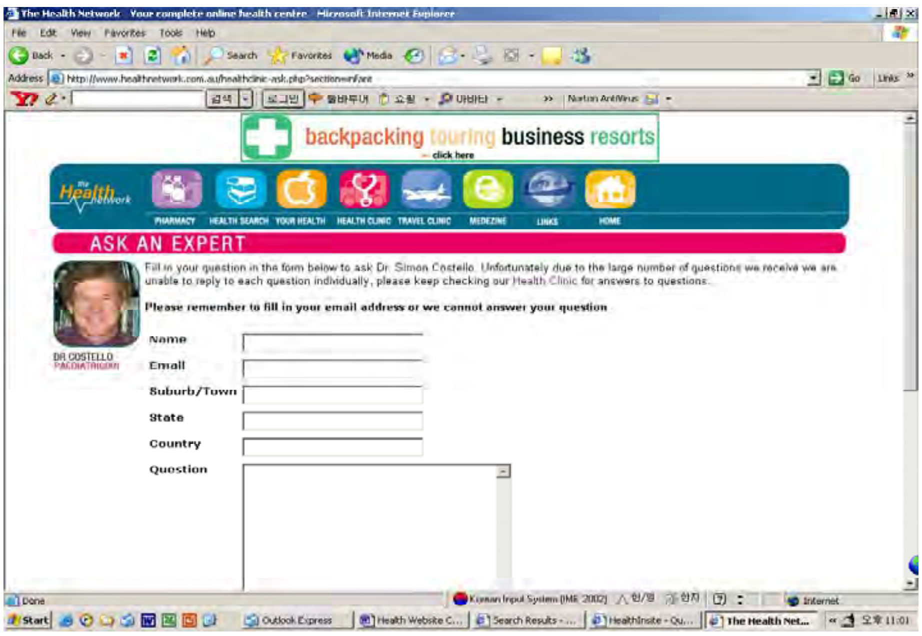

Figure 12. Thesaurus in HealthInsite

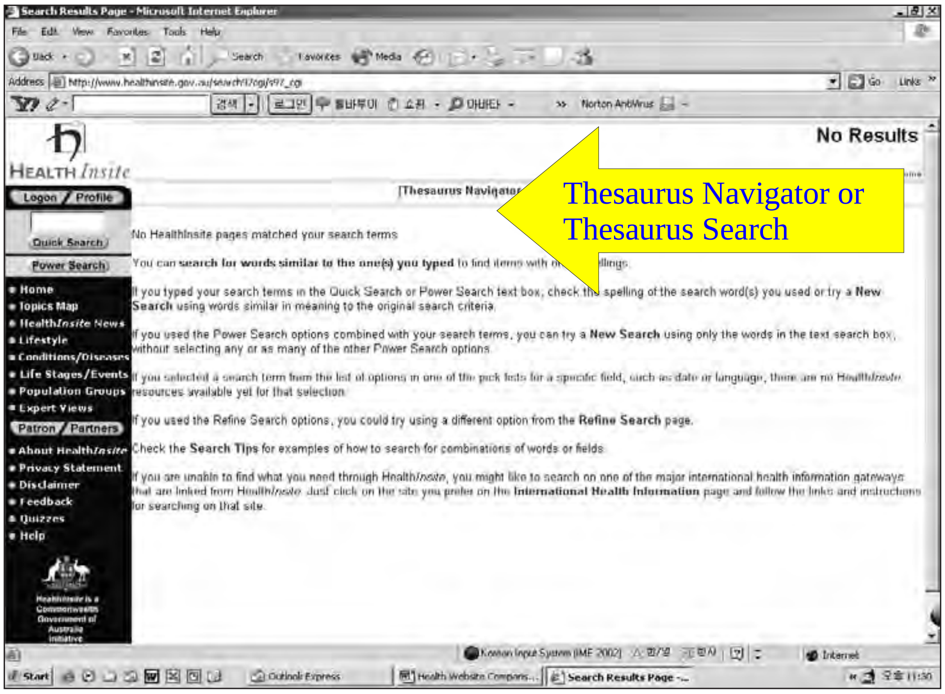

At present a thesaurus is only implemented to store the names of diseases but is not useful in searching for types of drugs. And, the information on diseases is only available if the correct spelling is typed in. Also, Medical Subject Headings – MeSH is used in medical portals which makes it extremely difficult for users to navigate, i.e., they have to understand the tree hierarchy, which is expressed all in generic/medical terminology.

Analysis of Results

Table 2 provides a comparative summary of medical portals. It demonstrates that very few of the intelligence features identified in the literature and listed in the section on portal technology are currently implemented in medical portals, and none of the portals analysed have more than three of them present.

Most of the portals had a search engine, the exception being Rural Health. However, the position of the search engine was not always obvious and in some cases was hard to find For instance, it took some effort to find the search engine in the Health*InfoNet* as it is located on a separate page as opposed to a rectangular box on the front screen, as in most of the portals.

None of the portals provided spell checking, sounds-like indexing, parsing, ontology, or decision facilities. Health*InfoNet* had features where if you typed the first three letters correctly, it could retrieve the information.

Health*Insite* offered personalization via self-registration. It also offered some level of thesaurus, in a form of a list of all topics covered in the site. However, on the whole, the Health*Insite* had more intelligence features than the other sites analyzed.

CONCLUSION

The advantage of Web-based medical portals lies in their ability to make medical information

Table 2. Medical portal comparison

X = No, absence of the feature *Yes = Presence*

Australian Medical Portal	Search Engine	Spell check	Sounds like index	Parsing	Ontology	Personalization	Thesaurus	Dec. Facilities
BetterHealth Channel	Google	X	X	X	X	X	X	X
Health*Insite*	Yahoo	X	X	X	X	Yes	Yes	X
Rural Health	X	X	X	X	X	X	X	X
Health*InfoNet*	Yes	X	X	X	X	X	X	X
HealthConnect	Yes	X	X	X	X	X	X	X
Medicine Australia (MedAu)	Yes	X	X	X	X	X	X	x
HealthNetwork	Yes/ selective	X	X	X	X	X	X	X

available anywhere in the world at any time. The latest trend in health Internet usage shows that the Internet is here to stay and will be a new dimension in our lives (Shepherd et al., 2000).

However, at present not many intelligence features have been implemented for medical Web sites despite the high level of development and availability of the theoretical approaches (such as general portal architectures, artificial neural networks, and fuzzy logic) and growing evidence that there is widespread interest in the Internet medical development area. This absence can lead to high levels of dissatisfaction by users.

The frustration felt by many users is understandable (Finkelstein & Aiken, 2000), as demonstrated by the results of our medical portals comparison. From this evaluation of general medical portals, it is clear why tailored extraction of information is difficult.

The analysis of seven Australian medical portals suggests the following categorization:

1. **Portals with search engines:** Better Health, Health*Insite*, Health*Infonet*, Health*Connect*, and MedAu.
2. **Portals with a knowledge repository:** Rural Health.
3. **Portals with a combination of 1 and 2:** Health Network.
4. **Portal as a gateway:** Rural Health.

From our analysis it can be concluded that from the users' perspective, the most important features to ensure that the information available from the portal is relevant and useful are the **quality of the search engine** and the **level of intelligence** that can be incorporated into the search.

The portal's advanced search facility should ensure that users can retrieve relevant information with minimum clicks and format of input. The search facility covers the "pull" function of the portal; whereas personalization provides a means for pushing the right content depending on some kind of user profile (Probst et al., 2000).

None of the seven Australian community medical portals had sufficient intelligence features to satisfy users with diverse backgrounds and needs. The challenge lies in ensuring that only relevant medical information is retrieved. Portals are complex Web-based systems that can act as gateways to achieve this goal. The use of intelligence built into portal systems, this can help to achieve this goal and facilitate efficient information retrieval.

Portal technology is rapidly improving with the aim to better serve the community. Modern portals are built with intelligent agents, providing artificial intelligence as a part of portal functionality to improve information retrieval (Jafari & Sheehan, 2003). Intelligent portals can improve their performance by learning from experience. Those portals will develop a better understanding of human nature and thus become better tools for meeting users' expectations and information needs.

Chapter 5.16
Health Portals and Menu-Driven Identities

Lynette Kvasny

Jennifer Warren
The Pennsylvania State University, USA

INTRODUCTION

In this article, we make a case for research which examines the cultural inclusiveness and salience of health portals. We make our case from the standpoint of African-American women. While healthcare should be a ubiquitous social good, health disparities exist among various demographic groups. In fact, health disparities have been placed on the U.S. disease prevention and health promotion agenda. *Healthy People 2010* is an initiative sponsored by policy makers, researchers, medical centers, managed care organizations, and advocacy groups across the country. Although there is no consensus regarding what a health disparity is, sponsors agree that "racial and ethnic minorities experience multiple barriers to accessing healthcare, including not having health insurance, not having a usual source of care, location of providers, lack of transportation, lack of child care, and other factors. A growing body of evidence shows that racial and ethnic disparities in health outcomes, healthcare access, and quality of care exist even when insurance, income, and other access-related factors are controlled."[1]

In addition to healthcare, African American women have less access to the internet. Even at equivalent income levels, African Americans are less likely than either whites or English speaking Hispanics to go online. Demographically, the composition of populations not online has not changed dramatically since 2000. Overall, 60% of the total U.S. population is online with African Americans making up 11% of the total U.S. population, 8% of the online population, and 14% of the offline population. However, when looking at those who are offline, African Americans are more likely than offline whites or Hispanics to believe that they will eventually go online (Lenhart, 2003).

Although online health information is available from multiple sources, we focus solely on those health portals sponsored by the U.S. government. We made this choice based upon some early interviews with physicians and managers at a healthcare facility which serves predominantly African American clients. We learned that most clients exhibited a low degree of trust in information provided by pharmaceutical companies and other sources which seemed too commercial. Instead, clients searched for information from recognizable sources, and tended to use portals and search pages like Yahoo and Google. We found that portals sponsored by U.S. government agencies were received positively by clients. Also, portals like healthfinder.gov and cdc.gov are highly regarded by the Medical Library Association[2]. Moreover, the government is entrusted to uphold values of democracy and social justice therefore the health information that they provide should be accessible to a demographically diverse audience.

To gain insights into the cultural inclusiveness and salience of health portals, we use Nakumura's notion of menu-driven identities. For Nakumara (2002), the internet is a discursive place in which identity is enacted. She uses the term "menu-driven identities" to signify the ways in which content providers represent identities through the design of the interface and the personalization of content, and users perform their identity as they engage with the content. In what follows, we discuss health disparities and the promise of the internet in redressing inequities. Next, we further explain the ways in which users perform identity and health portals represent identities. We do this by theorizing about the health portals as mediating two-way communication between users and information providers. We conclude with directions for future research.

BACKGROUND

Health portals hold promise as an informational source for improving the health of historically underserved populations. This promise is extremely exciting given the state of health disparities in the U.S. We know from prior studies that health provider bias, stereotyping, prejudice, and clinical uncertainty may contribute to disparities along the lines of gender, class, race, and ethnicity (Balsa & McGuire, 2003). For instance, in a study by Bird and Bogart (2001), 63% of survey participants indicated that they had experienced discrimination in their interactions with their healthcare provider because of their race or ethnicity. Similarly, African Americans interviewees reported perceived discriminatory experiences such as inferior treatment, negative attitudes, being treated as if they were unintelligent, being ignored, inappropriate allegations, and racist remarks (Hobson, 2001). These negative experiences may profoundly impact attitudes towards receiving care, and willingness to comply with physician recommendations. For example, Hobson (2001) found that nearly 27% of African American survey respondents reported that, as a result of a discriminatory event, they were more hesitant to seek health services. Others avoided the healthcare facility (25.6%), avoided the provider (23.1%), avoided the personnel involved (10.3%), stopped using specific services (15.4%), or used service less frequently (7.7%).

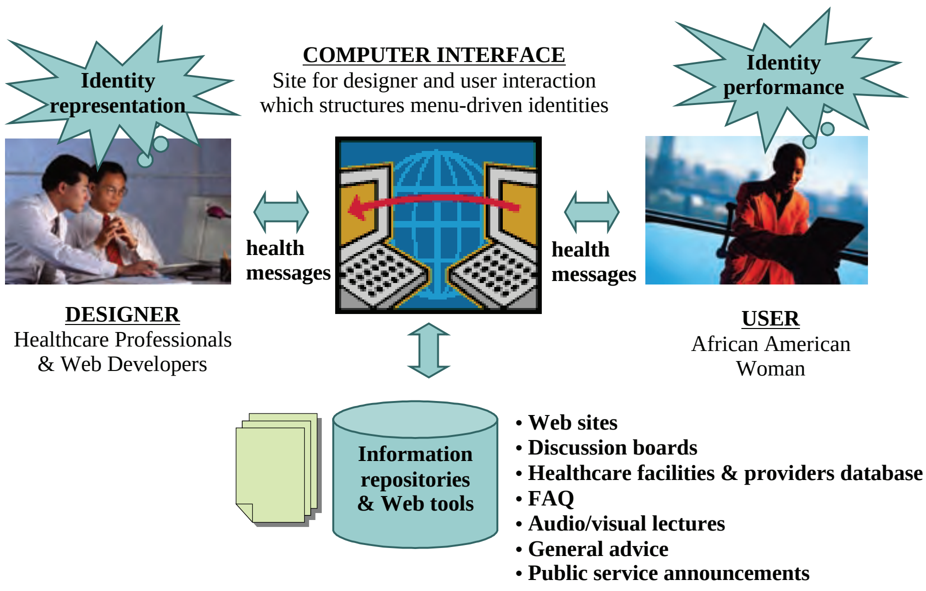
Computer mediated communication may help minorities, women and other underserved groups to receive healthcare information in a more hospitable climate. The popularity of the internet as a medium for health communication is evidenced in two ways. First, the number of health-related Web sites has dramatically increased from a mere 15,000 sites in 1999 (Rice, 2001) to 100,000 as of 2003 (Cates, 2003). Secondly, although these sources vary in quality and relevance, the number of people seeking online health information rose to 97 million in 2001 from 60 million in 1999 (Rimal & Adkins, 2003). In a 2002 national survey (see Figure 2), researchers found that 73 million people in the U.S. or 62% of internet users have gone online to search for health information. On a typical day, about 6 million Americans go online for medical advice. This exceeds the number of Americans who actually visit health professionals according to figures provided by the American Medical Association (Fox & Rainie, 2002). And while 42% of Americans say they don't use the internet, many of them either have been internet users at one time or have a once-removed relationship with the internet through family or household members. In fact, some exploit workarounds that allow them to use the internet by having email sent and received by online family members and by having others in their home do online searches for information they want (Lenhart, 2003). Women are more likely than men to say their latest search was at least in part for someone else—62% compared to 50% of men. Women are also more likely than men to seek healthcare and health information both online and offline (Fox & Fallows, 2003).

Identity

As an increasing number of Americans obtain health-related information online, it is important to consider that the internet is not race and gender neutral. Rather, it is a discursive space in which identities can be represented, performed, swapped, bought, sold, and stolen. Users can create profiles to personalize their experience, and create avatars which serve as visual representations of the body in cyberspace. But while spaces for fluid subjectivity abound, the internet often fails to accommodate minority cultural identities (Kolko, Nakamura, & Rodman, 2000; Kvasny, forthcoming).

Identities are inextricable from communication and are enacted in messages (Hecht, 1993). These enactments transmit and exchange values, beliefs, and norms, which may or may not affirm individuals' or groups' understandings of their own identities (Jackson, Warren, Pitts, & Wilson, under review). Identities also act as interpretative frames in the communication process (Hecht, 1993). Messages are filtered through and made sense of in relation to how individuals perceive themselves. If health messages communicate an identity, which is in conflict with how African American women perceive themselves, then the information may be viewed as unusable and we have done little to combat health disparities. As

Figure 1. Menu-driven identities



with all communication, messages that diverge from the identities of minority populations are unlikely to prove effective. Hence, health information must be situated within the target audiences' sphere of experiences and understandings, or they may go unheeded.

When users search and consume information online, they perform identity. In fact, identity is the first thing that you do (create a profile or user account) before you can perform any activity. Identity performance is often a practical necessity constructed by designers who create the interface. Nakumara (2002) uses the term "architecture of belief" to signify how designers, through their choice of keywords, images, and use of language, create interfaces which represent the identities of some idealized user population(s). The interface reflects the cultural imagination of the designer, and performs familiar versions of race, gender, sexual orientation, and class. The relation between the user and the interface has been termed "menu-driven identity" performance and representation (see Figure 1) (Nakumara, 2002).

Thus, contrary to the popular notion that physical characteristics are erased online, the fact that Web users must reveal aspects of their identity suggests that bodies are often "outed" in cyberspace. For instance, we often have to define our race, gender, age, weight, marital status, and other identity factors when using health portals. In a cultural sphere such as health, these aspects of identity are crucially important factors to be considered, not superficial characteristics to be erased. Consequently, identity is not entirely fluid and physical bodies remain important even though they are largely hidden.

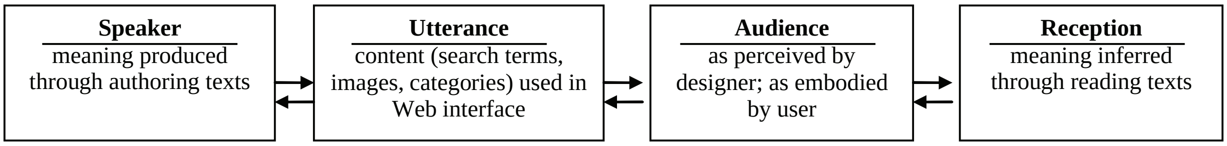
Health Portals

Health portals are made spaces in which identities are enacted through computer mediating conversations between users and designers. The interface serves as a site for the production, representation, distribution, and reception of texts (health messages) which convey meanings that affects relations of power. The distinctive rhetorical conditions of the speaker, utterance, audience, and reception are created as the designer and user co-create a communicative situation in cyberspace (see Figure 2).

In what follows, we demonstrate how menu-driven identities are produced on two government Web sites. The first example is taken from the U.S. Department of Health and Human Services healthfinder portal—http://www.healthfinder.gov/justforyou/ (see Figure 3). The navigation scheme tends to reflect the unspoken biases and categories imposed by the more privileged actor (the government sponsor) in the communicative situation. Users must select an identity which is limited to two gender categories, four age categories, four ethnic/racial categories, and five roles.

For African American women, predefined categories force the performance of race and gender in ways that marginalize, and in some cases deny, their existence. This occurs when there is limited space for identity expression because the categories reproduce the limited number of choices based on historical labels and ideologies around race, gender, age, and role. Health portals, therefore, become another discursive field in which African American women are rendered invisible because they are assumed to be only African American or female—multiple selections are not allowed because there are no categories which capture both race and gender. Other underserved groups, such as gays and lesbians, are rendered completely invisible because they have no category. White is also omitted from the choices, but this is because whiteness is assumed as the default category and simply goes without saying. These familiar versions of identity are scripted and ascribed by designers when they create interfaces based upon these types of simplified categorizations. Notice how the author "selected very specific information from our library so that it is easy to zero in on health topics of special interest to you. Just choose one of the special groups below."

Figure 2. Communicative situations



This example demonstrates how Web portals may serve as platforms for reproducing simplified discourse around difference. Category schemes are not simply passive tools through which labeling takes place, but rather are the outcomes of practices of meaning making. Designers of classification schemes constantly have to decide what categories are important, and in doing so, they develop an economy of knowledge that articulates omissions and inclusions, and ensures that only relevant features are classified (Bowker & Star, 1999). In doing so, health portals limit choices and the full participation of people who exist at the margins because users can only take the paths prescribed by the interface.

A second Web site taken from the Center for Disease Control, Office of Minority Health—http://www.cdc.gov/omh/Populations/populations.htm (see Figure 4)—demonstrates the instability of categories. For instance, race is an unstable signifier, which is socially constructed in dissimilar ways in various cultures. Blacks in the U.S. include all (including mixed race) people who trace their ancestry to Africa, but Blacks in South Africa don't include people of mixed African and European ancestry. In Britain, Black includes people with ancestry to non-African parts of the former empire such as Pakistan and China (Kolko, Nakamura, & Rodman, 2000). Racial signifiers are also unstable because they

Figure 3. Healthfinder3

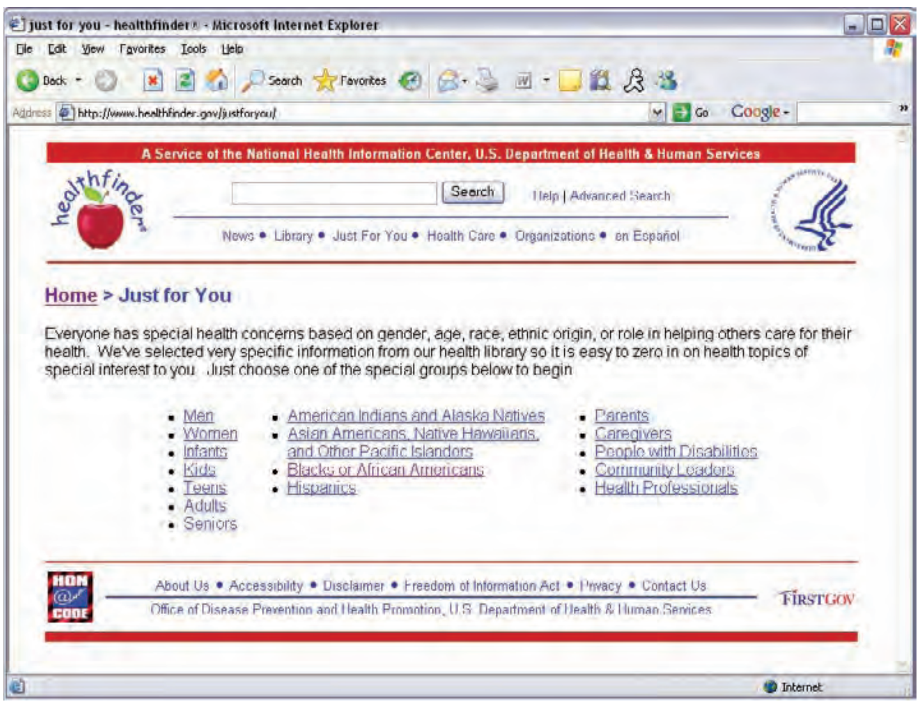


Figure 4. The center for disease control

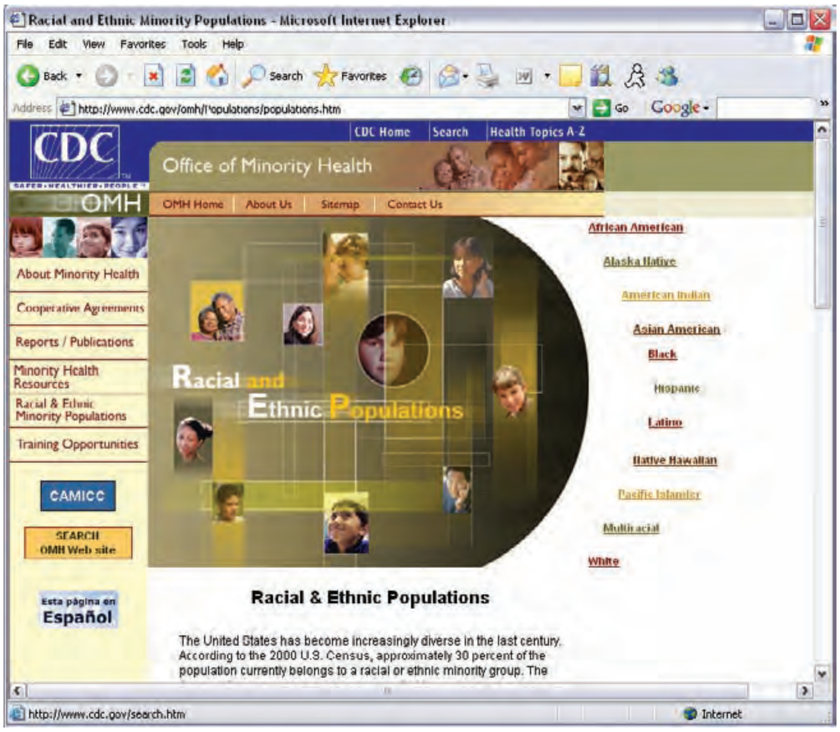

change over time. In the U.S., for example, people of African ancestry have been labeled Negro, Black, and African American.

In this health portal, the categories have been expanded to include white. Multicultural Americans are included even though it is difficult to make generalizations about health conditions because little research exists about this group. On the surface, it looks as though African American is treated as an ethnic marker distinct from Black, a racial category which would include people throughout the African Diaspora. However, when selected, each category is linked to the same Web page. Hispanic and Latino are also listed as two distinct categories which, when clicked, send the user to a single Web page.

FUTURE TRENDS

Given the increasingly diverse populations of internet users and the growing usage of eHealth resources, we pose several important questions for future research:

1. How are underserved groups socially constructed on health portals?
2. What do these social constructions suggest about inclusiveness and health disparities?
3. What types of information do members of underserved groups seek, and why?
4. How well do existing government health portals serve the needs of underserved population?
5. How might we design more inclusive information resources?

We also suggest that existing health portals could better serve the needs of underserved groups. While we cannot account for the accuracy of the information provided through these portals, we did observe a wealth of information that is pertinent to various demographic groups.

The challenge that we raise in this article is how best to tailor user interfaces to improve the online experiences of culturally diverse users. A tailored user interface would include:

- A mixture of media formats including texts, audio, video, and slide presentations. Images should be representative of diverse people. Single page checklists, fact sheets, and brochures may be especially useful for women who are obtaining information for other family members and friends.
- Texts that are comprehensible by low-literacy users and availability in languages other than English.
- The ability to select multiple identities. This could be done with checklists or a menu structure that enables users to drill down through several demographic categories. For instance, a middle aged African American women could select from the *gender, race/ethnicity, age* categories to refine her information.
- Normative categories such as white and heterosexual should be listed explicitly.
- The ability to declare identities in ways that go beyond demographics. For instance status such as smoker, diabetic, HIV positive, and cancer survivor are important components of identity that influence health care needs and outcomes
- Spaces such as chat rooms and forums for users to act as speakers and authors in the communicative situation.

CONCLUSION

The internet offers a space where African American women and other underserved groups can become empowered health consumers who access health information on their own terms (Ferguson, 1997). However, it is important to understand the extent to which online health information is inclusive of diverse users. Providing computers and internet access, and showing underserved groups the value proposition of online health resources are simply not enough. We must also consider the cultural salience of content and inclusiveness of the interface design.

KEY TERMS

Digital Divide: The term "digital divide" describes the fact that there exist people who do and people who don't have access to—and the capability to use—modern information technology, such as the telephone, television, or the internet. Access to these resources follows along demographic lines such as gender, income, race, ethnicity, geography, and age.

Health Disparity: Some demographic groups, such as racial and ethnic minorities, experience multiple barriers to accessing healthcare, including not having health insurance, not having a usual source of care, lack of transportation, lack of childcare. A growing body of evidence shows that health disparities persist even when insurance, income, and other access-related factors are controlled.

Health Portal: A Web site often sponsored by a large institution, which provides extensive information and contains links to a wide range of health and medical information on the internet.

Identity: Hecht (1993) identifies four frames through which identity is communicated. *Personal identity* involves self-concept, and develops through socially ascribed meanings and behaviors which are learned as one is socialized in a society (e.g., Black women stereotyped as mammy—the nurturer; jezebel—the seductress; sapphire—the wisecracking emasculating women; the welfare queen—the lazy, economically unstable mother of many bad kids). *Enacted identity* focuses on how messages express identity (e.g., I'm a black woman). *Relational identities* are those formed through one's relationships (e.g., I'm a mother). *Communal identities* are those shared by groups of people in some particular community (e.g., I belong to the Penn State community).

Menu-Driven Identity: This term signifies the ways in which content providers represent identities through the design of selection-oriented interfaces that are used to personalize content. Conversely, the term signifies the ways in which users perform their identity as they navigate within the choices that are both enabled and constrained by the interface.

Chapter 5.17
Assisting Users Seeking Medical Information through Government Portals

Jane Moon
Monash University, Australia

INTRODUCTION

There has been an explosion in the number of different types of portals in the last decade, and at the same time there has been a lot of confusion with them, especially in relation to the enormous number of portals and their differences from Web sites or Web-pages. This coincides with increased use by consumers seeking medical information on the Internet, and with the important role played by medical portals for evidence based medicine.

This article explores current portal technology available from an evaluation of market leaders in the industry and identifies important functional components that are necessary in building an intelligent portal to assist users seeking information on the Internet.

The emphasis will be on government to consumer portals (G2C) and uses two reputable government portals Betterhealth and Healthinsite as examples to discuss issues involved with those.

BACKGROUND: INCREASED USE OF PORTALS FOR SEEKING MEDICAL INFORMATION

Reliance on portals for medical information is high, and recent statistics show that this trend is growing. At the same time medical information is widely dispersed and information retrieval is inadequate (Shepard, Zitner, & Watters, 2000). There is an urgent need to develop portals that help users to retrieve quality information.

The National Health Medicine Advisory Council reported that better health outcomes are predicted when users are better informed, suggesting the need for digitization of health services (Bodenheimer, Lorig, Holman, & Grumbach, 2002; Kennedy, 2002; National Health Information Management Advisory Council, 2001). However this is yet to be confirmed, as Internet content has not yet proven to be satisfactory. There is a lot of concern about the materials found on the Internet (Ciolek, 1997, Moon, 2005).

Modern portals are built with the aim of better catering for the different needs of users. Portal technology is improving and features such as knowledge management, content management, and search engines, along with effective Web site design, help users to find information more effectively, and yet portals remain ineffective in information retrieval (Clarke & Flaherty, 2003; Elias & Ghaziri, 2004; Quirk, 2001; Rao, 2001). An effective evaluation tool to assess the validity and effectiveness of the portal is quintessential in assisting both users and portal builders.

PORTALS

Portal terminology has been loosely used in the industry and the term "portal" means different things to different people. Some argue that the word "portal" should be used as an adjective—"portal framework," "portal structure," and "portal architecture"—rather than as a noun as it is commonly used (Roth, 2003). Others are confused by the difference between a Web-page or Web site and a portal. The same confusion is applied to health portals vs. medical portals. The following sections seek to clarify these terms.

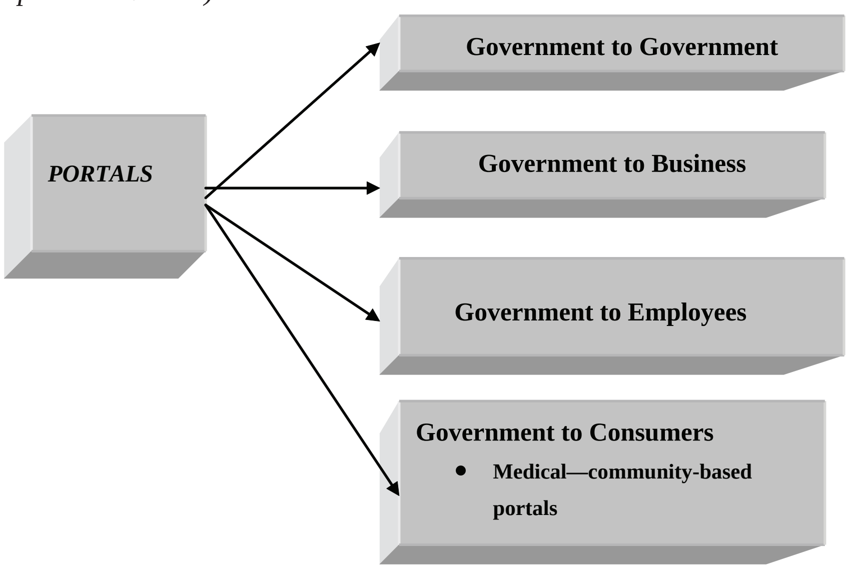
Definition of Portals

For the purpose of this research, the working definition of a portal is an Internet-based information system providing uniform access to different sources of information in an enterprise and maintaining dynamic links to information resources (Moon & Burstein, 2004). A portal supports communication within the enterprise, and connects people with information and applications they need for performing tasks. Unlike a conventional Web site, portals should support both push (subscription) and pull (search) functions in assisting users to gain access to essential contextual information (Probst, Raub, & Romhardt, 2002; Shepard et al., 2000).

Portals vs. Web sites

The word "portal" is often confused with Web sites. The difference between Web sites and portals is that the former are static and the latter are

Figure 1. Government portal market segment diagram (Adapted from Collins, 2003; Clarke and Flaherty, 2003; Shepard et al. 2000)



dynamic. Portals are Web-based, have dynamic links to the information resources, effective information and document managers and connect people with information. A portal is dynamic, can have personalisation features built into it and has the ability to bring together "business professionals involved in their area of interests" (Hazra, 2002, p. 623). A portal is a mechanism to deliver content, using a Web browser. It runs on an application server, and can integrate with knowledge management and workflow. It must unify a large range of applications, services and information flows.

A Web site is static, and is a collection of Web pages relating to a given subject, including and beginning with the home page; for example, a company Web site. A portal is often confused with a Web server where many different Web sites can be stored on a single machine. Companies generally have many Web sites that are stored by commercial Web servers in different locations, sometimes worldwide.

For the purposes of this chapter, any Web sites which have at least one of these listed features is referred to as a "portal."

CLASSIFICATION OF PORTALS AND FUNCTIONALITIES

There was an explosion in the number of different portals in the late 1990s. A great multitude of terms are used to describe different types of portals. Some examples are: EIP (enterprise information portal), corporate portal, community portal, employee portal, business intelligence portal, horizontal portal, vertical portal, public portal and private portal, to name just a few. These names are dependent on who the stakeholders are (Collins, 2003; Portals Community, 2004).

A government portals can be categorized broadly into four types depending on the stakeholders (government to government, government to business, government to employees, and government to consumers).

- G2G (Government to Government): Supports work flow between government sectors and assisting and collaborating work, not accessible to consumers
- G2B (Government to Business): Supports business flow, activities, suppliers, and partners for distribution and supply chain management
- G2E (Government to Employee): Supports the access and availability of personalised information to employees
- G2C (Government to Consumer): Supports ordering, service, support, and billing for customers

All of the portals in Figure 1 fall in to the function of the following three types:

- Knowledge Portal: Has the ability to combine information, but provides no commercial transaction
- Decision-Based Portal: Collection of information from a wide variety of sources, which can be structured or unstructured
- Process-Based Portal: Changing focus to delivery, user-centric, collecting information to be distributed to future processes such as business to consumers (B2C) or business to business (B2B), where transactions are involved

Recent development has been on process-based portals, those that promise to deliver information based on user needs. All of the previously mentioned portals are rapidly evolving to support changes in the information needs of customers, businesses, suppliers, and individuals. The names of portals vary according to services and the users they serve (Wege, 2002).

Portal Server Technology

Portals integrate diverse interactions: access to information, applications, and people. The

infrastructure, which is a connection between hardware and software, is critical for the deployment of a portal. The portal server technology items needed are:

- Hosting Service Provider: The hosting service provider can be internal (the IT department within the organization), or external (an application service provider (ASP)) or an off-site hosting services vendor. Hosting service providers are responsible for maintaining the portal services. The tasks involve systems management and site administration
- Platforms: Several types of platforms have evolved. The most pervasive platform is the Operating System, especially Microsoft Windows OS, Windows 2000, and Windows NT. Others include Macintosh (for client layer), Unix, and its variants (Sun Solaris, Linux, IBM AIX, IBM OS/390) for the servers also. Some traditional main frames are OS/390, OS/400, etc
- Interoperability: Interoperability is crucial to the success of the portal. A typical portal would integrate several Web based applications (Microsoft and Sun architecture), XML, and database applications as well as desktop applications (word processors and spread sheets). A good portal would consolidate all these applications into a single organized desktop
- Personalization: Portal personalization can be made at different levels. An individual can have personal settings; a group of people sharing the same function can have group settings. An organization can choose its own settings. These features allow the portal to be customized according to needs
- Single Sign-On (SSO): Signing on only once to get access to all the facilities portals offer is crucial. This is a significant time saving in logging on to different sites, and a significant reduction in training and also time saving for administrators in re-issuing passwords for those who have forgotten them (Collins, 2003, p. 39; Portals Community, 2002, p. 12; Wege, 2002).

Functional Components of Medical Portals

Portals should provide wide functionality to allow users to find information, and to manage, categorize, and use applications. They should ensure that the features needed by employees in the organization are met. The implementation of functionalities will vary depending on the nature of the business. Some of the functionalities that are available and can be implemented in medical portals are as follows:

- Browse/Navigate Documents: Allowing users to search for and locate information manually by navigating a directory structure
- Collaboration: An important aspect of a portal and a powerful tool. It includes instant messages such as "chat," document sharing, video conferencing, virtual conferencing, and discussion forums
- Content Management: A process of approving, authoring, delivering, maintaining, and publishing content integrated with or accessed from a portal or other Web site. This can be implemented as a separate component with a common database accessible through the portal
- Directory: A directory within the portal's enterprise taxonomy. It is a collection of data structured into a hierarchy of categories
- Document Management: Similar to content management but dealing mainly with control and management of an enterprise's documents. It involves managing electronic files including scanned images of pictures and documents
- Personalization: Portal personalization can be made at different levels. An individual can have a personal setting; a group of people sharing the same function can have group settings. An organization can set up its own setting. This feature allows a portal to be customized according to needs
- Search Engine: The ability to search is the fundamental implementation of a portal. It allows users to browse the content, retrieve information on a content basis, and link to other repositories for information
- Subscribe/What's New?: Allows users to register an interest in a particular aspect of the portal. Portals then notify the user when any changes in the content occur
- Taxonomy: A classification scheme to organize information. Additional functionalities, such as metadata added to taxonomy, could help to organize documents into different categories that could make the information easy to browse, search, or navigate ideally.
- Online Community: Opportunity for users with similar interests to discuss their medical conditions and experiences. This could range from sharing experiences of treatment to discussing medical conditions and alternative medicine (Collins, 2003; Millen, 2000; Moon & Burstein, 2004; Tushkar, 2000).

THE IMPORTANCE OF INTELLIGENT MEDICAL PORTALS

The term "intelligent medical portal" refers to a Web gateway environment that allows users with varied medical interests and diversified backgrounds to access medical resources and information to support their decision-making processes, which often involve critical medical problems.

Current medical portals do not provide for people with different educational backgrounds, age, ethnicity, location (urban or rural), and stages of disease.

For example, there is no specific information for a 63-year-old female with early breast cancer or for a 35-year-old mother experiencing advanced breast cancer living in a rural area. The hyperlinks regarding breast cancer seem to employ a "one-size-fits-all" approach (McKemmish, Burstein, Manaszewicz, & Fisher, 2002).

In the case of breast cancer, a third of sufferers in Australia live rurally. For them the quality of information is absolutely critical, often life-threatening (Manaszewicz, Fisher, Williamson, & McKemmish, 2002). The development of an intelligent portal is to some extent a response to this problem. A major concern is that there are no real safeguards and standards concerning the "quality, precision, trustworthiness, currency, and authorship of this information" (Ciolek, 1997, p. 5).

How can a portal be made to behave intelligently so that users can easily gain access to vastly distributed medical information? McKemmish et al. (2002) suggests an intelligent portal "will improve the structure and manage the quantity of information presented" (p. 5). Indeed an intelligent portal should provide information that is high-quality, relevant, and adequate. It should provide for the needs of users by helping them to solve issues that are often critical to life. With the use of intelligent portal technology, combining knowledge management issues of personalization and decision support, the needs of Internet users of medical portals could be improved.

Intelligence Features

Previous research has established intelligence features that are available technically as follows (Moon & Burstein, 2004):

- Search engine
- Spell checking
- Sounds-like index
- Parsing
- Ontology
- Personalization
- Thesaurus

As medical jargon, treatment and drug names are often very difficult to remember and spell, it seems that it is essential to implement the available technology previously mentioned as much as possible to assist users in their search for medical information.

Australian Medical Portals

Despite the surge of interest and importance of the Internet for providing users with medical information, users were dissatisfied with the results. The following table illustrates the results of intelligence features against seven Australian medical portals.

All the portals had search engines. In general, most of them lacked in providing any form of intelligence. HealthInsite is the only portal that provided "personalization" and a "Thesaurus."

Evaluation of Portal Vendors on Intelligence Features

For the purpose of this research, it was important to look for what was currently available on the market in terms of functionalities for medical portals that make them more intelligent.

To do this it was necessary to explore various vendors of portal software and find the functionality available as well as to compare vendor's views with users' views to check the validity of vendor's claims. Though the technology and the concept of the portal have been around for more than 10 years, the idea of implementing portal solutions as a whole package is still fairly new. Most of the portal solutions that are available are developed to solve commercial problems, and are expensive.

After the evaluation of leading providers of portal software, eighteen high-profile providers were chosen for the analysis of intelligence features.

All the leading portal software packages provided most of the intelligence features. Only two vendors, Autonomy and ATG, provided AI, in particular artificial neural networks, for their search. ATG is in partnership with Autonomy for their search engine.

FUTURE RESEARCH

The results of this study confirm wide use of Government portals in searching for medical information. However, the study indicates that Australian medical portals have a limited intelligence features and are not meeting the needs of their users despite of the available technology. Further research should be undertaken in:

- Intelligent Medical Portals: How intelligence features can be effective in implementing medical portals.
- Implementing Intelligent Agents: Implementing intelligent agents such as "digital secretary," which acts as personal secretary, or "digital sister-in-law," which helps users with movie suggestions, make portals smarter (Jafari & Sheehan, 2003).
- User Profiles: Better identification of common profiles of information usage and matching these with correct content by employing the best available technology to improve user acceptance of portals.

CONCLUSION

The research reports that current Australian medical portals are not meeting their users' needs. The research sought to discover the ways to improve the portals technology to assist the users in their search for medical information. From the literature review and analysts reports the definition of portals and of the many different types of portals are identified.

The analysis of portal vendors amongst market leaders, the technical functionality available for portals was identified. All the portal vendors had most of the listed intelligent features with the exception of artificial intelligence (AI). Autonomy was the only vendor that provided with AI that of Artificial neural network.

An intelligent medical portal is one way of meeting consumers' needs. Understanding human search behaviour can help to improve the technology if this understanding is integrated into interface design. Available portal technology such as ANN and fuzzy logic can help to improve information retrieval. Further incorporating intelligence features and portal functionalities such as CM, DM and KM can add value to the service and thereby increase the effectiveness of portals.

KEY TERMS

Content Management: A process of approving, authoring, delivering, maintaining, and publishing content integrated within or accessed from a portal or other Web site. It can be implemented as a separate component with a common database accessible through the portal.

Health Portals: Health portals on the other hand, are broad; they cover a very wide range of health and medical topics, anything relating to health (e.g., shampoo products, cosmetics, diets, medicine, and alternative therapy. This research is concerned with the narrower cencept of medical portals.

Intelligent Medical Portal: Refers to a Web gateway environment that allows users with varied medical interests and diversified backgrounds to access medical resources and information to support their decision-making processes, which often involve critical medical problems.

Knowledge Management: This can be seen as a mechanism for capturing "know-how" and "know-why" in a knowledge repository.

Medical Portals: Medical portals provide information such as causes of diseases, medications, treatments, alternative therapies and lists of consultants. Medical portals can be either general or specific. General medical portals provide general medical information, for example BetterHealth or HealthInsite. Disease-specific portals provide information specific to a particular disease (e.g., cancer portal, breast cancer portal).

Portal: In Latin, the word porta means a gate or entrance. A portal can be defined as a gateway to information (Golier Inc., 1980). It is Web-based and connects a set of commonly used information or services via a link from a single Web page (Clarke and Flaherty, 2003; Elias and Ghaziri, 2004; Notess, 2002; O'Leary, 1999; Rao, 2001).

Chapter 5.18
Empowerment and Health Portals

Mats Edenius
Stockholm School of Economics, Sweden

INTRODUCTION

We know that interest in employing Web portals for communication between the health care sector and the public is constantly increasing (Kapsalis, Charatsis, Georgoudakis, Nikoloutsos, & Papadopoulos, 2004). We can also find an increasing demand for various kinds of such communication (Sciamanna, Clark, Diaz, & Newton, 2003). It promises to become an important and valuable tool for e-health (i.e., computer-based health care and health care management). Patients can log into a Web portal in order to find an appropriate medical treatment, communicate personal matters, and/or find the right way and place to find adequate health care.

In the last 10 years, we have also seen "empowerment" flourish, not least in an Internet context. In conventional research about Internet and Web portals, empowerment refers to a quite general process of gaining influence over events and outcomes. For example, it is argued that people are becoming more informed and managing their situations in better ways thanks to portal solutions and thereby becoming more empowered (Fergusson, 2004). Empowerment is central in the discourse of health and an important analytical concept to understand how portals work and can improve health care (Cathain et al., 2005).

In this article, I will argue that empowerment is indeed a fruitful concept to capture the potential of Web portals (in the health care sector). However, what is largely missing in the contemporary analyses is a more dynamic approach to analysing empowerment than found in conventional research, and how from such an approach we may justify the way Web portals are used to reach better results. The argumentation will be supported and illustrated by empirical material based on how different health portals are used.

UNDERSTANDING EMPOWERMENT: A TERM BASED ON POWER

As a researcher coming mainly from the social science and not medical science, it is natural to base an analytical discussion about empowerment on central thoughts on the concept of power. A modern definition of power tells us that power has to do with circumstances where one actor is able to make another actor perform against his or her will and interests (Lukes, 1974). Hardy and Leiba-O`Sullivan (1998) use Luke´s definition of power and explore it in terms of empowerment, in a way that could be very relevant to health portals too. They discuss how power is exercised by using various resources to influence the outcome of the decision-making processes. Several assumptions underlie this view of power. It says that all individuals are aware of their grievances and act upon them by participating in the decision-making process and using their influence to determine key decisions. We can find a whole range of possibilities related to health care where the physician brings different resources into the discussion (authority and information, etc) or hides information from the patient. Power could also be maintained by patients. They can abuse their power by giving the physicians spurious information for their own sake (to get drugs for example) or by misusing the health resources. The physician can also offer some information to the patient who becomes the sole decision maker. It is a situation that often is related to differences in cultures and deep values (e.g., Hofstede & Hofstede 2005) between paternalism and autonomy and between fidelity and humanity.

Power, rather than simply being exercised within decision-making processes, could also be used to exclude certain issues and patients from that process. Physicians could have the possibility to squeeze patients out and not let them come to the places where the decisions are made.

What both these two dimensions of power are based on is a situation where all parties more or less know their status and their will. But what about if the patients do not know what is best for them because the communication has been distorted? What this third dimension of power tells us is the importance of investigating what the fundamental base is that takes place in the decision arena. The patients could be said to be duped, coerced, or manipulated into political inactivity (or the opposite way around) via a Web portal (or by not accessing one).

Inspired by these thoughts we can draw the scheme presented in Table 1.

The scheme can help us to analyse empowerment in the context of Web portals; for example, can patients gain access to the decision arena thanks to a portal, etc? By using such a scheme, we also say that technology performs in a determined way and is therefore, in principle, determinable. However, to understand Web portals and empowerment I suggest it could also be fruitful—in a quite pragmatic way—to loosen up such a view by linking the discussion to the insight that we also apprehend and constitute the world through a technological frame, which is not innocent in this context. What I mean is that Web portals do not strictly answer this or that question, satisfy this or that demand, or extend this or that capacity. Rather, as Arnold (2003, p. 236) calls a substantive approach:

Technology works at a more fundamental level, it enframes the world such that the question is changed in a certain social context along with the answer, the need is changed along with its gratification, and direction is changed along with the mechanism.

So, a Web portal also enframes a particular brand of reality and functions therefore as a kind of knowledge making. This world is continually working to structure our thoughts and our thinking and acting processes.[1] The problem with the conventional way of regarding empowerment and Web portals is that the logic does not allow for opposite effects to be placed within the same effect frame. My argument is that an analytical discussion about Web portals and empowerment has much to gain from being complemented by a more—what could be called—dynamic approach. I will illustrate this by examples taken from two case studies—one focuses on Vårdguiden (Edenius & Westelius, 2004) and the other one on different patient communities[2] (Edenius & Åberg, 2005). Both of these case studies are based on interviews of users and owners of different health portals.

EMPOWERMENT AND HEALTH PORTALS: TWO MINI CASES

Vårdguiden

Vårdguiden is the Stockholm County Council's Web portal for health care and telephone consultation. The portal is a neutral arena where citizens in Stockholm can get information about the health care sector and get health care advice. What could be said to be unique with Vårdguiden, compared with most other Web health portals, is that it includes some interactive services. At the time of our study (2004), the portal included three such different communication services. Patients who had registered as users of the system could book, alter, and cancel appointments with physicians. They could also renew a prescription and renew registration on the sick list.

The patients really loved the portal. They said that they can reach health care in a good way thanks to the portal. The patients stress how thanks to the written language they have been able to communicate certain matters in different ways. They have been able to use the written discussion with the physicians as qualitative check. They can always go back to what they have discussed and the physicians´ answers. They also say that thanks to the portal they have gotten important information about their illnesses, information, and knowledge they can bring with them to their meeting with the health care. It is not a big leap to say—even if the analysis is quite schematic for illustrative purpose—that using the portal could help the patient in many different ways to become more empowered (cf. ability to mobilize resources, gaining access, and consciousness-raising). But, something else is going on at the same time. A more dynamic approach tells us something in addition.

Thinking in Terms of a Booking System

Several patients expressed a desire for more control over finding an appropriate date and time to see a physician. In the system, patients could request an appointment either morning or afternoon, adding a few sentences in free format. The reason for this (limited) selection of options was that the design group, while giving the patient some possibility to specify preferences, had decided to allow the health care provider considerable discretion in the booking procedure. However, the ability to request an AM or PM appointment did not decrease the patients' desire for an even more sophisticated time-booking system. One user said for example:

You could do it like the motor vehicle inspection site. There, you can decide on the date and the time. You can tick the time you want, and then it's yours.

In this case, the users only seem to be concerned with the functionality of the portal as a booking system. They do not view it as a means of making contact with their health care provider.

	First Dimension	Second Dimension	Third Dimension
Power of A over B.	Control of resources.	Control of decision-making processes.	Control of meaning.
Empowerment of B requires.	Acquisition of resources and ability to mobilize them.	Ability to gain access to the decision arena.	Consciousness-raising.

Compared to their previous experiences with booking systems, this appointment booking system seemed rather constrained and afforded the user less control than other booking systems. However, the user demand for quicker service and greater control when utilizing the portal does have a basis. The user's knowledge of the application is created through making generalisations based on other applications they are familiar with.

Thinking About the Organisation of Health Care

As previously seen, the system generated a demand for further control. However, the way the patient uses the system also imparts knowledge about how the health care is administrated. We can say that the portal opened a gate through which you could see more clearly what was going on in the health care administration.

One comment concerns the use of communication channels, questioning the rationality of the health care providers:

But why can't they reply to an e-mail if they can talk on the phone? Then, they would be rid of the call and could attend to the e-mail instead.

A number of comments also concerned how the Web service put them in contact with the least booked doctor (and maybe the least experienced), and how the e-messaging channel of communication was believed not to match the existing routines at the hospital. The e-messaging service can also convey the impression that the administration does not work properly. As one patient said:

Getting a reply…I had a letter with an appointment time. I do not know how long it took, but I am sure that it was a number of days before I received the letter. I also received an e-mail, but it said that I would receive a letter by post. Then I had the feeling that one hand did not know what the other was doing.

This quotation conveys a sense that the Web portal is more of a black box than traditional ways of communicating with the health care provider in a potentially empowering way. This black box is disturbing to the users, and they want more control, or at least to be able to look into the box, to achieve increased transparency.

Patient Communities

There are many statements that could be interpreted as the patients having become empowered by participating in a patient community too. Actually, it lies at the heart of patient communities. As a vice president of a community said:

Take these pills and get back in 3 months', or 'we write a letter of introduction from a doctor to the doctor specialised in rheumatology,' this is hard to influence with IT but how you get there and are able to make those demands, that is what we are trying to support our members with ...

The information found on the portal is frequently very practical. *The portal* supports their members by giving them advice and writing out lists of questions the patients can ask when seeing a doctor. The patient community is also based to a high extent on different people actively sharing their experiences by communicating online. This is done by different Web-based tools such as writing messages in the *guest book*, discussing in a forum, or traditional chatting. Another example of Web-based communication is the function *question of the day*, which is one of the strongest signs that the patient community is expecting to have some kind of dialogue with their members. By sharing this kind of information, it could be said that the members become aware that they are not alone and understand that it is possible to demand things since they learn that many people have already asked, wondered, or requested the same thing. Relating these statements—tentative as they might appear—to the analytical scheme of empowerment tells us that the patient communities could indeed empower the patient, by giving them resources and the ability to use them, ability to gain access to the decision arena, and not at least by raising consciousness.

Now a more dynamic approach; the fact that the knowledge is shared, extended, and widely spread is one of the strongest tools for a patient to use in the role as an independent patient. The identity issue appears to be very important for the member since they get empowered by speaking the same *language* based on a mutual understanding, as one patient said:

It has been useful to me in situations when everything feels meaningless and you feel disappointed with the doctors…people who understand!

In this non-medical related information service, the patient community is providing an essential type of information, not clinically related to the disease, but to the human being behind the disease who is dependent on practical solutions for daily life. This information seems even more important for the member and contains practical tips, advice, and support on how to handle day-to-day things. The uniqueness about this kind of information is that, since it is not scientific, the health care does not give any information about it, even if these kinds of questions appear to be the most important ones to the patient. The members *talking* means that they teach each other and learn from each other when discussing different issues around the disease.

Another function of the patient community is to follow up on the information given to the patient in a medical/health situation. The instructions/information is corrected, adjusted, developed, and diversified by the patient community to suit the patient/member better. In a way, this means that they give the patient distance to what the health care informs them about. Which in turn means that the members' *new* knowledge leads them to act and think more freely than before, leading to more independence.

I have an example of a girl at a conference, we were suppose to have supper at 6 PM, but she came and said to me, 'I have to eat my supper at 5.30,' ok, 'why' I asked her, 'I have to eat at that time because that is what my doctor told me,' ok but we are going to eat at 6, 'no I have to eat at 5.30!' I told her to take a sandwich or something in the mean time to be able to wait for the dinner at 6…. This person was so focused on what the doctor told her, how she should live her life, instead of looking at 'what can I do to have a normal life in my situation?'

According to the previous quotations, we could say that patient communities are taking the lead and science is following. Since patient communities have the *empirical* experience, in that they hear, see, and understand the patients' problems in another way than health care does, you could say they are the ones *making the doctor's rounds* based on empirical research. Such as the patient community is responsible for a certain way of creating knowledge based on experience from members who have done this in reality and practised it over many years. The patient community is the *practical researcher*, like a pioneer in patients' knowledge of health care, however not under the flag of scientific knowledge. As formulated by a patient:

There are no medical doctors who will tell a patient who suffers from pollen allergy wanting to eat an apple, because it is common to suffer from cross-allergy against apples, if you run it in the microwave for one minute the proteins disappears. That is one thing, which if you are talking to the doctor they would never say something like that, we have different roles, but I think that it is our strength in this …

Hence, the point is that the patient community and its Web portal application can offer the patient something the public health care cannot. They give the patient different knowledge compared to health care in general. The patient community considers the members as individuals who are in need of practical advice and not only general information. That is why communicating, using the members' language and not that of medical professionals, is a winning concept. In more theoretical terms we can say that the patient communities can maintain (at least partly via the portal) an embedded and embodied kind of knowledge, which allows for the recognition of individual diversity and the relevance of particularity. It recognises a role for practical reasons as opposed to a health care that could more be described in disembodied and disembedded terms, supported by proliferation of different techniques that have a universal relevance and may be applied to any patient (cf. evidence based medicine).

FUTURE RESEARCH OPPORTUNITIES

From what is said previously, I don't argue that everything is on the move. Several authors have stressed, and believe in, the possibility for actors to manage dynamic meanings too (cf. Giddens 1979). Therefore, it is maybe time not only to discuss how people can reach empowerment through Web portals, but also how we can manage the new kind of knowledge, which using a portal will generate. In the case of Vårdguiden, it might be done with information to meet the patients' new knowledge. The illustration of patient communities shows a more complicated case where we can ask if the patients overall could be empowered, while health care is stuck in a rather clear modern scientific discourse. The question is difficult to deal with, but nonetheless important to focus on and to research further.

CONCLUSION

This article is an analytical attempt not only to capture the concept of empowerment in a health portal context, but also to expand such a discussion. Using a Web portal is an active framing process animated by forces, tensions, and interests. I have argued that the tricky concept of empowerment could be fruitfully empirically discussed, starting from three different dimensions of power. However, I have also argued that empowerment is not only a process of problem-solving or emancipating processes, but at the same time a process of problem-constructing and thereby making the concept of empowerment more extensive; compared to something that might be more or less reached thanks to a portal in a deterministic way. This is a far cry from the realist view of empowerment, but nevertheless also an important way for analysing and discussing empowerment in an empirical context. Hopefully, my illustrations could be one starting point to discuss how we can improve the potential of portals in line with human behaviour.

KEY TERMS

Deterministic Approach: Begins with science and technology and ends with social conditions.

Disembodied Knowledge: Knowledge that has a universal relevance.

E-Health: Computer-based health care and health care management.

Embodied Knowledge: Knowledge, which allows for the recognition of individual diversity and the relevance of particularity.

Empowerment: A process of gaining influence over events and outcomes.

Power: Circumstances where one actor is able to get another actor to perform against his or her will and interests.

Substantive Dynamic Approach: Technology enframes the world such that the question is changed in a certain social context along with the answer.

ENDNOTES

1. What I really do is, in a quite pragmatic way, to use a blend of a theoretical orientation that is referred to as the "Social Construction of Technology" and a more "Substantive" approach (e.g., Feenberg, 1999)
2. The Swedish Rheumatism Association, the Swedish Asthma and Allergy Association, and the Swedish Diabetes Association, including their Youth associations.

Chapter 5.19
Digital Divide and E-Health Implications for E-Collaboration Research

Michele Masucci
Temple University, USA

INTRODUCTION

E-health has rapidly gained attention as a framework for understanding the relationship between using information and communication technologies (ICTs) to promote individual and community health, and using ICTs for improving the management of health care delivery systems. The use of e-collaborative tools is implicit to the delivery and access of e-health. Development of the capacity to transmit and receive digital diagnostic images, use video telecommunications for supporting the remote delivery of specialized care and surgical procedures, and the use of e-communication technologies to support logistical elements of medical care (such as scheduling appointments, filling prescriptions, and responding to patient questions) are just a few ways in which e-communications are transforming how medical care is embedded within institutional, organizational, family, and community settings.

The emerging field of e-collaboration focuses attention on the need for society to critically examine how electronic communication technologies facilitate, shape, and transform the ways in which organizations, groups, and communities interact. There are many works that explain how to (a) develop e-health systems, (b) assess the use of such systems, and (c) analyze the health outcomes that can be achieved with effective e-health applications (Brodie et al., 2000; Eder, 2000; Spil & Schuring, 2006). Less attention has been paid to how advances in e-collaboration research might inform e-health applications development and scholarly discourse. Because of this gap in the literature, few discussions pertain to understanding patient perspectives about the advantages and disadvantages that may result from rapidly emerging interconnections among access to health care, health information, health support systems, and ICTs (Berland et al., 2001; Hesse et al., 2005; Gibbons, 2005; Gilbert & Masucci, 2006).

E-HEALTH AND THE DIGITAL DIVIDE

Facilitating equitable e-health remains a difficult challenge because of persistent disparities in using and accessing ICTs among vulnerable and marginalized population groups (Atkinson & Gold, 2002; Brodie et al., 2000; Gibbons, 2005; Skinner, Biscope, & Poland, 2003; West & Miller, 2006). More research is needed to examine how differing experiences, self-efficacies, and adaptive styles among users of e-communication tools relate to the collaborative aspects of accessing and delivering health care (Atkinson & Gold, 2002; Hsu et al., 2005; Katz, Nissan, & Moyer, 2004). In particular, the collaborative aspects of implementing effective e-health policies could focus on such issues as (a) the role of educational training in using e-systems for accessing health information, health care provider consultations, and health management protocols, (b) the effects of alternative information delivery systems for enhancing patient care and community wellness, (c) the ways in which patient knowledge acquisition processes are related to the use of e-communication systems, (d) the privacy concerns related to e-collaboration strategies for accessing patient health care records, and (e) the tradeoffs associated with a movement to integrate e-communication approaches across the continuum of health care access by patients and health care providers.

In addition, e-collaboration research can lead to an understanding of the ethical implications of advances in e-health. Such methodological approaches as social action research applications in e-collaboration can result in creating tools for implementing e-health systems (such as using e-mail exchanges to foster system compliance) while also investigating the means by these approaches work to improve e-health outcomes (Kock, 2004, 2005). What society stands to gain from inquiry into these issues is a greater understanding of how e-collaborative approaches can enhance the rapid move toward using e-technologies in achieving patient health outcomes and managing the delivery of health care systems (Gibbons, 2005).

Gilbert and Masucci (2005, 2006) have examined the ICT use frameworks among such population groups as a basis for determining the most effective means of understanding and supporting empowerment goals for those groups. A focus on e-health suggests that a consideration of values and experiences with ICTs could connect an understanding of how individuals relate educational training, ICT access, health knowledge acquisition, and health care access to examine the ultimate value placed on the adoption of e-health approaches for one's personal as well as family health (i.e., Cline & Haynes, 2001; Cotten & Gupta, 2004; Houston & Allison, 2002; Kickbush, 2001; Kivits, 2006; Reddick, 2006). And, as e-collaboration tools are examined for their potential to support equitable access to e-health systems, it is important to understand that the context within which they are used relates directly to the potential outcomes that can be achieved.

For instance, an e-health system that is designed to use e-mail reminders for checking blood pressure at home among patients with diabetes may not be effective if the health care provider examines the e-mails once per week due to workplace constraints. E-mail messages sent from a privacy-secured e-mail system within a hospital may not be accessible from remote locations by health care providers, further delaying responses to patients. Patients may not have frequent access to e-mail systems as a basis for reporting blood pressure or other health characteristics. An understanding of the use of the tool for enhancing e-health delivery should examine context as well as how different ICT use patterns shapes perspectives about (a) the benefits of e-health systems, (b) the challenges associated with learning how to use such systems, and (c) the different ways in which patients and providers approach e-communications and other e-collaboration tools for implementing such systems.

IMPLICATIONS FOR USING INTERNET TELEMEDICINE TO MANAGE HEALTH CONDITIONS

Internet telemedicine refers to the use of health communication tools delivered through the use of Web interfaces for managing specific health conditions. Implicit in the use of Internet telemedicine is the goal of using such systems to foster collaborations among patients and health care providers to manage specific health conditions and procedures. Such collaborations by definition recreate the geographies of health care access and delivery (Cutchin, 2002). This reconstitution of patient-provider communications can involve such e-communication enabled tasks as (a) transmitting self-monitored information about specific health conditions to physician accessible data bases, (b) patient and provider tracking of variables related to specific health conditions, and (c) improved patient-provider communications about the implications of trends related to specific conditions.

The collaborative roles of patients and health care providers ultimately take shape around the use of specific e-communication tools for specific health conditions. Patient empowerment has the potential to increase as they are drawn into more proactive involvement in the gathering and examination of data pertaining to their health conditions (Prokosch, Ganslandt, Dumitru, & Ückert, 2006).

A recent study of the use of an Internet telemedicine system to manage risk factors for cardiovascular disease illustrates the complexities involved in examining the relationships among geographic, social, and networked access to the Internet among low income patients (Masucci et al., 2006). The activities that were undertaken to improve the likelihood that individuals impacted by digital divide barriers would use the Internet telemedicine system included (a) developing and implementing an internet training protocol that addresses infrastructure and educational barriers to accessing ICTs among participants enrolled in the study, (b) assessing self-efficacy issues related to acquiring skills needed to use the internet communication tool developed for the study, and (c) analyzing social, demographic, and spatial patterns associated with health outcomes among patients who use the system (Masucci et al., 2006).

The participant group using the Internet telemedicine system was generally representative of people who have mitigated access to ICTs due to a combination of economic status, educational background and age (NTIA 1995, 1998, 1999a, 1999b, 2002, 2004). The 44 participants in the study were from inner-city Philadelphia and rural (non-suburban) northeastern Pennsylvania, with an average age of 60. Fifty-two percent of the study participants were African American; 73% were women; nearly 65% earned less than $25,000. The study found that training participants to use the telemedicine system for self-monitoring such information as blood pressure, steps walked, weight, and number of cigarettes smoked, resulted in strong compliance using the system, with 84% sending data after being trained (Masucci et al., 2006).

Discussions held during the training sessions suggest that inexperience with using e-communications is closely associated with living at the economic and social margins of society for many individuals. Most participants (66%) had no prior Internet experience; those who did were often relying on settings with old computers and low bandwidths (Masucci et al., 2006). However, nearly all participants placed a high value on using telemedicine and e-communication tools for managing their health. This may account for their willingness to allocate time needed to negotiate the problem of accessing ICTs outside of the home and involving others to assist them with using the system. Among those who had prior experience, use of the telemedicine system relied on accessing ICTs through the support of family members, community groups, shelters, and local libraries in order to use the telemedicine system. This involved needing to learn about the locations and terms of use that would apply to each setting. It also required that their understanding of the Internet telemedicine system was transportable among the different settings they used.

Perhaps due to the patchwork of access described by participants, significant gaps in their conceptual understanding of how e-communications and the Internet function needed to be addressed in the training discussions. Nonetheless, each had specific interests in gaining information through using the Internet, indicated through the wide variety of Internet uses demonstrated through training sessions. Included were searches related to specific health conditions, applying for jobs, shopping, games, recipes, and e-mail. Few seemed to understand the implications of designing the system to be Health Insurance Portability and Accountability Act (HIPAA) compliant. However, the issue of information privacy was a central theme of training discussions. Despite the limited experiences using ICTs among many participants in the study, discussions were highly nuanced. Participants expressed concerns about protecting personal identifying information (such as study IDs, usernames and passwords, and social security numbers), maintaining privacy around Internet search procedures, and the potential for e-communications with health care providers to be read by unauthorized individuals.

CONCLUSION

The perspectives gained through this study about the use of ICTs for managing health are important ones to consider in the debates about equitable uses of e-collaboration among patients and health care providers. Particularly as e-health approaches are increasingly relied upon to deliver health care, the embedded nature of e-communications in Internet telemedicine systems has the potential to empower patients in their interactions with health care providers and improve their ability to effectively use information related to their health disseminated through the Internet. However, such factors as (a) the availability of computers and the Internet at home, (b) prior ICT use experiences of individuals, (c) awareness of health information resources available on the Internet, and (d) skill levels with using e-communication tools and overall technological literacy, can affect the overall ability of an individual to benefit from using such systems. Moreover, it is likely that individuals who come from the most disadvantaged groups will continue to manage a tightly knit set of circumstances including low education and literacy levels, low income, and marginal housing stability, to benefit from e-health approaches such as using Internet telemedicine systems. Individuals and families who are challenged in all of these ways may have specific ideas about how they can benefit from e-health yet struggle to achieve the technology self-efficacy required to gain optimal results.

These concerns form the basis for a significant societal ethics and policy debate. How can individuals from marginalized groups maximize opportunities to benefit equally from e-health advances? A dialogue about this issue must attend to the underlying health disparities that are associated with socio-economic vulnerability. Internet health systems need to be developed with the needs of underserved populations at the forefront of design considerations. Perhaps one approach is to increase efforts to develop systems and information resources that address the health concerns faced disproportionately by marginalized groups, such as increased risks for diabetes and cardiovascular disease, as compared with mainstream populations. Another consideration is to develop systems that can be accessed and used by those with limited experience and skill using ICTs. In the case of the telemedicine system developed for this study, the patient interfaces were purposefully designed to be easy to read, free of distracting hyperlinks, and intuitive for individuals with basic literacy levels.

These changes were implemented based on learning about the skill levels of likely users and their perspectives about the value of the system. Prior to the design changes being implemented, the system was information rich, to the extent that patients with little prior experience using ICTs did not know where or how to get started. It is critical for the development of equitable e-health systems that the system development strategies reflect a concern for the highly contextual ICT experiences of potential users. An understanding of the value of health information, e-health delivery systems, and telemedicine by marginalized groups can be accomplished through interacting around the use of ICTs. This requires breaking the social isolation that can exist among groups through finding opportunities for collaborating around the shared goals for developing e-health systems. The use of e-communications for such collaborative processes may seem implicit, but given the digital divide barriers that may constrain some, the form and meaning of e-collaboration may have to be adjusted to reflect existing disparities. This work shows that such adjustments can provide insights into the complex array of decision-making that forms the context for the use of e-communication tools for improving health.

KEY TERMS

Digital Divide: The National Telecommunications and Information Administration developed a report series (NTIA, 1995, 1998, 1999a and b, 2000, 2002, and 2004) that conducted an analysis of the ownership and use of computers by households in the U.S. The reports indicated that disparities between the households with the highest and lowest degrees of computer use and Internet access were related to income, race, and gender. The reports called the disparities a "digital divide."

E-Health: The use of information and communication technologies (ICTs) to support individual and community health through creating health management information systems, electronic scheduling systems, electronic prescription services, transmittal of health records and diagnostic imagery among providers, and the remote delivery of care and consultations.

E-Health Ethics: Also referred to as Health Internet Ethics (Hi-Ethics), considerations to ensure the equitable distribution of health benefits for individuals and families through using e-health to disseminate health services. Concerns include protecting information privacy, ensuring that current, reliable health information, and advice is shared using e-health approaches, and that access to services is available to all.

HIPAA: The Health Insurance Portability and Accountability Act created standards for regulating the transactional records related to the delivery of electronic health care. This involved creating national identifiers for health care providers, insurance plans, and places of employment. HIPAA requirements also exist to protect the privacy and security of health information.

Internet Telemedicine: The use of Web interfaces for accessing and delivering telemedicine services.

Technological Literacy: The knowledge, skills, and self-efficacy required to critically engage advancements in technologies and technological influences on daily life.

Telemedicine: The delivery of medical care between settings that are geographically separate through the use of telecommunication systems, including traditional telephone systems and electronic communication systems.

Chapter 5.20
Benefits Derived from ICT Adoption in Regional Medical Practices:
Perceptual Differences Between Male and Female General Practitioners

ABSTRACT

Information and communications technologies (ICTs) are being used more and more by general practitioners (GPs) in their day-to-day activities. While a number of studies have shown that ICT adoption and use can provide real benefits to medical practices, there have been few studies to determine whether the perception of those benefits is uniform across the sector. This study examines whether differences in the perception of benefits exist between male and female GPs. The results suggest that the groupings and priorities of benefits arising from ICT use differ substantially between male and female GPs. Results also show, amongst other things, that male GPs are focussed on business efficiency, while female GPs are focussed on communication and practice expansion.

INTRODUCTION

The use of ICTs within medical practices is by no means a new phenomenon. An examination of the literature provides numerous studies detailing the design of clinical ICT systems (Baldwin, Clarke, & Jones, 2002; Hsu et al., 2005; Pelletier-Fleury et al., 1999) as well as the uses of such systems within medical practice or health care facility (Ammenwerth, Mansmann, Iller, & Eichstadter, 2003; Catalan, 2004; Shohet & Lavy, 2004; Waring & Wainwright, 2002). Along with the increased adoption and use of ICTs in the small-to-medium enterprise (SME) sector (MacGregor, 2004a; MacGregor & Vrazalic, in press; Stockdale & Standing 2004; Woerndl, Powell, & Vidgen, 2005), there has been an increased interest both by academics as well as practitioners in the use of ICTs in the overall management of medical practices (Anderssen, Vimarlund, & Timpka, 2002; Ash, Gorman, Seshadri, & Hersh, 2004; Leung, Yu, Wong, Johnston, & Tin, 2003). These studies suggest that health care managers and professionals are increasingly examining ICTs, not only to improve medical services but to reduce costs and to operate more effectively and efficiently.

Not only has there been an increased use of ICTs both within the SME sector as well as the medical sector, a number of studies (Boerma & van den Brink-Muinen, 2000; MacGregor & Vrazalic, in press; Teltscher, 2002,) have shown that there is a substantial increase of females in the wider SME sector as well as in general practice. The increase in female participation and ICT adoption has, not unexpectedly, given rise to studies concerning the role of gender in ICT adoption and use. A number of studies (Brush & Hisrich, 1999; Buttner & Moore, 1997; Carter, 2000; Sandberg, 2003; MacGregor & Vrazalic, in press) have found gender differences in the perception of benefits derived from ICT adoption in the small business sector. Yet despite the increasing numbers of females in the workforce, there have been no studies examining whether differences exist in the perception of benefits derived from the use of ICTs between male and female GPs.

The purpose of this paper, then, is to examine whether the groupings and priorities of benefits derived from ICT adoption, differs between male and female GPs in regional Australia. As almost all of these practices are, by nature, specialized small businesses, the study examines the benefits (both the intrinsically medical benefits as well as the more general small business benefits) derived from ICT adoption and use.

The paper begins by providing a brief review of the literature concerned with gender differences from the wider small business sector. The paper then examines gender differences within the general practice sector as well as those differences found in the adoption and use of ICTs. It further investigates the nature of benefits derivable from ICT adoption and use, both from a general SME perspective as well as from a medical perspective. A description of the study and results are presented. This includes a series of Factor Analyses of the benefits derived from ICT adoption and use by male and female GPs. Finally the implications of the study results are discussed along with conclusions.

Gender Differences in the SME Sector

As most general practices in regional Australia are specialized small businesses, it is appropriate to examine the findings from this "wider" perspective, before examining medical practices or the use of ICTs. It is also appropriate to note the observations of Baker, Aldrich, and Liou (1997) and Carter (2000), who found that research into gender differences in the ownership/management of SMEs is scarce by comparison to research that has examined SMEs in general. Nonetheless, there are a number of interesting findings in the literature that compare various facets of gender differences in the ownership/management of SMEs. Studies by Carter (2000) and Brooksbank

(2000) suggest that that the primary motivation for moving into the SME sector is the desire to become self-employed. An examination of the United Kingdom's labor force figures for the 1990s shows that while the growth in self-employment for males was 4.73%, the growth in self-employment for females was 19.06% (Labour Force Survey 1990-1999). Studies by Nillson (1997), Brush & Hisrich (1999), and Sandberg (2003) have provided similar figures in Europe, the United States and Scandinavia.

A number of studies (Carter, 2000; Rosa, Hamilton, Carter, & Burns, 1994; Sandberg 2003) have examined gender differences both in the acquisition of financing and the use of that financing within the small business. A study of 600 UK SMEs (Carter & Rosa, 1998) found that males were more likely to make use of bank loans and overdrafts than females. Indeed, females were less likely to use or rely on financial institutional arrangements including cheaper sources of financing, such as extended supplier credit, than were their male counterparts. The UK study also showed that, on average, the capital expenditure on actual start-up by female owner/managers was 33% of that spent by males.

Not only has the use of financing been shown to differ between males and females, Carter (2000) and Sandberg (2003) have shown that the ability to access financing often differs between male and female owner/managers. Many of these studies have concluded that while financial institutions may have a nondiscriminatory policy, through stereotyping, the application of those policies are often prejudiced against women.

The increased difficulty of obtaining financing by female owner/managers has impinged on four areas:

- the ability to raise start-up financing (Carter, 2000);
- differences in guarantees required to attract financing (Carter, 2000; Sandberg, 2003);
- Attraction of ongoing financing through females' failing to penetrate the informal financial networks (Sandberg, 2003); and
- sexual stereotyping (Carter 2000)

A number of recent studies (McGregor & Tweed, 2001; Verheul, Risseeuw, & Bartelse, 2002) have examined differences in management style between male and female small business owner/managers. These studies found that female managers of SMEs were more relaxed with giving instructions to staff through informal conversation than were their male counterparts. Indeed, while the male managers stressed the role and use of power, female managers stressed the importance of interpersonal communication. Both studies also found that female owner/managers were more likely to hire external expertise and were more inclined to develop business strategies that were specific to their particular business than were their male counterparts.

Studies in Sweden (Sandberg, 2003) and New Zealand (McGregor & Tweed, 2001) showed that:

- female owner/managers paid more attention to business-to-business links;
- female owner/managers paid more attention to strategic alliances than males;
- female owner/managers managers were more mindful of both their customers and their staff than were male managers;
- female owner/managers were significantly better at dealing with the details of the day-to-day business; and
- female owner/managers were far more aware and capable of managing budgets than their male counterparts.

The role of networking, particularly social networking, has become an important area of research and government strategy within the small business sector. Networks provide: legitimacy (Dennis, 2000), business and technical support (MacGregor, 2004b), business structure (O'Donnell, Gilmore, Cummins, & Carson, 2002), distribution of power (Johanisson, Ramirez-Pasillas, & Karlsson, 2002), and business process, including supply chain management (Johanisson et al., 2002). It is interesting to note that while female managers tend to be less formal than male managers within their own businesses, when it comes to dealing with other managers in a business networking situation, male networks are often far more informal than female networks (DeWine & Casbolt, 1983; Smeltzer & Fann, 1989).

More recent studies (Brush, 1997; Carter, 2000; Carter & Rosa, 1998; Sandberg, 2003) support these earlier findings, adding that females appear to be less welcome in social networks often resulting in a reduced ability to use network partners to gain financing or attract technical or marketing assistance.

Gender Differences Among GPs

There have been a number of studies examining gender differences among GPs. Chambers & Campbell (1996) and Boerma and van den Brink-Muinen (2000) found that female GPs apply fewer technical procedures than males. A study by van den Brink-Muinen, Bensing, and Kerssens (1998) found that female GPs were more attentive to problems from staff than were their male counterparts.

In a large study of 8,183 GPs from across Europe, Boerma and van den Brink-Muinen (2000) found a number of gender differences between male and female GPs. These included data that showed that:

- female GPs more inclined to work fewer hours,
- female GPs tended to allocate more time to patients,
- female GPs had less technical equipment at their disposal,
- female GPs made fewer house calls,
- female GPs were less involved in services outside the practice (with the exception of providing training), and
- female GPs preferred group practices to solo practices.

The study by Boerma and van den Brink-Muinen (2000) provided a number of interesting implications for the future provision of care in general practice. These included the likelihood that with the increase in numbers of female GPs, there would be a similar increase in the number of group practices that would allow female GPs work flexibility and the ability to limit the need for a full-time commitment. The finding that female GPs had less technical equipment at their disposal suggested that modifications may need to be made in the education of medical practitioners.

In light of the findings by Boerma and van den Brink-Muinen (2000), it is appropriate that gender differences in the use of the Internet is now considered.

Gender Differences in Internet Use

A number of early studies (Gilroy & Desai, 1986; Meier & Lambert ,1991) found that males were less anxious about using computer technology than females. Yet, according to Gebler (2000), female Internet users exceeded male users in the year 2000. The implications of this event are significant considering the previous research into the use of the Internet by females. Shade (1998) and Sheehan (1999) both found that females were more concerned with privacy and security issues and, subsequently, more cautious about using the Internet for online shopping and trading. Presumably, the same concerns may apply to female business owners considering electronic commerce (e-commerce) adoption.

With the proliferation of ICTs, particularly into the small business sector, a number of studies have explored potential determinants of Internet use and found gender to be an influential variable in predicting this use (Sexton, Johnson, & Hignite, 2002). Other studies have attempted to develop frameworks to explain gender differences in Internet use and online behaviour (see, for example, Rodgers & Harris, 2003).

Although the gap between male and female Internet adoption rates has disappeared, resulting in a more gender-balanced use of the Internet, differences remain in how the Internet is actually used. For example, Akhter (2003) found that men were still more likely to use the Internet for shopping than women. This would suggest that males may be more open to e-commerce adoption as business owners because they are more willing to adopt the technology as consumers. However, empirical evidence of such a trend is still unavailable. Although our knowledge of gender differences in relation to *Internet* adoption as users and consumers is broad, our understanding of gender differences in relation to *e-commerce* adoption as business owners is scant and inadequate. One exception is a study of e-commerce and teleworking in 112 Spanish small businesses by Perez, Carnicer, and Sanchez (2002). The authors found that small businesses with female managers were significantly more concerned with the difficulty of using the technology, than were their male counterparts. The study also cited cost of the technology and changes to work procedures as being of more concern to female managers.

As already indicated, all regional general practices are really specialized small businesses. It is appropriate, then, that we examine the findings from the wider SME literature before considering the literature specific to general practice.

Benefits of ICT Adoption (SMEs)

There have been many studies concerned with the benefits derived from ICT adoption. Some of these studies (MacGregor, 2004a) have shown that benefits often fall into the category termed intangible benefits and are often not realized by owner/managers at the time of adoption. The following section will examine some of the findings.

Studies by Poon and Swatman (1997) and Abell and Lim (1996) found that SMEs benefited in their ability to reach new customers and new markets through the use of ICT. This finding also has been supported in more recent studies (Quayle, 2002; Raymond 2001;, Ritchie & Brindley, 2000; Sparkes & Thomas, 2001;, Vescovi, 2000).

Earlier studies found that other benefits reported by SME operators included lowering of administrative costs (Abell & Lim, 1996; Poon & Swatman, 1997;), reduced lead time (Abell & Lim, 1996), increased sales (Abell & Lim, 1996), improved relations with business partners (Poon & Swatman, 1997), and improved quality of information (Abell & Lim, 1996; Poon & Swatman, 1997). A recent study by Quayle (2002) found that benefits derived from ICT use, as reported by SME owner/managers, included reduced administrative costs, reduced production costs, reduced lead time, reduced stock, improved marketing, and improved quality of information, while Tetteh & Burn (2001) found that the adoption of ICTs substantially increased internal efficiency.

As mentioned, many of the benefits enjoyed by small businesses are intangible. Woerndl et al. (2005) found that many small businesses involved in ICT use had expanded their activities beyond those performed prior to adoption. Stockdale and Standing (2004) found that benefits included changes in business methods and costs, enhanced levels of communications, stimulated competition, and reduced transaction costs. Hurwitz (2000) concluded that ICT adoption led to greater potential for partnerships, while Brunn, Jensen, and Skovgaard (2002) showed that ICT use led to flexibility in administration and communication.

Benefits of ICT Adoption (Medical)

The adoption and use of ICTs within the health care sector is not entirely a new phenomenon. Studies of the National Health Service (NHS) in the United Kingdom by Gallagher (1998) noted that among other benefits were the ability to undertake strategic planning and better manage the health care environment. Rees (1998), in a similar study, noted that the use of ICTs appeared to enhance efficiency. Pullen, Atkinson, and Tucker (2000) showed that costs were better managed using certain forms of ICTs. These studies are supported by the findings of Nelson and Alexander (2002). It is interesting to note, however, that despite the apparent benefits, the approach to the design of ICT inclusions has been questioned by several authors (Gelnay, 2002; Shohet & Lavy, 2004; Waring & Wainwright, 2002), who noted that many fail to fully account for all the stakeholders of the enhanced system.

Other benefits noted in the literature include contact with other clinicians regarding patient care (Baldwin et al., 2002); elimination of redundancy in patient care (Pelletier-Fleury et al., 1999); enhancements to the effectiveness of the practice (Andersson et al., 2002); control of economic demands (Prop, 2000); improved patient care (Leung et al., 2003); and order entry of consumables by the practice (Ash et al., 2004).

METHODOLOGY

A series of interviews with GPs was undertaken to develop a set of benefits that are derived from ICT adoption (see Table 1). A questionnaire was then developed. Respondents were asked, amongst other things, to rate the benefits of ICT adoption across a 5-point Likert scale (1 very unimportant, 5 very important). Respondents also were asked their gender. The 690 surveys were distributed across five locations in Australia (Illawarra, Hunter, Ballarat, S.E.NSW, and Rockhampton). The scales of measurement were tested for reliability using a Cronbach's alpha reliability test. Cronbach's alpha was 0.942, indicating a high level of reliability.

RESULTS

Responses were obtained from 122 GPs, giving a response rate of 17.9%, which is within normal limits (10-30%) for questionnaire studies using mail-out as a vehicle (Sohal & Ng, 1998). Of the respondents 88 were male, and 34 were female.

An examination of the correlation matrices (available from the authors) suggested the use of factor analysis as a statistical method to investigate any separate underlying factors and to reduce any redundancy in the correlation matrix. The results of Kaiser-Meyer-Olkin MSA (0.880 for males; 0.718 for females) and Bartlett's test for sphericity (χ^2=1169, p=0.000 for males; χ^2=463 p=0.000 for females) indicated that the data set satisfied the assumptions for factorability. Principle components analysis was chosen as the method of extraction in order to account for maximum variance in the data, using a minimum number of factors. A three-factor solution was extracted for males with Eigenvalues 9.316, 1.546, and 1.150, while a four-factor solution with Eigenvalues 7.745, 2.312, 1.564, and 1.294 was extracted for females. Both were supported by an inspection of the Scree plot. Table 2 provides the total variance for both.

In both cases, the resulting components were rotated using a Varimax procedure to achieve simple structures. Tables 3 and 4 provide summaries of our data analysis and findings.

DISCUSSION

The first and most obvious difference between the findings in Tables 3 and 4 is that while male GPs considered that there were three factors underlying the benefits derived from ICT adoption,

Table 1. Benefits of ICT adoption and use

Expanding the patient/customer base by broadening the area of coverage
Improvement to business efficiency
Reduction of the overall workload
More time on patient care
Reduction of costs
Improvement in the way the business is operated
Allowing the business to expand
Information storage and retrieval
Communication with fellow GPs
Communication with other medical organisations
Disease management
Streamlining accounting and billing
Adding to the skills of the practice
Communication with hospitals
Ordering drugs
Communication with general practice business suppliers
Reducing the importance of remoteness in the provision of medical care

female GPs thought there were four. A comparison of the two tables, however, shows that there are several other important differences. While male GPs considered that expansion of the practice was part of the overall business effectiveness and rated this secondary to medical and business efficiency (Table 3), female GPs considered expansion of the practice to be aligned with communication and considered it to be of primary importance (Table 4). One possible explanation for this may be found in the earlier study of Boerma and van den Brink-Muinen (2000), who noted that female GPs preferred group practices, worked fewer hours, and tended to spend more time with patients. If this were the motivating force, it would explain the logical grouping of communication and practice

Table 2. Total variance explained

Males			
Component	Eigenvalue	**% Variance**	**Cum. %**
Med./bus. efficiency	9.316	54.798	54.798
Business effectiveness	1.546	9.097	63.894
Communications	1.150	6.766	70.660
Females			
Communication/expansion	7.745	45.559	45.559
Business efficiency	2.312	13.600	59.159
Efficient patient care	1.564	9.200	68.359
Communication with suppliers	1.294	7.614	75.972

Table 3. Rotated component matrix (male GPs)

Benefits of ICT adoption and use	**Medical and business efficiency**	**Business effectiveness**	**Communication**
Expanding the patient/customer base by broadening the area of coverage		0.734	
Improvement to business efficiency	**0.564**	**0.565**	
Reduction of the overall workload		0.694	
More time on patient care		0.745	
Reduction of costs		0.750	
Improvement in the way the business is operated		0.641	
Allowing the business to expand		0.535	
Information storage and retrieval	0.855		
Communication with fellow GPs			0.718
Communication with other medical organizations	0.648		0.631
Disease management	0.611		
Streamlining accounting and billing	0.766		
Adding to the skills of the practice	0.673		
Communication with hospitals			0.603
Ordering drugs			0.623
Communication with general practice business suppliers			0.741
Reducing the importance of remoteness in the provision of medical care			0.738

expansion (Table 4, column 1) as one mechanism to compensate for working fewer hours.

A comparison of Tables 3 and 4 shows that three benefits, "Reduction of the overall workload," "More time on patient care," and "Reduction of costs," were considered to be part of the improvement to business practice and effectiveness by males. By comparison, females loaded these benefits to a separate factor termed efficient patient care (Table 4, column 3). This again supports the earlier findings of Boerma and van den Brink-Muinen (2000), who found females spent longer with patients and were more attentive, both in time and procedure, with their patients than were males.

Tables 3 and 4 also show that male GPs considered ordering of drugs to be part of communication, while female GPs considered it to be part of patient care. Similarly, female GPs separated communication with suppliers from communication with other medical practitioners, hospitals, or medical associations. It is interesting to note that both groups considered business efficiency to be a greater benefit derivable from ICT adoption and use than improvement to patient care.

The results of this study are significant in several ways. The analysis has shown that e-commerce benefits can be grouped in relation to three main factors for males and four for females. This gives researchers a powerful explanatory tool because it reduces the "noise" in the data. Instead of accounting for 17 different benefits, the advantage to GPs of adopting and using ICTs can be

Table 4. Rotated component matrix (female GPs)

Benefits of ICT adoption and use	Communication and expansion	Business efficiency	Efficient patient care	Communication with suppliers
Expanding the patient/customer base by broadening the area of coverage	**0.643**			
Improvement to business efficiency		**0.747**		
Reduction of the overall workload			**0.743**	
More time on patient care			**0.799**	
Reduction of costs			**0.809**	
Improvement in the way the business is operated		**0.744**		
Allowing the business to expand	**0.460**			
Information storage and retrieval		**0.780**		
Communication with fellow GPs	**0.828**			
Communication with other medical organizations	**0.847**			
Disease management	**0.812**			
Streamlining accounting and billing		**0.881**		
Adding to the skills of the practice		**0.670**		
Communication with hospitals	**0.691**			
Ordering drugs			**0.580**	
Communication with general practice business suppliers				**0.837**
Reducing the importance of remoteness in the provision of medical care				**0.711**

explained in relation to one of three or four factors. The rotated component matrices shown in Tables 3 and 4 also enable the prediction of the scores of each individual benefit, based on the score of the other factors. Whereas before researchers have identified various benefits (such as the ones listed in Table 1), this is the first time a study has shown that certain benefits can be logically grouped according to three or four factors.

CONCLUSION

The results of this study are significant in several ways. The analysis has shown that e-commerce benefits can be grouped in relation to three main factors for males and four for females. This gives researchers a powerful explanatory tool because it reduces the "noise" in the data. Instead of accounting for 17 different benefits, the advantage to GPs of adopting and using ICTs can be explained in relation to one of three or four factors. The rotated component matrices shown in Tables 3 and 4 also enable the prediction of the scores of each individual benefit, based on the score of the other factors. Whereas before researchers have identified various benefits (such as the ones listed in Table 1), this is the first time a study has shown that certain benefits can be logically grouped according to three or four factors.

The results of this study also showed that the perception of benefits of ICT adoption and use in medical practices appear to differ depending on the gender of the GP. The results show that both the grouping as well as the priority of the groups differs substantially between male and female GPs. The current study appears to support the earlier findings of Boerma and van den Brink-Muinen (2000), who found, amongst other things, that female GPs have less technical equipment at their disposal. While the level of availability of technical equipment was not examined, the results of the current study suggest that female GPs see ICTs primarily as business oriented, while male GPs rated, as their highest priority, a medical benefit for their adoption and use. Clearly further research needs to be undertaken to determine whether the day-to-day use of ICTs by male and female GPs differs and the implications of any differences to patients.

The results of this study also show that ITC adoption benefits can, indeed, be grouped, simplifying the discussion of benefits in general. The apparent relationship of gender to perception of benefits is worthy of further examination because by formally explicating it, researchers and governmental organizations engaged in promoting ICT adoption will have more comprehensive knowledge about the issues and factors that have an effect on the relationship and will be able to provide better advice to GPs on ICT adoption.

Chapter 5.21
Factors Motivating the Acceptance of New Information and Communication Technologies in UK Healthcare:
A Test of Three Models

Janice A. Osbourne
Brunel University, UK

Malcolm Clarke
Brunel University, UK

ABSTRACT

This paper discusses the use of three published models, the Technology acceptance model (TAM), Rogers diffusion of Innovation theory (IDT), and the Triandis theory of interpersonal behaviour (TIB), and attempts to bring them together in an integrated model to better predict the adoption of new information and communication technologies by a cohort of health professionals within UK primary care in an attempt to aid implementers in bringing technology in at an organizational level.

INTRODUCTION

Over the last 25 years, public healthcare delivery has been undergoing continuing changes. This has included the use of new information and communication technologies in a bid to improve services to patients, speed up waiting times, and addressing structural problems in the National Health Service (NHS). These changes have been largely driven by technical competence on the medical side but not matched sufficiently in technical organizational improvements. This article discusses the use of three published models, the Technology Acceptance Model (TAM), Rogers Diffusion of Innovation theory (IDT), and the Triandis Theory of Interpersonal behaviour (TIB), and attempts to bring them together to assist in the political decision to bring technology in at the organization level too.

PUBLIC HEALTHCARE IN THE UK: AN OVERVIEW

Within the United Kingdom, there exists a plethora of organizations and bodies providing the majority of healthcare in the UK including general practitioners to accidents and emergency departments, and dentistry. These organizations all fall under the National Health Service (NHS), the publicly funded healthcare system of each part of the UK, which in theory is managed by the Department of Health. Services provided under this organization are characterised by free service to all citizens and is divided into two levels of care, primary and secondary.

In the United Kingdom, a patient must first see their own doctor (referred to as the GP) located in close proximity to the patient's home. GP's are the first point of contact for users in the UK. This level of service provided is known as primary care. At present, 90% of all health and social care contacts with the NHS are through primary healthcare (NHS, 2001). Primary healthcare is provided through a combination of general practitioners and community medical workers. Services such as district nursing and child health monitoring are provided by community medical workers. If specialist help is required by a patient, he or she will be referred to a hospital or a consultant by their GPs. This is referred to as secondary care, as self-referral is not allowed and the clinical condition presenting normally cannot be dealt with by a primary care specialist and so is dealt with at this level.

One major problem in the NHS is that of communication between hospital specialists and general practitioners particularly in inner city areas. The written communication between GPs and consultants have been highlighted as being of poor quality (Rowland, 1992) and often having poor educational value (AGHTA, 1996). This problem has led to problems occurring in the outpatient referral system in terms of delays for hospital appointments, leading to frustration by patients (DOH, 1991).

In addition to this, there have been problems with out of hours GP services (Hallam, 1994), which has led to recommendations being made for more access to the healthcare system through entry points such as NHS Direct (Rogers, Chapple, & Sergison, 1999).

The government, in an effort to modernize the National Health Service and to deal with the numerous structural problems, have emphasized in policy initiatives the vision for connecting health policies with the capabilities of new information and communication technologies, which are able to provide new kinds of service that are more responsive to public needs and speed up access to healthcare. *The Information Strategy for the Modern NHS* (1998-2005) was seen as both visionary and relevant to the needs of the NHS. In the *Information for health* policy document for example, removing distance from healthcare was seen as a goal of the innovative technology Telemedicine.

Opportunities in the field of telemedicine will be seized to remove distance from healthcare, to improve the quality of that care, and to help deliver new and integrated services. GP's will be able to send test readings or images electronically to hospital specialists many miles away and in the same way receive results and advice more quickly (National Health Service Executive, 1998)

One of the major programmes, which the government has initiated, is the National Programme for IT for which an overview is provided.

National Programme for IT (Formerly NPfit)

The National Programme for Information Technology (Npfit) came about in 2002 as a result of the UK government's decision to make an unprecedented investment in information technology as essential to its plans for the National Health Service. This programme has been seen as one of the most expensive information technology programmes in the world with costs estimated to run over £18billion over ten years. (Brennan, 2005).

The programme aims to connect 30,000 general practitioners and 270 acute, community, and mental health trusts to a single, secure, national system to make information available when and where it is needed, including to patients themselves (Hutton, 2004).

In tracing its history, the Npfit programme came about as a result of suggestions made in the Wanless Treasury's report (Wanless, 2002). The report gave reasons as to why previous targets set by the NHS Executive, of all NHS trust having electronic medical reports implemented by 2005, had not been achieved. These reasons included budgets for information technology being used to relieve financial pressures elsewhere instead of locally and an inadequate setting of central information technology (IT) standards.

The Report recommended that the NHS double the proportion of its budget invested in information technology to 4%, to bring it closer into lines with the healthcare in the United States, which has a budget of 6%. They concluded that without a major advance in the effective use of information and communication technology, the health service would find it difficult to deliver the efficient high quality service, which the public will demand. The government's response to this was to allocate £2.3bn for a new national programme for IT (Doh, 2002). The Primary aim of the programme is **for** electronic patient records to be implemented in all acute trusts by the end of 2007. In 2005, the government established an agency, *Connecting for health*, as the single national provider of IT, which would deliver the National programme ensuring the maintenance, development, and effective delivery of the IT products and services delivered by the former NHS information authority.

There are several products that the National Programme plans to deliver, which includes:

- **A National Care Record System (NCRS):** *Connecting for health* plans to produce holistic records for patients from birth to death gradually, holding a review of the person's health and all his or her health contacts within the National Health Service. This summary patient record called the "spine" will be accessible 24 hours a day, seven days a week by health professionals, whether they work in hospitals, primary care, or community services.
- **Electronic Booking:** This programme, *Choose and book*, will allow GPs and other primary care staff to make initial hospital or clinic outpatient appointments at a convenient time, date, and place for the patient. If the patient prefers, he or she can make their appointment later online or through a telephone booking service.
- **Electronic Transfer of Prescriptions:** This will allow for prescribers to create and transfer prescriptions directly to a patient's community pharmacist and the Prescription Pricing Authority (PPA). It's aim is to reduce reliance on article prescriptions and it is expected to reduce prescription errors and provide better information at the point of prescribing.
- **New National Networking Service (N3):** This will provide the NHS with world-class networking services, including secure broadband connectivity, from every site where NHS services are delivered or managed

Based on the expenditure of this and similar programmes, we deduce that money is available so the choice is between spending the time to do it well, seeing that the government intends to have information technology playing a central part in healthcare within the very near future, or to do it badly on time. This then leads us to look at external models on which to identify factors, which play a part in technology adoption.

DEVELOPMENT OF RESEARCH MODEL

There have been several theoretical perspectives, which have been used to study the determinants of IT acceptance and adoption across a variety of disciplines including Communications (Rogers, 1995), Sociology (Wejnert, 2002), and Information systems research (Knol & Stroeken, 2001).

Intention-based models and behavioural decision theories have been used to explain usage of information systems (e.g., Agarwal & Prasad, 1997; Davis, 1989) and results further show that behavioural intentions are significantly and positively correlated with actual behaviour. According to these theories, user adoption and usage behaviours are determined by intention to use information technology, which in turn is influenced by beliefs and attitudes about information technology.

Although there are many theories, which can be used to explain intention we have selected three. The technology acceptance model, the theory of interpersonal behaviour, and Rogers innovation and diffusion model. These models will form the basis of our conceptual model.

Technology Acceptance Model (TAM)

The technology acceptance model (TAM, Davis, 1993) is described as the most dominant theoretical model in information technology acceptance (Misiolek, Zakaria, & Zhang) and is an adaptation of the Theory of Reasoned Action (TRA, Fishbein & Ajzen, 1980). The TAM's goal is to provide an explanation of the determinants of computer acceptance that is generally capable of explaining user behaviour across a broad range of end-user computing technologies and user populations (Davis, Bagozzi, & Warshaw, 1989).

The TAM identifies two beliefs perceived usefulness and perceived ease of use, as being of primary importance for computer acceptance behaviour. The model posts that a users adoption of an information system is determined by behavioural intention, which is determined by the user's belief about the system, similar to the TRA. The model differs from the TRA in that behavioural intention is viewed as being determined by the individual's attitude and perceived usefulness. The TAM does not however include the subjective norms of the TRA as it was not found to be significant (Davis, 1989).

The Triandis Theory of Interpersonal Behaviour

The Triandis model (Triandis, 1980, see Figure 1) explains individuals' behaviour in terms of what they have always done (habit), by what they think they should do (social norms) and by the consequences, they associate with a behaviour (perceived consequences). The model also contains aspects that are directly related to the individual, for example attitudes, genetic factors, intention, and behaviour and others that are related to the individual's environment, for example culture, facilitating conditions, and social situations.

Rogers Innovation and Diffusion Theory

The Innovation and Diffusion Theory proposes that an innovation is an idea or practice perceived as new by an individual, group, or organization

(Rogers, 1995). Diffusion is described as the process by which an innovation spreads. The individuals' decision to accept or reject an innovation occurs in the following stages, awareness of the innovation, which leads to an attitude being formed towards it based on the individuals perception of the innovation. The decision to adopt or reject is then made, implementation takes place, and the individual confirms his or her decision. The perceived characteristics of an innovation include its relative advantage, compatibility, complexity, trialability, and observability (Rogers, 1995).

REASONS BEHIND INTEGRATION

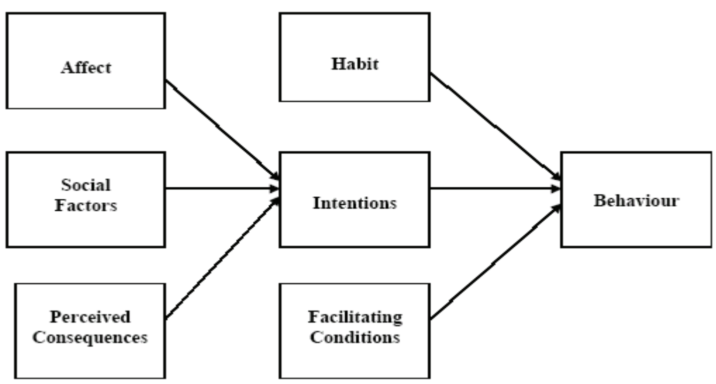
Previous models described here can contribute to our proposal of an integrated model in a variety of ways, which are:

Incompleteness

Although strong empirical support for the TAM has been established through numerous studies (Karahanna, Straub, & Chervany, 1999; Venkatesh & Davis, 2000; Venkatesh, Morris, Davis, & Davis, 2003), the TAM has had several criticisms levelled at it, including not offering sufficient understanding to provide system designers with information needed for creating and promoting user acceptance of systems (Mathieson, Peacock, & Chin, 2001), and its assumption that its use is volitional, which means that in there are no barriers to prevent an individual from using a technology or a system if he or she chose to do so (Mathieson et al., 2001). There may be situations in which an individual wants to use an IT, but is prevented by lack of time, money, or expertise (Chau & Hu, 2001; Taylor & Todd, 1995). Given the fact that the information and communication technologies, including mobile health technologies (described as computing technology, comprising software, hardware, and communications specifically associated with mobility, Zaslavsky & Tari , 1988) are fairly new to health professionals, the possibility exists that they may choose not to use the technology because they may not have sufficient skills or the ability to use the technology, hence the model would not give a complete picture of factors affecting adoption.

Because of the uncertain theoretical status of the TAM, Davis (1989) dropped the subjective norm, which has resulted in studies using the TAM seldom including variables related to the social environment. Technology adoption in healthcare is a current hot topic at the moment and we believe that social pressure plays an important role in explaining reasons behind their use.

Figure 1. Triandis Theory of Interpersonal Behaviour



Similarities Between the Models

Although these theories focus on different determinants to explain consumer behaviour in the adoption of technology, they have similarities:

1. The TAM and the Triandis model are both intention-based models, which assume that attitudes influence intention, which determines behaviour and the actual use of the technology.
2. Perceived ease of use in TAM is related to the complexity construct of the Innovation Diffusion theory in fact the complexity construct is the exact opposite of the Perceived ease of use construct.
3. Perceived consequences in the Triandis model construct is similar to the construct of perceived usefulness (PU) in the TAM and similar to relative advantage in the Innovation Diffusion theory.

We have divided the technology adoption process into three factor areas, those related to the social environment, those related to the technology, and those related to the individual. We find the Triandis model most relevant for factors related to the social environment; for the technology related section we find the attributes from the diffusion of innovation, which concentrates on both the technology and its compatibility and the TAM more suitable; and for those related to the individual, we find the IDT and the Triandis model more suitable. As these models do not give a complete overview on their own, we find it necessary to combine the three to evaluate adoption.

AN INTEGRATIVE MODEL

Given their complementary nature, a model that integrates the key research constructs from TAM, TIB, and EDT should explain more variance in IT usage intention than either model alone. Such an integrated model is depicted in Figure 3. In this section, we discuss how the assembled model attempts to do the duties assigned to it.

Social Factors

An individual's perception of social pressure to perform or not perform a behaviour affects intention, (Fishbein & Ajzen, 1975). Perception of social pressure refers to an individual's perception of whether individuals close to or important to them think that they should or should not perform a behaviour. Consequently, we view social factors as norms, values, and roles, which influence an individual's intention to adopt medical technology. These values in our context may be conveyed by interaction with patients and peers.

There are varying views on physicians being influenced socially. It has been suggested that general medical practitioners are influenced in their decision-making by medical specialists, who are seen as being innovative and creative. (Blumberg, 1999). Such opinion leaders can activate local networks to diffuse an innovation by facilitating transfer of information (Young, Hollands, Ward, & Holman, 2003).

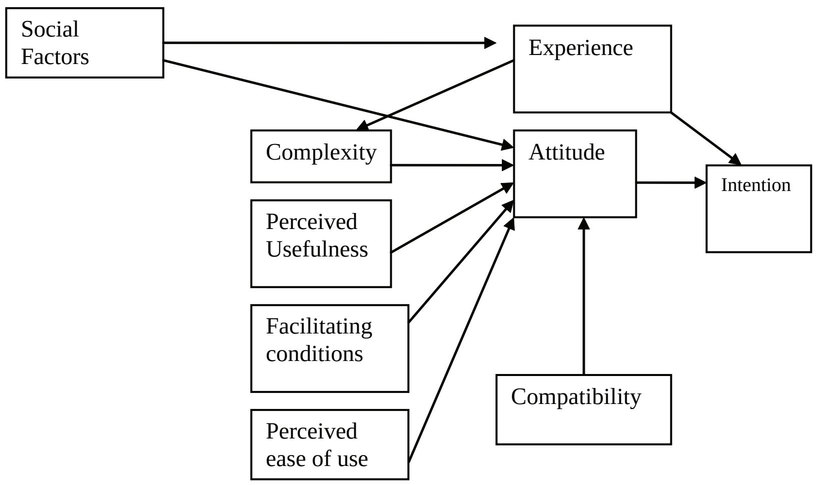
Perceived Usefulness

Among the many possible influences on technology use, Davis (1989) suggests that two determinants are of particular importance: perceived usefulness and perceived ease of use. Perceived usefulness is the tendency of people to use or not use a technology to the extent they believe it will help them perform their job better.

Perceived Ease of Use

PEOU is the degree to which a person believes using a particular system would be free of effort, and if the performance benefits of usage are outweighed by the effort of using the technology (Davis, 1989). Hence, the more complex the inno-

Figure 2. Integrated model



vation of an information technology, the lower the probability of its adoption will be (Rogers, 1995). Applying this to technology adoption in the NHS, technologies perceived to be user friendly will be more appealing to both patients and practitioners. Perceived ease of use refers to ease of using the technology, sending data electronically as in the case of mobile technology, obtaining the data necessary to proceed with consultations as in the case of General Practitioners.

Facilitating Conditions

Facilitating conditions are the objective factors that make a behaviour easy or difficult. In the Triandis model, facilitating conditions are important determinants of behaviour. Even if intentions to perform the behaviour are high, the habits are well established and the physiological arousals are optimal, there may be no action/behaviour if the situation or objective factors do not warrant the behaviour (Triandis, 1980). A simplified explanation of this is that facilitating conditions are important in that individuals with the intention of accomplishing something may be unable to do because their environment prevents the activity from being performed.

Triandis hypothesizes that facilitating conditions directly affect the actual behaviour rather than intentions because he argues that one might

Figure 3. Comparison of the three models

	TAM	TIB	IDT
Variables	Perceived ease of use	Social factors	Relative advantage
	Percieved usefulness	Facilitating conditions	Trialability/Experience
	Attitude	Perceived consequences	Compatibility
		Genetic Factors	Complexity
		Cultural Factors	Observability

Key:
TAM : Technology Acceptance Model
TIB : Triandis Theory of interpersonal behaviour
IDT : Innovation Diffusion Theory

have the intention to perform a certain act, but if the environment does not support this behaviour then the act will most likely not be executed. We define facilitating conditions as those factors in an individual's environment that facilitate the act of adopting technology. Empirical investigations have shown that facilitating conditions could also have a significant positive impact on attitude (Chang & Cheung, 2001).

We expect facilitating conditions to have a positive influence on technology adoption.

Perceived Consequences

According to Triandis, each act or behaviour is perceived as having a potential outcome that can be either positive or negative. An individual's choice of behaviour is based on the probability that an action will provoke a specific consequence.

Relative Advantage

Relative advantage is the degree to which an innovation is perceived as better than the idea it supersedes. Physician perceptions of new technologies affect the adoption of innovation in clinical practice. For example, physician perceptions related to teledermatology suggest that this new technology needs to be quick, efficient, reliable, and easily used (Weinstock, Nguyen, & Risica, 2002). If new technologies are too time consuming or complicated, they may not be widely adopted and used. In a study on the perceptions of GPs towards teledermatology, the results reported a preference for reliable, efficient, and easy-to-use technology (Collins, Nicolson, Bowns, & Walters, 2000).

Trialability/Experience

Trialability is the degree to which an innovation may be experimented with a limited basis. The more adopters experiment with a new technology and explore its ramifications, the greater the likelihood that the innovation will be used during early stages of adoption (Agarwal & Prasad, 1997; Natek & Lesjak, 2006).

Intention

Behavioural intention refers to "instructions that people give to themselves to behave in certain ways" (Triandis, 1980) or their motivation regarding the performance of a given behaviour. In our model, intention refers to health professionals' motivation to adopt information technologies.

Attitude

According to Fishbein and Ajzen (1980), "attitude is a learned predisposition to respond in a consistently favorable or unfavorable manner with a given object." Attitude is directly related to behavioural intention and adoption because people will only intend to perform behaviour for which they have positive feelings (Han, Harkke, Mustonen, Seppanen, & Kallio, 2005; Marino, 2004). We hypothesise that attitude is positively related to the users intention to use new ICTs in healthcare

Compatibility

This construct has not been included in most studies on technology adoption apart from those using the IDT (Cho,). Compatibility refers to the conformity of an innovation in our case new ICTs with the values and beliefs of users and with previously introduced ideas and needs (McCole, 2002). Therefore, the adoption of a new technology depends on its compatibility with existing practices. The importance of technology compatibility with the organization and its tasks has been shown to be a significant factor in successful technology implementations (Cooper & Zmud, 1990).We hypothesise that compatibility is positively related to the user's attitude towards new ICT's in healthcare.

DISCUSSION

The primary objective of this paper was to compare two of the more dominant technology acceptance and adoption models in IT research, namely the TAM and the IDT as well as a less popular model from the social science, the TIB, then extend these models to an integrated model of IT acceptance and adoption.

On their own these models do not fully evaluate the acceptance of technology by individual, however when integrated the weaknesses of the individual models are totally cancelled out by the strengths of the integrated model.

As described earlier, the TAM assumes that there are no barriers to preventing an individual from using a technology if he or she wished. The IDT and the TIB however feature variables, which can affect adoption by the individual, hence filling one of the gaps of the TAM. The Triandis models which attempts to cover all the major component of the individual and their environments with its 34 variables is somewhat difficult to test by virtue of its complexity hence only the variables relating to our study have selected. The IDT focuses on the process of adoption as well as the, this is complementary with both perceived characteristics of the technology complimenting both the TIB and the TAM

Based on these factors, we believe the integrated model will have better explanatory power of user adoption of technology. However dear readers, as with any cake, the proof is in the eating and as such, we will shortly be conducting an exhaustive study on a cohort of health professionals within a Primary Care Trust given new medical technology as part of a government modernization initiative to see if the model lives up to expectation. We ask that you wait with bated breath!

Chapter 5.22
Gender Differences in Adoption and Use of a Healthcare IT Application

INTRODUCTION

Information technology (IT) adoption and diffusion is a central concern of information systems research and practice. The most widely-accepted method in IT adoption and diffusion research, the technology acceptance model (TAM; Davis 1989), posits that perceived ease of use and perceived usefulness are fundamental determinants of user acceptance. However, TAM and its subsequent research makes little or no reference to gender effects (Adams, Nelson, & Todd, 1992; Chin & Gopal, 1995; Venkatesh & Davis, 2000), despite the fact that researchers have shown that socio-cultural factors, such as gender and ethnic differences, influence human perceptions and behaviors (Hofstede, 1980). These socio-cultural factors can result in differences in user responses to technology innovations (Gefen & Straub, 1997).

Aiming to provide theoretical extensions to the TAM model, researchers have shown that gender differences may relate to beliefs and use of IT. For instance, males and females are found to demonstrate distinct adoption behavior in use of a wide spectrum of IT applications, such as e-mail (Gefen & Straub, 1997), mobile telephony (Ling,

2000) and Internet (Kraut, Scherlis, Mukhopadhyay, Manning, & Kiesler, 1996). Nevertheless, the exact gender effect remains a controversy. Some researchers believe that females are less technology inclined, less motivated and, therefore, less competent in masculine computer and technology culture (Wilder, Mackie, & Cooper, 1985; Qureshi & Hoppel, 1995). Others, in contrast, argue that females have the ability to be proficient in adopting new technologies (Turkle, 1995). Some research results indicate that females tend to favor some technology innovations and use them more effectively than males, such as computer-mediated communication (Kraut et al., 1996; Morahan-Martin & Schumacher, 1997).

In health care, influence of physician gender has long been noted in resident education and many practice areas. Researchers find the procedural and obstetrical care pattern of practice differs between male and female residents (Chaytors, Szafran, & Crutcher, 2001), and physician gender significantly affects treatments in adult primary care practice (Boulis & Long, 2004). An understanding of these socio-cultural issues is also of vital importance towards success of health care IT applications. This study is thereby designed to assess medical residents' acceptance and adoption of a Clinical Reminder System (CRS), by examining several key user characteristics that may relate to adoption and use of the system.

BACKGROUND

CRS is a class of computerized clinical decision support systems (CDSS) that send just-in-time alerts to clinicians when potential errors or deficiencies in patient management are detected. Beneficial outcomes of CDSS have been documented in many studies along a number of dimensions, including compliance with treatment standards, reduced costs and improved health outcomes (McDonald, Hui, Smith, Tierney, Cohen, Weinberger et al., 1995; Curtin, Hayes, Holland, & Katz, 1998). Several systematic reviews have also shown that CDSS can be an effective means of implementing medical guidelines to enhance clinical performance in wide-ranging aspects of medical care (Hunt, Haynes, Hanna, & Smith, 1998; Kaplan, 2001). However, most of these studies either focus on the accuracy and relevance of the computer-aided recommendations, or use experimental or randomized controlled clinical trials (RCCT) designs to assess system or clinical performance. Very few studies of CDSS involve a naturalistic design in routine settings with real patients (Kaplan, 2001). It is not clear whether a CDSS that has been shown to be effective in a laboratory setting will be fully utilized by end-users in clinical environments, and whether these users will adapt their practice style to efficiently accommodate computer-generated reminders.

Clinical users also differ in many ways. It has been recognized that individual users' experiences and their opinions or reactions to a technology make a difference in whether or not the technology will be adopted (Straub, Limayem, & Karahanna-Evaristo, 1995). Nevertheless, few studies have used individual-level data to measure the magnitude of user differentiation and the impact of such differentiation on technology adoption.

The present study aims to address some of these limitations. First, the system under evaluation, CRS, has been integrated into the daily operations of an ambulatory clinic. Second, longitudinal usage data for an evaluation period of 10 months were collected from computer logs, providing an objective and non-intrusive measure of the actual use over time. Third, a novel developmental trajectory method is applied to the usage data to identify groups that demonstrate distinct adoption behaviors, and to relate estimated group configurations to a variety of user characteristics.

The next section describes CRS and its basis in principles of evidence-based medicine. The study site and data collection procedures are then discussed, followed by a presentation of the trajectory analysis method for analyzing the usage data. The findings are presented next, and the final section presents some concluding remarks.

CRS AND EVIDENCE-BASED MEDICINE

Evidence-based medicine is the distillation of a large volume of medical research and standards into treatment protocols for diseases and preventive care procedures that represent the most accurate knowledge available (Sackett, Rosenberg, Muir Gray, Haynes, & Richardson, 1996). Evidence-based medicine has been widely applied to systematically review, appraise and use clinical research findings to aid the delivery and provisioning of optimum clinical care to patients.

The clinical decision support application that we developed, CRS, incorporates evidence-based medicine principles to assist in patient management decisions. It integrates the hospital's administrative, laboratory and clinical records systems into a single application, and uses patients' current medical status to provide reminders to clinicians at the point of care that reflect evidence-based medicine guidelines. Reminders generated by CRS take the form of recommendations to have tests scheduled and performed, receive vaccinations, alert clinicians to review abnormal test results or closely monitor patients with medical conditions that require unscheduled intervention. The CRS deployed at the time of this study is a distributed windows application based on client-server architecture. The clients are written in Visual Basic and communicate with an Oracle database server via the hospital's internal computer network. Evidence-based medicine guidelines are programmed in Oracle PL/SQL procedures.

STUDY SITE AND DATA COLLECTION

The study was conducted in the primary care clinic of an urban teaching hospital offering comprehensive health care services. Given the availability in every exam room of desktop computers installed with CRS, residents used the system during patient encounters.

Data collection started on February 1, 2002. In this study, we report 10 months of usage data to identify distinct user groups and maturation of their interaction with the reminder system. There were 44 active residents registered in the application. Activities generated by three of them are removed from the analysis since there were no visits recorded for these residents in 6 or more continuous months.

We have included in the study several key attributes of users that may relate to their human, contextual and cultural characteristics that in turn affect system use. These attributes are: general demographics including gender and citizenship (U.S. vs. non-U.S.); computer literacy identified by use, knowledge and optimism of computer systems; and frequency of encounters (work load). These attributes are found to influence adoption behavior in some other contexts (Berner & Maisiak, 1999). We have excluded a few other potentially influential attributes, because they are (a) invalid in the context, such as medical specialty (all users are internal medicine residents); or (b) lack of variation in the sample, such as age (mean 29.6, standard deviation 2.1); (c) sample size too small for defined subgroups, such as year of residency; or (d) inaccessible to us in recorded form, such as evaluation of residents' clinical performance (due to confidentiality concerns).

DEVELOPMENTAL TRAJECTORY ANALYSIS

We use a novel method, developmental trajectory analysis (DTA), to study user adoption behavior of this reminder system. DTA is a semi-parametric, group-based approach for identifying distinctive groups of individual trajectories within the population and for profiling the characteristics of group

Figure 1. Developmental trajectories of three distinct groups

Computer use score	33.54	33.0	33.56	34.13
Computer knowledge score	32.96	36 **	31.33	31.38
Computer optimism score	53.19	48.56	52.78	58.88 ***

* Monthly average
** Significantly higher than that of the moderate user group at .05 level
*** Significantly higher than that of the light user group at .001 level

members (Nagin, 1999). It has provided valuable insights into studying physical aggression among youth (Nagin & Tremblay, 1999, 2001) and Web utilization and saturation patterns (Christ, Krishnan, Nagin, Kraut, & Guenther, 2001).

A "developmental trajectory" describes the course of a developmental behavior over age or time. DTA assumes that the population is composed of a mixture of distinct groups defined by their developmental trajectories. This method is useful for modeling unobserved heterogeneity in a population, where trajectories vary greatly across population subgroups both in terms of the level of behavior at the outset of the measurement period and in the rate of growth or decline over time. DTA also provides a multivariate procedure to examine impacts of individuals' characteristics on group membership probability, so the influence of the social-cultural factors, such as gender differences, can be evaluated.

Figure 2. Mean group membership probabilities for gender and citizenship

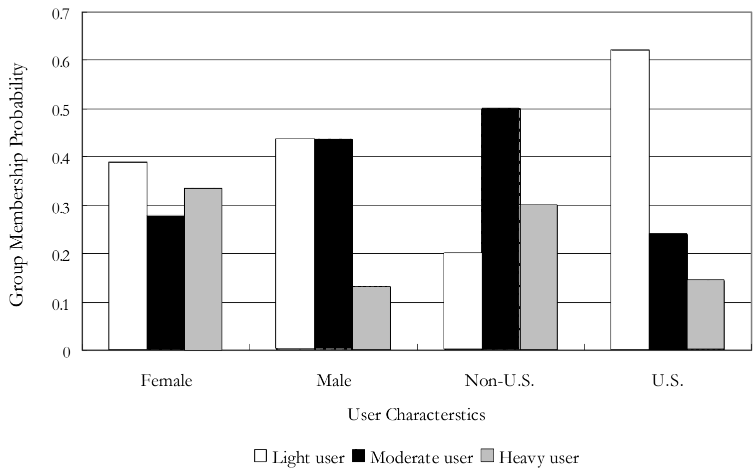

Table 2. The impact of user characteristics on the probability of assignment to usage groups

Variable condition	User Group		
	Light	Moderate	Heavy
Multinomial logit coefficients			
Gender - female	–	-.56 (-0.62)	.27 (0.24)
Non-U.S. citizen	–	1.67 (1.87)	.68 (0.6)
Computer use	–	.045 (.39)	.23 (1.46)
Computer knowledge	–	-.09 (-.985)	-.06 (-.546)
Computer optimism	–	.31 (2.18)	.98 (1.59)
Predicted membership probabilities based on multinomial logit model coefficient estimates			
Without user characteristics	.49	.36	.15
Gender - female only	.54	.27	.19
Gender - male only	.46	.41	.12
Non-U.S. citizen only	.29	.57	.14
U.S. citizen only	.63	.22	.15

RESULTS

The Trajectories

The developmental trajectories obtained from usage data are depicted in Figure 1. Bold and light lines denote observed and predicted trends, respectively. Observed data values are computed as the mean use rate of users assigned to each of these groups identified by estimation, and expected values are computed using DTA model coefficient estimates. We label these three groups as “Light” users, “Moderate” users and “Heavy” users, each comprising 17, 15 and 9 individuals (41.46%, 36.59% and 21.95%, respectively, of all users).

Figure 1 also reveals developmental trends of the adoption behavior. Users classified as “Light” initially utilized the system in about 35% of their encounters, and this rate remained steady over the 10-month study period. “Moderate” users had the highest initial use rate, about 70%, but this rate consistently decreased over the study period to a level comparable with that of the “Light” users. “Heavy” users had an initial use rate of approximately 50%, and this rate increased consistently to about 100% at the end of the study period. Changes in the use rate for members of the moderate group are of particular interest, since it indicates “Moderate” users demonstrated strong enthusiasm initially, while followed by a gradual decline in their use of the system.

Group Profiling

We now examine the association between adoption behavior and user characteristics to identify potential causal relations. Group profiles are shown in Table 1. For example, female users account for two-thirds of the heavy user group, whereas male residents account for two-thirds of the moderate user group. The lower portion of Table 1 shows real-scale measures. On average, each resident saw 8.44 patients each month during the study period (standard deviation 1.89); the maximum count of daily patient encounters is five, but this only occurred a few times. Since the frequency of patient encounters, monthly or daily, was low and relatively evenly distributed among residents, we do not deem this variable useful and will exclude it from further analysis.

The last three rows of Table 1 present the residents’ computer literacy assessments obtained from Cork’s instrument, measuring physicians’ use of, knowledge about and attitudes toward computers (Cork, Detmer, & Freidman, 1998). These three items can be roughly interpreted as how often physicians currently use computers, how much they know about computers, and their relevant beliefs and attitudes. As indicated by Table 1, “Light” users have the highest computer knowledge score and “Heavy” users have the highest computer use and computer optimism scores.

Figure 2 shows the group membership probabilities for each of the categorical variables. For example, male users tend to cluster in the light and the moderate user groups, and non-U.S. citizens are more likely to be present in the moderate user group, whereas U.S. citizens are more likely to be present in the light user group.

Group profiles (see Table 2) are a collection of univariate contrasts. A multivariate procedure is provided in the DTA model to construct a more parsimonious list of predictors to sort out redundant variables as well as to control for potential confounds. Table 2 shows the impact of the covariates of interest on group membership probabilities. The upper panel shows coefficient estimates and t-statistics. We use the light user group as a *contrast group*. That is, for the light user group, the impacts of the covariates are set to zero, and the coefficient estimates for other groups are interpreted as measuring the impact of the covariates on group membership probabilities relative to that of the contrast group.

Table 2 shows the impact of gender on group membership probabilities. If a user is female, the probability of her being in the heavy user group is increased while the probability of her being in the moderate user group is decreased, compared to the probability of membership in the light user group. The lower panel of Table 2 shows the predicted membership probabilities based on multinomial logit model coefficient estimates. For each row, the impact of a single factor is evaluated. Being a female alone increases the probability of membership in the heavy user group. Similarly, having non-U.S. citizenship alone decreases the probability of membership in the light user group and increases the probability of being in the moderate user group. Impact of computer literacy also emerge: A higher score on previous computer use or computer optimism increases the probability of being in the heavy user group, and a higher score on computer optimism increases the probability of being in the moderate user group. In contrast, computer knowledge does not seem to affect usage significantly.

CONCLUSION

In this study, we assess 41 medical residents' acceptance and adoption of a clinical reminder system for chronic disease and preventive care management in an ambulatory care environment. We use a novel developmental trajectory approach to identify distinct groups, following distinct usage trajectories, among those who recorded use of the reminder system within an evaluation period of 10 months. We find that users in this study can be clustered into three groups: "Light" users, who used the system steadily over time for about 35% of their patient encounters; "Moderate" users, whose initial use rate was the highest (70%) among all groups but declined steadily to a level comparable with that of "Light" users; and "Heavy" users, whose use rate, initially moderate (50%), increased to nearly 100% at the end of the evaluation period.

We find that several user characteristics are correlated with usage levels and group membership probabilities. Females are more likely to be frequent users, while males demonstrate the other extreme. Female residents' tendency to comply with system use may be explained by social influence processes, such as subjective norm and their inclination to follow orders. Besides the gender influence, citizenship and attitude towards computers also play a role: Non-U.S. citizens are more likely to be frequency users than U.S. citizens, and computer optimism, rather than previous use and knowledge of computers, increases a user's probability of being a frequent user.

With awareness of such potential causal relations, researchers and practitioners can utilize user characteristics as a means of predicting future levels of usage and adoption. Gender-differentiated training programs and other just-in-time intensive strategies also can be developed and implemented to accomplish higher levels of technology acceptance and use and to minimize undesirable adoption behaviors.

KEY TERMS

Clinical Decision Support System (CDSS): A class of computer applications typically designed to integrate a medical knowledge base, patient data and an inference engine to generate case-specific advice. They intend to support clinical diagnosis and treatment plan processes and promote use of best practices, condition-specific guidelines and population-based management.

Clinical Reminder System (CRS): A computer system developed at Carnegie Mellon University and The West Penn Allegheny Health System. This system uses patients' medical history to provide just-in-time reminders to clinicians at the point of care that reflect evidence-based medical guidelines.

Developmental Trajectory Analysis: A semi-parametric, group-based approach for identifying distinctive groups of individual trajectories within the population and for profiling the characteristics of group members.

Evidence-Based Medicine: The distillation of a large volume of medical research and standards into treatment protocols for diseases and preventive care procedures that represent the most accurate knowledge available.

Health Informatics: A field of study concerned with the broad range of issues in the management and use of biomedical information, including medical computing and the study of the nature of medical information itself.

Information Technology Adoption: A micro process that focuses on the stages through which an individual passes when deciding to accept or reject the innovation of an information technology.

Medical Guideline: A document with the aim of guiding decisions and criteria in specific areas of health care, as defined by an authoritative examination of current evidence (evidence-based medicine). In the U.S., the National Guideline Clearinghouse publishes and maintains guidelines.

Random Control Trails (RCT): In RCT, study participants are assigned at random to either a control or treatment group to avoid bias and assure more objective results. People in the treatment group receive the new drug or are treated with the new device; the control group participants receive a more standard treatment, no treatment or a placebo (a look alike that has no active drug).

Technology Acceptance Model (TAM): An information systems theory that models how users come to accept and use a technology. The model suggests that when users are presented with a new software package, perceived usefulness and perceived ease-of-use are two primary factors that influence their decision about how and when they will use it.

Chapter 5.23
Social Construction of Gender and Sexuality in Online HIV/AIDS Information

The Pennsylvania State University, USA

INTRODUCTION

HIV (human immunodeficiency virus) and AIDS (acquired immunodeficiency syndrome) represent a growing and significant health threat to women worldwide. According to the United Nations (UNAIDS/WHO, 2004), women now make up nearly half of all people living with HIV worldwide. In the United States, although males still accounted for 73% of all AIDS cases diagnosed in 2003, there is a marked increase in HIV and AIDS diagnoses among females. The estimated number of AIDS cases increased 15% among females and 1% among males from 1999 through 2003 (Centers for Disease Control and Prevention, 2003). Looking closer at HIV and AIDS infections among women in the United States, Anderson and Smith (2004) report that HIV infection was the leading cause of death in 2001 for African-American women aged 25 to 34 years, and was among the four leading causes of death for African-American women aged 20 to 24 and 35 to 44 years, as well as Hispanic women aged 35 to 44 years. The rate of AIDS diagnoses for African-American women (50.2 out of 100,000 women) was approximately 25 times the rate for white women (2 out of 100,000) and 4 times the rate for Hispanic women (12.4 out of 100,000; Centers for Disease Control and Prevention). African-American and Hispanic women together represented about 25% of all U.S. women (U.S. Census Bureau, 2000), yet they account for 83% of AIDS diagnoses reported in 2003 (Centers for Disease Control and Prevention).

Women's vulnerability to HIV and AIDS may be attributed to gender inequalities in socioeconomic status, stereotypes of AIDS as a gay-male disease, and cultural ideology around sexual practices such as abstinence, monogamy, and condom use. Because of cultural mores and socioeconomic disadvantages, women may consequently have less access to prevention and care resources. Information is perhaps the most important HIV and AIDS resource for women, and the Internet provides a useful platform for disseminating information to a large cross-section of women. With the flourishing use of e-health resources and the growing number of public-access Internet sites, more and more people are using the Internet to obtain health-care information. Over two thirds of Americans (67%) are now online (Internet World Statistics, 2005). On a typical day, about 6 million Americans go online for medical advice. This exceeds the number of Americans who actually visit health professionals (Fox & Rainie, 2002). Studies also show that women are more likely to seek health information online than are men (Fox & Fallows, 2003; Fox & Rainie, 2000; Hern, Weitkamp, Hillard, Trigg, & Guard, 1998). HIV and AIDS patients are among the health-care consumers with chronic medical conditions who increasingly take the Internet as a major source of information (Kalichman, Weinhardt, Benotsch, & Cherry, 2002).

As more Americans go online for health information, the actual efficacy of the information consumption becomes salient. Recent digital divide studies call for shifting from demographic statistics around technological access to socially informed research on effective use of technology (Gurstein, 2003; Hacker & Mason, 2003; Kvasny & Truex, 2001; Payton, 2003; Warschauer, 2002). Although the Internet provides a health information dissemination platform that is continuous, free, and largely anonymous, we should not assume that broader access and use will be translated into positive benefits. We must begin to critically examine the extent to which e-health content meets the needs of an increasingly diverse population of Internet users.

To combat the AIDS pandemic, it is necessary to deliver information that is timely, credible, and multisectoral. It has to reach not just clinicians and scientists, but also behavioral specialists, policy makers, donors, activists, and industry leaders. It must also be accessible to affected individuals and communities (Garbus, Peiperl, & Chatani, 2002). Accessibility for affected individuals and communities would necessitate targeted, culturally salient, and unbiased information. This is a huge challenge. For instance, health providers' insensitivity and biases toward women have been documented in the critical investigation of TV programs (Myrick, 1999; Raheim, 1996) and printed materials (Charlesworth, 2003). There is a lack of empirical evidence to demonstrate the extent to which and the conditions by which these biases are reproduced on the Internet. In what follows, we provide a conceptual framework for uncovering implicit gender biases in HIV and AIDS information. This framework is informed by the role of power in shaping the social construction of gender and sexuality. We conclude by describing how the framework can be applied in the analysis of online HIV and AIDS information resources.

BACKGROUND

Gupta (2000) has explored the determining role of power in gender and sexuality. Gender, according to Gupta, concerns expectations and norms of appropriate male and female behaviors, characteristics, and roles shared within a society. It is a social and cultural construct that differentiates women from men and defines the ways they interact with each other. Distinct from gender yet intimately linked to it, sexuality is the social construction of a biological drive, including whom to have sex with, in what ways, why, under what circumstances, and with what outcomes. Sexuality is influenced by rules, both explicit and implicit, imposed by the social definition of gender, age, economic status, ethnicity, and so forth (Dixon Mueller, 1993; Zeidenstein & Moore, 1996).

What is fundamental to both sexuality and gender is power. The unequal power balance in gender relations that favors men translates into an unequal power balance in heterosexual interactions. Male pleasure supersedes female pleasure, and men have greater control than women over when, where, and how sex takes place (Gavey, McPhillips, & Doherty, 2001). Therefore, gender and sexuality must be understood as constructed by a complex interplay of social, cultural, and economic forces that determine the distribution of power. As far as HIV and AIDS, "the imbalance in power between women and men in gender and sexual relations curtails women's sexual autonomy and expands male sexual freedom, thereby increasing women's and men's risk and vulnerability to HIV" (Gupta, 2000, p. 2; Heise & Elias, 1995; Weiss & Gupta, 1998).

Based on this feminist approach to theorizing gender and sexuality, Gupta (2000) categorized HIV and AIDS programs in terms of the degree to which historical power dynamics in gender and sexuality were maintained. The categories summarized in Table 1 are depicted in Figure 1 ranging from the most damaging to the most beneficial ones.

In the theory of social construction, HIV and AIDS are represented as a set of social, economic, and political discourses that are transmitted by media (Cullen, 1998). In symbolic interactionism's theory of gender, mediated messages in advertising, TV, movies, and books tell quite directly how gender is enacted (Ritzer, 1996). As the latest platform for computer-mediated communication, the Internet may also adhere to these gendered representations. We theorize that online HIV and AIDS information follows a similar pattern of power reconstruction, and that these categories could be applied to empirically determine how and why online HIV and AIDS information reproduces these power relations.

FUTURE TRENDS

This theoretical framework could be employed in empirical studies that deconstruct online materials to demonstrate how HIV and AIDS gain their social meanings at the intersection of discourses about gender and sexuality. Prior studies in this area have focused on the cultural analyses of AIDS (Cheng, 2005; Sontag, 1990; Treichler, 1999; Waldby, 1996) rather than structural determinants of risk such as political policy, globalization, industrialization, and the economy. Cultural analysis is based upon the belief that this disease operates as an epidemic of signification based on largely predetermined sexual and gendered conventions. The female has now become socially constructed as a body under siege in AIDS discourse. This gendered body is not, however, a stable signifier. Previously, the body was constructed as white, gay, and male. Now the global discourses on HIV and AIDS have constructed the body as third world, heterosexual, and female. Thus, we see a feminization of HIV and AIDS.

Analysis of the social construction of AIDS using this framework could occur at different levels of analysis and with various populations. We conclude with a few examples.

- Garbus et al. (2002) provide a categorization of HIV and AIDS Web sites that could be used for a cross-category or within-category analysis of the representation of gender and sexuality.
- Cultural ideologies around condom use for AIDS prevention and reproductive health could be studied.
- Given the wide disparities in HIV and AIDS infections among women in the United States, research is needed to examine the discursive practices surrounding HIV and AIDS, socioeconomic status, geographic region, and ethnicity or race.
- The absence of lesbians in the HIV-AIDS and women discourse can be analyzed.
- The social construction of the female body in the HIV and AIDS discourse can be studied.

Table 1. Categories of HIV and AIDS programs based on gender and sexuality

Category	Description
Stereotypical	The damaging stereotypes of men are reinforced as "predator, violent, irresponsible" and women as "powerless victims" or "repositories of infection".
Neutral	The target is the general population instead of either gender or sex. Despite no harm done and "better than nothing", the different needs of women and men are ignored. Very often the basis is research that only has been tested on men, or works better for men.
Sensitive	The different needs and constraints of individuals based on their gender and sexuality are recognized and responded to. One example is to provide female condoms. Thus women's access to protection, treatment or care can be improved, but little is done to change the old paradigm of imbalanced gender power
Tranformational	The aim is to transform gender relations to make them equitable. The major focus is on the redefinition of gender roles at the personal, relationship, community and societal levels.
Empowering	The central idea is to "seek to empower women or free women and men from the impact of destructive gender and sexual norms". Women are encouraged to take necessary actions at personal as well as community levels to participate in decision-making. One misunderstanding that needs to be corrected is that empowering women isn't equal to disempowering men. The fact is more power to women would eventually lead to more power to both, since empowering women improves households, communities and entire nations.

Figure 1. Continuum of the social construction of gender and sexuality

- Discursive practices surrounding HIV and AIDS, gender, and development in developing countries are a potential research subject.
- The tension in the social construction of women as both vulnerable receivers and immoral transmitters of this deadly disease can be deconstructed.

CONCLUSION

HIV and AIDS are a complex and pressing issue. It is not just an issue of health, but has also been framed as an issue of personal responsibility, economics, development, and gender equity. It impacts every nation and individual across the globe. In this article, we argue that the increasing epidemic of HIV and AIDS among women is also an issue of information. We propose a framework for unpacking discursive practices that construct women as the new face of HIV and AIDS. We also provide examples of problem domains in which the feminist analysis informed by this framework can be conducted.

KEY TERMS

Digital Divide: Unequal access to and use of computers and the Internet resulting from such socioeconomic gaps as income, education, race, and age.

E-Health: The applications of the Internet and global networking technologies to medicine and public health.

Empowerment Theory: The study of how perceptions of power affect behaviors and how individuals can increase their power through social interaction.

Feminist Theory: Women-centered theory that treats women as the central subjects, seeks to see the world from the points of women in the social world, and seeks to produce a better world for women.

Gender: Expectations and norms of appropriate male and female behaviors, characteristics, roles, and ways of interaction that are shared within a society.

Sexuality: Social construction of a biological drive, including whom to have sex with, in what ways, why, under what circumstances, and with what outcomes.

Social Construction of Information: Information is examined not as objective missives, but rather as data inextricably intertwined with the social settings in which they are encountered.

Chapter 5.24
Community-Based Information Technology Interventions for Persons with Mental Illness

Rosanna Tarsiero
University of Pisa, Italy

ABSTRACT

The chapter provides the reader with an overview of the problems persons with mental illness experience in their everyday life, and guides readers through how ICT access and usage can be approached in order to empower such a marginalized population in both developed and developing countries. It argues that, since isolation is their main problem, networking those people with reliable sources of medical information, providers of distance training and learning, and online self-help communities can have a profound impact on lifting their marginalization. The author hopes that the role ICT can play for these people will no longer be overlooked or neglected, and that policymakers will be inspired to use ICT worldwide to defeat mental illness by implementing solutions tailored on these people's needs.

INTRODUCTION

In thinking about information and communication technology (ICT) helping people with disability, what generally comes to the minds of the researchers are assistive technology tools, like haptic devices providing tactile representations for visual stimuli on a display to persons with visual impairments (e.g., Colwell, Petrie, Kornbrot, Hardwick, & Furner, 1998), similar to the principle of Braille. However, physical disabilities are not the only disabilities that can benefit from ICT assistance.

When one thinks of ICT for development, the thought goes to the pioneering work of the United Nations Development Program (UNDP) in information technology for development initiated in 1993 (UNDP, 2001). Since the United Nations (UN) Secretary-General's words: "Communication and information technology have enormous potential, especially for developing countries, and in furthering sustainable development" (Annan, 1997, p. 1), and the annual World Bank report two years later, new perspectives and understandings led to the inclusion of widespread availability of ICTs into the Millennium Development Goals (UN, 2000b). In order for ICT to help generate changes, it needs infrastructures, domestic and external human resources (Mansell & Wehn, 1998). Thus, the UN launched the United Nations Information Technology Service (UNITeS) initiative (UN, 2000a; UNITeS, n.d.), in which external human resources, the United Nations Volunteers (UNV), join domestic people to solve local development problems through ICT (UNV, 2005). Nevertheless, people in developing countries are not the only ones who can benefit from ICT as a means to their daily development, as reported in many studies on ICT interventions. Populations living in rural areas of the developed countries are also in need of ICT interventions for their development (Huggins & Izushi, 2002).

Finally, the thought of ICT and networking for marginalized communities usually leads to thinking of a group of people who share one or more characteristics, values, and goals, and whose members proactively escape marginalization through some technology-mediated interaction with other people and/or through access to some valuable empowering resources (Phipps, 2000).

People with mental illness somehow belong to all of these categories and more. Many of them have a disability, in that they have special needs to be accommodated and fulfilled, mainly pertaining to emotional skills (MacDonald-Wilson, Rogers, Massaro, Lyass, & Crean, 2002). They need resources for a safe, strong, and sustainable development of their own community, in terms of information on illness and benefits, social networks, job opportunities, housing, and so forth. Finally, they are marginalized, not only and not just because mainstream people exclude them, but also due to the illness and its consequences which generate accessional relational impairment, along with chronic external and internalized stigmas.

In North America, studies on ICT services for persons with mental illness mainly focused on mental health records (Puskar, Aubrecht, Beamer, & Carozza, 2004), telemedicine (Gutierrez, 2001), and e-therapy (International Society for Mental Health Online & Psychiatric Society for Informatics, 2000), while in Europe they focused on delivering community-based mental health services (Draper & Rigby, 2000; Rigby, Lindmark, & Furlan, 1998) and enhancing communication between mental health providers and consumers (Castelnuovo, Gaggioli, Mantovani, & Riva, 2003). As far as nonprofit organizations, the most common use of the Internet for activities related to mental health is advocacy (e.g., National Alliance of Mentally Ill in the United States and Mind in the United Kingdom). In developing countries, ICT solutions have been implemented for general health only and with the specific purposes of delivering continuous medical education, telemedicine, and health e-governance (Chandrasekhar & Ghosh, 2001).

It goes beyond the scope of this chapter to examine cultural differences in causative beliefs on mental illness and in its treatment options (for a review of current theories, see Lonner, Dinnel, Hayes, & Sattler, 2004). Because of the cultural appropriateness of community-based treatments and its therapeutic successes in both developing countries (Barrio, 2000) and in developed countries (Simmonds, Coid, Joseph, Marriott, & Tyrer, 2001), and because of the potentiality of ICT to address such interventions worldwide, this chapter will focus on community-based approaches involving ICT in both these settings, highlighting differences whenever encountered. This chapter will try to show how it is possible for people with mental illness to achieve empowerment through community-based ICT interventions, and how ICT can be an appropriate answer as well as a powerful tool in both developed and developing country settings.

For this to happen, however, it needs to carefully address the issue from three unfolding perspectives: (1) psychosocial factors involved in mental illness, (2) ICT intervention design, and (3) strategic planning.

BACKGROUND

Mental health is a main problem even in countries with high rates of infectious disease (McKenzie, Patel, & Araya, 2004). In fact, people with mental and behavioral disorders are about 450 million worldwide, as many as overall Internet users in 2002 (McKenna & Green, 2002). It is calculated that one person in four will develop one or more mental or behavioral disorders during their lifetime (WHO, 2001). These rates clearly dispel the myth that mental illness is due to some sociological issues linked to higher income or education (McKenzie et al., 2004) and that it is just a problem of rich countries.

Low-income countries estimated direct mental illness costs do not reach developed country levels. That is because the lower availability of resources and coverage of mental health care services in low-income countries tend to raise productivity loss and other indirect costs instead, which account for a larger proportion of overall costs (WHO, 2001). Also, in most developing countries, available resources are misallocated, in terms of favoring low-cost-effective provisions, are not equally available to all the population, and are ineffective, while in middle-income developing countries health costs are exploding (World Bank, 1993). Using the *disability-adjusted life years* (DALY) as an indicator of burden due to the illness (World Bank, 1993) is very useful for psychiatric disorders, in that it accounts for both premature deaths due to suicide and years wasted to chronic disability. Nevertheless, even if mental illness outcome does not imply psychiatric disability in the majority of cases, neither in the developed nor in developing countries (Goldberg & Lecrubier, 1995), and people in the latter have a better prognosis for schizophrenia (Hopper & Wanderling, 2000; Sartorius et al., 1986) and mental illness in general (Jilek, 2001), 5 of the 10 actual leading causes of disability and premature death worldwide are still due to psychiatric conditions (WHO, 2004).

While rich countries neglected community-based approaches in favor of more individualistic ones (McKenzie et al., 2004), a joint paper from ILO, UNESCO, and WHO suggested community-based ones to be the best approach to use in low-income countries (1994). More individualistic Western approaches can be dangerous on other ethnicities (Barrio, 2000), while community-based approaches on Westerners are beneficial (Simmonds et al., 2001), and both the European Union (WHO European Ministerial Conference on Mental Health, 2005) and the United States (U.S. General Accounting Office, 2000) are adopting them. Developing countries, focusing on community-based interventions, obtained significant successes, most noteworthy for post-partum depression in Hong Kong and Fiji (Becker & Lee, 2002). However, those studies mainly focused on prevention, which can be successfully exerted in community-based settings without generating personal feeling of stigma, therefore leading to overall lesser drop-out rates.

Even though effective and appropriate, community-based interventions for persons with mental illness still present some difficulties in their actual implementations, mainly because of such community hallmarks: (1) mental illness as main, shared characteristic; (2) marginalization as social determinant; and (3) remitting impairment in communication among members as peculiarity to address.

One of their major problems is how to overcome difficulties with respect to communication among members, because the definition of community does not fully apply in these settings, unless interaction among members is proactively fostered. They share some characteristics (e.g., mental illness, stigmatization, marginalization, low self-esteem), some goals (e.g., stability, recovery, empowerment, self-determination), and under certain conditions (e.g., belonging to the same kind of self-help group) even values and methods to accomplish those goals. Nevertheless, since psychiatric illnesses are invisible and often concealed or denied in fear of stigma, members of the same theoretical community may be unknown to each other. This accounts for the possible lack of interaction, interaction that is essential to create and sustain a functional community of peers with which to share values and pursue common goals.

A second problem of community-based approaches is, paradoxically, the meeting settings. Again in fear of stigma, people with mental illness are tempted not to make use of available face-to-face community-based programs. Regardless of the benefits, enrollment can force disclosure, in that workers for the supporting association and any other person on the street might see them getting to the meeting place. Something similar is known to happen in both developed and developing countries when accessing mental health care (Eapen & Ghubash, 2004) and/or welfare, where just being enrolled generates fear of stigma, to the point of avoiding enrollment or withdrawing from an awarded benefit (Stuber & Kronebusch, 2004).

Addressing community-based interventions through ICT also poses other problems, in terms of ICT, Internet access, and issues arising from it. Depending on countries and actual location within that country, in both developed and developing countries ICT infrastructures, telephones, and power lines can be more (or less) available (ITU, 1997, 2004). Usually, developed countries have a lesser number of under-served areas and less people living in rural areas, while in developing countries, an average of 70% of citizens live away from urbanized areas. In both settings, cities are better served in terms of infrastructures, telephones, and power lines. Since the success of the "Asian Tigers," especially Korea, is largely due to the heavy investment government put in building infrastructures such as Internet backbones and letting the market do the rest (ITU, 2004), some governments of middle-income countries already invested into providing the country with a discrete number of backbone nodes (Mansell & Wehn, 1998).

However, access to ICT is still distributed in a very unequal way between developed and developing countries (Paua, 2003; Pentland, Fletcher, & Hasson, 2004). Within developed countries, there are many smaller digital divides (ITU, 1997), depending on income, education, and location of Internet users (Phipps, 2000). In developing countries, higher costs and lack of infrastructures and reliable continuous electric power (Mansell & Wehn, 1998), costs of hardware equipment, use of a non-English language and non-Westerner cultures sum up with lower income, education, and computer literacy. Higher rates of population living in rural areas (Chandrasekhar & Ghosh, 2001; Paua, 2003) extend the divide.

In developed countries, governments, businesses, and nongovernmental and nonprofit organizations addressed those divides by lowering Internet access fees and/or supporting tax-exempt personal computer purchases (European Council, 2000). These provisions can have an impact on actual Internet user numbers because infrastructure and electric power are already present and reliable in most countries, and even when they are not, those governments usually have or can easily get access to funds for their realization. Furthermore, there are a lesser number of people living in rural zones, average income allows users to purchase required hardware and software, education is high enough to know (or easily learn) how to use ICT, English is spoken as a first or second language, and users belong to the "dominant" Internet culture.

In developing countries, higher relative costs (especially when compared with lower wages), lack of infrastructures, and lack of reliable electric power induced many governments and non-profit organizations to opt for implementing a system of shared accesses rather than personal ones (Pentland et al., 2004). These authors also highlight the widespread use of wireless technology as a possible alternative to shared access, similarly to what happens in rural areas of developed countries, in that wireless is less expensive than copper lines, and cables in general have difficulties reaching remote areas (ITU, 2004). Pentland et al. advocate the use of an asynchronous wireless service like DakNet, implemented in India with success. Rural populations, thanks to a bus with a wireless device, get asynchronous Internet access that allows them to send and receive e-mails, for example with the purpose of interacting with governmental offices and thus saving in high transportation costs.

Aside from infrastructure, in many countries Internet access still has its own, separate costs, and universal Internet access is not a reality yet. In general, access fees are higher in Europe than in North America, because flat rates are less common in Europe. However, both Europe (European Council, 2000) and North America (Greenstein, Lizardo, & Spiller, 1997) enacted access policies for lowering access cost with the aim of reaching rural and low-income areas. A way both developed and developing countries addressed this problem is shared accesses in public places. In developed countries, hospitals, schools, and libraries generally have some provision for citizens to freely access e-government and information. In developing countries, public kiosks have this function (Badshah, Khan, & Garrido, 2004).

Even if all these considerations are necessary beyond any doubt, especially when considering ICT implementations in developing countries, Mansell and Wehn (1998) observed how too often ICT debates are geared on hardware requirements rather than software design and information content. Knowledge, its production, its circulation, and its sharing confer to a society the capability of sustaining development via the Internet (Lundvall, 1992). The appropriateness of those attributes can make all the difference in the demand for ICT applications, more so for people with mental illness for which Saraceno and Barbui (1997) theorized that the service-delivery richness, not service availability in itself, is responsible for better outcomes in developing countries.

Aside from information retrieval, the Internet can be used for online networking, since online networks can use asynchronous communication to promote a sense of community (Schuler, 1996). Community-based ICT has theoretical grounds to be employed for people with mental illness. Online settings are of help because of their remoteness and lack of physical cues. Remoteness can play a pivotal role for different, converging reasons. Most importantly, it eliminates barriers to service fruition, especially the ones consequent to symptoms and medication side effects (e.g., agoraphobia, anhedonia, low energy, dizziness) that most characteristically prevent people with mental illness from venturing outside and interacting with others. In developed countries, person with mental illness can be helped to get low-fee home Internet access, because of widespread connectivity. In developing countries and wherever resources and connectivity are limited, asynchronous wireless communication similar to DakNet is a possible way to allow participation into such online communities, because sending and receiving e-mails does not take much bandwidth. Secondarily, online settings are more disinhibiting (McKenna, Green, & Gleason, 2002; Suler, 2004) and people with mental illness are less afraid of being judged for their appearance and for what they have just disclosed (McKenna & Bargh, 1998). Since it is extremely unlikely for participants in the same online community to also live in the same physical community, advantages of disclosure might be full (for an overview on disclosure, see Ralph, 2002).

Though the findings related to virtual community behavior originated in rich countries, they have been already transposed with success to virtual communities in the developing world (Wagner, Cheung, Lee, & Ip, 2003). According to these authors, online communities in developing countries (in this study, Africa, Armenia, Bangladesh, China, India, and Peru) differ from their counterparts in developed countries because they: (1) are knowledge oriented, (2) require an e-mail hub to save bandwidth, (3) have interaction-generated content, and (4) are highly autonomous in nature. However, these findings were relative to virtual communities generated for e-governance purposes only, ruling out a virtual community as a source of emotional support a priori due to its expensive settings. Though this might be true for illnesses whose treatment is promptly available, because professionals are available and/or because the person does not have problems in reaching out to such professionals, those considerations might not apply to people with mental illness, for which self-help can cut costs in terms of favorable outcome of the illness. It is also important to highlight how the Chinese virtual community, that also served as support, became integrated at the same cost as others, possibly because of the higher value such culture poses on collaborative behavior.

Online self-help groups overcome participation barriers, because they are available in timing and locations in which face-to-face groups are not. If members have home computers and access, such as in developed countries, online groups are available every day of the week for as long as the member wishes to use them. If members access through kiosks, like in developing countries, they are available whenever the kiosk is open.

Physical cues take a heavy toll on contributing to prejudices and stigma. They determine whether a relationship of any kind will develop, just on some external characteristics. Some mental illnesses can be evident from just the way a person dresses, so appearance is a major concern for such people and rejections based on look are not that unusual. Therefore, the lack of physical cues, so characteristic of computer-mediated communication (Sproull & Kiesler, 1991), is a very important tool to foster acceptance, trust, and relationships in marginalized online communities. The richer a media is, in terms of immediate feedback, focus on the recipient, language variety, and communication cues/channels availability (Daft & Lengel, 1986), the more overwhelming it can be, especially to persons with mental illness that already tend to have a lower stimulation threshold. Therefore, an impoverished media could be a consistent advantage for such persons.

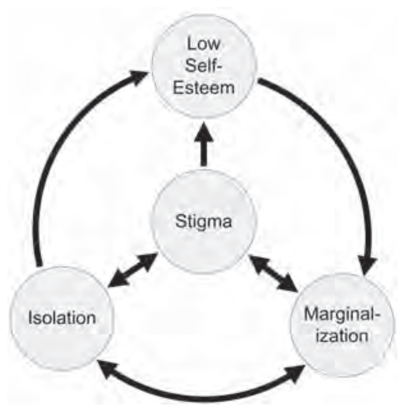
EMPOWERING ESCAPE FROM MENTAL ILLNESS

The Mental Illness Circle

Stigma, marginalization, isolation, and low self-esteem influence each other deeply (Figure 1). Interventions addressing one of these problems, therefore, have repercussions on all the others, but rarely does addressing one problem at a time lead to any resolution. For this reason, it is preferable to implement strategies that simultaneously address each of the problems, even if every one is addressed just partially.

The most common kind of stigma people with mental illness face is the interpersonal one, or

Figure 1. Vicious circle of stigma, low self-esteem, isolation, and marginalization



external stigma. A growing body of literature from developing countries (for a review see Jilek, 2001; for some country profiles see: Hugo, Boshoff, Traut, Zungu-Dirwayi, & Stein, 2003; Karim, Saeed, Rana, Mubbashar, & Jenkins, 2004; Khandelwal, Jhingan, Ramesh, Gupta, & Srivastava, 2004; Raguram, Raghu, Vounatsou, & Weiss, 2004; Regmi, Pokharel, Ojha, Pradhan, & Chapagain, 2004; Shibre et al., 2001) confirms that external stigma is also a problem for people with mental illness located outside the developed world.

However, only five Western psychiatric disorder constructs were found to be applicable transculturally: schizophrenia, brief reactive psychoses, major depression, bipolar disorder, and anxiety-related ones (Ameen, 2002). Constructs like *trauma* are culturally bound syndromes (Eyber, 2002), as well as *koro* (Jilek, 2001). Even disorders found to be transculturally applicable manifest themselves with symptoms (Bhugra & Mastrogianni, 2004; Jilek, 2001) and verbalizations (Draguns, 1990) that still vary with culture, in a process called *pathoplastic*.

Different cultures stigmatize people for different reasons and in different ways. In developed countries, often because of media, persons with mental illness are frequently stigmatized as violent (Angermeyer & Matschinger, 1996; Glasgow University Media Group, 1996) and/or incompetent (Byrne, 1997), while in Nigeria they are regarded as being possessed by an evil spirit (Kabir, Iliyasu, Abubakar, & Aliyu, 2004) and in Haiti as being voodooed (Desrosiers & St Fleurose, 2002).

Also, different mental illnesses carry different degrees of stigma. As an example, Balinese people stigmatize people with obsessive-compulsive disorder much more than people with schizophrenia or depression, while the reverse is true for Japanese (Kurihara, Kato, Sakamoto, Reverger, & Kitamura, 2000), Latin Americans, and Caribbeans (de Toledo Piza Peluso & Blay, 2004).

Finally, within the same illness, different symptoms raise different reactions and concerns, which strongly depend on culture. In India, sadness is stigmatized more than physical complaints, and the difficulty to find somebody to marry because of mental illness is a major concern (Chowdhury et al., 2001), while in Western countries the concern is more about losing a job and inability of performing.

For all these reasons anti-stigma campaigns need to be tailored on cultural determinants of stigma (Angermeyer, Buyangtus, Kenzine, & Matschinger, 2004).

Whichever the set of mainstream assumptions contextual to the culture of people with mental illness live in, they are defined in terms of their disorder. This process of dehumanization creates a behavioral stereotype believed to be truly and accurately reflective of persons with mental illness, who become therefore marginalized through the culture of blame (Farber & Azar, 1999). Also, symptomatic experiences of persons with mental illness are reframed by mental health professionals through a technical jargon that is not always respectful of their feelings and experiential knowledge. This is an implementation of the culture of blame typical of stigma related to mental illness (Burton & Kagan, 2005). Because of past episodes (Hayward, Wong, Bright, & Lam, 2002), acute symptoms, medication side-effects, labeling due to diagnosis (in some cultures), changes in social status, and feelings of disempowerment, persons with mental illness internalize the stigma, which leads them to think to be the way the behavioral stereotype defines them to be. This internalized belief results in giving up on hope for the future and in feelings of impossibility to change their lives to attain people's respect and self-respect. According to Dinos, Stevens, Serfaty, Weich, and King (2004), stigma also influences acceptance of the diagnosis, adherence to treatment, and even daily functioning.

Regardless of causal mechanisms differing from developed to developing countries, there exists a very well-known association between poverty and mental illness (Saraceno & Barbui, 1997). Mental illness can induce economical marginalization, through disability and job loss, but also social marginalization, due to incarceration, stigma, symptoms, and low income. In developed countries, the lack of community ties and support is considered to be responsible for the worse outcome mental illness tends to have (Jilek, 2001). In developing countries, where societies are not so much fragmented and attention to social relationships is higher because of poverty (Payne, 2001), outcomes tend to be better (Sartorius et al., 1986). Marginalization prevents excluded people with mental illness from full personal, interpersonal, and social lives (Burton & Kagan, 2005), thereby lowering their self-esteem even further. Social status, to which marginalization is partly linked, shifts according to degree of activity and type of illness. Marginalization itself can lead to low self-esteem and isolation other than disempowerment (Burton & Kagan, 2005). Marginalization due to joblessness, low-income, lower education, and disability also lowers connectivity in developed countries like the United States (Pew Internet and American Life Project, 2003). Limited access to resources also diminishes greatly the opportunity of exiting this vicious cycle and creating meaningful relationships.

Internalized stigma and the shame elicited by symptoms are reinforced by lack (or unavailability) of accurate de-stigmatizing information and resources on the illness and its course. That leads to possible symptom hiding in the attempt to avoid facing a hopeless illness that, in turn, enhances stress levels and worsens the illness itself. A recrudescence of the illness endangers the characteristics of available social networks, possibly severing such availability. Internalized stigma also correlates negatively with self-esteem (Link, Struening, Neese-Todd, Asmussen, & Phelan, 2001), empowerment, and recovery orientation (Ritsher, Otilingam, & Grajales, 2003). For all these reasons, "existential loneliness" is often the hallmark of the person with mental illness (Nystrom, Dahlberg, & Segesten, 2002).

On a personal level, any illness has the potential to make a person feel defective, more so mental illness, especially in those societies whose fulcrum is mind, intelligence, control, power, performance, and rationality. Though culture can influence the weight such constructs have, self-esteem and life satisfaction are cross-cultural (Diener & Diener, 1995). This, too, endangers pre-existing social networks and these persons' trust in their capability of forming new ties, generating a self-fulfilling prophecy.

There are many kinds of initiatives to attenuate stigma, marginalization, isolation, and low-self esteem. Anti-stigma campaigns are based on the contact hypothesis — that is, people who had previous contacts with persons with mental illness have less stigma. Many campaigns are also based on the biomedical model of mental illness. In both cases, however, results have been contrasting. The contact hypothesis has been confirmed in several studies conducted in Germany (Angermeyer & Matschinger, 1997), in the United States (Roth, Antony, Kerr, & Downie, 2000), and in Russian populations (Angermeyer et al., 2004), but refuted in those conducted in Nigeria (Ohaeri & Fido, 2001), Oman (Al-Adawi et al., 2002), and Hong Kong (Callaghan, Shan, Yu, Ching, & Kwan, 1997). Social distance, defined as unwillingness to get close to people with mental illness, has multiple components, each needing to be addressed (Lauber, Nordt, Falcato, & Rossler, 2004). Nevertheless, attributing mental illness to biological causes seems to be counterproductive, in that in most recent studies it was repeatedly found to increase social distance (Angermeyer, Beck, & Matschinger, 2003; Dietrich et al., 2004). A way to explain these findings is to think the biological metaphor associates persons with mental illness to some degree of unpredictability (Read & Law, 1999) or perceived lack of power over the condition itself. In some settings, the biological model of mental illness can enhance stigmatization by depicting persons with mental illness at par, resulting in patronization. At the same time for some other reasons, the sociological model of mental illness can reduce the sense of personal responsibility and control. Blaming the illness on something external to a person, such as trauma or society, does not address the psychological reaction to the illness and the person's role in reacting against the illness. However, in both the cases, persons with mental illness are reduced to by-products of a chemical imbalance or victims of society malfunctions.

Other ways to provide against stigma, isolation, and low-self esteem are self-help groups, some of which also address resource development and/or mental illness advocacy. The main characteristic of self-help groups is their aim at individual change (Kurtz, 1997, p. 4), and the mechanism by which the change happens is the individual actions to help themselves (Borkman, 1999, p. 4). The self-help movement was born in the United States with Alcoholics Anonymous, but it quickly spread to the rest of the world (Armstrong, 1993). Self-help groups have a defined goal or a set of defined goals (e.g., alcohol moderation for Moderation Management, sobriety with the help of a Higher Power for Alcoholics Anonymous, sobriety without the help of a Higher Power for Rational Recovery, etc). They also have a well-defined method to accomplish their goal that varies from ideology to ideology, each being unique of that group (e.g., a book of Abraham Low's for Recovery Inc., the Big Book for Alcoholic Anonymous, etc). Other than being change-oriented, self-help groups are led by peers, participation in them is voluntary and are free of charge (Kurtz, 1997, p. 4).

In developed countries, the interest in self-help groups was promoted by the high cost of medical services, the lack of alternative to the bio-medical model, and the emphasis on prevention (Reissman & Carroll, 1995). This model can be adopted in developing countries as they lack medical services due to high cost, lack alternatives to traditional healing models, and often focus on prevention as a requirement of mental health assistance programs. So, in 1997, the United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP), in an attempt to improve the condition of persons with disability by supporting the spreading of self-help to developing countries, published the *Guidelines on Establishing and Strengthening Self-Help Organizations of Disabled Persons*. Self-help ideology matches the sustainable development concept because "…the capacity to acquire and generate knowledge in all its forms, including the recovery and *upgrading of traditional knowledge*, is perhaps the most important factor in the improvement of the human condition" (Bezanson & Sagasti, 1995, pp. 5-6). It is useful to remember how the success rate in treating mental illness depends on the *number* of available options, *not* on the kind of options available (Halliburton, 2004). Among the many benefits of self-help groups are: (1) information sharing, (2) engaging in problem solving, and (3) developing social networks. Self-help groups also allow the ability to assist more persons with less money, a useful characteristic for both developing country setting and developed countries with managed care systems (Murray, 1996).

To date, there is no online community-based outreach program that systematically addresses reduction in marginalization, stigma, isolation, and low self-esteem of people with mental illness through the use of ICT and networking. Even if some of the self-help groups mentioned above have an online presence, there is not any online self-help group advocating for this kind of provision to be extended worldwide as first-line community-based intervention for people with mental illness.

Breaking the Cycle Through Community-Based ICT

There is at least one moment in the lives of persons with mental illness in which they come to experience isolation. All of a sudden, they become sick with basically no information on the illness, no idea on where to start searching, no social support, and no available community resource.

Community-based ICT solutions have to take into account possible hurdles in their implementation, mainly: (1) literacy and culture, (2) ideology and culture, and (3) peculiarities of online self-help and culture.

Literacy and culture. Online groups tend to be multicultural, because their members usually join from several countries. Unless the group is a regional one or speaking a language spoken in only limited parts of the world, online communities require higher literacy in participants (in terms of knowing a second language and being fluent in text-based communication). However, multicultural environments have better chances for a positive outcome in helping people with mental illness, because they offer more options than a one-culture-only would.

Ideology and culture. Any self-help group intervention needs to be designed in terms of ideology (approach to the illness and its drawbacks), shared values (kind of interaction among members that is being proactively fostered), and shared goals (ways to overcome everyday problems created by the illness). It is essential for a self-help group to trust members enough to share stories and experiential knowledge in an accepting and respectful climate, so the ideology has to encompass some provisions for encouraging people of all cultures to express themselves.

Peculiarities of online self-help and culture. Self-help is a "holistic approach to people's cultural, economic, and social needs" (Braithwaite, Waldron, & Finn, 1999) that is a strong asset in an intercultural, distributed environment. However, Internet groups differ from face-to-face groups in their dynamics (McKenna & Bargh, 1998, 1999; McKenna & Green, 2002) and present special challenges, because group member fluency, as well as their computer literacy, social condition, formal education, financial status, sex, ethnicity, and age, can vary greatly. Cultural barriers are not immediately apparent and when they become so, they can be surprising to deal with, especially because of the disinhibiting effect of the medium.

Of the many possible community-based ICT interventions, three are worthy of being suggested as starting points: (1) medical information retrieval, (2) online learning and training, and (3) online self-help.

Information retrieval. According to the Pew Internet and American Life Project (2003), more than 8 out of 10 Americans have searched specific information on the net and 93% of those surfers searched medical information at least once. Among medical disorders, 39% of people search information about psychiatric disorders (Pew Internet and American Life Project, 2002). In the developing world, kiosks have the purpose of connecting people to information. People with mental illness are in particular need of online information about their disorder, because even buying books on mental illness in a bookstore can be somewhat stigmatizing, since families and friends of persons with mental illness also get stigmatized, in a process called *courtesy stigma* (Angermeyer, Schulze, & Dietrich, 2003). Furthermore, asking the doctor for the exact diagnosis and explanations connected with it is a behavior that depends on culture and pre-existing patient-doctor relationship (Bensing, Roter, & Hulsman, 2003; Ohtaki, Ohtaki, & Fetters, 2003).

Though most medical information on the Web is available for free, availability does not imply reliability, any more than reliability implies comprehensibility. The first quality initiative, Health On the Net (HON) foundation, was launched in 1995. HON has multiple aims: codifying a set of features that qualifies a site with medical information as reliable, issuing a certification of medical information quality (HON seal), defining a procedure to check on sites that display the HON seal, and doing some sort of *post-marketing surveillance* on certified sites (Nater, Boyer, & Eysenbach, 2000). Though the site assessment is a rigorous process, unfortunately HON certification is released on a voluntarily basis. That means it cannot be imposed on every site with medical information, but just revoked in case of non-compliance with HON Code of Conduct. For a review of all Internet health information quality initiatives, see Risk and Dzenowagis (2001). In searching the Net for medical information, some basic medical literacy skills are required, in order to also discriminate what is evidence-based from what is not (Sackett, Rosenberg, Muir Gray, Haynes, & Richardson, 1996). Medical information is of particular importance for people with mental illness, because psycho-educational interventions are shown effective in mental illnesses management and relapse prevention, especially bipolar disorder (Colom et al., 2003, 2004). Online psycho-education has been recently proven effective as well (Christensen, Griffiths, & Jorm, 2004). Furthermore, from an individual perspective, knowledge is empowering in itself, because it gives people the sensation that they are able to gain control over their lives.

The Internet is also useful in helping people with mental illness to gather information and connect to resources that can assist them in improving their income status (e.g., welfare, cash and energy assistance programs, housing, etc). To show all the importance of such provisions, Thomson, Petticrew, and Morrison (2001) report how housing improvement has a promising impact on physical and mental health outcomes. Many advocacy and governmental sites have useful link collections, nevertheless they rarely explain laws and regulations in layman terms, or offer assistance of some sort in filling out the paperwork. Some states in the U.S. and some European countries have benefit portals by which it is possible to check qualifications in advance, so not to apply uselessly. In developing countries, asynchronous broadband connectivity may ensure this same kind of service (Pentland et al., 2004).

Online training and learning. As Lundvall (1992) stated, "The most fundamental resource in our economy is knowledge" (p. 1). In the United States, over half of surfers used the Net to perform a search somehow related to online training and/or education (Pew Internet and American Life Project, 2003), and improved access to education is another strategy suggested by WHO (2004) to fight mental illness. Online training and/or learning can be a way to include persons with mental illness into a productive society. For this reason, its designers have to know which kind of training content they might need. Macdonald-Wilson et al. (2002) found that the most important functional limitations people with mental illness have regarded both interpersonal and cognitive skills. This implies that the training people with mental illness need more is on soft skills. Online learning, being self-paced and remote, is highly susceptible of accommodation, satisfying the most frequent kinds of accommodation requested by such people: flexible schedule (EEOC, 1997) and interpersonal facilitation with colleagues (Zuckerman, 1993). However, this is not always possible in developing countries, because of bandwidth and hardware limitations (Mansell & Wehn, 1998). Effective online learning environments are learner centered, knowledge centered, assessment centered, and community centered (Bransford, Brown, & Cocking, 1999). That means it takes into account the learning style of the learner but also of the discipline that is being taught, giving many opportunities for assessment, peer-assessment, and self-assessment, without neglecting the online social interactions upon which learning depends (Kreijns, Kirschner, Jochems, & Van Buuren, 2004). Staying at home even when regularly taking classes, asynchronous communication brainstorming and socialization, course material flexibility, and accommodation (in terms of colors, fonts, and formats) allow people with mental illness to better cope with symptoms, and possibly complete course materials and assignments even in conditions under which they would not be able to go to school and perform. More accommodations enhance performance, and that in turn increases self-efficacy (Bandura, 1994) and self-esteem. Online learning is more cost effective (Mansell & Wehn, 1998), especially when it takes cultural differences into account.

Online self-help. According to Moore (2000), social interaction is the primary use of home computers, and e-mail is the most used computer application in the United States (Pew Internet and American Life Project, 2003), as well as in Ghana (Dzidonu, 2004). Surfers do not limit their interactivity to private e-mails. In fact 84% of American Net surfers contacted an online community and 79% stayed in contact with it, while 26% used e-mail to contact a local group (Pew Internet and American Life Project, 2001). Social support and strengthening community networks are strategies recommended by WHO (2004) as primary prevention for mental illness. Creating an online community network is a sustainable target, because many search engines also offer free group membership, and that does not raise costs of this intervention, nor require special software. In order to make it an attainable goal as well, some considerations on online communication and dynamics are mandatory. Online written communication is a hybrid between oral and written communication (Bordia, 1996), more precisely a written substitute for oral communication (Jonsson, 1998). Pennebaker and Seagal (1999) studied written expression of emotions comparing it with talking, showing how they have the same effect, as long as emotions are involved in both cases. By storytelling, even in written form, people are helped in reframing and overcoming their stories. Also, people with invisible stigmatized conditions can benefit more from this intervention if they focus on what makes them different from non-stigmatized populations rather than what makes them similar. Computer-mediated communication is less inhibited than face-to-face (Suler, 2004) and has a hyper-personal effect (Walther, 1996). According to this theory, online communication can exceed face-to-face, especially in that personality cues that would normally go unnoticed assume stronger meanings. Furthermore, the information flow in computer-mediated interaction is slower (Liu, 2002) and less overwhelming, especially to people with mental illness. Having the possibility of thinking more before replying is a definitive advantage for people dealing with impulsivity. Some of these theories could be why computer-mediated communication has such an excellent impact on virtual groups for marginalized people (McKenna & Bargh, 1998). McKenna et al. (2002) also noticed how people experiencing social anxiety, difficulties with social interactions, and isolation prefer to locate more often their "real self" online.

There are a number of reasons why online settings could be an appropriate tool for people with mental illness as far as social support is considered. Because having a solid support network is essential to recovery and the need of socialization is part of the feeling of empowerment, the main problem to address is how to form a stable community for people with mental illness, and which type of community to form. Both support and self-help groups are available alternatives. Self-help groups are more suitable to this task, because their ideology and method are well-defined: theoretical foundations can be tested, effectiveness and outcome evaluated, they can be both reproduced in similar realities and adapted to different settings. On the contrary, support groups often do not have a codified method, rely too much on the individual that leads them, and outcomes are unpredictable and difficult to even detect since there is no expected behavioral change as a consequence of attendance. Peers volunteering to lead such a self-help community have to be trained in that specific ideology. They also have to be trained in online group dynamics and in online community design, because creating community networks cannot be done successfully without considering the community members right from the start (Andrews, Preece, & Turoff, 2001). Group size (Foth, 2003) and dynamics (McKenna & Green, 2002) are important variables to consider for successful community design.

FUTURE TRENDS

Using information technology and networking for the empowerment of people with mental illness worldwide is a very stimulating challenge. For what pertains to people with mental illness in low-income countries, it involves bridging the existing digital divide between developed and developing countries (Paua, 2003). It also involves bridging the many smaller digital divides embedded in the developed societies (Mansell & Wehn, 1998; Paua, 2003). Such a complex process is not only about finding funding sources to bridge those gaps, but it is about allocating resources and using existing technologies and infrastructures in a quite creative way (UNCSTD, 1997).

Some implementation ideas on how to move from this point on can be borrowed from a managerial perspective. In strategic planning, needs and nature of the services to be offered have to be assessed, along with its possible competitors.

Possible interventions for people with mental illness can be roughly divided in two categories: one provided by professionals (like psychiatrists, psychologists, and social workers, more present in developed countries, and Ayurvedic and religious healers, more present in developing countries) and another provided by peers (in the form of self-help or support groups). A third form would be group therapy, in which a professional leads a group of peers. Potential competitors of online self-help groups are face-to-face groups and e-therapy. The former have the same advantages of their online counterparts, save for timing and locations, plus the big advantage for people who are not literate enough to use a computer. In developing countries, where population is mainly rural, transportation costs for going to a self-help face-to-face meeting have to be considered. E-therapy does not have transportation costs, but fees are quite high and it could be culturally inappropriate for people in developing countries. Competitors of medical online information are face-to-face medical information and information following other paradigms of treatments for mental illness. The latter could be culturally more appropriate and therefore could be inserted in community-based ICT informational intervention as one more option to have, thereby enhancing outcome responses (Hulliburton, 2004). Finally, online learning/training's main competitor is an onsite one, which in developing countries is feasible mainly in urbanized areas.

Among risks and pitfalls of community-based ICT approaches, the refusal of this perspective by policymakers because of cultural shock has to be considered. Linguistic analysis of written communication nowadays allows us to distinguish persons with depression or prone to have it from persons without it (Rude, Gortner, & Pennebaker, 2004), persons with suicidal ideation from persons without it (Stirman & Pennebaker, 2001), and even liars from honest people (Newman, Pennebaker, Berry, & Richards, 2003). Therefore, existing tools should be able to understand written communication with much higher reliability than in the past. Though missing of physical and social cues (Sproull & Kiesler, 1991), computer-mediated communication does not lack in nonverbal cues. In fact, time (chronemics, see Walther & Tidwell, 1995) and distance (proxemics, Jeffrey & Mark, 1998; Krikorian, Lee, Makana Chock, & Harms, 2000) are nonverbal cues that do convey, for example, the importance of the conversation topic for a given person. Emoticons are used (Walther & D'Addario, 2001), as well as verbs, to transform equivocal into univocal statements, like for example during jokes. Therefore, the effective use of these tools allows the user to utilize computer-mediated communication in a far richer way than in the past. Nevertheless, many persons, also among information technology professionals, are still polarized on neglecting social communication nuances in favor of task orientation, and interpreting differences between computer-mediated and face-to-face communication as pre-mediated inferiority (or superiority) to one over the other. They often still insist in not modifying their communication style according to the media they use. Working with information technology and networking for empowering people with mental illness teaches both researchers and policymakers how to overcome old myths and rigid constructs. Ultimately, what technology is able to bring us strictly depends on how the medium is being used. Researchers can decide to shape the technology or be shaped by it (Schuler, 1996), and it is up to them to make a responsible choice, never forgetting how the choices will have repercussions on the rest of society, nevertheless.

In order for an information technology organization to be able to lead the change, it also needs a shift in its attitude toward leadership. Just recently, Sosik, Jung, Berson, Dionne, and Jaussi (2004) analyzed the differences between the older *strategic leadership* and the newer *strategy-focused leadership.* In the latter case, leaders do not focus on strategy, but on how to produce an organization that is focused on strategy. They connect people, technology, work processes, and business into a community. This construct has the big advantage of adding social capital to the leadership process. In ICT organizational settings, this is even a more precious skill, especially when dealing with initiatives for developing countries.

Convincing mainstream funders, donors, developers, and colleagues of the theoretical foundations, practical effectiveness, and cost effectiveness of such approaches will be necessary in order to create the required shift to use existing resources, technologies, and infrastructures in a different, more creative way. An excellent way to do so is to validate the theories with research, within an evidence-based framework. Mutated from medicine (Sackett et al., 1996), this approach to implementations and policies are, slowly but increasingly, substituting opinion-based and consensus-based guidelines and becoming *best practices.* With an evidence-based approach, the implementer may be able to have a theory, produce evidence of its appropriateness, and implement reproducible programs based on it. Moreover, the other users will be able to use the same words meaning the same definitions. These concepts will be portable from one situation to another.

In developed countries, information connectivity is already very high, so using this viable and available technology for people with mental illness and scientifically testing the outcome not only has its rationale, but is definitely more sustainable than insisting in reaching consensus-based approaches or in using old opinion-based methods. In developing countries, another reason to favor evidence-based approaches is because resources for marginalized people of any kind are spare and misallocated and cannot be unethically wasted in implementing solutions whose effectiveness is unproven.

In ICT in general, but especially in those programs designed to technologically assist developing countries, the social aspect of interaction is often neglected in favor of a more technology-based approach. Rather than exporting the "developed" approach, they could rather learn how to use the focus on community that is used in other countries. Because connectivity alone does not ensure community (Foth, 2003), the developer's attention has to shift from how to access information to how to *use* information (Lundvall, 1992; Menou, 2001) and assist this shift with careful community design as opposed to mere system design. Factors to take into account when designing a community are: provision of socio-cultural animation, population of the network, attention to sociability, and care for human-to-human ties (Foth, 2003). This is even more important for people with mental illness for whom empowerment, positive personal interactions, social support, and community networks are social protective factors (Hosman, Jané-Llopis, & Saxena, 2005). Therefore, interventions addressing ICT and network usage for people with mental illness have the potentiality to be the primary prevention, thus opening up a further unexplored scenario.

Implementation of online psycho-educational, self-help, and training projects, even in isolation from one another, could test the feasibility of this model and discover its possible pitfalls, with particular regard to gathering and packaging information for psycho-education, searching, and selecting possible old and new self-help models that want to try online delivery of service, training of peers providing online services, feasibility of cheap online training and learning for this population, and usability of online learning materials, also in terms of culture.

Given the high potential for the sustainability and effectiveness of this approach, researchers in the field should focus on: how to build fully functional and effective online self-help groups, how to promote standardization in medical information site user ratings, and how social learning can be integrated into online communities.

CONCLUSION

People with mental illness worldwide are a very large community, often marginalized for concomitant socio-economical factors. Among poorest members, not just access to medical care, but even access to reliable information about the illness, and social and network support — including training resources — are denied, impaired, or otherwise jeopardized by the absence of resources, infrastructures, and economical support to provide reliable Internet access to their population. Illness, poverty, but also lower social status, low self-esteem, stigma, and no hope for a better future make it virtually impossible for them to exit from this vicious marginalized cycle. To persons in these conditions, empowerment sounds like nothing but a word. And it is precisely for this reason that empowerment at personal, interpersonal, and societal levels becomes essential.

People with mental illness might have difficulties interacting with others, both other persons with mental illness and *normal* ones. This may be true whether they are actively symptomatic or not. If symptomatic, the Internet can be their only access to low-cost reliable medical information, as well as providing networking opportunities with other persons with mental illness. If not symptomatic, access to ICT and networking can be a valid answer to many practical problems to escape poverty and marginalization. With a computer and Net access, they can connect with resources of any kind, even when low self-efficacy and self-esteem rather than the illness itself do not allow them to venture into the world. This is especially true for persons with mental illness who also belong to another stigmatized population (e.g., LGBT, minorities, people with physical disabilities, jobless, HIV-positive, low-income, etc.). Therefore, in both developed and developing countries, ensuring low-cost connectivity is the starting point to move further in assisting people with mental illness, whenever literacy is high enough to utilize it.

But even when they have the financial and material resources to buy what they need in order to get connected, like in developed countries, they might not know where they need to go to address their informational, social, and learning needs. Financial provisions to consistently enhance the connectivity of people with mental illness would be a beginning, but that has to be followed by a package of designed resources to acquire information, social networks, and resources that could really make a difference in their life.

Many online interventions could empower them. Ensuring psycho-education, e-learning, and supportive facilitation interventions to people with mental illness is a challenge that will give them capacity and skills to overcome these challenges and participate equally, as they deserve.

In this context, bridging the digital divide has become a rehabilitative challenge, particularly bringing affordable ICT, network access, and sustainable interventions to jointly address stigma, marginalization, isolation, and low self-esteem. Unfortunately, the world cannot be changed as long as the initiators are reluctant to change their mindset, adopting an eclectic approach and being open to paradigm shifts on how to utilize the available resources.

KEY TERMS

Community-based approaches: Strategies that address problems of disadvantaged populations through the involvement of the community they belong to, as a whole but at different levels. Community-based interventions encourage promotion of service delivery, equitable opportunities, human rights, and quality of life of such populations through implementations taking place into venues familiar to the target populations (i.e., churches, libraries, schools). This kind of approach is becoming increasingly popular due to both its sustainability and trans-cultural effectiveness.

Computer-mediated communication: Communication between two or more persons that happens through technological devices, such as a computer and the Internet. These interactions differ from face-to-face ones in that they are written, remote, and lack physical cues. They can be synchronous (like chat rooms or instant messaging) or asynchronous (like e-mails). However, they are able to foster a sense of community, thereby generating social capital.

DALY: Method for calculating the health impact of a disease in terms of reported (or estimated) cases of premature death, disability, and days of infirmity due to illness from a specific disease or condition. For each disease or risk factor, DALY is calculated as the annual sum of the years of life lost due to premature mortality and the *years lived with disability* in the population for that health condition. DALY extends the concept of potential years of life lost due to premature death to include years of *healthy* life lost by virtue of being in states of ill health.

Online self-help: Online self-help groups aim at individual change by helping people help themselves, like traditional self-help groups but in online settings. They overcome the participation barriers traditional self-help groups have by taking advantage of the anonymity and disinhibition characteristic of online settings, in order to foster deeper disclosure and acceptance, with particular respect to embarrassing situations, non-mainstream preferences, and stigmatizing health conditions.

Patient education: Interventions for providing persons with an illness with some medical education about their disorder in order to improve compliance to hygiene measures and medications, recurrence prevention, management of the illness, short-term and long-term outcomes, and quality of life. Health care professionals, qualified publications, and/or trained peer-counselors usually distribute medical information. For many illnesses this is a low-cost, evidence-based intervention.

People with mental illness: Mental illness displays itself as difficulties in behaving, thinking, and/or interacting with other persons, and has very high rates worldwide. Symptoms vary from accessional relational impairment, along with chronic external and internalized stigmas, to actual psychiatric disability that needs accommodation. Furthermore, people with mental illness also experience stigma, marginalization, isolation, and low self-esteem that influence one other and the illness course deeply.

Virtual learning: Consists of acquiring formal education through the Internet, generally in a self-paced way. A variety of online environments are available (Web interface, e-books, e-mails, e-groups, tele-classes, chat rooms, instant messaging, one-to-one tutoring, study buddy, group work, and others), and all are learner centered, knowledge centered, assessment centered, and community centered. Even though virtual learning is not suitable for all kind of learners, it is usually more cost effective than traditional onsite learning.

Chapter 5.25
The Impact of Professional Certifications on Healthcare Information Technology Use

Neset Hikmet

Anol Bhattacherjee
University of South Florida, Tampa, USA

ABSTRACT

This study examines the effects of professional certifications such as JCAHO on healthcare information technology (HIT) usage in healthcare organizations and user satisfaction with such usage. Using survey data collected from healthcare administrators in a nation-wide sample of 347 hospitals and long-term care facilities, we provide evidence that professional certifications do indeed enhance HIT usage and user satisfaction, at least within specialized user groups such as healthcare administrators. We further demonstrate that this increase in HIT usage due to professional certifications increases with facility size and is more prominent for larger hospitals than for smaller long-term care facilities, though the same cannot be said of user satisfaction. Our study suggests that professional certifications can be used as a valuable tool for motivating HIT usage, while also drawing attention to an under-examined area of HIT research.

INTRODUCTION

As the cost of healthcare has soared in the United States, rising to $1.7 trillion or 15.3% of GDP in 2003 (CMS, 2005), the role and use of healthcare information technology (HIT) has come into increased focus. HIT, in this context, refers to a wide range of clinical systems such as electronic medical records (EMR), computerized patient order entry (CPOE), and pharmacy information systems, and administrative systems such as patient billing systems, budgeting systems, and scheduling systems, that are expected to streamline healthcare delivery to patients, improve healthcare quality, and reduce delivery costs. In the report presented to the U.S. Congress by the Medicare Payment Advisory Commission (MEDPAC, 2004), HIT was identified as having the potential to significantly improve the quality, safety, and efficiency of healthcare. A similar report by the National Health Leadership Council (NBCH, 2005) identified HIT as the critical foundation for promoting health system reform, generating productivity and performance improvement, and producing significant cost reduction in healthcare expenditures.

As healthcare organizations face increasing pressure to invest in HIT, many healthcare managers are struggling to find ways to motivate physicians, nurses, and administrators to use the implemented HIT. Clearly, technology deployment is futile if users do not use the technology, use it inappropriately, or find ways to circumvent its usage. For instance, in 2003 doctors at the prestigious Cedars-Sinai Medical Center at Los Angeles rebelled against their newly installed CPOE system, complaining that the system was too great a distraction from their medical duties, forcing the withdrawal of a system that was already online in two-thirds of the 870-bed hospital (Freudenheim, 2004). The Leapfrog Group (an advisory group associated with the National Academy of Sciences) estimated that, of the nation's 300 non-governmental hospitals (6% of all hospitals in the U.S.) that have implemented comprehensive HIT systems, only 40 of these systems (less than 1%) are routinely used by of doctors for ordering prescriptions and laboratory tests (Freudenheim, 2004).

One technique that is expected to motivate HIT use among hospital administrators is professional certifications (Chow, 2001; Watcher, 2004). Many hospitals nationwide seek certification from the Joint Commission of Accreditation of Healthcare Organizations (JCAHO) to demonstrate their commitment to quality in healthcare delivery through the use of HIT and to meet eligibility requirements for participation in the government's Medicare and Medicaid programs (Associated Press, 2004). A significant requirement of JCAHO certification is continuous monitoring and tracking of a variety of operational statistics such as design of new services, implementation of safety plans, and infection control, which require the use of HIT. Furthermore, information management, potentially using HIT, is a key concern in the JCAHO certification process, including management of patient-related information, use of comparative information, and the transmission of national hospital quality measure data (JCAHO, n.d.). Hence, it is incumbent upon healthcare administrators to use the available HIT appropriately in order to meet and continue JCAHO certification status for their facility.

In this paper, we examine whether professional certifications such as JCAHO are indeed effective in motivating HIT use among administrators in healthcare settings. Additionally, we are interested in knowing whether JCAHO-induced HIT usage patterns vary across different types of healthcare organizations such as hospitals and long-term care facilities (nursing homes). Given the size and revenue differences between hospitals and long-term care facilities and the consequent availability of slack financial and technological resources to devote to HIT-driven quality initiatives such as JCAHO certifications, one may expect the motivation for JCAHO and HIT usage to be different across these organizations. Furthermore, given the broader scale and scope of hospital operations relative to long-term care facilities, the benefits of JCAHO may be disproportionately larger for the former than the latter.

Examining these issues is important for both practical and research reasons. From a practical standpoint, though JCAHO certification is eagerly sought by healthcare facilities nationwide, there is no evidence yet that such certification indeed yields significant quality and performance gains through the use of HIT. Though professional certification may be one potential tool in a manager's arsenal to motivate organizational HIT use, at least within certain user groups such as healthcare administrators, to the best of our knowledge, no prior study has yet examined whether such certifications are effective in the first place. Our study addresses this gap by examining the effect of certifications on HIT use by using field survey data collected from a random national sample of healthcare executives working for JCAHO certified and non-certified hospitals and long-term care facilities. If professional certifications are indeed effective in enhancing HIT usage and improving healthcare delivery, as expected, then organizational investments in such certifications and/or similar quality initiatives will be cost-justified. Furthermore, our study may also provide some evidence as to which type of healthcare organization stands to benefit most from JCAHO certification and related HIT usage.

From a research perspective, understanding the role of professional certifications is interesting also because much of the prior research on HIT usage has focused almost exclusively on user perceptions of the usefulness and ease of use of a given HIT, users' personal attributes such as information-seeking preference and Internet dependence, and situational characteristics such as healthcare needs (e.g., Wilson & Lankton, 2004). However, currently we know little about what organizational and/or structural factors can motivate given HIT deployment and usage among healthcare organizations to improve healthcare delivery. For instance, one of the stated concerns of the U.S. government is to understand organizational factors that enable or hinder HIT use among healthcare organizations (AHCPR, 1998). The ultimate goal of our work is to provoke enough interest among academics to study the underlying structural factors, such as professional certifications, that may help explain why HIT deployment is more successful in some organizations and less successful in others.

The rest of the paper proceeds as follows. In the next section, we present our research hypotheses and theoretical rationale for the same. In the third section, we describe our empirical methods for data collection and analysis to test the our hypotheses. Following this, we discuss our observed findings and their implications and limitations. The paper concludes with a summary of our key findings and suggestions for future research.

RESEARCH HYPOTHESES

JCAHO is a non-profit organization whose mission is "to continuously improve the safety and quality of care provided to the public through the provision of health care accreditation and related services that support performance improvement in health care organizations" (www.jcaho.org). As part of their accreditation procedure, JCAHO has been independently auditing the operational and quality performances of healthcare facilities in the U.S., once every three years, since 1994. Even though JCAHO certification is not mandatory for hospitals or other healthcare facilities, it is a prestigious award that implies that the facility is in compliance with the standards set by the accrediting organization and routinely implements and evaluates required quality indicators in all functional areas of the organization, including management of information (Watcher, 2004). Further, JCAHO certification is required for a healthcare facility to participate in Medicare and Medicaid programs, which are often large revenue sources for many healthcare organizations.

The JCAHO accreditation or re-accreditation process is based on a site visit, during which the JCAHO team evaluates how well a hospital meets more than 500 standards specified in the . This data is then aggregated into 46 "grid elements," 16 "performance areas," an overall performance score (on a 0 to 100 scale), and an accreditation decision (e.g., accreditation with commendation, conditional accreditation, accreditation denied, unaccredited, etc.). One key performance area recently added to the certification process is the "management of information," which includes grid elements such as information management planning, availability of patient-specific information, data collection and analysis, literature to support decision making, and use of comparative information. JCAHO certification requires formal evaluations of each of the metrics just mentioned and an ongoing organizational commitment to meeting JCAHO standards, performance elements, and scoring requirements.

JCAHO accreditation and re-accreditation procedures require hospital administrators to continuously monitor and document a wide variety of healthcare and patient safety statistics, such as adverse drug events and infection occurrences. Though JCAHO does not regulate what kind of HIT should be deployed or how it should be used or managed, it does encourage HIT usage as a reliable and timely means for tracking patient and healthcare quality information. For example, Standard IM.1.10 in JCAHO manual relates to information planning: "The hospital plans and designs information management processes to meet internal and external information needs"; and Standard IM.4.10 addresses information-based decision making: "The information management system provides information for use in decision making" (MLANET, 2006). The heavy record keeping, information processing, and periodical reporting needs imposed by JCAHO are therefore expected to motivate healthcare executives to aggressively deploy and utilize HIT to conform to JCAHO needs. Furthermore, meeting the JCAHO objectives by virtue of their HIT usage can be expected to enhance healthcare administrators' satisfaction with HIT usage, in consonance with positive associations between technology usage and user satisfaction reported in the information technology implementation literature (DeLone & McLean, 1992). These expectations lead us to hypothesize:

H1. Administrators in JCAHO certified facilities have (a) higher HIT use and (b) higher user satisfaction than those in non-JCAHO certified facilities.

JCAHO accreditation and re-accreditation require substantial financial and technological resources on the part of the accredited facility. Sophisticated HIT systems and applications are required to continuously track and monitor a wide variety of JCAHO performance and quality metrics and take remedial actions if things go wrong. A high level of financial resources and technological expertise is required to not only achieve such capability, but also to maintain it over the long-term. Larger organizations such as hospitals are likely to have more slack resources to devote to HIT investments than smaller organizations such as long-term care facilities. Once the appropriate HIT system is implemented, the better fit between the technology and administrators' tasks (e.g., tracking JCAHO metrics, etc.) may be expected to enhance their actual usage of HIT. Further, larger organizations, by virtue of their greater scale and scope of operations, are often able to distribute the benefits of JCAHO certifications over a wider array of services and divisions, resulting in greater satisfaction among healthcare administrators. Hence, we propose:

H2. The effect of JCAHO certification on (a) higher HIT use and (b) higher user satisfaction is greater for administrators of hospitals than for long-term care facilities.

RESEARCH METHODOLOGY

Survey Approach

Empirical data for testing our hypotheses was collected via a mail survey of healthcare administrators in hospitals and long- term care facilities throughout the United States. We focused specifically on healthcare administrators as the key informant in our study because these individuals were responsible for meeting JCAHO tracking and reporting needs and were expected to use HIT systems to do so. Our sampling frame consisted of a list of healthcare organizations purchased from a list broker that specializes in healthcare mailing lists. This list included the name, address, and type of healthcare facilities (e.g., hospital, long-term care) throughout the U.S., along with the names, addresses, phone numbers, and titles of senior executives (e.g., chief executive officers, presidents, managers, supervisors) in those organizations. A stratified sampling scheme was utilized, in which we categorized organizations in the sampling frame into three strata based on facility type: hospitals, long-term care facilities (e.g., nursing homes or assisted living facilities), and community health centers[1]. A sample of 6,713 respondents, divided proportionally (10% of each population stratum) among the three strata, was selected randomly as targets of our survey research.

Our survey followed the approach recommended by Dillman (1978), intended to maximize response rates and minimize non-response bias. Using this approach, we first sent out post-cards to our target respondents informing them of the pending arrival of a survey questionnaire regarding the role and use of IT in the healthcare sector and soliciting their participation in this survey. Twenty postcards were returned as "non-deliverable" due to invalid addresses or the addressee having moved to a different organization. Valid subjects were then mailed the questionnaire booklet, along with a personalized cover letter and a postage-paid envelope for mailing back responses. Five weeks later, the questionnaire was mailed to non-respondents again, followed five weeks later by a reminder card urging them for the third time to respond to the survey if they had not already done so.

Following this multi-round survey, 550 surveys were returned, for an overall response rate of 8.2%. To test for non-response bias, we conducted two multinomial distribution tests comparing the distribution of facility type (hospitals and long-term care, vs. community health centers) and respondents' position (upper management vs. administrative staff) in our sample with that of the population (as aggregated from the facility data provided by our mailing list provider). Chi-square analyses for these differences were non-significant for both facility type (χ^2=5.61, p=0.16) and respondent's position (χ^2=2.53, p=0.11), suggesting that our sample was reasonably representative of the target population. The population and sample distribution for these two dimensions are shown in Table 1.

The community health centers stratum was dropped from further analysis because very few of the responding centers were JCAHO certified or were interested in JCAHO certification. Additionally, being local, non-profit, and community-owned, and serving low income and other underserved communities, the vision and operational structure of community health centers were significantly different than that of hospitals and long-term care facilities. This divergence in vision and goals likely resulted in different motivations for HIT use or non-use in these facilities, further justifying their omission from our data sample. However, the remaining two strata were retained in our study because of higher levels of JCAHO certifications in these strata. Furthermore, hospitals were much larger in size (in bed count, number of employees), scope of operations (e.g., procedures served), and availability of resources than long-term care facilities. Hence, these facilities can respectively be considered to be proxies of large and mid-sized organizations. A comparative examination of these two facility types therefore not only helped us assess the generalizability of the effect of professional certifications, but also helped us examine whether organizational size might have had some influence on the hypothesized effect.

Variable Operationalization

Our two independent variables of interest were professional certification (presence vs. absence of JCAHO certification) and facility type (hospitals

Table 1. Population and sample distributions

	Sampling Frame	Percentage	Study Survey	Percentage
Position				
Upper Management	4642	69.4	398	72.2
Administrative Staff	2051	30.6	152	27.6
Facility				
Hospital	1666	24.9	144	26.1
Long-Term Care	3671	54.8	316	57.4
Community Health Centers and Others	1356	20.3	91	16.7

Table 2. Descriptive statistics

		Professional Certification		
Facility Type		JCAHO Certified	Non-Certified	Total
Hospital	Number of observations (%) Mean HIT use Mean user satisfaction	98 (85.2%) 59.82 10.10	17 (14.8%) 25.24 8.35	115 (100%)
Long-Term Care	Number of observations (%) Mean HIT use Mean user satisfaction	58 (25.1%) 25.34 9.89	174 (74.9%) 22.20 8.98	232 (100%)

Legend: HIT use scores were calculated as a sum of 10 items that captured the number of hours spent by the respondent on using 10 common HIT applications in the healthcare sector, such as reporting, billing systems, forecasting, etc. User satisfaction scores were calculated as a sum of two 1-7 Likert scales. Hence, overall satisfaction scores for each respondent ranged from 2 to 14.

vs. long-term care facilities), and our two dependent variables were HIT usage and user satisfaction. The independent variables were captured as single fill-in measures in our survey questionnaire (e.g., whether the facility was JCAHO certified or not, and whether it was a hospital or a long-term care facility).

HIT usage was measured as the number of hours respondents (healthcare administrators) used HIT per day. Specifically, our survey questionnaire asked respondents (healthcare executives) to enter the number of hours they spent per week at work using 10 common HIT applications, such as reporting systems, billing systems, and error tracking systems. Self-reported hours across these 10 categories were added to create an overall HIT use score for that respondent. This detailed elaboration of usage statistics across different HIT was expected to elicit the respondents' true level of usage, which is often masked in self-reported usage measures employing Likert and similar scales.

User satisfaction with HIT use was computed by summing two seven-point Likert-scaled items (anchored between "strongly disagree" and "strongly agree") that asked respondents the extent to which they were satisfied with the IT available at their workplace and the level of support they received from IT staff at work. This satisfaction scale was based on a similar scale developed and validated by Tan and Lo (1990). Likert scale was appropriate for this measure because satisfaction was a perceptual construct and is best measured as such.

DATA ANALYSIS AND FINDINGS

Sample Characteristics

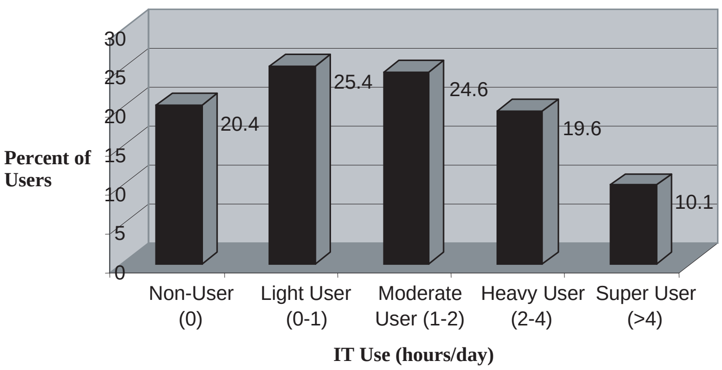
Following two rounds of reminders, our field survey resulted in an effective sample size of 347. This sample consisted of 115 hospitals and 232 long-term care facilities. Overall, 156 of the 347 facilities in our sample were JCAHO certified, and 191 were not. Ninety-eight of the 115 hospitals in our sample (85.2%) were JCAHO-certified, but only 58 of the 232 long-term care facilities (25.1%) enjoyed this certification, demonstrating a divergent pattern of JCAHO certification between these groups. This pattern is indicative of the organizational makeup of these two facility groups. Many long-term care facilities have fewer employees and perform tasks of less complexity in comparison to hospitals, thus making their recording and reporting activities a less important task for administrative staff and consequently resulting in the reduced dependence on JCAHO certification. Sample breakdown by groups, along with HIT use and user satisfaction means within each group, are reported in Table 2.

For descriptive analysis, we classified respondents into five categories based on their overall level of self-reported HIT use: (1) non-users: 0 hours per day, (2) light users: 1 hour or less per day, (3) moderate users: 1-2 hours per day, (4) heavy users: 2-4 hours per day, and (5) super users: more than 4 hours per day. This classification was based on an initial pilot study of healthcare executives (Hikmet & Burns, 2004). The frequency distribution of HIT use is shown graphically in Figure 1. It is interesting to note from this figure that more than 20% of the healthcare administrators in our sample did not use HIT at all, and more than 70% spend two hours or less per day on work-related HIT use. While this apparent low level of use may reflect respondents' time constraints at work, the required tracking and reporting by JCAHO and similar regulatory organizations are not bound by such constraints.

Hypotheses Testing

To test for the two hypotheses stated earlier, we first conducted a two-way multivariate analysis of variance (MANOVA) test to examine whether our two independent variables, professional certification (JCAHO vs. non-JCAHO) and facility type (hospitals v.s long-term care facilities), and their interaction had any significant effects on our two dependent variables of interest: HIT use

Figure 1. Extent of HIT use



and user satisfaction. MANOVA results, shown in Table 3, were significant for both professional certification (F=8.34, p<0.001) and facility type (F=3.67, p=0.026), while the interaction term between the two variables was weakly significant (F=0.97, p=0.053).

Next, we conducted follow-up analysis of variance (ANOVA) to examine which of the dependent variables experienced significant effects. As seen in Table 3, professional certification had a significant effect on both HIT use (F=7.17, p=0.008) and user satisfaction (F=9.46, p=0.002), when controlled for facility type. In contrast, facility type had a significant effect on HIT use (F=7.10, p=0.008), but not on user satisfaction (F=0.250, p=0.618), when professional certification was controlled. The interaction between professional certification and facility type also had a significant effect on HIT use (F=4.98, p=0.026), but not on satisfaction (F=0.94, p=0.332).

These analyses validate our first hypothesis that JCAHO certifications not only increases HIT use among healthcare administrators (Hypothesis H1a), but also increases user satisfaction with such use (Hypothesis H1b). HIT usage was more pronounced in larger facilities such as hospitals than in mid-sized facilities such as long-term care facilities, but user satisfaction experienced no such differential effect across facility types. Focusing on the interaction effect posited in the second hypothesis, we find that JCAHO certification had a stronger effect on motivating HIT use among hospital administrators than those in long-term care facilities (validating Hypothesis H2a), but did not increase user satisfaction among hospital administrators significantly more than those in long-term care facilities (failing to support Hypothesis H2b). Implications of these findings are discussed in the next section.

DISCUSSION AND CONCLUSION

Implications for Practice

The findings of our study confirm that healthcare managers can indeed motivate HIT usage within their organizations by proactively engaging in and obtaining professional certifications such as JCAHO. The incentive to maintain JCAHO accreditation works as an adequate incentive for healthcare administrators to use HIT systems appropriately to meet the monitoring and reporting requirements of JCAHO. Furthermore, administrators appear to be satisfied with their HIT usage, despite the demanding needs of JCAHO accreditation and re-accreditation. However, we do not have any evidence to examine whether this higher level of use among healthcare administrators translates into higher usage among other user groups such as physicians or nurses. Additional studies, with different subject populations, are required to examine those trends.

Table 3. MANOVA results

Independent	MANOVA		Dependent	ANOVA	
Variable	F-statistic	p-value	Variable	F-statistic	p-value
Prof. Certification	8.34	<0.001	HIT Use	7.17	0.008
			User Satisfaction	9.46	0.002
Facility Type	3.67	0.026	HIT Use	7.10	0.008
			User Satisfaction	0.25	0.618
Prof. Cert. x Facility Type	2.97	0.053	HIT Use	4.98	0.026
			User Satisfaction	0.94	0.332

Hospitals in our study experienced a larger increase in HIT use from JCAHO certification than long-term care facilities. Extrapolating this size effect, we expect that smaller-sized organizations such as doctors' offices stand to benefit least from professional certifications and, hence, professional certification programs may not be a worthwhile investment for smaller organizations such as long-term care facilities and community health centers. Furthermore, user satisfaction is expected to remain relatively invariant across facility types between JCAHO certified and non-certified groups. Hence, managers should measure HIT usage and not user satisfaction to evaluate the outcome of JCAHO certification process, and more so for smaller facilities.

Implications for Research

Our study contributes to HIT research by providing preliminary empirical evidence regarding the role of professional certifications on HIT use and user satisfaction in healthcare organizations. Though such certifications undoubtedly enhance an organization's stature and prestige in its community and signal its commitment on quality processes, their effect on HIT use in particular was unclear and unexamined prior to this study.

Our study also draws attention to organizational factors such as professional certifications that managers can control to motivate HIT usage within their organizations. While much of the prior HIT usage research has focused on personal or cognitive factors, such as perceived usefulness and perceived ease of use as antecedents of IT usage and user satisfaction (e.g., Wilson & Lankton, 2004), and has demonstrated good predictive abilities, it is worth noting that such factors cannot be controlled by managers and are therefore less relevant from a practitioner standpoint. In that sense, our study goes beyond predicting IT usage to the more relevant question of examining how organizations can proactively manipulate HIT use though professional certifications.

Though our study was conducted in a healthcare setting, our findings can be expected to be generalizable to other industry sectors. For instance, many firms in other industries seek ISO-9000 from the International Standards Organization to signal their commitment to similar quality improvement initiatives. Software firms often participate in CMM (Capability Maturity Model) certification initiatives from the Software Engineering Institute for similar reasons. However, additional studies are required to test for these effects.

Limitations of the Study

Finally, like most other empirical studies, our research was not without limitations. First, this study was conducted within the narrow context of healthcare organizations. Hence, our findings may not be readily generalizable to other industry sectors without conducting additional studies to test our reported effects in other industry contexts (e.g., manufacturing or service). Second, we viewed professional certification as an instance of a quality initiative, since such certification requires prior evaluation of organizational processes and procedures in accordance with the certification agency's norms and expectations. However, one may debate whether certification is an accurate or reasonable proxy of quality programs. Hence, the value and importance of our findings may be limited in instances where professional certification is not consistent with organizational quality initiatives. Third, the nature and substance of professional certifications vary widely across certification agencies, their scale and scope of certification, and certification metrics employed. Though JCAHO certification is viewed as being one of the most comprehensive and prestigious quality certifications in the healthcare industry, similar certifications from other agencies may be less valued. Such variance in certification quality may mitigate the nature of HIT use effects across certification agencies.

Future Research Directions

This study examined only two of several organizational factors, namely professional certifications and facility type (size), that can motivate HIT usage and user satisfaction among healthcare organizations. There may be more such organizational factors with comparable or greater predictive ability, and we encourage future research to uncover and investigate those factors. Second, we observed that the effects of some of these organizational factors are invariant for user satisfaction, while varying for HIT usage. Since HIT usage tends to be positively correlated with user satisfaction, this divergence of effects is theoretically perplexing. Additional research is required to examine potential reasons for such divergence. Third, future research can also examine the generalizability of our study's findings across other industry sectors (e.g., financial or technology), across other user groups (e.g., physicians or nurses), and across other forms of professional certification (e.g., ISO-9000 or CMM).

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of medical informatics, more specifically related to successful IT governance in the healthcare sector. Particular contributions address the implementation of large IT projects in healthcare institutions and the effective measurement of cost efficiency in healthcare. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of the role of IT in both healthcare and medical research.

Chapter 6.1
Governing Health Care with IT

Reima Suomi
Turku School of Economics and Business Administration, Finland

INTRODUCTION

The pressures for the health care industry are well known and very similar in all developed countries: altering populations, shortage of resources as it comes to staff and financial resources from the taxpayers, higher sensitivity of the population for health issues, new and emerging diseases, just to name a few. Underdeveloped countries have different problems, but they also have the advantage of being able to learn from the lessons and actions the developed countries made already, maybe decades ago. On the other hand, many solutions also exist, but they all make the environment even more difficult to manage: possibilities of networking, booming medical and health-related research and knowledge produced by it, alternative care-taking solutions, new and expensive treats and medicines, and promises of the biotechnology.

From the public authorities point of view, the solution might be easy: outsource as much as you can out of this mess. Usually, the first ones to go are marginal operational activities, such as laundry, cleaning, and catering services. It is easy to add information systems to this list, but we believe this is often done without a careful enough consideration. Outsourcing is often seen as a trendy, obvious, and easy solution, which has been supported by financial facts on the short run. Many examples show that even in the case of operational information systems outsourcing can become a costly option, not to speak of lost possibilities for organizational learning and competitive positioning through mastering of information technology.

In this article, we discuss how information technology and health care industry work together. Information technology is a valuable resource that must be managed within the health care industry. At the same time, information technology has the potential to renew the whole industry. Good practices in both must be supported by good IT governance.

Health care is a big resource user in every country. In Table 1 we have percentages of health care expenditures in relation to gross domestic product in selected countries, where the percentage is very high (WHO, 2004). As one can see, the cost explosion phenomenon hits both rich and poor countries, even though the wealthiest countries are well presented in the list.

Health care costs can be born by different parties within a national economy. Shares of different potential cost carriers vary from national economy to economy:

- The national government, directly or through different indirect arrangements such as separate funds or public insurance institutions
- Municipalities or other local public actors
- Private insurance institutions
- Employers
- The patients themselves

For example, in the United States, the raising costs of health care born by the employers have been a topic of much academic and industry discussion (Berry, Mirabito, & Berwick, 2004). Sadly enough, there is controversial evidence whether information technology can lower the total costs of running health services (Ammenwerth, Gräber, Herrmann, Bürkle, & König, 2003; Ko & Osei-Bryson, 2004).

There are few other forces than modern information technology that could cut down costs in the health care industry. In addition to cost cutting, information technology can provide extended productivity and is an ingredient in the processes that cumulate towards better care practices. But advantages from information technology are not to be harvested without constant focus on IT governance issues in the industry.

Table 1. Top 20 percentages of health care expenditure in relation to gross domestic product in 2001 in selected countries (WHO, 2004)

USA	13.9
Lebanon	12.2
Cambodia	11.8
Switzerland	11.0
Uruguay	10.9
Germany	10.8
Timor-Leste	9.8
Marshall Islands	9.8
France	9.6
Jordan	9.5
Argentina	9.5
Canada	9.5
Greece	9.4
Surimare	9.4
Australia	9.2
Palau	9.2
Portugal	9.2
Iceland	9.2
Croatia	9.0
Belgium	8.9

BACKGROUND

We have found the following reasons for the late adoption of modern information technology in the health care sector (Suomi, 2000):

- Fragmented industry structure
- Weak customers
- Strong professional culture of medical care personnel
- Hierarchical organization structures
- Handcrafting traditions
- One-sided education
- Big national differences in processes

We will next discuss each of these issues in greater detail.

Fragmented Industry Structure

Good competitors and customers are a key to success for any company and industry (Porter, 1990). Unfortunately, the health care sector has not been able to enjoy from neither of them. For a long time health care has been considered as a faceless public service, where normal competitive forces are not in effect. Health care organizations have not felt each other as competitors, and neither have they documented productive cooperative behavior. First with penetrating privatization the situation is starting to change.

Weak Customers

As it comes to customers, most often they get into touch with the industry when in a critical and sensitive situation, where bargaining power is very low. Bad service has just to be suffered. First during the last few years the concept "customer" has started to substitute the word "patient." Regulative bodies have become active in this respect, and for example in Finland a special patient-ombudsman has been institutionalized and legislation on patient reclamation and insurance has been introduced. In general, new technology is seen as a method to empower patients (Beun, 2003).

Strong Professional Culture of Medical Care Personnel

Professional cultures can have a profound outcome on organizational outcome. Within the health care sector, there are many strong professional cultures, the strongest of them being those of doctors and those of the nurses. People seeking to these professions usually value human interaction, and are not much up for abstract systems such as computers.

Hierarchical Organization Structures

A part of hospital organization has always been a strong hierarchical, professional and specialized structure. Work on the computers, unfortunately, is low on the hierarchy list, especially of course in the activities of keying in patient data that would be a natural thing to do for the doctors. As EITO (1995, p. 46) put it: "*for many Health Care applications, the most difficult obstacles can be social and cultural*." It is well known that information system development and application can be very difficult or at least different from less bureaucratic organizations than the health care.

Handcrafting Traditions

Even when we conclude that health care is a very information intensive industry, it has not been considered as such one. A good doctor is valued because of his handcrafting skills, especially in surgery, and it is not being understood that behind the handcraft operations a vast amount of knowledge is needed. Some, anyway, have understood that human body is the most complex entity in the world and of which information and knowledge has been collected over thousands of years.

One-Sided Education

Education of health care personnel has traditionally not focused on computer skills. Even the classical university tradition has kept medical and natural science (and thus computer) faculties apart from each other. Fortunately, during the last years, the drive for deeper cooperation between different science fields has begun to bear fruit.

Big National Differences in Processes

Patient care is very culturally bound, and especially the administrative processes behind vary greatly from one country to another. This, of course, makes standardization very difficult and the industry a bad target for suppliers of standard software and platforms. Neither do we have any dominant players in the field that would behave in the market as strong customers and trend setters.

Currently, however, not even the health care industry can not escape the tsunami of modern IT.

IT has to be governed within the industry and IT and governance structures meet in two ways. At one side, IT enables new governance structures for the health care industry. On the other, it is an object needing governing. As both sectors offer a multitude of new possibilities, innovations are called for in the industry.

IT governance thinking matures in organizations as any other discipline. Van Grembergen, De Haes, and Guldentops (2003) defined the following stages in their IT Governance Maturity Model:

- Nonexistent
- Initial/ad-hoc
- Repeatable but Intuitive
- Defined Process
- Managed and Measurable
- Optimized

Needless to say, in the health care industry, IT governance thinking is nonexistent or initial/ad hoc in the best situation.

HEALTH CARE, GOVERNANCE, AND IT

The Meaning of IT Governance Structure in Health Care

IT is an old acronym for information technology. Very often it is now replaced with the term *ICT,* referring to information and communication technology. This is to emphasize the communication services that are developing very fast, such as the Internet and mobile services. The letter "C" is often upgraded to the second dimension—alongside communication it can refer to contents. IT or IT governance is defined (IT Governance Institute, 2001) as follows:

IT governance is the responsibility of the board of directors and executive management. It is an integral part of enterprise governance and consists of the leadership and organizational structures and processes that ensure that the organization's IT sustains and extends the organization's strategies and objectives. (p. 10)

For many there is a temptation to understand governance as just a synonym for *management*. This is an oversimplification. Management is a goal-oriented activity, whereas governance is often given from outside, and organizations just have to live with it. This is not to say, that all governance structures would be beyond management control: most governance structures management can influence—at least on the long run. The long run is a key term in many aspects: When referring to governance structures, we talk about structures that are semipermanent and are not changed very frequently. *Structure* is a term closer to *architecture* than to *infrastructure*: governance structures are architectural terms, and are then implemented into infrastructures through different organizational forms. Therefore, the terms *organization form* and *governance structure* are

Table 2. Comparison of terms management, organizational form, and governance structure

	Management	Organizational Form	Governance Structure
Time perspective	Short	Medium	Long
Focus	Action	Internal organization	Interorganizational structures
Management Control	In action	Easy	Difficult
Metaphor	Communication channels	Infrastructure	Architecture
Character	Concrete	Formal	Abstract

not synonyms. Organizational forms are more formal and touch upon one organization, whereas governance structures are found in a richer selection of forms and organize themselves over a number of organizations. Table 2 summarizes our discussion here.

Governance structures are present in almost any human decision making situation. In Table 3, we have a collection of key aspects of IT governance structure issues in health care.

IT AS A TOOL TO BE GOVERNED IN HEALTH CARE

Information and communication technology needs management in health care organizations as in any other organization. Yet the issue seems to be very difficult for the health care organizations. Morrissey (2003, p. 6) paid attention to the fact that health care organizational culture is often hostile to new information technology: "*The expression 'Culture eats Strategy for lunch' has never been more accurate than with physician order entry.*" At the same time he documents the frustrations many hospitals and health care organizations have felt in the case of information technology: "*We have bought enough technology and we're not getting the expected value out of it.*" Haux, Ammenwerth, Herzog, and Knaup (2002, p. 19) have paid attention to the weak management of information technology and systems in health care organizations: "*The health care institutions, especially hospitals, must emphasize professional information management more strongly in their organizations.*"

Ross and Rockart (1996) have defined the following success factors for successful IT management:

- Achieve two-way strategic alignment
- Develop effective relationships with line management
- Deliver and implement new systems
- Build and manage infrastructure
- Reskill the IT organization
- Manage vendor partnerships
- Build high performance
- Redesign and manage the federal IT organization

Next, we discuss these issues in the health care IT context.

Two-way strategic alignment means that the organizational strategy affects the IT strategy, and vice versa. The current tumult of health care IT is partly a result of the fact that the effect of IT on health care processes has been denied for too long.

Effective relationship with line management means that communication is fluent and the parties aim at common goals. Effective communication needs a common language. Unfortunately, medical people and IT professionals do not always speak the same language. The applications the staff members use are the face of the information technology to the whole organization. A deliberate balance with investments to the infrastructure as well is needed. Functional applications can not be built on a flimsy base, but overinvestment in infrastructure is always a danger threatening organizations (Broadbent, 1999). Typical key applications of a hospital are electronic patient records (EPRs) and picture archiving and communication systems (PACSs).

Even in the health care organizational environment, IT professionals are under constant educational and skill renewal pressure. One of the big challenges meeting them is that patient data must move over traditional organizational boundaries and therefore must be able to deliver professional services in networked and often virtual organizational settings. The same issue is central in the management of vendor relationships: health care organization's IT staff must be able to integrate solutions from several vendors or, even better, they must be able to put enough pressure to vendors to self integrate their solutions.

Table 3. IT governance structure issues in health care

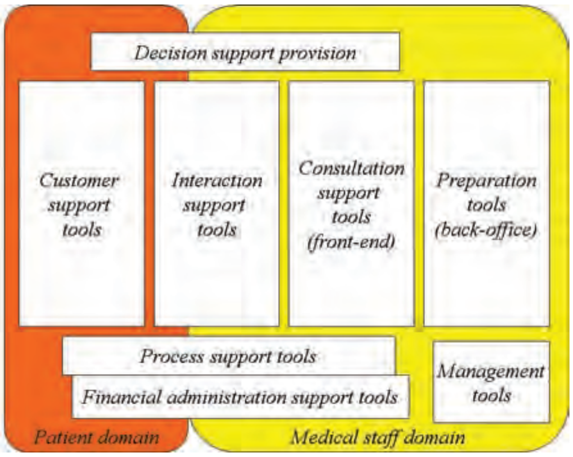
IT as an enabler

- Health-related information on the Web
- Private-public sector cooperation
- Allocation of patients to different levels of care
- Customer contacts distribution between electronic and classical means
- Ownership, structure and allocation of patient, population-level and other critical data
- Electronic forums for patients to interact
- Electronic prescription systems

IT as an object to be governed

- New legislation needs because of the new data processing possibilities
- Data privacy and security
- Structure and status of the information resource management in health care units
- IT-general management partnership
- Sourcing decisions of IT
- Charging arrangements on IT-services

Figure 1. Classification of IT tools in health care



Performance of IT solutions is dependent on many factors. Typical critical resources are time and money. Lack of money can be seen in undersized hardware and software solutions, and lack of IT-professionals time culminates in bad designs for the solutions.

Federal IT organization means that there are both centralized and decentralized IT units in the organizations. Even in big hospitals there is usually just one big IT unit. The federal structure problematic comes more into the foreground in the interorganizational settings of systems.

IT AS A TOOL FOR GOVERNANCE IN HEALTH CARE

How can information technology help in governing health care? We can approach this issue by taking a look at the application areas of IT in health care organizations. We propose the classification as shown in Figure 1, as adapted from (Suomi, 2000). The classification is a conceptual one, and actual information systems met in health care settings might fit several categories of the framework's systems.

The heart of our classification is in the interaction between the medical personnel and the patient, a kind of basic value-adding chain. In addition to the basic value chain in the middle of the figure, there are certain supporting functions and systems needed.

The figure divides the systems into systems for the use by the patient/customer (patient domain) and by the medical staff (medical staff domain).

We further differentiate between two basic use scenarios of these systems:

1. (patient) self-care scenario
2. (patient-medical staff) interaction scenario

In addition we have the activities of the health care professional or organization, that are not connected to any specific individual patient interaction, but they are of less interest for our analysis here.

SELF-CARE SCENARIO

The self-care scenario means that the patient tries to manage his or her disease or illness without individual professional help. Decision support provision in the self-care scenario helps in self-diagnosis and in deciding whether professional help is needed or not. Internet-provided information is a key component in this category.

Customer support tools help the patient with the daily management of the disease or illness. For example, easy-to-use tools to make different measurements (such as blood pressure) belong to this category. Process support tools are related tools, but focus in the self-care scenario more on the total life cycle of the disease. An example might be computerized tools for keeping track of different measurements. Financial administration tools help in managing the disease or illness condition financially.

INTERACTION SCENARIO

In the patient-medical staff interaction scenario, decision support helps to diagnose the patient and to decide what kind of care he or she needs. Now the decision is made in cooperation between the medical staff and the patient, not just by the patient, as in the self-care scenario.

Customer support tools are used in the same way as in the self-care scenario, but there they also help the patient to prepare for the interaction with the medical professionals.

Interaction support tools are active in the situations where the medical staff and the patient meet. This meeting can take many forms: it can be a physical meeting, a virtual meeting through electronic means, or some combination of these. Doctors often want to keep physical meetings technology free, but technology can help even in these cases, say to facilitate communication in the case of sense disabilities or language problems. In a virtual meeting, different systems such as phone or e-mail services belong to this category as well as those different applications of telemedicine.

Consultation support tools and preparation tools are to be used by the medical staff. Consultation support tools help the medical staff members during an individual customer consultation, whereas preparation tools are active outside the actual customer interaction. An example of consultation support systems might be a system used to support surgery operations.

In our analysis, the information domains are important. Customer support tools contain information for the patient and are used by him or her. Interaction support tools contain joint information and are used by both patients and medical staff. Consultation support tools contain patient-specific information that is targeted just for the medical staff.

To clarify the proposed value chain, take the example of a laboratory test. For the test, the customer might have to prepare himself or herself by not eating anything. The customer might obtain this information the hospital's Web site or a customer-support tool. An electronic patient card that would help in identifying the patient during the testing would be an interaction support tool. Analyzing the test would be a back-office function for the preparation tools. Analyzing the laboratory results and working out how to tell the results of the test to the customer in a comprehensive way could be facilitated by a consultation support tool.

Process support tools in the interaction scenario help in organizing the interactions between the patient and the medical staff (e.g., different consultation time reservation, queue management systems). Financial administration of the patient-medical staff interaction is one part of this. Electronic systems for handling prescriptions also belong to this category.

Finally, a health care organization has to maintain a lot of management routines that are not connected to any individual patients. Resource planning and management systems and statistics keeping are examples of this domain.

The information in Figure 1 is not to say that the different health care systems would be independent isles of automation. All the systems included in the figure should be integrated by a comprehensive electronic patient record.

FUTURE TRENDS

In Table 4, we list the most dramatic changes we will see in the health care sector because of modern IT and the challenges these changes cast on the IT governance.

One of the biggest changes in the industry is that information related to health, diseases,

Table 4. Future changes in the field of health care introduced by modern IT and the challenges to IT governance produced by them

Future changes in the field of health care introduced by modern IT	**Challenges to IT governance**
The amount of free medical information will grow very fast	Mechanisms to rate different information sources have to be developed
Patient self-care will grow in importance	Systems to support self-care must be developed
Patient empowerment will gain in importance	Customer rights and decisions must be tracked in medical information systems
Interaction between patients and medical staff will increasingly turn away from physical meetings to electronic means	Electronic means to facilitate patient-medical staff communication must be developed
Data collected about patients will grow in amount and quality	Data privacy needs even more concern
Medicalization of the society	Medical and other information systems will have to be linked sophistically
Costs of medical care will continue to raise	Cost monitoring will grow in importance
Focus should turn from individual care-taking episodes and consultations to long-term care-taking relationships and processes	Pressures to develop electronic patient records
Resources of the area will not grow as fast as demand	Information systems must be used for process redesign

sickness, and medicines is not scarce. Internet is a rich source of such information, at different levels of expertise, and in different languages. The gap between what information is available and what a health care professional should know is growing fast (Weaver, 2002); similarly, the pressures for laymen to know about medical issues grow. Decision support is needed more than ever in this plentitude of information. Different solutions should be found to differentiate right information from wrong, especially in the case of information targeted for laymen, such as most of the information found on the Internet.

Free information will shift the power balance between health professionals and patients: More often, the patients are the best experts on their disease, and self-care will grow in importance. Systems to support self-care must be developed. Different electronic forums or virtual communities will offer the patients forums to share experiences and peer advice, to the healthy ones as well as to the chronic and acute sick (Utbult, 2000).

If the patients get more empowered, they should too get more responsibility. Health care information systems should not just keep track of medical staff decisions, the decisions taken by the patients should also be recorded to the systems.

Similarly, the interaction between the patients and health care professionals is going to change: Electronic means are going to take share from face-to-face meetings (Cain, Sarasohn-Kahn, & Wayne, 2000; Gilson, 2003). A key survival factor for all the electronic sources of health information and all communication channels to be used by the patients is how they can build and sustain customer/patient trust (Luo & Najdawi, 2004).

Medicalisation of the society (Conrad, 1992) is a strong trend. Increasingly more issues in human life are seen as belonging to the sphere of medical expertise. If and when we accept this trend, medical decision makers need information about our lives in many aspects. As patient data can be electronically cumulated into huge databases, these databases can be used for different statistical, research, and other purposes. This calls for care and proper legislation giving the ramifications for data usage. For example, often the need of integrating data about one's health and social life arises, if effective care is looked for. Needless to say, we enter a difficult area where data privacy issues gain in importance.

Science and industry will continue to produce increasingly effective cure methods and medicines, but not always without increased costs. It is clear that not everyone can be granted the best possible care with public finances. Systems for keeping track of costs and making cost-informed care-taking decisions will be needed in the future.

For organizing patient flows through the health care system modern IT offers many possibilities. A key issue is to follow the long-term development of the patient, not to focus just on short-term episodes of care. This puts pressures on the electronic patient record systems.

Resources can be saved or wasted through care-taking decisions. It is for sure that in many nations the total share of health care costs is at its top already, so current resources should be used more efficiently. Efficiency, among other things, means that patients are taken care of in the best and most effective places, be they public or private, and of right level of expertise. This all calls for extensive process redesign and system support for that. Should patient data be all the time available anywhere though electronic means, would the Healthcare Supply Chain be much more effective (More & McGrath, 2001).

CONCLUSION

Health is undoubtedly among the most important issues for all people. In a modern society, the threats towards health are changing all the time, but at the same time the possibilities to maintain health and to cure illnesses also grow exponentially. The task is to make needs and solutions to meet in an effective way. This is about information and communication technologies and governance structures.

Modern IT allows health care organizations to structure themselves in new, innovative ways and simultaneously to empower the customers to interact with the organizations, with fellow patients and information sources in revolutionary new ways. In this environment, health care professionals too have to adjust their roles.

Managing and building governance structures for IT in health care organizations is not that much different from other organizations. Even in health care organizations the scope and status of information resource management has to be decided. Issues such as sourcing decisions, charging arrangements and data privacy and security issues all deserve their attention. There are, anyway, certain problems that need to be solved in this area:

- Data privacy and security needs are extremely important and might sometimes conflict with optimal care.
- As the area is new, legislation is often lagging behind.
- The field is a meeting place for two strong professional cultures, that of medical doctors and IT professionals, which might bring along difficulties.

KEY TERMS

Electronic Patient Record: All health-related information related to a patient in electronic form, assembled as a single entity.

Electronic Prescription: Prescriptions created and handled in electronic form in an integrated information system.

Health Care Supply Chain: A managed set of activities related to the health care activity of a patient organized so that all information needed is all the time available and that the participants in the chain have a complete picture of the total process.

Picture Archiving and Communication System: A system for capturing, storing and distributing medical images. These systems are fast turning from storing analog images to storing digital images.

Sourcing Decision: Whether to buy goods/services from the market or to make them self—alone or in different alliances.

Virtual Community: A social aggregation on the Internet when people interact long enough to form personal relationships.

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 537-544, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 6.2
Entrepreneurial IT Governance:
Electronic Medical Records in Rural Healthcare

ABSTRACT

Governance is traditionally viewed as a formal authority structure. Information Technology (IT) governance parallels this in that it refers to the patterns of authority over IT. However, traditional control theories of governance, particularly those applied to IT, may not apply in rural healthcare settings. Healthcare has significantly underinvested in IT. Even today, the vast majority of healthcare transactions occur via telephone, fax, paper, and EDI; much data is not captured, is captured incorrectly or inefficiently, and is difficult to retrieve and use. Employing an established IT governance framework, and working from the fundamental assumption that IT is a vital tool in the capture and use of healthcare data, the authors explore the appropriateness of the traditional IT governance framework within a rural healthcare setting. We present an innovative, non-authoritative, relationship-oriented approach for those seeking successful adoption of IT as a means of improving healthcare in rural settings.

INTRODUCTION

Healthcare is arguably the most transaction-intense industry in our society. Yet compared to other industries, healthcare has significantly underinvested in information technology (IT). Even today, the vast majority of healthcare transactions occur via telephone, fax, paper, and electronic data interface (EDI). The result of this archaic information communication system is that much data is not captured, is captured incorrectly or inefficiently, and is difficult to retrieve and use (Barber, Caillouet, Ciotti, & Lohman, 1994; Wager, Lee, & Glaser, 2005).

Health information is typically spread throughout the healthcare organization and held in incompatible legacy systems with little or no interconnectivity or interoperability (Pendharkar, Khosrow-pour, & Rodger, 2001). Healthcare executives are focused on improving the quality, reducing the cost, and expanding access to healthcare, but cannot improve what cannot be measured and cannot measure inconsistently captured or inaccessible information that is reported and held in non-compatible homegrown systems and databases.

In an industry where the paper medical record has been considered the "gold standard," Electronic Medical Record systems (EMR) are believed to be an increasingly vital facet for improving patient safety and quality of care, operational efficiency, and compliance with regulations while reducing medical errors and decreasing the risk of lawsuits. Still, EMR is perceived by many to be a money pit rather than a source of efficiency, income, and enhanced quality of care.

United States healthcare is struggling with decision-making, implementation, standardization, and connectivity surrounding the EMR. This is indicative of the unsystematic and independent nature of healthcare organizations in the United States. "The medical industry still has no clear common goals for IT and very few universally accepted standards" (Sobol & Prater, 2006, p. 74). Fewer than one in five hospital information technology (IT) executives report that their organizations have a fully operational EMR. Only 8% of physicians report using computerized order entry systems (CPOE) and only about one-third of U.S. hospital emergency and outpatient departments use EMR ("Study Shows Limited", 2005). In fact, the number of healthcare organizations reporting a functional EMR actually decreased from 19% in 2004 to 18% in 2005 (Lawrence, 2005).

Perhaps no single industry is as complex and convoluted in its structure, process, and "product" as the U.S. healthcare industry. It is constituted from a tremendously diverse set of public, private, and quasi-public organizations and agencies ranging in size from very small (i.e., solo physician offices) to very large (i.e., integrated health systems), cost reimbursement governmental programs (Medicare and Medicaid), and private organizations (Blue Cross/Blue Shield, and other private insurers). Additionally, it is often said that only the nuclear power industry is more heavily regulated than U.S. healthcare. In this schizophrenic environment, other healthcare organizations are both partners and competitors. Yet, within this complicated and multifaceted industry, organizations strive to meet their missions and serve their patients, constituents, and communities. How are decisions made in such an environment? More specifically, given the expected benefits of modernizing healthcare with information technology, how are IT governance decisions made in what is often referred to as a constant state of chaos?

This manuscript describes a rural family practice residency program that implemented an EMR. The residency program, which trains primary care physicians and provides primary care services to widely disbursed rural communities, received a federal grant for the acquisition and implementation of the EMR, with the simple initial goal of enhancing the practice's clinical research capabilities. As the purchase and implementation of the EMR progressed, however, the practice's simple research goal mutated and morphed into a much larger goal of extending the system throughout rural clinics and providers in the region.

IT GOVERNANCE IN HEALTHCARE

Traditionally, governance is "defining and realizing missions and goals, establishing strategic direction, policies and objectives to that end, and monitoring implementation" (McNally, 2003). Governance commonly concerns the patterns of authority that determine the use of organization resources and the integration of differences among organizational interests (Daily, Dalton, & Cannella, 2003; Sundaramurthy & Lewis, 2003).

Viewed as a set of formal authority relationships, an organization's Board of Directors or Trustees governs through its relationship with top management, and in turn, top management governs departments through its relationships among various subunits. IT governance parallels corporate governance in that it refers specifically to the patterns of authority over IT resources and the means for integrating IT interests. IT governance decisions determine the design of the technical infrastructure, the form of application management, and the alignment of the organization's corporate strategy and integrated information practices (Sambamurthy & Zmud, 1999).

Although the terms are often used interchangeably, IT governance and IT management are related, yet separate, endeavors. "Whereas the domain of IT management focuses on the efficient and effective supply of IT services and products, and on the management of IT operations, IT governance faces the dual demand of (1) contributing to present business operations and performance, and (2) transforming and positioning IT for meeting future business challenges" (Peterson, 2004, p. 44). Perhaps the trickiest aspect of IT governance is leaping that fence that divides the technical from the managerial world. While IT professionals certainly must go a long way toward being able to positively communicate with business process owners, functional managers need to invest a similar effort in understanding the terminology used within IT with a goal of recognizing how some seemingly technically focused decisions have real business consequences.

Weill and Ross (2004) regard the establishment of IT principles as the most fundamental governance decision an organization must make regarding the employment of IT. IT principles embody executive level-attitudes regarding the role information technology is to play in supporting the organization's mission and strategy. For example, while some healthcare professionals may view IT as a "necessary but evil" expense, other healthcare professionals may view IT as providing a strategic investment that can not only reduce the cost of providing healthcare but also ultimately improve the quality of healthcare provided. These attitudes are directly reflected in the organization's IT governance principles and policies and establish a basis for the identification of applications that the enterprise desires to implement. In the healthcare industry, applications directly contribute to patient care as well as support the organization's administrative functions. Decisions concerning IT principles and application needs drive the technical decisions concerning the organization's IT architecture and IT infrastructure.

Finally, the organization must make IT investment and prioritization decisions. Not only must management decide which software applications will best serve their organization's needs, but they must also determine how much to invest in the IT infrastructure.

These five areas (establishment of IT principles, identification of applications, IT architecture, IT infrastructure, and IT investment and prioritization) are the most important decisions made under the conceptualization of IT governance employed in this manuscript. While architecture and infrastructure decisions may be quite technical, organizations with well-designed IT governance mechanisms ensure that the IT principles and application needs drive design and infrastructure investment.

It is important to note that Weill and Ross (2004) are less concerned with what decisions are made than with ensuring that organizations have effective mechanisms in place to make these decisions. In their study of IT governance processes at 256 enterprises, they found the ability of senior management to accurately describe how these decisions were made proved to be the best predictor of high governance performance (Weill, 2004). Similarly, Schweiger, Melcher, Ranganathan, and Wen (2006) conclude from their Family Medical case that "communication to employees, both implicit and explicit, plays a significant role in the diffusion process" of IT (p. 90).

The need for management to describe decision-making processes is similar to the McGinnis, Pumphrey, Trimmer, and Wiggins (2004) argument that traditional control theories of governance applied to IT may not apply in rural healthcare settings. Rather, these authors posit that governance is a pattern of social relations integrating organizational activities. Contrary to the dominant paradigms of hierarchy, power, and resource based governance, coordination and communication appear to provide the most effective mechanism for IT governance for at least some healthcare organizations.

Healthcare organizations face uniquely challenging circumstances in establishing effective IT governance mechanisms required for the infusion of information technology into the day-to-day provision of medical services. Cost remains an almost insurmountable barrier to IT adoption, particularly in medical groups; many practices simply cannot afford the upfront costs. Medical practices also face physician and staff resistance to the use of EMR systems (Darr, Harrison, Shakked, & Shalom, 2003). EMRs "have been over-engineered and are not intuitive, forcing physicians to spend more time clicking through screens and menus to get their work done" (Brown, 2005, p. 48).

While healthcare lags other U.S. industries in IT adoption, IT is increasingly vital to healthcare's efforts to fulfil its missions and reach performance and productivity goals (Goldsmith, Blumenthal, & Rishel, 2003). The provision of high quality care can be enhanced and better monitored by the effective and appropriate use of IT (Zabada, Singh, & Munchus, 2001). According to the Institute of Medicine (1998), safety, effectiveness, patient centeredness, timeliness, efficiency, and equitability are the characteristics necessary for delivering excellent patient care. Each of these vital characteristics can be enhanced, monitored, and improved by the appropriate use of IT via effective governance.

Within the context of IT, an entity must continuously adjust to a rapidly changing environment or risk falling behind the competition. Healthcare entities have turned to, and have become increasingly dependent upon, IT as a means of creating efficiencies and providing more effective service.

METHODOLOGY: AN INTERPRETIVIST CASE STUDY DESIGN

This study employs a single-site case study design to provide a fine-grained examination of the creation and operation of an EMR system in a university affiliated medical practice providing healthcare services to a rural population. We take an interpretive philosophical approach illustrated by an analogy developed by Slife and Williams (1995). In describing interpretive ways of knowing, they ask the reader to consider the difference between a map of a city and an informal account of that city provided by a resident. The map, while admittedly an interpretation, represents an abstraction of an objective reality, depicting "only those features of the place that would remain unchanged even *if no one lived there* (e.g., patterns of streets, layouts of buildings)." The informal account from the city resident is quite different although ultimately as informative, perhaps more so. While "necessarily personal, incomplete and biased…" the personal account might describe the best places to eat or sections of town to avoid. By providing such description, the informal account "gives *meaning* to the town, from a native's point of view." Certainly it is not the only description or possible interpretation but it is legitimate nonetheless.

As are many scholars, we are interested in understanding IT within the healthcare industry. The selection of a single-site case study is particularly appropriate when investigating complex social phenomena where establishing appropriate boundary conditions between the phenomenon of interest and its environment is problematic (March, Sproull, & Tamuz, 1991; Stake, 1994; Yin, 1994). The selection of a single-site case study was further warranted given the family practice residency's status as an early adopter of IT within its segment of the healthcare industry.

Research activities and processes included in this study can be grouped into the following categories:

- **Data collection:** While documentary evidence was examined, the primary data sources were 14 face-to-face interviews with seven key informants at the practice. The selection of participants was purposive, and snowball techniques identified additional informants. Key informants are listed in Table 1. Interviews were organized around the research question but were conducted using the "active interview" approach (Fontana & Frey, 1994; Holstein & Gubrium, 1994).
- **Data analysis:** Analysis consisted primarily of the creation of a case narrative that seeks to accurately reflect interviewee perceptions. The objective was to develop an accurate and rich description of a phenomenon as seen through the eyes of the study participants. Related literature is referenced to provide useful context.
- **Validity and reliability assessments:** The authors used the results of the unstructured interviews to develop narrative themes representing participants' varied perspectives. Where possible, we used participant checks to test whether our interpretation of interview data fairly represents participant views (Altheide & Johnson, 1994; Miles & Hubrman, 1994; Patton, 2002).

Rather than conducting some variation of discourse analysis typically associated with interpretive studies, the authors' construction of the case narrative presented in Section 4 should be read as a case history and Section 6 as historical interpretation or analysis consistent with a historical and ante-narrative method recommended by Dalcher (2004), which is particularly appropriate for the study of information system failures. While we do not perceive the subject implementation effort as a failure, the knowledge as it concerns IT gov-

*Table 1. List of key informants**

Informant	Position
Joseph (Joe) Clark, M.D.	Director of FM
Robert (Bob) Wood, M.D.	Associate Director of FM
Rita Ford, Pharm D.	Director of Grants, Research and Information Systems
Anne Wright	Director of Information Technology
John (Jack) Hopkins, M.D.	Third Year Resident Physician
James (Jim) Wilson, M.D.	First Year Resident Physician
Mary Miller	Accounts Receivable Manager

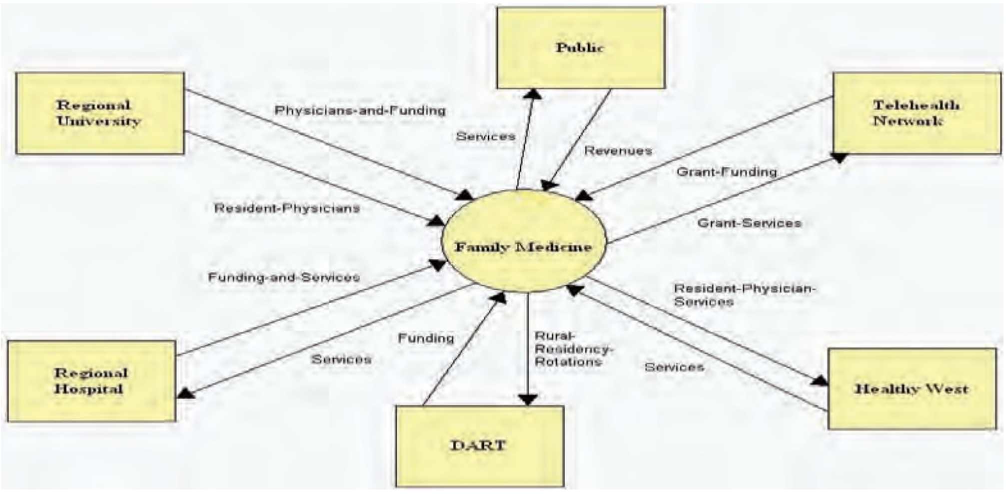
Figure 1. Family medicine relationships



ernance practices is "fragmented, distributed and hidden with the context" (Dalcher, 2004, p. 306). Dalcher argued that traditional research methods are unsuitable for studying information system failures because of the emergent properties inherent in such failures and an inability to "clearly delineate causes and effects" (Dalcher, 2004, p. 306). We simply are extending Dalcher's methodological recommendation to include a wider variety of IS implementation experiences.

These procedures demonstrate the authors' commitment to employing disciplined data elicitation and analysis techniques consistent with recommendations of leading qualitative researchers and methodologists.

FAMILY MEDICINE

Family Medicine (FM) is a health provider in the intermountain region of the Rocky Mountains that also serves as a Family Practice Residency Program (RP). RPs for family medical practice typically require three years of post-doctoral experience. FM's RP is a department in the College of Health Professions at the state university. FM is located in a city of 55,000, a regional hub for farming and ranching communities. In addition to providing family medicine, the residency physicians also participate in outreach to rural healthcare clinics within the region, rotating within the five rural clinics managed by another partner, Healthy West (HW). The residency program at FM is also part of the Demonstration: Assistance in Rural Training (DART) project, a regional funding program for residency rotation in the rural environment.

FM is managed by a Director, Joe Clark, M.D. who is on the faculty of the university and on the medical staff at Regional Medical Center (RMC). All physicians and residents at FM are on both the university faculty and hospital staff.

There are two additional upper management positions at FM. Bob Wood, M.D., Associate Director and Rita Ford, Pharm D. is Director of Grants, Research, and Information Systems. Wood and Ford had been pursuing acquisition of an electronic medical record (EMR) system with numerous unsuccessful grants. A principal justification for the EMR was quality data for research purposes. An opportunity arose for FM to address its EMR needs by participating in a grant request by the Telehealth Network (TLN) of the university, as TLN also shared in the rural healthcare mission. The environment that FM operates within is represented in Figure 1.

A time line of the events involved in the selection and implementation of the system is represented in Table 2. A brief discussion follows.

After receiving the grant, Clark initiated an investigation into EMR vendors. A committee of physicians experienced with EMR evaluated a number of systems, narrowing them to three viable, wireless enabled, EMR systems. Following system selection, Clark hired Anne Wright who designed, acquired, and built the wireless network that would serve as the systems backbone. Next, a third-year resident, Dr. Jack Hopkins, spent a week at a medical practice that had recently implemented the selected system, General Electric's Centricity.

After Hopkins return, Wright planned the implementation of the EMR. First, she began to build interfaces with the hospital's system to enable Mary Miller, accounts receivable manager, to phase in the billing system. Miller spent approximately three months making certain that charges generated by both FM and the hospital for FM patient services were accurately captured and billed. At the end of this reconciliation period, FM began to invoice patients and insurance providers and maintain accounts receivable independent of the hospital billing system. Next, Wright began to build interfaces between the hospital's laboratory, radiology, and pharmacy to provide the systems charting functions with supporting data. Third, patient data was input as data entry personnel were being trained on the system. Finally, Hopkins assisted in providing training on using the EMR to FM's other physicians.

As the initial EMR implementation at FM was commencing, Wright began to extend the system to the homes of physicians and residents. For example, first-year resident Jim Wilson received training in the EMR at the clinic from Hopkins, and had his home system configured for terminal server services by Wright. Wilson, a native of the region, will have received almost all of his residency training with an EMR, and can do his paperwork and patient research from his home as well as the clinic.

Table 2. Sequential events in electronic medical record implementation at family medicine

Event	**FM Participants in study**	**Actions**
Grant Process	Wood, Ford	Grant received for systems in both statewide Residency Programs.
System Selection	Clark	Advising group formed, EMRs assessed, EMR software selected. IT Director hired.
System Implementation	Wright, Hopkins, Miller, Wilson, Clark	Hardware selected, visits made, system installed, users trained, data input, system maintained, common system configuration implemented, chart room eliminated, transcription eliminated. Advising group formed for system implementation conflict resolution.
Implementation Follow-up	Wood, Wright, Wilson	Quality of data source, addition of information technology assistant, benefits of broad system availability, additional time for file maintenance.

An overriding strategy for systems implementation governance was initiated by Clark. The advisors from system selection had warned Clark about conflicts that frequently arose during the implementation of EMRs. To alleviate this, Clark formed an implementation advisory committee which consisted of community members, hospital representatives, and a network of associates who had been "down the path" of EMR implementation. This committee enabled Wright to mitigate opposition to specific system implementation issues by providing firm guidance in areas of physician and staff systems conflict.

All paper medical records and charts were eliminated from FM six months after the initiation of system conversion. One year after the initiation of the conversion, Wood noted that a major benefit of the EMR was chart availability; no longer did physical charts need to be located and physically shared by one caregiver at a time. A downside to this, mitigated by the elimination of the transcription department, was the time it took to input the documentation and assessment of patient visits. Wood also commented that the conversion from the paper system to the EMR made them aware of inaccuracies in the previous chart system.

Twelve months after initiating the system conversion, Wright saw herself in an enhanced role. The remaining funding from the grant was being used to implement a similar system in the state's other Residency Program. Wright found herself as a consultant for this project in addition to supervising an IT support person at FM.

DISCUSSION

While this study was originally conceived of as a traditional IT implementation case, the authors' attention gradually was drawn to the *ad hoc*, almost serendipitous, manner in which the EMR project was conceived, developed, and implemented. Having a familiarity with the IT governance literature, as well as recognizing the common perception that the health industry has been slow in its adoption of information technology, we refocused our analysis and conducted follow-on interviews to obtain a better understanding of the influence of formal and informal IT governance mechanisms on the formulation and execution of the EMR initiative. In this section, we extend our discussion of relevant IT governance literature and applicable U.S. healthcare policy to further lay the groundwork for our identification and analysis of four issues to be addressed in the development of IT governance mechanisms particularly relevant to the diffusion of IT-enabled healthcare services in the rural United States.

The benefits expected to be derived from information technology are so significant that in 1996, the U.S. government enacted the Health Insurance Portability and Accountability Act (HIPAA). The act directed the U.S. Department of Health and Human Services to provide a set of rules governing health information. The rules have been created to standardize the communication of electronic health information between and among healthcare providers to protect and secure private individually identifiable health information. Notably, the legislation does not recognize potential risks associated with establishing an EMR system, nor does it include significant provisions intended to safeguard patient privacy (Fedorowicz & Ray, 2004).

Despite the legislative mandate of HIPAA, progress in the implementation of EMR capabilities has been slow (Lawrence, 2005) and resistance exists to the use of EMR systems, particularly on the part of physicians (Darr et al., 2004). Furthermore, studies exist indicating that practicing physicians and other healthcare professionals have reason to be cautious concerning much of the hyperbole expounding the cost savings and healthcare benefits to be derived from EMR systems. In a seminal article, Eric Brynjolfsson failed to find any significant correlation between increased IT investments and multiple measures of financial success indicating that IT investments do not always deliver the anticipated benefits (1994). While there have been many explanations offered for his unexpected and counter-intuitive finding, the conclusion that must be drawn is that organizations are capable of making good and not so good investments in information technology.

The research on IT governance has provided important insights into an organization's ability to effectively translate IT investment into desired outcomes. Weill et al. (2004) declared "IT value depends on more than good technology" and have concluded "effective IT governance is the single most important predictor of the value an organization generates from IT" (Weill et al., 2004, p. 3-4). Accordingly, an examination of the IT governance function associated with the implementation of EMR at FM practice should prove useful.

As previously discussed, Weill et al. (2004) identify key IT governance decisions: IT principles, IT architecture, IT infrastructure, business application needs, and IT investment priorities. Without intending criticism of Weill et al.'s work, the FM case does not easily conform to the model depicted in their governance arrangement matrix. An analysis of this lack of fit provides insight into the unique challenges faced within the healthcare industry and suggests a need for further elaboration of IT governance theory to better accommodate the needs of enterprises operating in complex inter-organizational environments.

To explore this issue further within the context of our case study, we focus our discussion on four important areas: defining the enterprise, scale and resources, social governance, concluding with some cautionary observations.

1. Defining the Enterprise

While not discounting the emergence of complex inter-organizational relationships emerging in many commercial industries, establishing or defining pragmatic organizational boundaries within the health industry is uniquely difficult. As previously outlined, FM is a cooperative venture jointly supported by a public university and county owned regional medical center. Furthermore, FM, by hosting Family Practice residents, must maintain a relationship with and support the standards of the broader medical education community and the DART regional medical consortium.

The governance models proposed by Ross and Weill apply to a more cohesive organizational form where enterprise boundaries, while complex, are still generally identifiable. The quasi-public and heavily regulated organizational environment in which FM operates simultaneously permits a degree of independence and entrepreneurship with respect to FM internal operations and initiatives yet FM remains answerable to and under the jurisdiction of two much larger and independent institutions (i.e., the regional medical center and the state university). Despite the complex set of inter-relationships, FM was able to act in an entrepreneurial manner in initiating this EMR project. Lacking many of the formal policies and decision-making mechanisms associated with larger enterprises, FM established an advisory committee to participate in making substantive project decisions. The use of this *ad hoc* advisory committee additionally served to promote the active cooperation of its larger governing institutions.

As enterprises increasingly cooperate in the development of standardized IT-enabled processes, IT governance models will likely require elaboration to reflect the external entities (e.g., industry standards organizations) that may strongly influence application and infrastructure development dictating the magnitude and allocation of IT resources. We do not mean to imply that organizational management will be able to abrogate its IT governance responsibilities. On the contrary, greater effort will be required to monitor and perhaps attempt to influence external developments so that organizational needs can be met. While much of this effort will necessarily lie within the technical domain, the significant intertwining of technology and business (healthcare) processes will necessitate the involvement of medical and administrative professionals.

2. Scale and Resources

Despite its close association with two multi-million dollar enterprises, FM is a relatively small, independent organization that, on a general scale and scope, resembles many private physician practices. On average, FM sees 60 patients per day with an average of 15,660 patient visits per year. FM's current practice size is 12,000 patients.

There are 14 staff physicians at FM, whose salaries are funded by the university and RMC, as is Clark's salary. The number of program graduates is 50, half of whom are practicing in rural communities. Presently, there are 17 Family Practice residents in the Residency Program. The remaining staff of 20 employees is funded by RMC. Without the availability of the TLN grant, this initiative could not have been undertaken. There was no anticipated financial return on EMR investment for the FM. Certainly, there are various financial savings resulting from reducing some of the labour intensive administrative processes (e.g., transcription of physician notes and maintaining paper medical records). However, these savings were not expected to cover the full cost of the software application and expanded IT infrastructure.

In addition to supporting FM's research mission, the benefits of EMR are expected to accrue over time in the form of improved healthcare for patients for a variety of reasons more fully described in other literature (see for example Amatayakul, 2001; Brown, 2005; Chung, Choi, & Moon, 2003; Hough, Chen, & Lin, 2005; Snyder, Paulson, & McGrath, 2005; Rosenbloom, Grande, Geissbuhler, & Miller, 2004; Stausberg, Koch, Ingenerf, & Betzler, 2003). The expected quality of healthcare benefits are certainly non-trivial. However, the extent and timing of improved healthcare are not known with certainty and have not been quantified. Furthermore, given the structure and rigidity of Medicare, Medicaid, and third party reimbursement policies, the cost of improving healthcare cannot be passed on to the majority of FM's patients.

In short, it is difficult for small and independent practices to justify making investments in EMR particularly until the full costs of implementing and operating an IT infrastructure with requisite degrees of performance, reliability, and security are truly understood. The Weill and Ross IT governance model primarily reflects the profit-making motivation of modern commercial enterprises. Given the diverse participants, in both size and profit motivation, and given the public good anticipated to result from more effective IT employment within the health services industry, the establishment of effective IT principles becomes paramount. Healthcare participation in the development of IT principles will likely be expanded beyond the decision archetypes identified.

3. Social Governance

FM faces complex governance challenges. It operates under the supervision of two significant yet independent institutions, the university, and the regional medical center. It is obliged to support the disparate needs of these two institutions, yet operates largely as an independent practice. The convoluted governance structure has contributed to the evolution of socially constructed entrepreneurial governance processes focused on identification and accomplishment of jointly held objectives in a manner that virtually defies clear explanation. The social collaborative processes conducted among members of these distinct institutions and within the FM practice provided the basis for the entrepreneurial approach observed in the launching and execution of the EMR project.

The initial motivating idea for launching the EMR project at FM was straightforward and needs driven. A practicing physician with research and educational responsibilities desired a better way to analyze data generated by the FM practice. Lacking resources, a search for grant funds resulted. In seeking the grant funds, the researcher's needs were aligned with state and federal initiatives to improve rural healthcare, which legitimately related to the mission of the practice. In evolving its project goals to meet this broader objective, FM management displayed flexibility and opportunism reminiscent of the "garbage can" model of decision making described by Cohen, March, and Olsen (1972).

The social collaborative culture of the enterprise was further demonstrated by the *ad hoc* creation of the advisory board that assisted in the refinement of technical and functional requirements, evaluated alternatives and recommended the product that was finally purchased. In addition, a separate *ad hoc* group was utilized to assist in the actual system implementation. As internal participants negotiated the configuration and use of the application, a group of physician practitioners experienced in using EMR was recruited. This second committee counselled the practice concerning implementation and use of specific features and provided an independent third party to deflect, depersonalize, and resolve conflicts among the practice's staff.

The pattern of decision-making appears to fit with the McGinnis et al. (2004) work specific to the healthcare industry. In that study of rural healthcare providers, the authors posited that overall institutional governance reflected a pattern of social relations employed to integrate organizational activities. Both cases emphasize the importance of informal organizational mechanisms and are consistent with other research investigating strategic IT alignment (Chan, 2002). The importance of emergent social relationships contrasts with the structural determinants typically described in governance research. Tellingly, Weill and Ross concluded that the specific pattern of IT governance mattered less than the ability of study participants to accurately describe the governance processes used within their respective organizations (2004). While not explicitly addressing the issue of informal organizational relationships, their findings appear to indicate that a strong degree of "transparency" within the governance processes is indicative of more effective IT governance. It becomes a question for future research as to whether such transparency is associated with the development of strong social relationships identified by McGinnis et al. (2004).

4. Cautionary Notes

Thus far we have focused on the positive aspects of the FM's EMR initiative. Yet the ad hoc approach to the formulation of this initiative has engendered risks as well.

The two physicians most responsible for the initiation of this effort, Clark and Wood, confess to having a relatively limited knowledge of information technology. While this undermines any argument that technology is being chased for technology's sake, there was a risk that the resource and management commitments required to maintain reliable and secure services, once implemented, would not be fully understood.

A technical lead was not hired until after the grant had been awarded. Fortunately, FM was able to bring on an exceptionally talented individual. Admittedly, the previous statement smacks of hyperbole, but we shall explain. One person assumed overall technical responsibility for:

- Design, specification, and implementation of required IT infrastructure.
- Installation, configuration, and customization of EMR applications and data base management systems (DBMS).

- Complete oversight of the execution of migration from paper to electronic records.
- Coordination and development of customized interfaces with regional medical center applications (e.g., billing, scheduling, and laboratory applications).
- Development and implementation of security architecture including compliance with HIPAA guidelines and regulations.
- Provision of user training and being FM's help desk.

Essentially, one individual is serving as strategic IT planner, systems (including servers, desktops, tablet PCs, network, DBMS, and applications) architect, project manager, systems administrator (for all systems previously identified), trainer, and help desk.

Therein lies a serious problem. Beyond the apparent difficulty in identifying an individual possessing requisite technical and managerial knowledge and skills to accomplish these tasks, there is an important contingency that a single individual is unable to address. That is, Anne Wright constitutes a single and absolutely critical point of failure. While this type of problem is not unheard of even in very large enterprises, it far too common in small healthcare practices. This "single point of failure" structure is evidence of weaknesses in the IT governance processes in this study and has significant implications for the healthcare community as discussed next.

CONCLUSION AND LIMITATIONS

In summary, governance serves to coordinate organization decisions and activities both vertically from top to bottom and laterally across organization functions and departments. Thus, governance is the mechanism that assures that strategy formulation and implementation produce desired organizational performance. However, in the chaotic U.S. healthcare environment, where local and regional health organizations are both competitors and partners, we suggest that IT governance theory should be extended to explicitly address the implications of evolving industry technology standards and practices. Furthermore, governance theory must also recognize the "public good" nature of health services and the impact of government legislation and regulation on the development and evolution of enterprise IT principles. Finally, even within the context of strong industry and legislative influence, governance theory should recognize that an entrepreneurial style of governance exist among and between organizations.

Further research is needed to determine whether this governance approach is suited to other U.S. healthcare organizations or other nations. It is generally accepted that the U.S. healthcare system differs from that of almost all other industrialized nations in that the rest of the industrialized world has socialized healthcare or socialized insurance. However, the lessons learned regarding the strategies employed by the Family Medicine residency program in IT governance may fit other rural healthcare organizations.

The exploratory nature of this work is a limitation. This is a preliminary assessment of IT governance in one specialized setting—a family practice residency program associated with a state university. Using qualitative date from a descriptive case study means care must be taken in generalizing our findings and conclusions to other rural healthcare facilities. However, this preliminary work will pave the way for other studies of IT governance in rural healthcare. Using a variety of qualitative and quantitative techniques, researchers may wish to further examine issues of leadership, decision making, coordination, and entrepreneurship in governance.

The literature discussing EMR identifies significant potential benefits to be derived from effective EMR implementation. IT governance research strongly suggests that a lack of executive involvement in IT governance decisions (i.e., deferring too many decisions to the IT staff, significantly increases the risk of not deriving expected value from IT investments). Healthcare professionals expend tremendous time and energy in developing the knowledge base required to provide healthcare services. There is an understandable reluctance on the part of many such professionals to invest even more time and effort in learning the capabilities and limitations of information technology. However, as information technology becomes increasingly embedded in the day-to-day processes of providing health services, such an investment will be required. The fact is that not only does information technology have the potential to significantly improve patient care; misuse can be expensive, dangerous, and potentially deadly.

The impact of this governance strategy on other rural healthcare providers in the region needs to be assessed in the future. Perspectives on improved patient healthcare provided by the EMR should be assessed from the physician, professional/non-clinical staff, and patients involved in the rural environment.

Chapter 6.3
Governance Structures for IT in the Health Care Industry

Reima Suomi
Turku School of Economics and Business Administration, Finland

INTRODUCTION

The pressures for the health care industry are well known and very similar in all developed countries (i.e., altering population, shortage of resources for staff and from taxpayers, higher sensitivity of the population for health issues, new and emerging diseases, etc.). Underdeveloped countries experience different problems, but they have the advantage of learning from the lessons and actions that developed countries underwent perhaps decades ago. On the other hand, many solutions also exist, but they all make the environment even more difficult to manage (i.e., possibilities of networking, booming medical and health-related research and knowledge produced by it, alternative caretaking solutions, new and expensive treatments and medicines, promises of biotechnology, etc.).

From the public authorities' points of view, the solution might be easy—outsource as much as you can out of this mess. Usually, the first services to go are marginal operational activities, such as laundry, cleaning, and catering services. It is easy to add information systems to this list, but we believe this is often done without a careful enough consideration. Outsourcing is often seen as a trendy, obvious, and easy solution, which has been supported by financial facts on the short run. Many examples show that even in the case of operational information systems, outsourcing can become a costly option, not to mention lost possibilities for organizational learning and competitive positioning through mastering of information technology.

BACKGROUND

We have found the following reasons for the late adoption of modern information technology in the health care sector (Suomi, 2000):

- Fragmented industry structure
- Considerable national differences in processes
- Strong professional culture of medical care personnel
- One-sided education
- Handcrafting traditions

- Weak customers
- Hierarchical organization structures

ICT and governance structures meet in two ways. On one side, ICT enables new governance structures for the health care industry. On the other, it is an object in need of governing. As both sectors offer a multitude of new possibilities, innovations are called for in the industry (Christensen, Bohmer, & Kenagy, 2000).

IT governance thinking matures in organizations as any other discipline. Van Grembergen, De Haes, and Guldentops (2003) have defined the following stages in their IT Governance Maturity Model:

- Non-existent
- Initial/ad-hoc
- Repeatable but intuitive
- Defined process
- Managed and measurable
- Optimized

Needless to say, in the health care industry, IT Governance thinking is non-existent or initial/ad hoc in the best situation.

THE MEANING OF ICT GOVERNANCE STRUCTURE IN HEALTH CARE

IT is an old acronym for information technology. Nowadays, it is replaced often with the term ICT, referring to information and communication technology. This emphasizes the communication services that are developing very quickly, such as the Internet and mobile services. The letter *C* is often upgraded to the second dimension: alongside communication it can refer to contents. IT or ICT governance is defined (IT Governance Institute, 2001) as follows:

IT governance is the responsibility of the board of directors and executive management. It is an integral part of enterprise governance and consists of the leadership and organizational structures and processes that ensure that the organization's IT sustains and extends the organization's strategies and objectives.

For many, there is a temptation to understand governance as just a synonym for management. This is an oversimplification. Management is a goal-oriented activity, whereas governance is

Table 1. Comparison of terms management, organizational form, and governance structure

	Management	Organizational Form	Governance Structure
Time perspective	Short	Medium	Long
Focus	Action	Internal organization	Inter-organizational structures
Management Control	In action	Easy	Difficult
Metaphor	Communication channels	Infrastructure	Architecture
Character	Concrete	Formal	Abstract

Table 2. ICT governance structure issues in health care

ICT as an enabler
- Health-related information on the web
- Private-public sector co-operation
- Allocation of patients to different levels of care
- Customer contacts distribution between electronic and classical means
- Ownership, structure and allocation of patient, population-level and other critical data
- Electronic forums for patients to interact
- Electronic prescription systems

ICT as an object to be governed
- New legislation needs because of the new data processing possibilities
- Data privacy and security
- Structure and status of the information resource management in health care units
- ICT-general management partnership
- Sourcing decisions of ICT
- Charging arrangements on ICT-services

often given from the outside, and organizations just have to live with it. This is not to say that all governance structures would be beyond management control; management can influence most governance structures, at least in the long run. The long run is a key term in many aspects. We talk about structures that are semi-permanent and not changed very frequently. Structure is a term closer to architecture than to infrastructure; governance structures are architectural terms and are then implemented into infrastructures through different organizational forms. The terms *organization form* and *governance structure* are not synonyms. Organizational forms are more formal and touch upon one organization, whereas governance structures are found in a richer selection of forms and organize themselves over a number of organizations. Table 1 summarizes our discussion.

Governance structures are present in almost any human decision-making situation. In Table 2, we have a collection of key aspects of governance structure issues in health care.

FUTURE TRENDS

One of the biggest changes in the industry is that information related to health, sickness and medicines is not scarce. Internet is a rich source of such information, at different levels of expertise and at different languages. The gap between what information is available and what a health-care professional should know is growing very fast (Weaver 2002). This will shift the power balance between health professionals and patients: increasingly often the patients are the best experts on their disease. Different electronic forums or Virtual Communities (Rheingold 1993) related to health are born on the Internet. They have different services and values to offer to the healthy ones and to the chronic and acute sick (Utbult, 2000). Similarly, the interaction between the patients and health care professionals is going to change: electronic means are going to take share from face-to-face meetings (Cain, Sarasohn-Kahn & Wayne 2000; Gibson 2003).

For organizing patient flows through the health care system modern ICT offers many possibilities. Should patient data be all the time available anywhere though electronic means, would the

Healthcare Supply Chains be much more effective (More & McGrath 2001). Effectiveness means that patients are taken care of in the best and most effective places, be they public or private, and of right level of expertise. As patient data can be electronically cumulated into huge databases, these databases can be used for different statistical, research and other purposes. This calls for care and proper legislation giving the principles.

Managing and building governance structures for ICT in health care organizations is not that much different from other organizations. Even in health care organizations, the scope and status of information resource management has to be decided. Issues such as sourcing decisions, charging arrangements, data privacy, and security issues all deserve their attention. There are certain problems that need to be solved in this area:

- Data privacy and security needs are extremely important and might sometimes conflict with optimal care.
- As the area is new, legislation is often lagging behind.
- The field is a meeting place for two strong professional cultures—medical doctors and ICT-professionals—that might bring along difficulties.

CONCLUSION

Health is undoubtedly among the most important issues for all of us. In a modern society, the threats towards health are changing all the time, but at the same time, the possibilities to maintain health and cure illnesses grow exponentially. The task is to make needs and solutions meet in an effective way. This is about information and communication technologies and governance structures.

Modern ICT allows health care organizations to structure themselves in new, innovative ways, and simultaneously to empower the customers to interact with the organizations, with fellow patients, and with information sources in revolutionary new ways. In this environment, health care professionals also have to adjust their roles.

KEY TERMS

Electronic Patient Record: All health-related information related to a patient in electronic form, assembled as a single entity.

Electronic Prescription: Prescriptions created and handled in electronic form in an integrated information system.

Healthcare Supply Chain: A managed set of activities related to the health care activity of a patient, organized so that all necessary information is available all the time and the participants in the chain have a complete picture of the total process.

Sourcing Decision: Decision whether to buy goods/services from the market or to make them self. Sourcing decision can be made as an independent decision unit or as a part of a bigger group.

Virtual Community: A social aggregation on the Internet when people interact long enough to form personal relationships.

Chapter 6.4
Changing Healthcare Institutions with Large Information Technology Projects

Matthew W. Guah
Erasmus University Rotterdam, The Netherlands

ABSTRACT

This article reviews the development of institutional theory in direct relations to historical changes within the UK's National Health Service (NHS) with an eye to contributing to the theoretical specification of healthcare information processes. This is done partly by extending certain paradigms (see Meyer & Rowan, 1991; Powell & DiMaggio, 1991; Tolbert & Zucker, 1994) through a proposed model of causes and consequences of variations in levels of institutionalisation in the healthcare industry. It reports findings from a 5-year study on the NHS implementation of the largest civil ISs worldwide at an estimated cost of $10 billion over a 10-year period. The theoretical basis for analysis is developed, using concepts drawn from neo-institutionalism, realisation of business value, and organisational logic, as well as mixed empirical results about the lack of IT investments value in the NHS. The findings suggest that large scale, IT change imposed upon a highly institutionalised healthcare industry is fraught with difficulty mainly because culturally embedded norms, values, and behavioural patterns serve to impede centrally imposed initiatives to automate clinical working practices. It concludes with a discussion about the nature of evaluation procedures in relation to the process of institutionalising IS in healthcare.

INTRODUCTION

An historical overview of IT projects in the UK's National Health Service (NHS) during the last six decades is presented here with the intention to both clarify the links between institutional theory and previous traditions of sociological work on organisational structure. The initial exposition of this theory by works of established institutionalists (Meyer & Rowan, 1991; Scott, Ruef, Mendel, & Caronna, 2000; Tolbert & Zucker, 1994) focuses on the ways of challenging dominant theoretical and empirical traditions in organisational research. While this article clarifies some ambiguity and elaborates on the logical and empirical implications of a phenomenologically based version of institutional theory, the primary aims are to clarify the independent theoretical contributions of institutional theory to analyses of the NHS and to develop this theoretical perspective further in order to enhance its use in empirical research in other healthcare environments (internationally and globally).

Markus (1983) claims that interaction theory draws together three principal strands of resistance: (1) internal factors, (2) technical problems, and (3) political context. This theory has been highly influential in IS strategy and other social sciences generally since Markus first developed the ideas over two decades ago. The focus here (see Table 1) is on how interaction theory offers a new way of looking at IS implementation in the healthcare industry.

Much has been researched in the last few decades about the major lack of a coherent implementation strategy for IS (Sambamurthy & Zmud, 1994) in the healthcare industry (Stevens, Schade, Chalk, & Slevin, 1993; Vogel, 2003). Most of such claims have been levelled against an apparent "productivity paradox" with respect to investments in healthcare management (in general) and IS (in particular). The Wanless report (2002) and Committee on Quality Health Care in America assessment report by Institute of Management (2002)—both national government's mandated investigations into the UK and USA national healthcare systems respectfully—among others, have failed to find a convincing body of evidence that investment in healthcare IS is associated with increased output (refuting the productivity paradox), but not with healthcare value as measured by patient satisfaction.

WHAT IS INSTITUTIONALISM?

Institutionalism is continuously being used to mean different things by researchers of political science, economics, and sociology. Lowndes (1996, p. 182) presents institutionalism as informal codes of behaviour, written contracts, and complex organisations with four elements:

- A middle-level concept. Institutions are devised by individuals and therefore constrain individuals' actions. Institutions here are seen as part of the broad social fabric and medium for individuals' day-to-day decisions and other activities. DiMaggio and Powell (1994) argue that institutions shape human actions, imposing constraints while providing opportunities for individuals.
- Having formal and informal aspects. Lowndes (1996) views institutions to involve formal rules or laws, which allows informal norms and customs to be practiced. That is because some institutions are not

Table 1. Implementation theory: Usage, fitness, relationship and sufficiency

Authors	IS Implementation	Theory Description
Lucas, 1993	Appropriate use of IS	Process theory explaining appropriate IS use Variance theory linking use with business value
Grabowski & Lee, 1993	Strategic fitness of IS	Process-type relationship between strategic fit and performance of IS
Markus, 1983	Relationship of IS assets	How IS investment do or do not become IS assets How IS assets do or do not yield improved organisational performance
Sambamurthy & Zmud, 1994	Insufficient to produce impacts	Process model connecting raw material inputs to outputs Variance theory of IS management competencies and IS impacts Variance theory linking impacts and business value

consciously designed nor neatly specified, yet part of habitual actions by its members. Such institutions may be expressed in organisational form and relate to the processes within.

- Having legitimacy. Legitimacy in institutions goes beyond the preferences of individual actors. Such preferences are valued in them and go beyond their immediate purpose and outputs.
- Showing stability over time. Lowndes (1996) views institutions as gaining their legitimacy due to their relative stability over time, and their links with a "sense of place."

New institutionalists generally view institutions to have "the humanly devised constraints that shape human interaction" (North, 1990, p. 3) what March and Olsen, (1989) refer to as "rules of the game" (p. 162) that organisations and individuals are constantly expected to play the game. Another stand taken by new institutionalists sees informal institutions (tradition, custom, culture, and habit) are embedded in culture and conventions defined as behaviour structuring rules (March & Olsen, 1989; North, 1990). New institutionalists stress embodied values and power relations of institutions together with interaction between individuals and institutions (Lowndes, 1996). They attempt to distinguish between informal institutional rules and personal habits. Such distinction forms the basis for the definition of institution in this research where informal conventions and their impact upon the NHS and its partners are being explored.

Research Methodology

The research study began in 2001, with the initial interest of conducting an exploratory-descriptive study in 10 NHS hospitals to explore why, "historically, the NHS has not used or developed IT as a strategic asset in delivering and managing healthcare" (Department of Health [DoH], 2000). Intensive literature review unveiled few longitudinal studies, which systematically and rigorously examined how IT systems were introduced and changed over time. There were very limited studies that examined inter-organisational relationships between different constituents in the adoption and diffusion of IT systems (NHS directorship, hospital management systems, or IT suppliers and patients). Not only were most of these studies descriptive and lacked a historical dimension, they presented IS in healthcare as largely theoretical with most contributions reporting the findings of a specific IT project implementation using simple success and failure criteria—Scott et al. (2000) being among the most significant contributions.

Using such a relevant and wide-ranging backdrop this research study recognised that it was important to extend the empirical enquiry for two reasons: (1) exploratory-descriptive case studies on a single organisation (or one hospital) would not elicit in-depth and rich data to develop any meaningful analysis and conclusions on how IT was being deployed and managed; and (2) the introduction of a large scale, IT-enabled change program needed to be researched at the wider societal, organisational field and individual levels, covering an extended period of time, to understand the processes of institutionalisation (Tolbert & Zucker, 1994). The research study was therefore designed to capture the myriad of views and opinions about the national program over a 5-year period to build a rich picture of such processes underpinning large scale IT change.

Three methods of data collection were adopted: (1) a range of academic, government, and industry studies on the healthcare sector were assembled—both UK and healthcare services in other countries. The materials proved invaluable for understanding the societal, economic, political, cultural, and technical differences in healthcare nationally and internationally; (2) participation in trade fairs, conferences, workshops, and exhibitions on healthcare—focusing on general or more specific healthcare activities. These events

Table 2. Numbers of interviews conducted

Categories of Interviewees	Year 1		Year 2		Year 3	
	Contacts Made	Persons Interviewed	Contacts Made	Persons Interviewed	Contacts Made	Persons Interviewed
NHS Information Authority	32	5	30	10	10	15
Major IT Service Providers	90	56	60	45	17	12
Primary Care Trusts Admin	15	5	25	12	22	12
Secondary Care Trust Admin	0	0	9	3	7	4
Local NHS IT Managers	15	6	20	11	60	42
Medical Consultants	3	1	8	4	9	6
Nurses & Junior Doctors	13	3	15	3	11	4
Healthcare Researchers	35	20	20	8	10	7
Total Interviews		105		96		102

also generated many useful research contacts that proved invaluable for targeting interviews. (3) A semi-structured interview (see Table 2) schedule was used to enable interviewees to expand on their answers. While most interviews lasted for about 90 minutes, a limited number lasted just under an hour, with nearly all interviews being tape recorded and subsequently transcribed. Respondents were later contacted with feedback from the interviews and, where necessary, errors were corrected. This method of data collection was critical for allowing interviewees to raise additional themes, issues, and concerns that they felt were important to the research study. As a result of the political contention of some of the interview content, some interviewees asked that names of individuals and hospitals be anonymous.

After the initial 6 months of interviews, the scope of the study had to be extended, as it was important to elicit data and information from a wider range of respondents engaged in the implementation of the national program. These included IT service providers bidding for public sector IT contracts and doctors in general practices around the country. Most IT service providers offered critical insights into the political and procurement processes within the NHS and public sector more generally (Guah & Currie, 2004). General practitioners, on the other hand, offered useful insights about the communication channels underpinning the institutional processes underpinning the national program. Given the range of constituents involved, the resulting data were evaluated and interview schedules refined, ensuring questionnaires be more closely targeted to the professional and personal situation of the individual, as generic questions were less meaningful. The final questionnaire—consisting of 15 questions—was ultimately divided into the following major themes:

- ***Vision* for the national program:** overall vision and how it was compatible with individual hospital objectives.
- ***Strategy* for the national program:** Who was engaged with and how the strategy

was being communicated within different organisations.

- ***Implementation* of the national program:** What professional, managerial, and technical skills or capabilities were needed to implement various elements of the national program.
- ***Value delivery* for the national program:** The main risks identified by each hospital and how past IT failure could be avoided, as well as looking at the cost/benefit choices and issues for each organisation.
- ***Risk\analysis* for the national program:** The value being derived from the national program.

The aim was to get the perspectives of a number of different informants using structured interviewing, by building up intensive longitudinal cases which would, nevertheless, be amenable to statistical analysis. In this method, differences of perception of informants become part of the data, not an inconvenience to be explained away in the search for some objective truth.

DATA ANALYSIS

Content analysis was used to surface themes in the interview data that reflected participants' understandings related to systems implementation. The approach suggested by Weber (1990) was used to code the interview data. A set of codes used to classify the data was developed, based on concepts from the research literature and augmented with major additional concepts discovered by the researchers during the coding. We used a content analysis form where each sentence from the interview transcripts was assigned one or more codes. Each data element was coded with an assessment of the level of agreement in code assignments, involving a certain degree of recoding of data sources. As this was the first study that uses content analysis about modelling of system implementation in the NHS, a certain degree of recoding was considered acceptable.

Table 3 contains a list of the most frequently cited attributes and benefits of the system implementation model. The audiotapes were fully transcribed and individual hospital and service provider summaries were produced before conducting a content analysis of each transcript. After a complete review of all summaries, issues describing IS implementation strategies by iterative examination were identified. Certain themes emerged, which were explored using the competing values framework as an interpretive framework where appropriate (see Table 3). The trustworthiness of such analysis has been assessed by triangulation between data sources and exploring any differences in the researcher' interpretations during a couple of follow-up meetings with selected interviewees.

During the period of the field study, there was a continuing, vigorous, informal debate within NHS Information Authority as to the merits of establishing a fault proof IS implementation framework in healthcare, particular for the NHS, during this period of healthcare reform. Benefits in terms of improved quality, greater structure, and more discipline were widely accepted.

THE NHS CASE STUDY

The NHS is the institution responsible for all healthcare and services in the UK with the goal of undertaking this responsibility at no costs to the public, at the point of delivery. The NHS was created in 1948 by a parliamentary art of the UK government of Mr. Howard Wilson, after a national healthcare review by Mr. Black immediately after World War II. While the NHS operating environment has changed radically within the last six decades, only a few periods of strategic importance to the objective of this article will be revisited by the author.

Table 3. Frequently described implementation attributes and benefits

Implementation Attributes		
Item	**Count**	**% of Cat**
Applications work together	40	13
Data sharing	173	57
Common database	127	42
Real-time processing	106	35
Record once, use everywhere	121	40

Implementation Benefits		
Item	**Count**	**% of Cat**
Improved data accuracy/reliability	61	20
Lower costs of support, maintenance	212	70
Greater efficiency and productivity	167	55
New or increased functionality	106	35
Better management, decisions, analysis	136	45

The period from late 1980s to early 1990s brought in the advent of competitive bidding bringing long-term increase costs to the management of the NHS, as well as a feeling of internal market within the NHS. By the mid-1990s, management of IS in the NHS was division based. Divisions were spread across several sites and medical functions were centrally controlled. Computing services and IS development projects were beginning to be contracted to external private businesses, and staff at the NHS were beginning to feel disgruntled and unappreciated. The increasing influence of global communications, Internet, and other new technologies demanded a response from the NHS.

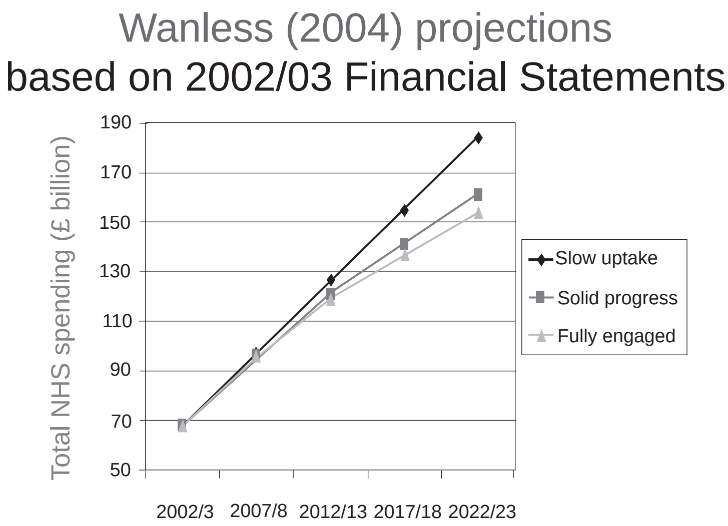
In the late 1990s the government increasingly recognised the opportunity to use IT to improve the delivery of service within the NHS. After a series of reviews of NHS IT service delivery, a more integrated and seamless IT organisation was recommended (DoH, 2000; Wanless, 2002). The NHS Information Authority embarked on the Integrated Care Report Service (ICRS) project to provide, among other services, a nationwide electronic patient database. The result was a document called "Information for Health" that specified the need for the complete automation and integration of various patient information databases in the country (DoH, 2000). The system was commissioned to selected IS service providers at a combined price of $10 billion.

In spite of its vision—to transformation IT—the NHS has a history of introducing large-scale IT development projects that have not been overall successes, with some suggesting failure rates of between 60 to 80% (Brown, 2001). Though the UK public sector spent around $3.5 billion annually on IT, the failure of major IT-enabled projects were characterised by delay, overspending, poor performance, and abandonment (National Audit Office [NAO], 2004, p. 3). At the political level, it is argued that "better IT is needed in the NHS because the demand for high-quality healthcare continues to rise and the care now provided is much more complex, both technically and organizationally" (Connecting for Health, 2004, p. 7). About $250 million is spent on management and administration in the NHS, a controversial figure, as many believe more doctors and nurses should be recruited (see Figure 1).

THEORETICAL ANALYSIS OF THE CASE

The NHS case study illustrates the dynamic nature of a national healthcare IS implementation, set within the context of a rapidly changing organisation. As with all large IT-enabled programs, the success or otherwise of the strategic plan is in its implementation (Doolin, 2004; Hendy, Reeves, Fulop, Huchings, & Masseria, 2005; Herzlinger,

Figure 1. NHS projected expenditures over two decades (Wanless, 2004)



1989). The lessons of IT costs versus medical decision making are well documented in the literature and involve the lack of alignment between the business and IT strategy (Luftman, 2000); a lack of ownership and leadership of the IT project among senior decision makers (Brown, 2001); poor risk assessment skills (Heathfield, Pitty, & Hanka, 1998); over-scoping of the functional and technical specification leading to IT projects becoming over-budget and late (NAO, 2004); poor communication between program/project managers and potential users of the system (Guah & Currie, 2005); inadequate resources to deliver/implement IT systems (Currie & Guah, 2006).

The empirical research found that issues of project risk were at the forefront of the minds of clinicians, general practitioners (GPs), hospital managers, and IT staff. Formal project management methods and tools were perceived as offering only part of the solution to mitigate the considerable risks from introducing the national program. The fragmentation was not just about the diversity of IT systems within the NHS, but also about the political geographical, social, organisational, and financial complexity of delivering healthcare.

The overriding view was for the national program to become an integrated IS across and beyond the NHS. The threats to achieving this were perceived by many clinicians to fall within the control of politicians and IT service providers rather than from NHS staff. Project risk mitigation was a complicated issue, compounded by the political and ideological considerations, such as the public-private partnership funding initiative (PFI), which facilitated the increasing use of private sector firms. While the NHS is often characterised as a top-down bureaucracy (Mohan, 2002), past achievements in IT development and implementation had often been initiated at a decentralised (hospital, departmental, unit) level. Although this was now discouraged by the centrist approach of the national program, staff participating in the research expressed concerns that any failures associated with IT project implementation may be labelled *staff resistance* rather than the shortcomings of external constituents, such as politicians, management consultants, or IT suppliers.

The success or failure of IS is inextricably linked with the dynamics of the organisation within which they exist. Miranda and Saunders (2002) have demonstrated the complex interaction of technical, social, cultural, and political elements that result in a failed IS. Equally, IS success depends on more than technical competence. The cultural and political environment of the NHS is difficult to study as it depends not only on the tangible organisational structure but also on the tacit knowledge and the perceptions of the participants (Guah & Currie, 2005). This is in addition to the cultural and political environment of an organisation that is not static but rather in a state of constant flux and dynamic change.

Institutionalism of IS in the NHS is concerned with processes of cultural persistence and change of healthcare processes. The survival of an organisation depends as much on conforming to societal norms of acceptable practice as to achieving high levels of production efficiency and effectiveness (Covaleski, Dirsmith, & Michelman, 1993). Prior work has shown that an organisation's formal structure, policies, and procedures serve to demonstrate conformity with the institutionalised rules and requirements of external constituents (DiMaggio & Powell, 1983; Meyer & Rowan, 1991). In light of these concerns healthcare in the UK showed that the national program was intended to play a high profile role within the heavily institutionalised environment of hospitals (Scott et al., 2000).

The UK healthcare system is infused with institutional logics emanating from various sectors across the organisational field. Healthcare is politically contentious where societal level logics developed by government are embedded into policies and procedures that cascade down to organisations where they are interpreted by various stakeholders including clinicians, managers, administrators, and patients. How these logics are interpreted varies according to the degree to which they affect changes to the perceived or real material resource environment of the institutional actors. The vision for the national program was infused with the institutional logics more commonly associated with the private sector, as an innovation that would contribute to greater productivity, efficiency, cost control, and customer satisfaction in healthcare delivery. Paradoxically, this externally directed institutional logic served to under represent and simplify the vast complexities and contradictions in how it was perceived, and reacted to, by those affected by government-led IT-enabled changed. Within the NHS, staff were increasingly sceptical about the merits of private sector logics, such as the PFI initiative, as their values, norms, and goals invariably placed financial considerations secondary to choices about patient care.

The proliferation of new entrants into the healthcare organisational field was a consequence of changing government policies over six decades. During this era of professional dominance, healthcare workers, particularly clinicians, enjoyed a level of freedom to define and structure their working practices. This extended to choices about the types of technology adopted and diffused across the NHS. As a new era emerged in the 1970s, which embraced managerialism as a way to enhance efficiency and performance, the European healthcare system was increasingly inundated with various managerial fads and panaceas, like BPR and change management (Herzlinger, 1989). An outcome of such interventions was that isomorphic structures across the NHS were increasingly threatened, as NHS managers were keen to demonstrate "best practice" examples through the adoption of the latest management ideas. Implicit in this logic was that NHS organisations that had not embraced "new ideas" ran the risk of being labeled as "against modernisation" or, at worst, "failing institutions."

Moving from an era of managerialism to one which increasingly advocates the use of "market mechanisms" to regulate and monitor healthcare services, efforts to differentiate NHS organisations still needs to be intensified further. The political rhetoric surrounding the right of patients to "choose" between one provider and the next is not likely to be based upon anything more than a crude assessment of the number of "stars" awarded a primary care trust (PCT), with those holding a low number becoming labeled as offering a less than adequate quality of service to patients. This will further fragment the organisational field of healthcare as the status of individual NHS organisations becomes increasingly differentiated on the basis of current and future evaluation criteria to measure performance. The topic of performance measurement was highly contentious, however, as respondents offering both a clinical and technical perspective believed that the emphasis upon target-setting was carefully designed to absolve politicians from responsibility by accentuating the role and accountability of professional groups.

The concepts of the organisational field, institutional logics, and governance systems are central to our understanding of how the healthcare system adopts and adapts to changes in the material-resource environment and the beliefs, rules, and ideas that comprise the value system. How and why these eras have emerged underpins our investigation into the UK NHS and facilitates our understanding of the nature and scope of large-scale change programs, and the extent to which they signal an institutional change within healthcare.

The institutional logics and governance systems must therefore be understood to explain why this type of change has occurred. In our investigation, we are concerned to apply our theoretical framework to help us understand how a large–scale, nation-wide technical change program is being adopted and diffused throughout the healthcare system and, more specifically, the changes in the organisational field, institutional logics, and governance systems that serve to encourage or inhibit such change.

TOWARDS BETTER VALUE IN HEALTHCARE DECISION MAKING

The national program is intended to help the situation healthcare managers presently face—with almost no say over the crucial factors which most managers anywhere else in the Western world and in other industries need to have in order to be effective (Wanless, 2004). The situation was brought about by a mixture of a quasi-medieval system and a control approach to managing patient data. Unlike other industries (i.e., banking and airline industries) where decision making leads to a good outcome, requires adaptation, and matching of the process to the individual customer, the healthcare industry may not necessarily provide a gold standard for a process that guarantees good outcomes for patients (Grabowski & Lee, 1993; Martin, 2003).

The previous is partly a result of humans being biological creatures and biological systems are inherently variable. As individuals we all have our own copies of genetic material—these materials mutate and evolve randomly. Because of the variability, the number of formulas and data points required to document each instantiation of a biological system constantly increases by several folds. Consequently, the number of conditions that need to be handled by uniform data standards is much greater than that required by standards for simpler physical, production or materials handling systems, however large or geographically widespread they may be. It takes into consideration that the patient's state of health is the result of the complex interaction between his/her unique genetics makeup, brain capacity, environment, and habits. Thus explaining why some individuals may be able to carry on fairly normal activities despite severe loss of 80% of their pulmonary capacity, others may be disabled by minor arthritis. Careful reproduction of a healthcare process that results in a good outcome for the former may not help the later.

Such scenarios dictate that the delivery of healthcare is not only unique in variety but also in the range of services and products. This explains why healthcare services are not typically chosen by the patient but by a more professional and knowledgeable representative (although these medics are increasingly being influenced by the pharmaceutical companies and/or government (Stevens et al., 1993). This shows just how the healthcare industry is different from others in the Western economy because the market in most industries is driven by the customer.

Health industry requirements are also exceptionally demanding in a number of areas. Most notable are the implications of violations of personal privacy while involving all those who need to know; dual responsibility for personal and public health; the complexity and expansion of the knowledge base and terminology; the high risk to the providers' livelihood combined with pressures to make critical decisions continuously and rapidly; and poorly defined outcomes. All of this is in the context of a "guild system" of responsibility, accountability, and power (Markus, 1983; Vogel, 2003). The healthcare industry also has to support personal and moral values, which in themselves are very complex. The judgments taken about personal attitudes to risk and potential benefit on interventions are all driven by our unique physical and mental makeup and local context—though our values are constantly changing over time.

The implementation of the national program demonstrates how healthcare services are perhaps the most complex large-scale business of UK's economy. More variability and uncertainty at the point of service, as to causality, processes, and to the outcome of that investment exists in healthcare delivery than in any other public sector. With such "variability and uncertainty" in the healthcare business, it is not surprising that identifying and measuring, let alone valuing, a financial return on investment (ROI) from computers in healthcare presents special challenges.

Value is a much broader concept than "benefits" as it implies the additional gain from one investment as opposed to another (Lucas, 1993; Sambamurthy & Zmud, 1994). The national program, like other IT projects, can generate value in many ways. As well as creating quality and process improvements, data from the system has utility that is much more subjective than that of any other resource (Guah & Currie, 2004). While data may be viewed as a commodity, asset, or resource, information is derived from the qualitative use of data and involves value judgments.

A number of the difficulties in "measuring" the national program's potential value the patients are that (Currie & Guah, 2006; Hendy et al., 2005):

- many infrastructure investments cannot be cost justified on an ROI basis;
- some of its sob-systems are being implemented to change difficult-to-measure NHS staff actions;
- many parts may be strategic systems, thus, eluding measurement;
- much of the new investment does not take into account the prior costs;
- efficiency (doing things right) is easier to measure than effectiveness (doing the right things); and
- since effectiveness (doing the right things) and innovation (doing new things) can not be readily quantified in terms of traditional outputs, improvements are not usually reflected in economic efficiency statistics.

While the effectiveness of a healthcare delivery process can be defined as "the extent to which a desirable outcome is achieved in a timely manner," the efficiency of healthcare delivery process could also be defined as "the extent to which healthcare delivery process is completed with the minimal consumption of resources." Consider the rather complex process of diagnosing and treating certain categories of patients in the NHS, most healthcare delivery processes can be effective (the patient achieves a full recovery and returns to his/her normal activities within 3 months) but relatively inefficient (say the patient had a 15-day inpatient stay, extensive ambulatory services, and consumed $300,000 in healthcare resources). The healthcare delivery process also can be ineffective (the patient has minimal subsequent capacity and never returns to his/her normal activities) but efficient (if the patient had a 3-day inpatient stay, a short post discharge ambulatory regimen, and consumed only $5,000 in healthcare resources). This demonstrates the need for healthcare managers to further strive for high effectiveness in combination with high efficiency and at the lowest possible costs.

Most components of the national program are intended for use in the NHS primarily to capture and manipulate data for improved—both clinical and administrative—decision making. Majeed (2003) suggests that part of the value anticipated from the national program derives from improvements in the effectiveness of the clinical decision-making process. It should enable physicians and nurses to make better, quicker decisions through mechanisms such as online access to evidence-based results for designated disease conditions, assistance in placing orders (detecting a drug-drug interaction before the order for a medication is actually placed), and receiving an alert electronically after a significantly abnormal test result (Keeler & Newman, 2001). Increasing the effectiveness of the clinical decision-making process should also lead to higher efficiency of that process, which should consequently lead to fewer errors being made and fewer resources being consumed. Among many problems highlighted by Majeed (2003), was the fact that necessary information was often difficult to obtain or simply unavailable, and what was available did not always support the clinical decision-making process.

Improved access to records means dramatically improved efficiencies in a variety of areas (Lucas, 1993). With the old paper-based system, the average turn-around time before laboratory and radiology reports reached the physician was several days. With the national program, diagnostic test results are available within seconds of being verified and has the potential of being brought to the physician's attention through their e-mails on the desktop or text message on a mobile (for telemedicine). In addition, the redundant orders that were often triggered by result delays have been virtually eliminated with the faster turnaround time, as well as with duplicate verifications for pharmaceutical orders (Majeed, 2003).

The national program will vastly improve communication between clinicians, particularly between nurses and physicians, and the emergency room and primary care physicians. It will give nurses instant access so that they can communicate with the doctors in the right way; the nurses are less frustrated because they do not have to go through the paper trail like they did before. These intangibles we know can be difficult to value but they are real enough to the participants.

CONCLUSION

The UK NHS is a highly institutionalised and complex system, which exists and operates both as a material-resource environment and a set of beliefs, rules, and ideas. Although these two environmental facets are conceptually distinct, material-resource environments are influenced by the institutional context. The selection of resources and how they are combined and deployed is determined by institutional beliefs and rule systems (Meyer & Rowan, 1991). By looking at the national program, this article has shown that implementing such a large IT project in the healthcare environment involves a supplier base that is seriously diverse, stretching from locally based specialists in particular applications and/or industry sectors to suppliers that are capable of applying a combination of sophisticated management techniques and technology investment to achieve new levels of process performance.

The primary contribution of this article has been to provide a theoretical basis drawing from institutional theory, which was used to analyse the NHS implementation of the national program. The theorisation goes beyond the relatively simplistic types of studies that dominate the IS literature today. Much to the contrary, it has been shown that an implementation strategy can accommodate elements such as the links between culture, contradiction and conflict, an analysis of detailed work patterns, and the dynamic and emergent nature of political involvement at national level.

The theory has been illustrated using limited empirical examples only, with a focus on the NHS systems, but it could be used to analyse any case study involving healthcare systems from any parts of the developed world. Viewed from a more critical perspective, however, any theory illuminates some elements of particular case situations and is relatively silent on others. The NHS has grown within an environmental niche that arose out of a complex interaction between the national healthcare environment, business environment, the organisational environment, and the people within the NHS. Changes within the organisation subsequently rendered the environment hostile to the national program, which was affected by its changing links with organisational structure and people, the changing responses of people within the NHS to the environment around them, and the changing individual and collective mindsets and understanding of those people. While a detailed discussion of ways in which this can be achieved is beyond the scope of this article, some broad approaches have been mentioned.

In the current environment of increasing demands for better quality of healthcare from patient and seemingly reduced amount of funding from national governments, the need for suitable institutional theory is increasingly common and the IS field must increase its understanding of the problematic issues involved and approaches to resolving them. It is hoped that this article makes a modest contribution to these goals.

Chapter 6.5
Information Assurance in E-Healthcare

Sherrie D. Cannoy
The University of North Carolina at Greensboro, USA

A. F. Salam
The University of North Carolina at Greensboro, USA

INTRODUCTION

There is growing concern that the healthcare industry has not adopted IT systems as widely and effectively as other industries. Healthcare technological advances generally emerge from the clinical and medical areas rather than clerical and administrative. The healthcare industry is perceived to be 10 to 15 years behind other industries in its use of information technology (Raghupathi & Tan, 1997). Incorporating new technology into the healthcare organization's processes is risky because of the potential for patient information being disclosed. The purpose of this study is to investigate the information assurance factors involved with security regulations and electronic medical record initiatives—a first necessary step in making the healthcare industry more efficient. Noncompliance of a healthcare organization's employees with security and privacy policies (i.e., information assurance) can result in legal and financial difficulties, as well as irreparable damage to an organization's reputation. To implement electronic medical initiatives, it is vital that an organization has compliance with security and privacy policies.

E-health technology is a relatively current phenomenon. There are two types of distance-related healthcare that are technology driven. Telehealth is known for involving telemedicine—medicine practiced over a distance, with the impetus of control being in the physician's hands (Maheu, 2000). E-health involves the patient or physician actively searching for information or a service, usually via the Internet (Maheu). Electronic medical records fall into the e-health category because the physician, healthcare partners, and patient would be able to access the information through an Internet connection.

Security and information assurance are critical factors in implementing e-health technologies. There is a lack of a well-developed theoretical framework in which to understand information assurance factors in e-healthcare. The theory of reasoned action (TRA) and technology acceptance model (TAM) enable a conceptual model of information assurance and compliance to be formed in the context of healthcare security and privacy policy. The relationship between behavior and intentions, attitudes, beliefs, and external factors has been supported in previous research and will provide a framework for ensuring compliance to security and privacy policies in healthcare organizations so that HIPAA (Health Insurance Portability and Accountability Act) regulations are enforced and electronic medical records (EMRs) can be securely implemented.

Traditionally, records in the healthcare industry have been paper based, enabling strict accessibility to records. This allowed for confidentiality of information to be practically ensured. The uniqueness of healthcare records and the sensitive information they contain is specific to the industry. Over the many years that medical records have been kept, those involved in the field have undertaken a self-imposed rule of stringently protecting the patient information while providing quality care.

The patient's expectation for confidentiality of personally identifiable medical records is also critical. According to Rindfleisch (1997, pp. 95-96), in his study of healthcare IT privacy, the threats to patient information confidentiality are inside the patient-care institution; from within secondary user settings which may exploit data; or from outsider intrusion into medical information. Rindfleisch (1997) examined specific disclosures which could release sensitive information such as emotional problems, fertility and abortions, sexually transmitted diseases, substance abuse, genetic predispositions to disease—all of which could cause embarrassment and could affect insurability, child custody cases, and employment.

The process of healthcare treatment includes not only the patient and physician but also nurses, office staff who send out bills and insurance claims, the insurance company, billing clearinghouses, pharmacies, and any other companies to which these processes can be outsourced. There is an estimate that states as many as 400 people may have access to your personal medical information throughout the typical care process (Mercuri, 2004). The government is also a partner in national health concerns, and also maintains databases containing information on contagious diseases, cancer registries, organ donations, and other healthcare information of national interest. (See http://www.fedstats.gov/programs/health.html for a listing of the databases.)

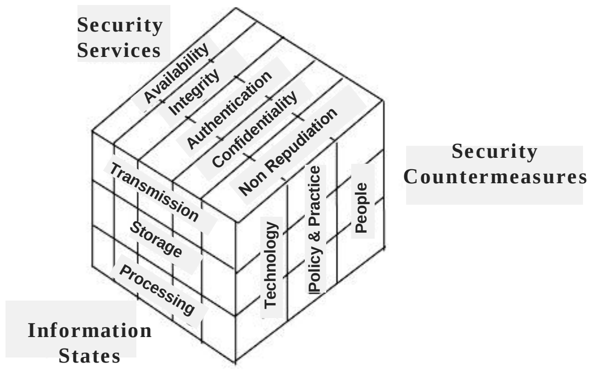
With the advent of government mandates such as EMRs and HIPAA regulations, the increased accessibility of sensitive records requires intense effort to create policies that limit access for those who are authorized. Although there is an area of information economics which views information as an asset that can be numerically valued for its benefit, the same perspective has not been adopted in healthcare. Especially in the United States, clinical information and patient care are considered proprietary (Hagland, 2004). There is no specific associated cost with one's medical information—what damage is done when one's medical information has been utilized improperly? Even though damages are ill-defined, there are regulations and standards for emerging technology in healthcare. The two most current important security and privacy issues involve HIPAA regulation and the government mandate for EMRs.

BACKGROUND

The HIPAA Regulation . . .

HIPAA was enacted in 1996 and covers insurance reform for ensuring preexisting coverage when changing jobs as well as the standardization of

Figure 1. Information assurance model (From Maconachy, Schou, Ragsdale, & Welch, 2001)



electronic transmissions. It consists of two components, the Security Rule and the Privacy Rule. If the rules are not enacted, there are severe financial penalties enforced by the government (Mercuri, 2004). Also, an organization risks having internal employees disclose information that would be of a confidential nature to patients, which could result in legal consequences.

The Privacy Rule (Markus, 2004) focuses on the use and disclosure of medical information, specifically that which is personally identifiable, also known as protected health information (PHI) in the industry. The goal of the Privacy Rule is to ensure protection of PHI across transmissions to health partners (insurance companies, billing clearinghouses, etc.). This requires the patient to fill out the Notice of Privacy Practices Patient Acknowledgment form, which suggests that the patient has read the HIPAA privacy information and allows the patient to determine the people to which one's PHI can be disclosed.

The Security Rule requires that PHI be protected specifically in electronic storage and transmissions. Implications for HIPAA compliance have been intense. Developing standards and security encryptions for existing software, as well as ensuring that third-party partners are compliant, has been time-consuming and costly. However, Privacy and Security Rule compliance will be critical for successful implementation of electronic medical record infrastructure.

Electronic Medical Records

An electronic medical record (EMR) contains a patient's medical history with a physician. The capture of one's medical information can be made available to authorized users such as other physicians, pharmacists, insurance companies, and the government. Due to the inherent virtualization of the record, the physician's office or hospital will not have physical control as they have in the past. Therefore, security measures, mainly technical components, are critical to EMR implementation. EMR records will also fall under the HIPAA Privacy and Security Rules. Since the healthcare industry has been reluctant to implement EMR plans for cost, security, or other reasons, the government has taken an active role to encourage development of EMRs through financial incentives. Healthcare and IT organizations are also collaborating to develop standards (Mercuri, 2004).

Measures Needed for Better Management

Handling of sensitive information will be vital to understanding the compliance for HIPAA regulation, as well as for the implementation of EMRs. With information now being stored and transmitted electronically, a new paradigm exists for power over the information. How organizations measure the success of HIPAA compliance will reflect on how sensitive information is handled. However, it is uncertain how the healthcare industry monitors this. The old adage of "what is not measured is not managed" comes to mind and one wonders if compliance will be monitored after training is administered and policies are implemented. The purpose of this study is to develop a preliminary framework of issues that determine compliance to information assurance and security policies.

Information Assurance

Figure 1 (from Maconachy, Schou, Ragsdale, & Welch, 2001) in which the aspects of information assurance are depicted. They discuss information assurance as an expansion of the "coverage, responsibilities, and accountability of security professionals" which includes "proactive offensive activities" (p. 307).

Aspects of security services, information, and security countermeasures fall under the information assurance (IA) umbrella. The focus of IA is integrating the relationships between these, since a weakness in one would result in a weakness in the entire system. The information can be either currently in storage, in processing, or in transmission mode. The Security Services are carried not only by technological details such as availability of the system, integrity of the data, authentication of users, and confidentiality, but by operations and procedures, and, most importantly, people. People "are the heart and soul of secure systems ... and require awareness, literacy, training, and education in sound security practices for the system to be secured" (Maconachy et al., p. 308). Whether or not a person follows a policy and uses the IA technology will determine how secure the system ultimately will be.

In terms of healthcare, information assurance provides a well-developed model in which to integrate the technological and behavioral issues in e-Healthcare security and privacy context. E-healthcare will be successful only if information assurance is carefully planned and monitored for compliance. In the premise offered for this research, information assurance is inherent in security and privacy policy compliance, and provides the structure for integrating the variety of research areas involved. Therefore, a theoretically-sound framework for incorporating TRA and TAM in the context of healthcare information assurance is proposed to bridge the gap between policy creation and policy compliance. This area has not been researched previously and will provide an important contribution to e-healthcare implementation in the industry, especially in bridging the gap between the technical and behavioral aspects of e-healthcare information assurance.

Government resources from Health and Human Services and associated National Institute for Standards and Technology (NIST) are helpful in framing the variables into a model for information assurance and compliance. The Department of Health and Human Services developed *Delivering Consumer-Centric and Info-Rich Healthcare: Framework for Strategic Action* (Thompson & Brailer, 2004), which discusses the readiness for change in healthcare, as well as a framework for action and leadership. NIST offers policy and security frameworks as well as healthcare tools and other assistance for both the clinical and administrative aspects (see http://www.nist.gov/public_affairs/healthcare.htm).

Healthcare Culture, Security, Compliance, and Information Assurance

It is often stated that an organization is only as strong as the weakest link. "When you start bringing in the users, your system is going to be as trustworthy as the least trustworthy person who touches it" (Baldwin, 2000). The opportunity with HIPAA and EMRs is to realize that privacy and security of PHI must be managed in a technologically driven environment. This supports our premise that, although technological tools can aid in monitoring security and privacy compliance, they cannot provide the comprehensive measure—comprehensive adoption includes people issues. Trish Markus (2004) questioned the establishment of a "culture of compliance," which advocates the management involvement and commitment through communication and training procedures. Mercuri (2004) quoted a chief information officer as stating that HIPAA "compliance is not sold in a bottle," therefore, "providing employees with policies and procedures for their job classification and requiring them to read and sign off on them" is not adequate (p. 27). Culture includes a shared vision and a positive link to company strategy. Indeed, organizational culture can determine if compliant attitudes, intentions, and behaviors will become second nature (Gue, 2002).

Theory-Based Research

Academic research in the healthcare area has been specific, usually technology-related versus theory building and testing. TRA and TAM are utilized for the purpose of this research because the factors including a person's attitudes, beliefs, and intention to adopt a technology such as EMRs and to examine one's intentions to comply with information assurance policy associated with those EMRs. Hu, Chau, and Tulu et al. (1999, 2002, 2003) researched TAM in the context of healthcare technology adoption, with mixed results. In their 1999 telemedicine study Hu et al. found that TAM is adequate, with exception to TAM's explanation of attitude and intention. Perceived usefulness was significant on intention to use telemedicine. For the physician to perceive telemedicine as being useful, Hu et al. (1999) suggested that proper user training is essential. Attitude also significantly influenced physician behavioral intention.

In similar studies, TRA was utilized and was extended in information technology usage. Amoako-Gyampah and Salam (2004) measured constructs for ERP (enterprise resource planning) project communication, training, belief in the project benefits, attitude towards ERP system, perceived usefulness, ease of use, and behavioral intention to predict usage of ERP systems. TAM was extended to external variables of project communication, beliefs in ERP system benefits, and training. Findings were significant for project communication and training affect on beliefs in the system benefits. Also, shared beliefs strongly affected both PU (perceived usefulness) and PEU (perceived ease of use) in the ERP setting.

An example of TRA utilization in another study by Salam, Iyer, Palvia, and Singh (2005) examined associations between the formation of trust, technology usage, and development of a relationship with a vendor website. It suggests that managers develop factors that affect the trustworthiness of their companies. This correlates to managing the factors that affect compliance with security and privacy policies.

Figure 2. Diagram of the theory of reasoned action

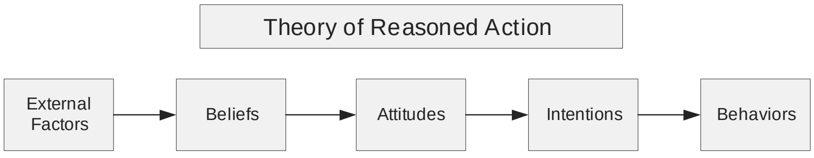


Figure 3. Diagram of the technology acceptance model

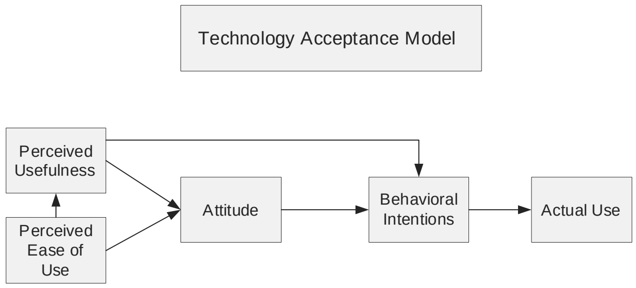


Capturing Information Assurance Issues in Healthcare IT Policy Implementation

The widely accepted theory of TRA has been utilized often to support the causal relationships between external factors, beliefs, attitudes, intentions, and behavior. TAM is a TRA spin-off and has supported the intention to use, perceived usefulness, and behavior when adopting new technology. This same theoretical basis can be used to examine the acceptance and compliance behavior of users who are to adopt new organizational policy. In the context of information assurance, the TRA model will capture the compliance of healthcare security and privacy policies (see Figure 2).

Our premise is that through one's external factors, beliefs, attitudes, and intentions, one will decide to either comply or not comply with security and privacy policies. We will examine the context of compliance with security and privacy policies within the TRA, because the user of the policy will, in essence, determine the success of such policies and compliance with HIPAA. The user can be defined as the physician, clerical staff member, IT staff, administrative staff, nursing staff, and so forth.

COMPONENTS OF THE FRAMEWORK

Organizational Culture

The main components of organizational culture which relate to information assurance compliance are management commitment and its enforcement of IA Policies. The extent to which management seems committed and is willing to enforce IA policies will affect how strongly one believes in management commitment and its enforcement of those policies.

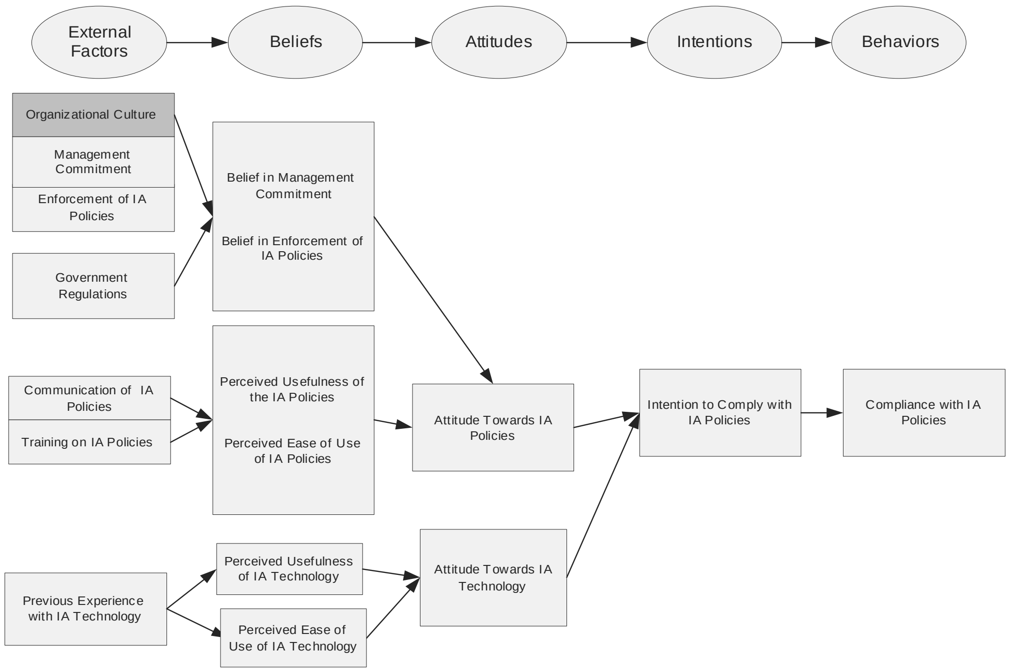
Government Regulations

Government regulations such as HIPAA and mandates such as EMRs will affect how strongly the management of healthcare organizations is committed to communicating and enforcing information assurance policies.

Training and Communication

Amoako-Gyampah and Salam (2004) found in their research on ERP implementation that Training and Communication influence the beliefs on attitude and its mediation effects on the intention to use an ERP system. Accordingly, training on IA Policies and the communication of those policies should also have an influence on the

Figure 4. A conceptual framework for applying the theory of reasoned action and the technology acceptance model in e-healthcare information assurance



perceived ease of use and perceived usefulness of such policies. If employees feel that training is helpful in information assurance and compliance, employers may be urged to offer further training, even in the maintenance phase, so that information assurance can be increased as much as possible. If the policies are communicated often, and in various ways, especially in how they are important and relate ensuring security and privacy of patient information, employees should be more apt to find it beneficial to use and comply with the policies.

Previous Experience with IA Technology

The TAM model is appropriate and supported in demonstrating the influence between a person's prior experience with a technology and how useful and easy that technology will be to use. Much of the research has shown that this perception of usefulness and ease of use enables one to develop attitudes towards that technology in order to determine whether they will use the technology (Davis, 1989; Venkatesh & Davis, 2000). In this case, the attitude towards technology will affect one's behavior and choice to comply with the policies. If the implementation of information assurance and security policies involves technological barriers that decrease functionality of the technology or are too difficult to manage, the user is less likely to use the technology, therefore, less likely to comply with the policy.

This framework captures how factors such as organizational culture, government regulations, training, policy, and previous experience lead to belief, attitude, and intention formation regarding IA policy compliance behavior. Belief systems such as management commitment, enforcement of policy, the ease of use and perceived usefulness of IA policy and technology, shape one's attitude towards IA technology and policy. This attitude development then affects one's intention to comply with IA policies and, therefore, actual compliance behavior.

FUTURE TRENDS IN E-HEALTHCARE

The environment for healthcare is changing rapidly, and the processes involved will transform how patient care is conducted. Along with the implementation of EMRs, the ultimate goal is the EHR (electronic health record), which will include the consolidation of a patient's lifetime health records from each healthcare provider. This EHR is a virtual roadmap that guides the physician in the journey to medical decision-making. Having this information at hand, even available via handheld devices, makes critical information available to physicians to share data while geographically dispersed. This is the dawn of telemedicine, which is already gaining popularity in New Zealand and Australia. Smart card technology is emerging as a new technology which can be applied to enable patients to carry their own virtual medical charts in their pockets (Raghupathi & Tan, 2002).

There are additional legal and financial issues to be handled in the future. The legal aspects of implementing telemedicine and EMRs need clarification. Who owns the EMR? Who will be responsible for attempts at unauthorized access? Will the patient be allowed to view and edit their EMRs—for example, add their living will or organ donor preferences (Pyper, Amery, Watson, Thomas, & Crook, 2001)? If a vendor is utilized to store healthcare data for an organization, what happens to the data if the company goes out of business (Songini & Dash, 2000)? Will insurance companies consider telemedicine consults for payment?

These legal, financial, and technical issues will need to be resolved so that the transformation of healthcare processes are successful and patient care is administered in the most appropriate manner possible, regardless of how, where, and what information is utilized to make the most informed medical decisions.

CONCLUSION

The contribution of this research is to propose a theoretically sound framework in which behavior and technology are analyzed in compliance and information assurance in e-healthcare. This will enable future research in moving the field forward in healthcare information assurance research and practice. The next step in this research is to examine how healthcare organizations can measure the success of security and privacy policy compliance to achieve an information assurance threshold. The importance of understanding compliance within this context will be critical to determining the success of security and privacy policies.

KEY TERMS

Confidentiality: Not releasing or disclosing information to unauthorized individuals, entities, or processes (Fariborz, Navathe, Sharp, & Enslow, 2003).

EMR: Electronic medical record; also known as EHR (electronic health record), CMR (computerized medical record) or CPR (computer-based patient record). There are subtle differences between these; for example, EHR is often used specifically for ambulatory care records (Marietti, 1998).

HIPAA: Health Insurance Portability and Accountability Act (1996) requires the secretary of health and human services to publicize standards for the electronic exchange, privacy, and security of health information.

- **Privacy Rule:** addresses the need for healthcare organizations to allow patients to choose how their information is disclosed
- **Security Rule:** addresses the security of electronic transmission of medical information

Information Assurance: Information operations that protect and defend information and systems by ensuring their availability, integrity, authentication, confidentiality, and nonrepudiation (Maconachy, Schou, Ragsdale, & Welch, 2001).

NIST: National Institute of Standards and Technology

- NIST was founded in 1901 and is a non-regulatory federal agency within the U.S. Commerce Department's Technology Administration. NIST's mission is to develop and promote measurement, standards, and technology to enhance productivity, facilitate trade, and improve the quality of life. (see www.nist.gov)

Privacy: The rights of individuals regarding collection, storage, processing and use in decision making about personal information about themselves (Turn, 1999).

Security: A collection of policies, procedures, and safeguards that help maintain integrity and availability of information systems and control access to their contents (Rindfleisch, 1997).

Telemedicine: "When physicians use electronic communication and information technologies to provide or support clinical care from a distance" (Patel & Rushefshy, 2002, p. 328).

This work was previously published in Encyclopedia of E-Commerce, E-Government, and Mobile Commerce, edited by M. Khosrow-Pour, pp. 600-607, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 6.6

Information Security Management in Picture Archiving and Communication Systems for the Healthcare Industry

Carrison KS Tong
Pamela Youde Nethersole Eastern Hospital & Tseung Kwan O Hospital, Hong Kong

Eric TT Wong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Like other information systems in banking and commercial companies, information security is also an important issue in the healthcare industry. It is a common problem to have security incidences in an information system. Such security incidences include physical attacks, viruses, intrusions, and hacking. For instance, in the U.S.A., more than 10 million security incidences occurred in the year of 2003. The total loss was over $2 billion. In the healthcare industry, damages caused by security incidences could not be measured only by monetary cost. The trouble with inaccurate information in healthcare systems is that it is possible that someone might believe it and do something that might damage the patient. In a security event in which an unauthorized modification to the drug regime system at Arrowe Park Hospital proved to be a deliberate modification, the perpetrator received a jail sentence under the Computer Misuse Act of 1990. In another security event (The Institute of Physics and Engineering in Medicine, 2003), six patients received severe overdoses of radiation while being treated for cancer on a computerized medical linear accelerator between June 1985 and January 1987. Owing to the misuse of untested software in the control, the patients received radiation doses of about 25,000 rads while the normal therapeutic dose is 200 rads. Some of the patients reported immediate symptoms of burning and electric shock. Two died shortly afterward and others suffered scarring and permanent disability.

BS7799 is an information-security-management standard developed by the British Standards Institution (BSI) for an information-security-management system (ISMS). The first part of BS7799, which is the code of practice for information security, was later adopted by the International Organization for Standardization (ISO) as ISO17799. The second part of BS7799 states the specification for ISMS. The picture-archiving and -communication system (PACS; Huang, 2004) is a clinical information system tailored for the management of radiological and other medical images for patient care in hospitals and clinics. It was the first time in the world to implement both standards to a clinical information system for the improvement of data security.

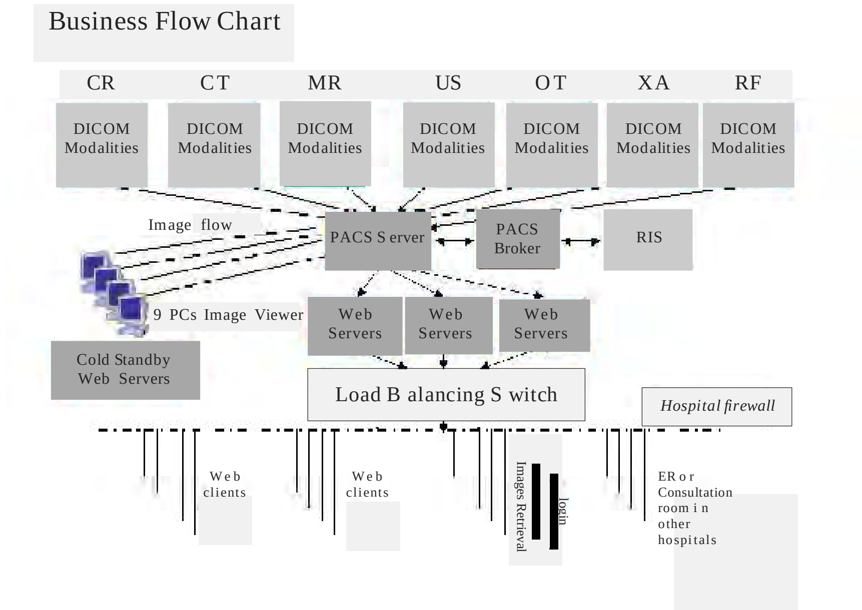
BACKGROUND

Information security is the prevention of, and recovery from, unauthorized or undesirable destruction, modification, disclosure, or use of information and information resources, whether accidental or intentional. A more proactive definition is the preservation of the confidentiality, integrity, and availability (CIA) of information and information resources. Confidentiality means that the information should only be disclosed to a selected group, either because of its sensitivity or its technical nature. Information integrity is defined as the assurance that the information used in making business decisions is created and maintained with appropriate controls to ensure that the information is correct, auditable, and reproducible. As far as information availability is concerned, information is said to be available when employees who are authorized access, and whose jobs require access, to the information can do so in a cost-effective manner that does not jeopardize the value of the information. Also, information must be consistently available to conduct business smoothly. Business-continuity planning (BCP) includes provisions for assuring the availability of the key resources (information, people, physical assets, tools, etc.) necessary to support the business function.

The origin of ISO17799/BS7799 goes back to the days of the UK Department of Trade and Industry's (DTI) Commercial Computer Security Centre (CCSC). Founded in May 1987, the CCSC had two major tasks. The first was to help vendors of IT security products by establishing a set of internationally recognised security-evaluation criteria and an associated evaluation and certification scheme. This ultimately gave rise to the information technology security-evaluation criteria (ITSEC) and the establishment of the UK ITSEC scheme. The second task was to help users by producing a code of good security practices and resulted in the *Users Code of Practice* that was published in 1989. This was further developed by the National Computing Centre (NCC) and later a consortium of users, primarily drawn from British industry, to ensure that the code was both meaningful and practical from a user's point of view. The final result was first published as the British Standards guidance document PD 0003, *A Code of Practice for Information Security Management*, and following a period of further public consultation, it was recast as British Standard BS7799: 1995. A second part, BS7799-2: 1998, was added in February 1998. Following an extensive revision and public consultation period in 1997, the first revision of the standard, BS7799: 1999, was published in April 1999. Part 1 of the standard was proposed as an ISO standard via the "fast track" mechanism in October 1999, and then published with minor amendments as ISO/IEC 17799: 2000 on December 1, 2000. BS7799-2: 2002 was officially launched on September 5, 2002.

PACS is a filmless (Dreyer, Mehta, & Thrall, 2001) and computerized method of communicating and storing medical image data such as computed radiographic (CR), digital radiographic (DR), computed tomographic (CT), ultrasound (US), fluoroscopic (RF), magnetic resonance (MRI), and other special X-ray (XA) images. A

Figure 1. Business flowchart of the Tseung Kwan O Hospital picture-archiving and -communication system



PACS consists of image and data acquisition and storage, and display stations integrated by various digital networks. Full PACS handles images from various modalities. Small-scale systems that handle images from a single modality (usually connected to a single acquisition device) are sometimes called *mini-PACS*.

The medical images are stored in an independent format. The most common format for image storage is DICOM (Digital Imaging and Communications in Medicine), developed by the American College of Radiology and the National Electrical Manufacturers' Association.

Tseung Kwan O Hospital (TKOH) is a newly built general acute hospital (built in 1999) with 458 in-patient beds and 140 day beds. The hospital is composed of several clinical departments including medicine; surgery; paediatrics and adolescent medicine; eye, ear, nose, and throat; accident and emergency, and radiology. A PACS was built in its radiology department in 1999. The PACS was connected with the CR, CT, US, RF, DSA (Digital Subtraction Angiogram), and MRI system in the hospital. The hospital has become filmless since a major upgrade of the PACS in 2003.

An ISO17799/BS7799 ISMS was implemented in the TKOH PACS in 2003. During the implementation, a PACS security forum was established with the active participation of radiologists, radiographers, medical physicists, technicians, clinicians, and employees from the information technology department (ITD). After a BS7799 audit conducted in the beginning of 2004, the TKOH PACS was the world's first system with the ISMS certification.

In this article, the practical experience of the ISO17799/BS7799 implementation and the quality-improvement process of such a clinical information system will be explained.

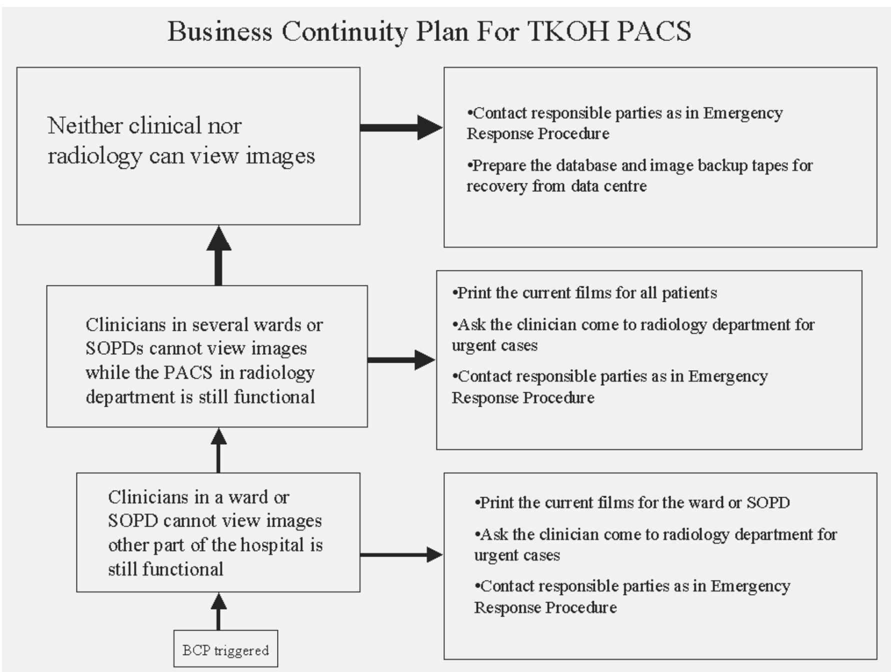
MAIN FOCUS OF THE ARTICLE

In TKOH, the PACS serves the whole hospital including all clinical departments. The implementation of ISO17799 and BS7799 was started with

Table 1. Result of BIA

ess No.	Location			Person		Level	bility	of Impor tance
1	PACS broker	Hardware failure	Patient demographic-data retrieval	Radiographers, ITD	Manual input of patient demographic data	1	1	1
2	PACS servers	Hardware failure	Image receiving	PACS team	PACS cannot receive new images	2	1	2
3	SAN	Hardware failure	Image online storage	PACS team	No online image available in PACS. User still can view the images in the Web servers.	2	1	2
4	PACS servers	Hardware failure	Image verification	PACS team	Image data maybe different from what is in the RIS	1	1	2
5	Image viewers	Hardware failure	Image reporting	PACS team, radiographers	Radiologists cannot view images in the PACS server for advanced image processing and reporting. However, they can still see the images in the Web servers.	2	1	2
6	Jukebox	Hardware failure	Image archiving to MOD jukebox	PACS team	Long-term archiving of the images. There is a risk of lost images in the SAN.	2	2	4
7	Tape library	Hardware failure	Image archiving to tape library	PACS team	Another copy of long-term archiving. There is a risk of lost images in the SAN.	2	1	2
8	Jukebox	Hardware failure	Image prefetching from MOD jukebox	Radiologists, radiographers	Users cannot see the previous images. They cannot compare the present study with the previous.	2	2	4
9	Tape library	Hardware failure	Image prefetching from tape library	Radiologists, radiographers	Users cannot see the previous images. They cannot compare the present study with the previous.	2	1	2
10	Web servers	Hardware failure	Image distribution to clinicians	Clinicians, radiographers	The clinician cannot make a diagnosis without the images.	3	2	6
11	Cisco switches	Hardware failure	Image distribution through Cisco switches	Clinicians, radiographers	The clinician cannot make a diagnosis without the images.	3	1	3
12	Load-balancing switch	Hardware failure	Web-server load balancing	PACS team	The clinician cannot make a diagnosis without the images.	2	1	2
13	RAS server and Cisco router	System malfunction	Remote maintenance	PACS team	Vendor cannot do maintenance remotely.	1	1	1

Figure 2. Business-continuity plan for the TKOH PACS



the establishment of an ISMS for the PACS at the beginning of 2003. For effective implementation of ISO17799 and BS7799 in general, four steps will be required.

1. Define the scope of the ISMS in the PACS.
2. Make a risk analysis of the PACS.
3. Created plans as needed to ensure that the necessary improvements are implemented to move the PACS as a whole forward toward the BS7799 objective.
4. Consider other methods of simplifying the above and achieving compliance with minimum effect.

Implementation of BS7799 Controls in the TKOH PACS Security Forum

A PACS security forum was established for the effective management of all PACS-related security issues in the hospital. The members of the forum were the hospital chief executive, radiologist, clinician, radiographers, medical physicists, technicians, and representatives from the information technology department. One of the major functions of the PACS security forum was to make the security policies for the management of the PACS (Peltier, 2001a). Regular review of the effectiveness of the management was also required.

Business-Continuity Plan

BCP (Calder & Watkins, 2003) is a plan that consists of a set of activities aimed at reducing the likelihood and limiting the impact of disaster events on critical business processes. By the practice of BCP, the impact and downtime of the hospital's PACS system operation due to some change or failure in the company operation procedure is reduced. BCP is used to make sure that the critical part of the PACS system operation is not affected by a critical failure or disaster. The design of this BCP is based on the assumption that the largest disaster is a complete breakdown of the PACS room in the radiology department of TKOH. The wards, the specialist out-patient department (SOPD), and the imaging modalities should still all be functional.

During the design of a BCP, a business-impact analysis (BIA) of the PACS was studied. The BIA was a study of the vulnerabilities of the business flow of the PACS, and it is shown in the following business flowchart.

In the above flowchart, image data were acquired by the CR, DR, CT, US, RF, MRI, XA, and other (OT) imaging modalities such as a film digitizer. The acquired image data were centrally archived to the PACS server, which connected to a PACS broker for the verification of patient demographic data with the information from the Radiology Information System (RIS). In the PACS server, a storage-area network (SAN), a magneto-optical disk (MOD) jukebox, and a tape library were installed for short-term, long-term, and backup storage. The updated or verified image was redirected to the Web server cluster (Menasce & Almeida, 2001) for image distribution to the entire hospital including the emergency room (ER) and consultation room. The load-balancing switch was used for nonstop service of image distribution to the clinicians. A cluster of Cisco switches was installed and configured for automatic fail-over and firewall purposes. The switches connecting between the PACS network and hospital network were maintained by the information technology department (*A Practical Guide to IT Security for Everyone Working in Hospital Authority*, 2004; *Security Operations Handbook*, 2004). A remote-access server was connected to the PACS for the remote service of the vendor.

Business-Impact Analysis

In the BIA (Peltier, 2001b), according to the PACS operation procedure, all potential risks and impacts were identified. The responsibilities

Table 2.

Step	Recovering Subprocess	Responsible Person	Process Location
1	Image distribution to clinicians	PACS team, contractor	Web servers
2	Image distribution through Cisco switches	PACS team, contractor	Cisco switches
3	Image online storage	PACS team, contractor	PACS servers, SAN
4	Image reporting	PACS team, contractor	Image viewers
5	Image prefetching from MOD jukebox	PACS team, contractor	MOD jukebox
6	Image prefetching from tape library	PACS team, contractor	Tape library
7	Image receiving	PACS team, radiographers, contractor	PACS servers
8	Image verification	PACS team, radiographers, contractor	PACS servers
9	Web-server load balancing	PACS team, contractor	Load-balancing switch
10	Image archiving to MOD jukebox	PACS team, contractor	Jukebox
11	Image archiving to tape library	PACS team, contractor	Tape library
12	Patient demographic-data retrieval	Radiographers, ITD	PACS broker
13	Remote maintenance	PACS team	RAS server and Cisco router

Table 3.

DRP Level Triggered	Scope	Recovery Time
1	Clinicians in a ward or the SOPD cannot view images while other parts of the hospital are still functional.	Half day for the recovering of subprocess no. 10
2	Clinicians in several wards or the SOPDs cannot view images while the PACS in the radiology department is still functional.	One day for the recovering of subprocess nos. 10 and 11
3	Neither the clinical department nor radiology can view images.	One week for the recovering of subprocess nos. 1 to 13

of relevant teams or personnel were identified according to the business flow of the PACS. The critical risk(s), which may affect the business operation of the PACS, could be determined by performing a risk evaluation of the potential impact. One of the methods in the BIA was to consider the contribution of the possibility of risk occurrence for prioritization purposes. The result of the BIA is shown in the following table.

In table 1, the responsible person for each business subprocess was identified to be PACS team, radiologists, radiographers, clinicians, or the information technology department. The most critical subprocess in the TKOH PACS was associated with the Web servers. Once the critical subprocess was identified, the BCP could be designed for the system as shown in the following figure. A responsible person for the BCP was also assigned.

Disaster-Recovery Plan

Disaster-recovery planning (DRP; Toigo, 1996), as defined here, is the recovery of a system from a specific unplanned domain of disaster events such as natural disasters, or the complete destruction of the system. Following is the DRP for the TKOH PACS, which was also designed based on the result of the above BIA.

Table 4.

Process Flow	Operation	Remark
Document Creation	Manuals, procedures, and work instruction should be written by the PACS team. Records should be kept in the general office.	If documents/manuals cover different departments, we should consider liaisons between different departments' roles.
Document Approval	Manuals should be approved by the chief of service (COS). Procedures and work instruction should be approved by the PACS manager. Records should be stored in the PACS room or general office.	Manual changes should be approved by the PACS manager.
Document Release	1. The distribution of manuals and procedures is controlled by the PACS manager. 2. The requirements from the customers and contracts related to information security of the PACS should be approved by the COS and released by the PACS manager.	Documents/manuals related to PACS should be signed by the PACS manager before distribution. The manual distributed should have a document number. Each personnel/department should update the document-control list regularly.
Document Revision	Manuals and documents should be amended by the document owner/department. If other personnel/departments are involved in the change, they should seek the approval from the owner/responsible departments.	Note the change and where the change is (e.g., which paragraph) on the first page. The original document/manual should be chopped or destroyed.
Document Check	For general manuals from an outsourcing party (e.g., Afga) or other department, if they are applicable for PACS operation, they should be approved and adopted for PACS operation.	For this kind of manual, if it has not been revised for 1 year, it should be reviewed.
Document Obsolescence	Obsolete documents should be collected by the PACS manager. There should be one copy (soft copy or hard copy) kept by the PACS.	Each personnel/department should keep the previous updated version of the document for future review. The other obsolete copy should be destroyed.
Document Execution	It should be guaranteed that the operator or other related PACS engineer should get the right document in the right version.	During operation, no document should be copied, duplicated, or distributed without appropriate approval.

Recovery Time for the DRP

During disaster recovery, timing was also important both for the staff and the manager. The recovery times of some critical subprocesses are listed as in the following table.

Backup Plan

Backup copies of important PACS system files, patient information, essential system information, and software should be made and tested regularly.

Security and Security-Awareness Training

Training (education concerning the vulnerabilities of the health information in an entity's possession and ways to ensure the protection of that information) includes all of the following implementation features.

i. Awareness training for all personnel, including management personnel (in security awareness, including, but not limited to, password maintenance, incident reporting, and viruses and other forms of malicious software)
ii. Periodic security reminders (employees, agents, and contractors are made aware of security concerns on an ongoing basis)
iii. User education concerning virus protection (training relative to user awareness of the potential harm that can be caused by a virus, how to prevent the introduction of a virus to a computer system, and what to do if a virus is detected)
iv. User education in the importance of monitoring log-in success or failure and how to report discrepancies (training in the user's responsibility to ensure the security of healthcare information)
v. User education in password management (type of user training in the rules to be followed in creating and changing passwords and the need to keep them confidential)

Documentation and Documentation Control

Documentation and documentation control serve as a control on the document and data drafting, approval, distribution, amendment, obsolescence, and so forth to make sure all documents and data are secure and valid.

Standard and Legal Compliance

The purpose of standard and legal compliance (Hong Kong Personal Data Privacy Ordinance, 1995) was to avoid breaches of any criminal and civil law; statutory, regulatory, or contractual obligations; and any security requirements. Furthermore, the equipment compliance of the DICOM standard can improve the compatibility and upgradability of the system. Eventually, it can save costs and maintain data integrity.

Quality of PACS

In a filmless hospital, the PACS is a mission-critical system for lifesaving purposes. The quality of the PACS was an important issue. One method to measure the quality of a PACS was measuring the completeness of the system in terms of data confidentiality, integrity, and availability. A third-party audit such as the ISO17799/BS7799 certification audit could serve as written proof of the quality of a PACS.

FUTURE TRENDS

Based on the experience in BS7799 implementation, the authors were of the view that more and more hospitals would consider similar healthcare applications of BS7799 to other safe-critical equipment and installations in Hong Kong.

CONCLUSION

ISO17799/BS7799 covers not only the confidentiality of the system, but also the integrity and availability of data. Practically, the latter is more important for the PACS. Furthermore, both standards can help to improve not only the security, but also the quality of a PACS because, to ensure the continuation of the certification, a security forum has to be established and needs to meet regularly to review and improve on existing processes.

KEY TERMS

Availability: Prevention of unauthorized withholding of information or resources.

Business-Continuity Planning: The objective of business-continuity planning is to counteract interruptions to business activities and critical business processes from the effects of major failures or disasters.

Confidentiality: Prevention of unauthorized disclosure of information.

Controls: These are the countermeasures for vulnerabilities.

Digital Imaging and Communications in Medicine (DICOM): Digital Imaging and Communications in Medicine is a medical image standard developed by the American College of Radiology and the National Electrical Manufacturers' Association.

Information-Security-Management System (ISMS): An information-security-management system is part of the overall management system, based on a business risk approach, to develop, implement, achieve, review, and maintain information security. The management system includes organizational structure, policies, the planning of activities, responsibilities, practices, procedures, processes, and resources.

Integrity: Prevention of unauthorized modification of information.

Picture-Archiving and -Communication System (PACS): A picture-archiving and -communication system is a system used for managing, storing, and retrieving medical image data.

Statement of Applicability: Statement of applicability describes the control objectives and controls that are relevant and applicable to the organization's ISMS scope based on the results and conclusions of the risk assessment and treatment process.

Threats: These are things that can go wrong or that can attack the system. Examples might include fire or fraud. Threats are ever present for every system.

Vulnerabilities: These make a system more prone to attack by a threat, or make an attack more likely to have some success or impact. For example, for fire, a vulnerability would be the presence of inflammable materials (e.g., paper).

Chapter 6.7
Modelling Context-Aware Security for Electronic Health Records

Pravin Shetty
Monash University, Australia

Seng Loke
La Trobe University, Australia

INTRODUCTION

The Internet has proven to be the most convenient and demanding facility for various types of businesses and transactions for the past few years. In recent years, business information systems have expanded into networks, encompassing partners, suppliers, and customers. There has been a global availability (Anderson, 2001; BSI Global, 2003) of resources over the Internet to satisfy different needs in various fields. The availability factor has called for various security challenges in fields where information is very valuable and not meant for all. Potential threats to information and system security come from a variety of sources. These threats may result in violations to confidentiality, interruptions in information integrity, and possible disruption in the delivery of services. So it is essential to manage the flow of information over the network with the required level of security. There are many security technologies and models that have been introduced which are capable of realizing the functions and objectives of information system security.

This article first gives a brief overview of what we term basic security policies of an integrated security model. Then it suggests context-based security policies for a health organization scenario using contextual graphs augmented with details about specific security actions, which relate to the security policies enumerated in the integrated security model.

The plan of the article is as follows. We first overview the three concepts in detail and briefly describe the concept of contextual (meta-policy) graphs. We then develop a context-based security meta-policy for securing patient records based on the security policies overviewed and discuss related work, before concluding the paper.

BASIC SECURITY POLICIES

Mobile ambients were first proposed by Cardelli and Gordon (1998a, 1998b) and then further extended by Bugliesi, Castagna, and Crafa (2004); and Braghin et al. (2002) were very efficient in modeling multilevel security issues. These three notions are very effective in modeling a foolproof security solution in a computing scenario by stating various security steps to be taken in the corresponding scenario. On this basis we have five cases that form the basic security policies in this article which we note can be concisely and precisely modeled using the mobile ambients formalism, though we omit such details of the formalism here and only describe the policies in plain language. The article uses them in appropriate scenarios depending on the context. Thus, the combined use of these five policies and a contextual graph representing the contexts of use of these policies provides a context-based security solution for pervasive environments. This section briefly describes the five policies using ambient (representing a boundary of security restrictions) notions.

Policy 1: Authenticate Returning Mobile Agent

When a privileged process (agent or person) leaves the parent ambient (e.g., a host institution) to execute some external independent activities, it relinquishes its local privileges and authority within its bounding parent ambient and ambient community. It exits the parent and might later return to the parent ambient. At this point an *authentication mechanism* is needed to check the authenticity of the returning original process. Cardelli and Gordon (1998a, 1998b, 1999) suggest that these high-level privileges must not be automatically restored to the returning agents/ processes without first verifying their identity. This is to preserve the security and integrity of the ambient as well as the services and resources contained within it.

Policy 2: Firewall Access

If any agent/process has to enter an ambient, it has to know the name of the ambient and also possess the capability to enter it. The functionality of firewall is achieved with the help of restriction primitives and with the help of anonymity of the ambient name. Thus without knowing the ambient name, no process or agent can exit or enter the parent ambient. This helps in achieving protection of the resources from unwanted agents. The ambient name could be interpreted as a secret password.

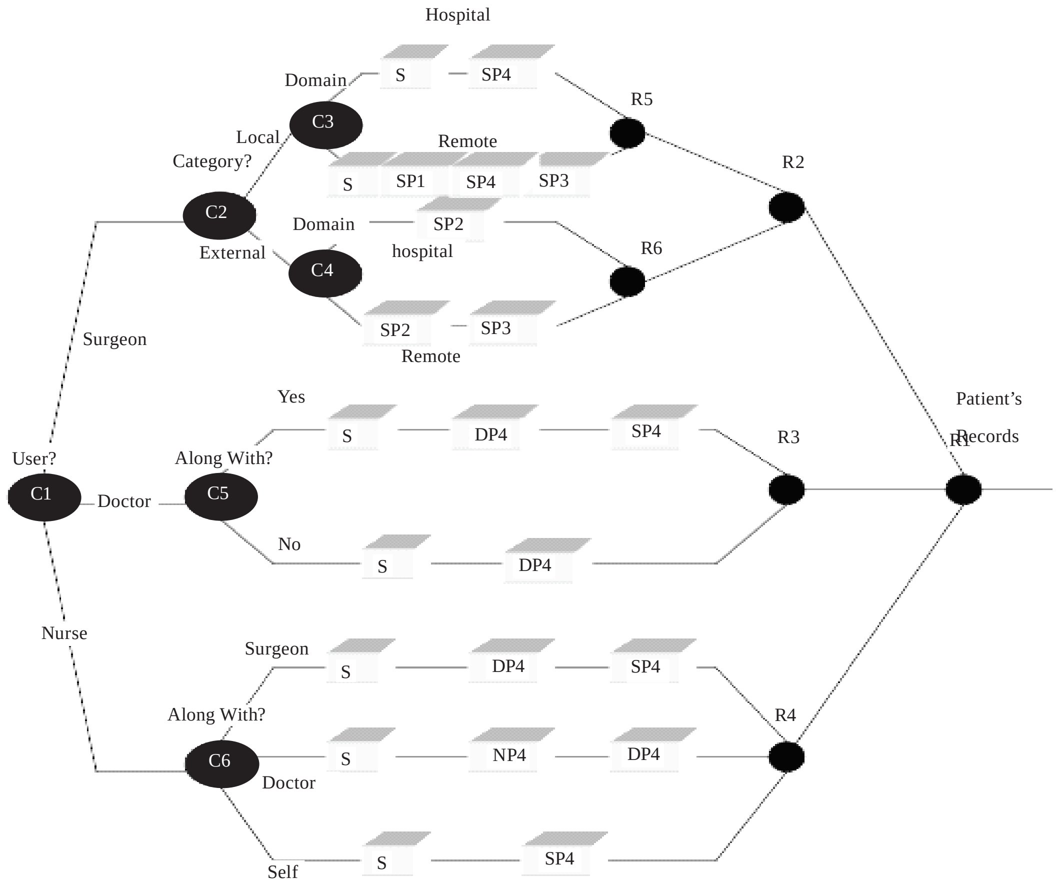
Policy 3: Encryption Using Shared Keys to Secure the Data While Communicating

Cardelli and Gordon (1998a, 1998b, 1999) also put forth the encryption primitives to communicate between two ambients or between an ambient and a remote agent. These primitives helped in maintaining the *confidentiality* of the message or data. Consider a Plaintext message *M*. The encryption of the plaintext message is done with the help of the encryption key *k*. A name can represent a shared key, as long as it is kept secret and shared only by certain parties. A shared key can be reused multiple times, for example, to encrypt a stream of messages. A message encrypted under a key *k* can be represented as a folder that contains the message and whose label is *k* (Cardelli & Gordon, 1998a, 1998b).

Policy 4: Security Across Multiple Levels

In general, an enclosed ambient environment would typically contain numerous subambients as well as active processes, agents, and information

Figure 1. Context graphs showing the various possible scenarios and security actions taken



resources. These groups of subambients within an ambient may be arbitrarily nested and organized in a hierarchical structure. Ambients and processes at the higher level of the nested structure are responsible for managing resources that are more vital and important than those at a lower level. In such multilevel environments, it is necessary to restrict the access to the flow of information depending upon the need and the security levels. Information can only flow from lower levels of security to higher levels and not conversely. A policy for this assigns levels to users and restricts information flow among the users.

Policy 5: Movement of Data and Entities Through Different Communities

The multilevel security policy mandatory access control security in the boxed ambients provided restricted access to information based on the various security levels in the hierarchical levels. The access is defined by the level at which the agents are which are predetermined based on their needs. But Braghin et al. (2002) were of the view that the implementation of mandatory access control security is complex, as agents and processes may move from one security level to another. The agents themselves may be confidential or may be carrying secure/confidential information. Thus there is no way of ensuring the agents will not be illegally attacked, accessed, or executed by untrustworthy entities at the lower security levels. The *security boundary* concept put forth by Braghin et al. (2002) guarantees absence of information leakage.

According to this concept, every high-level data or process should be encapsulated in a boundary ambient. A boundary ambient can be opened only when it is nested into another pre-specified boundary ambient. A policy for this states that the protected information cannot be read without being contained within some safety boundary (e.g., physically, an item cannot be viewed in the absence of a bodyguard).

CONTEXTUAL (META-POLICY) GRAPHS

Contextual meta-policy graphs are derived from contextual graphs (Braghin et al., 2002; Bugliesi et al., 2001a, 2001b). We replace the security actions in contextual graphs by security policies, which in turn, represent the security actions accordingly. By virtue of this embedding of policies (such as the five mentioned above) into a contextual graph, the graph becomes a meta-policy construct. The contextual meta-policy graphs are very general and can be used to depict security architecture in any scenario. The use of such graphs is to provide a high-level picture of the security framework, thereby avoiding lower details (security actions), which makes the overall architecture less cumbersome. The security actions are triggered according to the policies, which are predefined and programmed. The five security policies depicted in the integrated (in that such policies complement one another and have holistic coverage over security situations) security model above forms the basis of the graphs presented in this article. The contextual meta-policy graphs use various combinations of these five policies to define the various access paths to the patient's records. The next section presents the overall security architecture using such graphs.

SECURING ELECTRONIC HEALTH RECORDS USING CONTEXTUAL META-POLICY GRAPHS

The integrated security model discussed above is used to implement context-based security. The following model can be used in any context-aware situation. This article will explain the use of the model for securing health records. The various access possibilities depending on the context are described with the help of the contextual meta-policy graphs. This section is divided into two subsections. The first gives the details of the security policies used along with the low-level details (what security actions are triggered in each policy). The second subsection gives the actual approach for security purposes, along with an explanation of the individual access possibilities.

POLICY DEFINITION

This section outlines the various types of users associated with the electronic health records. It also specifies the various types of contextual information to be used for implementing the security policies. Finally, the various security actions to be taken depending upon the information received are also stated.

Roles: Surgeon, Doctor, Nurse.

Contextual Information Considered: Role, Location, Place

The five policies, collectively labeled the 'integrated security model', can be effectively used for implementing security in a hospital scenario for accessing a patient's records. The five policies can be described in context for the hospital scenario as follows.

The Secret code *S* in the diagram can be considered as a secret name of the hospital network, which has to be known by each and every local person who wants to access the patient's detail. This secret code is similar to the secret name of the ambient in the case of ambient terms. It is not known to foreign entities. The details about the individual usernames and passwords are stored in the systems database along with the corresponding roles.

Policy 1: Authentication

This security policy defines the way in which a valid user can access the hospital network once s/he is out of it. This type of authentication is required for the surgeon and the doctor who have to access the network and hence the patient's health records. When the surgeon goes out of the hospital network, temporarily s/he is given a secret password, which helps her/him to authenticate her/himself when s/he wants to access the network again. Apart from the local surgeon and the local doctor, no one else can access the records from outside the hospital. This security policy triggers the action such as asking the user for the secret password, which will help her/him to authenticate her/himself.

Policy 2: Foreign Agent Authentication

This security policy defines the access method for a foreign entity such as a surgeon from some other medical institution in case of emergency. The security infrastructure provides such foreign agents, which are required in case of an emergency with some special combination of passwords analogous to that of the foreign agents concept in mobile ambients. This security policy triggers actions such as asking the foreign agent for the three sets of passwords given to her/him. The first will help her/him to validate her/himself. In case the access is remote, then it is a password; otherwise, it is done by retina scan or any other biometrics. The second password is used to allow the external surgeon inside the network. The third password will help her/him to access the patient's records in the mode as per her/his role.

Policy 3: Encryption of Data

This policy secures the data from falling into destructive hands by using various encryption techniques. This security policy is required when the user is accessing the network from a remote place. For example, there might be a case where a local surgeon might have to access the patient record from a remote place and do some modifications according to the present condition of the patient. This transfer of data should be safe and confidential and not intercepted by a malicious intruder. Thus, encryption is required which is provided by this policy.

Policy 4: Security Levels

This security policy talks about role-based access control. In the hospital, the three main users considered in this article are the surgeon, the doctor, and the nurse. They have access to the patient's records in different modes and according to the need of their positions. For example the surgeon has the access to the records in all three modes (i.e., read/write/update). A doctor's access is limited to two modes (i.e., read/write), whereas the nurse's access is restricted to just one mode (i.e., read). This type of security hierarchy is analogous to the security level structure policy of the multilevel access model. This helps control access to the valuable resources depending on the role of the user in the medical institution.

Policy 5: Third-Party Authentication

This security policy discusses authentication from the third mediating party in the communication between two entities from different medical institutions. This type of authentication is required to make sure that the entities involved in the communication are authorized. This security policy plays an important role when an outside surgeon needs access to the medical record or communicates with the local network of the medical institution from a remote place. The third party should be a reliable party, giving the authorization of any information passed between the two communicating entities.

The five security policies defined above are based on the concepts of mobile ambients defined in the former sections and depict the various security approaches taken depending on the context. The next subsection elaborates on the various contexts in a hospital scenario and the appropriate security policies to be taken to have secured access to the patient's records using a context meta graph.

Security Paths Defined in a Contextual Meta-Policy Graph

The above model gives the overall security approach used in a hospital environment to access electronic health records of the patients. The behavior of the security infrastructure according to various contexts is described as follows:

1. **User→ Type→ Domain :: Surgeon→Local→Hospital:-** ***Policy 4.*** If the user is a local surgeon and s/he wants to access the patient's records from the hospital, then s/he has to follow security policy 4. When s/he tries to access the records, the system will ask for her/his username and password, which will depict her/his role in the institution. Being a surgeon, s/he enjoys the highest level of rights. S/he can access the records in all the three modes (read/write/update). For access from within the hospital, authentication can be provided by various biometrics.
2. **User→ Type→ Domain :: Surgeon→Local→Remote:-** ***Policy 1 + Policy 4 + Policy 3.*** When the local surgeon, say John, wants to access the information from outside the hospital, which can be in the case of an emergency, then a combination of three security policies is followed. First he has to get back into the hospital network by providing his secret key/password according to policy 1, which will validate him as a local user. Then with the help of his username and password, which is associated with his role (policy 4), he can access the records. As he is in a remote place, care should be taken that the data is not visible to the outside world. This is achieved by encrypting the channel according to policy 3. Thus, using the combination of three policies, the local surgeon is provided access to the records from a remote place.
3. **User→Type→Domain :: Surgeon→External→Hospital:-** ***Policy 2.*** In some emergency cases, it becomes necessary to invite an external surgeon to the local institution. For such cases, the system stores all the information of such emergency persons. Policy 2 defines the access for such a surgeon using predetermined passwords. The surgeon is provided with three sets of passwords. The first will help him/her to validate him/herself. The second password is used to allow the external surgeon into the network. The third password will help him/her access the patient's records in the mode according to his/her role. Biometrics instruments can provide the required authentication when he/she is accessing from the hospital. If the external surgeon is accessing the records from the hospital, then he/she can use his/her third password to get access according to his/her

role. The first and the second passwords are not required in this case.

4. **User→Type→Domain :: Surgeon→External→Remote:- *Policy 2 + Policy 3.*** When the external surgeon has to access the records from a remote place, then the access takes place as determined by the combination of two security policies. Policy 2 is as defined as above. In such a case, he/she must have all three sets of passwords with him/her in order to get into the hospital network and then access the patient's records. Policy 3 is used for encryption of the information to provide safe and confidential communication.

   The surgeon, whether local or external, does not need to be with any other staff, as he/she enjoys the maximum access rights. He/she has to follow the appropriate security procedures depending upon his/her category (i.e., local or external) and his/her location of access.

5. **User→Along with :: Doctor→ Along with Surgeon:- *Policy 4 (for doctor) + Policy 4 (for surgeon).*** When a local doctor wants to access the records, then s/he can do so by using a combination of policy 4 applied to two roles. If s/he is with the surgeon, then s/he can access the patient's record in a full mode (read/write/edit) with the same access privileges as the surgeon. But for this, the surgeon has to first specify her/his username and password according to policy 4 so that her/his role is specified. If the surgeon is not physically present in the hospital, then the doctor cannot access the records in full mode. Also, a doctor is not allowed access to the records from a remote place.

6. **User→Along with :: Doctor→ Alone:- *Policy 4 (for doctor).*** If a surgeon is not with the local doctor, then the doctor accesses the patient's information in the restricted mode (read/write). S/he can access the information according to policy 4. S/he has to present her/his username and password so that her/his role will be represented in the system. An important point in this security architecture is that the doctor can never access the patient's records from a remote place.

7. **User→Along with :: Nurse→ Along with Surgeon:- *Policy 4 (for nurse) + Policy 4 (for surgeon).*** A nurse, say Jane, is at the lowest security level in the hospital hierarchy. If she is with the surgeon, she is allowed to view the records in full mode as the surgeon has. For that, the surgeon must present his/her role to the system first, and then the nurse can access the information according to her role as in security policy 4. Remote access is not allowed in this case.

8. **User→Along with :: Nurse→ Along with Doctor:- *Policy 4 (for nurse) + Policy 4 (for doctor).*** When the nurse, Jane, is with a doctor in the hospital, then she can have access to the patient's information according to the doctor's privileges. The doctor first provides his/her username and password, and then the nurse can provide her role as per security policy 4. Remote access is also not allowed in this case.

9. **User→Along with :: Nurse→ Alone:- *Policy 4 (for nurse).*** When nurse Jane is alone, she is only allowed one mode (read). She can read the information but cannot delete or modify it. She can access the information using her username and password according to security policy 4. But she is not allowed to access the records from a remote place.

RELATED WORK

There has been some work on security policies in the field of electronic health records systems in past years. Reid, Cheong, Henricksen, and Smith (2003) presented a model that uses role-based access control to restrict the access to the health records on a need-to-know basis. The prototype described maintains databases consisting of explicit 'allow' and explicit 'denial' lists. The proposed model also permits allow and deny policies to successively qualify each other in a role hierarchy supporting inheritance. Thus, the access control framework exhibits a great flexibility and efficiency in the range of access policies that it can support.

Mostéfaoui and Brézillon (2004) put forth the concept of contextual graph for modeling security in context-aware environments. They present a new model for policy specification based on the new approach. The security policy based on such an approach depends on the contextual information of the user and the environment. Contextual graphs have proved to be very effective in modeling a complex situation. Mostéfaoui and Brézillon (2004) also mention how contextual graphs are used to model security in a context-aware environments. In their paper they gave an example of how context-based security is used in a hospital scenario, but it does not employ our meta-policy scheme in the way we do above.

CONCLUSION

Due to the ubiquitous nature of the today's computing world, security is of utmost important. The traditional static authentication techniques are no longer valid and justified. This situation is due to the lack of consideration for context in existing security systems. Context-based security helps the security policy to, in effect, adapt to the new "threats" as they come. It aims at providing flexible security models for distributed infrastructures, where the user and application environments are continually changing. In this article, we have presented an approach that helps with context-based security in a medical scenario. The type and nature of the authentications that are demanded by the security policy depend on the information that is collected from the environment. Further, the contextual graph approach helps to add/modify secure paths based on the newly detected contexts that need to be utilized for fine-grain security. The model presented is a generalized model that can be used in any context-aware environment or enterprise, from the office to factories.

KEY TERMS

Contextual Graph: Graph whose edges represent the values that context information take, and have three types of nodes: branching and recombination nodes, and nodes representing security actions. A path through the graph represents a security action taken in response to particular context information.

Mobile Ambients: A process calculi that emphasizes the notion of boundaries and how processes with such boundaries interact.

Pervasive Computing: Integrates computation into the environment, rather

than having computers which are distinct objects. Other terms for ubiquitous computing include ubiquitous computing, calm technology, things that think, and everyware (Wikipedia, n.d.).

Security Action: Action taken to secure a resource, from authentication to encryption to other informational and physical measures (e.g., putting a man on guard).

Security Policy: A description of security actions to take under different circumstances. Such policies are typically specified as rules in a formal language.

Outsourcing in the Healthcare Industry:
Information Technology, Intellectual Property, and Allied Aspects

ABSTRACT

The healthcare industry is being impacted by advances in information technology in four major ways: first, a broad spectrum of tasks that were previously done manually can now be performed by computers; second, some tasks can be outsourced to other countries using inexpensive communications technology; third, longitudinal and societal healthcare data can now be analyzed in acceptable periods of time; and fourth, the best medical expertise can sometimes be made available without the need to transport the patient to the doctor or vice versa. The healthcare industry will increasingly use a portfolio approach comprised of three closely-coordinated components seamlessly interwoven together: healthcare tasks performed by humans on-site; healthcare tasks performed by humans off-site, including tasks performed in other countries; and healthcare tasks performed by computers without direct human involvement. Finally, this paper deals with intellectual property and legal aspects related to the three-pronged healthcare services paradigm.

INTRODUCTION

Advances in computing and communications technologies are dramatically altering the healthcare landscape around the world in a number of ways such as:

- enabling detailed analysis of healthcare data to elicit underlying trends and interrelationships;
- facilitating storage, transmission, integration, and retrieval of healthcare records;
- enabling healthcare professionals to render assistance to patients separated by significant geographic distance from each other;
- monitoring the safety of medical procedures and pharmaceutical drugs; and
- bringing the latest healthcare information to the attention of healthcare professionals and others.

In this article, we take five operational scenarios, one from each of the five illustrative categories delineated above. In each operational scenario, at least one of the co-authors of this article played a significant role and therefore possesses first-hand knowledge of that healthcare application. The operational scenario is analyzed, post-facto, from the viewpoint of diagnosing what subset of tasks can be handled by evolving information technologies without significant human intervention, what subset needs to be performed on-site by humans, both now and in the foreseeable future, and what subset can be potentially performed by humans located at a significant distance from the patient.

Based on the above analysis, we postulate that the future healthcare industry is unlikely to adopt a mono-operational scenario in which all the tasks occur on-site (as happened in the past), off-site, or by machines alone. Instead, the healthcare industry will gradually adopt an operational model in which there is a seamless and symbiotic combination of all three modes of operation.

After examining the future healthcare industry model from multiple perspectives, we conclude that we need a new approach to intellectual property in order to adequately safeguard the interests of the relevant constituencies. Based on the forces that will motivate the change, we further assert that healthcare organizations that are unwilling to adapt and embrace the evolving three-faceted work paradigm will be at a competitive disadvantage to their peers. National, state, and local medical regulatory agencies will need to respond to market pressures in order to support the long-term interests of both medical professionals and patients in their respective jurisdictions.

COMPREHENSIVE ANALYSIS OF HEALTHCARE DATA

One out of eight women in the United States will develop breast cancer during her lifetime. Early detection is a woman's best defense against breast cancer, which is 97% curable when detected and treated at an early stage. Mammography is the gold standard for screening for breast cancer. With the trend towards people living longer lives and taking proactive measures on their health, the demand for mammography is increasing at a significant pace. Unfortunately, 10-20% of the cancers currently detectable by a screening mammogram are missed by the human radiologist, allowing the disease another year to progress. In addition, there is a high degree of liability on radiologists due to missed diagnoses. To mitigate this problem, some radiology screening centers employ two radiologists to read each case. This approach involves significant cost to support an additional radiologist, reduces the number of total mammograms that can be performed within a center, and is problematic due to the shrinking numbers of radiologists in the field of mammography, especially in the United States.

Based on the latest information available on the FDA Web site (October 2006), there were 8,832 FDA-certified mammography centers and 13,511 accredited units in the United States. In the year 2006, there were 34.6 million mammograms performed in the United States alone, which translates into a total market of $5 billion (at $150 per mammogram). Globally, there are over 200 million mammograms per year, which translates to a market running into several billions of dollars per annum. As the population of women over 40 increases and the awareness of proactive health measures, such as mammograms, gets enhanced, the number of mammograms increases every year. However, a decrease in mammogram centers and the number of radiologists in this field are negatively correlated with the demand.

The area of mammography and the aspect of errors in diagnosis (both false positives and false negatives) have been studied in detail by many researchers (Berlin, 2005; Ghate et al., 2005; Gilbert et al.; 2006; Khoo, Taylor, & Given-Wilson, 2005; Sickles, Wolverton, & Dee, 2002; Skaane, Kshirsagar, Stapleton, Young, & Castellin, 2006).

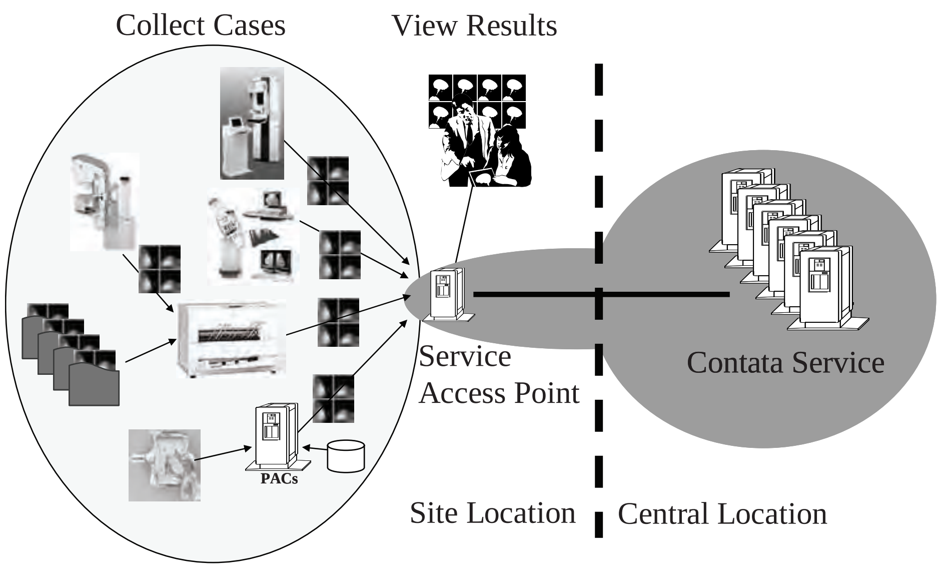
The use of computer-aided detection (CAD) techniques in mammography can mitigate the growing shortage of radiologists, as well as reduce or eliminate many of the instances of missed diagnosis. One of the authors of this article and several of his colleagues have developed new computer-based algorithms that allow a rapid analysis leading to the marking of cancerous and pre-cancerous regions, thereby providing a decision-support diagnostic facility to the radiologist. Using a CAD-based approach in conjunction with a human radiologist allows for the second reading of a mammogram, with the human radiologist actively involved in the process and making the final determination in each case. The advantages of the proposed approach are:

- The capital investment of using a CAD service is significantly less, when compared to that of employing a second radiologist.
- No additional hardware or space requirements are required.
- Current and previous cases can be made available to the radiologist online for necessary comparison.
- There is a minimal footprint in the workspace, allowing multiple radiologists to objectively view and analyze mammograms.
- Results and information can be made available anywhere via the Internet.
- Improvements to the algorithm and core technology can be readily disseminated.
- The approach is consistent with the trend towards teleradiology, allowing radiologists to perform analysis from anywhere, anytime.
- The proposed approach reduces the incidence of second visits and the level of patient anxiety by providing expert (specialty) second opinions when needed in a timely manner through a teleradiology model.

The proposed approach was developed in 2001 and 2002 (Gupta, Norman, Mehta, & Benghiat, 2002), and its technology component is described in Norman and Gupta (2002), which advocated that instead of taking the mammogram image and its interpretation by the radiologist at the same location, it would be more advantageous to use a geographically decentralized strategy that utilized the following principles:

- taking of the mammogram image by a technician at the location where the patient was available;
- transmitting the image to a central location where the image was analyzed by advanced data mining techniques and compared with other images;
- interpretation by a qualified radiologist at the same location where the centralized computing facility is located or at a different place altogether; and
- making the image available, with appropriate privacy and security safeguards, to the patient when she visits other clinics and to appropriate medical personnel with the patient's consent.

Figure 1. The integrated architecture for the use of on-site medical personnel, off-site medical personnel, and computer-based techniques for mammography and other medical applications



Based on unique and patentable distributed computing technology, a peer-to-peer model was implemented; it could act as a pure application service provider (ASP), a pure client application, or any combination in between. The proposed solution could:

- minimize or eliminate the costs of a "second reader";
- provide scalability for large, medium, and small centers (national and international);
- support the development of distributed teleradiology systems;
- decrease the liability factor for false readings; and
- improve equity of access to radiology services by employing only technicians on-site and performing both human and CAD readings off-site.

The proposed technology envisaged a long-term vision of "Image Anywhere." where there is a network of mammography screening centers in shopping malls across the country. A woman could step into a mammography center as easily as walking into a drug store. While the screening was performed at that site, the radiologist could be located hundreds of miles away looking at images from several mammography centers (via teleradiology) and could provide an opinion back to the concerned location within a few minutes of the screening time.

Finally, the proposed architecture and the technology could be readily adopted for use with all other types of medical images, as depicted in Figure 1. After establishing a track record with mammography CAD, the plan envisaged expansion into auxiliary applications (first medical, then non-medical). These include dentistry, CT colonography, and bone cancer detection.

The above concept was unanimously voted to be the first-place winner at the Big Red Venture Fund Innovation Contest, organized on an annual basis by Cornell University (2002). To the best of the authors' knowledge, this is the pioneer instance where the three-pronged strategy of using resident medical resources, off-site medical resources, and advanced computational techniques was explicitly delineated; this was done in the context of optimizing the productivity of radiologists, enhancing access to mammography centers by women, improving the quality of interpretation of mammograms, reducing the incidence of errors (both false positives and false negatives), and reducing the costs incurred in performing mammograms.

MANAGEMENT OF HEALTHCARE RECORDS

As healthcare costs continue to rise, researchers are exploring new options for enhancing the process of sharing medical data across disparate information systems, both within and across hospitals and other healthcare facilities. This has the potential to reduce costs by billions of dollars each year, estimated at $77.8 billion for the United States alone (Walker et al., 2005), and concurrently improve the quality of healthcare rendered to patients. Each of the entities in the current generation of hospital systems was built to function on an individual basis, with each island of information governed by its own idiosyncratic data model (Shortliffe, 1998). In the U.S., only regional interoperability has been implemented, so far, on an experimental basis (Halamka et al., 2005). The absence of a larger-scale interoperable system presents other problems too. For example, in the case of a plane crash or other catastrophic situation, the manual approach to accessing large numbers of patient records is very weak (Teich, Wagner, Mackenzie, & Schafer, 2002). There are several other facts that further strengthen the requirement for interoperable healthcare systems, such as:

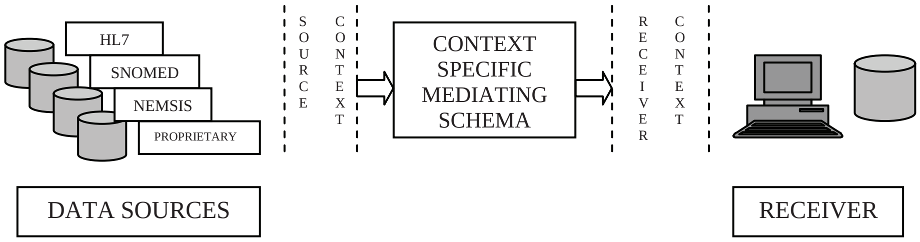
1. There is a large number of cases where institutions have split or merged, and existing data are physically distributed.
2. There are several 'mobile' individuals who frequently use medical facilities in different states or even countries.
3. The aged population contribute significantly to overall healthcare costs and very often have limited mobility.

This increases the requirement of access to healthcare records from a previous residence or transmittal of medical data to remote facilities for diagnosis rather than to move the patients themselves.

The challenges inherent in transforming disparate islands of data into an archipelago of integrated information have been highlighted by Gupta (1988) and others (Reddy, Prasad, Reddy, & Gupta, 1994; Arellano & Weber, 1998; Arts, Keizer, & Scheffer, 2002). The constituent systems differ in terms of data types, data definitions, data structures, data hierarchies, data categorizations, and underlying assumptions that are not expressly denoted in the concerned information systems. Imagine that you receive an electronic medical record of a new patient. The weight of the person as shown in the corresponding database field is 75. If you are a medical professional in the United States, your immediate reaction is that the person is extremely underweight, based on the assumption that weight is specified in pounds, whereas it is actually in kilograms. The U.S. is among the handful of countries that still use the traditional British system for most measurements; another county in this category are in Africa. Britain moved to the metric system a few decades ago. Ironically, the healthcare arena is the only one where the metric system has been adopted in the U.S. for measurement of mass and volume. However, many other types of differences continue to remain in terms of underlying assumptions of data types and other parameters; such assumptions are not revealed by looking at the data alone.

The above example highlights that healthcare data must often be converted from one form into another to facilitate communication, either at the

Figure 2. The use of the mediation approach to reduce the effort involved in integration data from heterogeneous information systems (adapted from Sarnikar & Gupta, 2007)



source or at the destination. The process of conversion of data, manually or by computer, involves significant costs and is prone to the loss of information (Barthell, Coonan, Pollock, & Cochrane, 2004; Shapiro et al., 2006). Since many healthcare applications require access to each other's data, and neither the source nor the destination is willing to do the required conversions, the only possible solution is to transform the data en route from the source to the destination.

The format and other details related to the data at the source are maintained in the source schema. The target schema contains the same types of underlying information for the destination. As the number of potential sources and potential targets increase, the number of likely transformations increases in a non-linear fashion. Haas, Miller, Niswonger, Roth, and Wimmers (1997), Milo and Zohar (1998), Abiteboul, Cluet, and Milo (2002), and Shaker, Mork, Barclay, and Tarczy-Hornoch (2002) advocated the use of middleware and the use of one common schema that incorporates data elements from multiple client schemas. The complexity of this common schema increases with the number of sources and targets, thereby restricting the use of this approach in large, diverse healthcare applications.

Wiederhold and Genesereth (1997) highlighted the fact that a single mediating schema in a large domain such as healthcare is not feasible; they advocated that the implementation of domain-specific data standards and mediators across heterogeneous medical information systems results in a cost decrease for mediating the transfer of data. Despite these findings, there is minimal standardization in the creation of healthcare information systems in the United States and in many other countries. This means, for example, that if there are "m" ambulance systems and "n" emergency department systems that could potentially need the medical data from any of the "m" ambulance systems, one could be dealing with as many as "m multiplied by n" transformations of data. Given the complexity of dealing with such a large number of possibilities, the process of data transformation is clumsy, time consuming, and costly (Gupta, 1998).

One approach to address the above problem of non-linearity is to create a mediating schema as the framework for reconciling heterogeneous information systems within and across hospitals and other healthcare facilities. Using the approach described in several papers, including Reddy and Gupta (1995), the number of necessary transformations can be reduced from "m x n" to "m + n". This requires that the mediating schema contain a core set of context-specific patient care-related information and a comprehensive methodology for specifying the ontology (vocabulary) of the relevant healthcare domain. The lattice-based context interchange approach, described by Reddy and Gupta (1995), allows evolutions of the semantics of data in the source or target schemas to be managed in a more effective manner as compared to traditional approaches. Differences in ontology always exist in large information systems (Wiederhold & Genesereth, 1997). Within a single hospital, each healthcare unit may collect, store, and process its own set of data, based on its own specialty and needs. The application of the mediating schema approach requires the careful study of the different ontologies, and the formulation of rules to transform data from one particular ontology to another.

Sarnikar and Gupta (2007) describe the problems and challenges involved in creating a mediating schema that would transfer data between the heterogeneous databases of a particular pre-hospital and ED system in the Boston area, and in extending the prototype system to cater to the idiosyncrasies of additional medical systems (see Figure 2). Based on the assessment of the size and complexity of the source and destination databases, as well as the associated data dictionaries, it was concluded that the mappings between single data elements needed to be done manually. This was based on the realization that the available software approaches to automate the mapping process between databases were frequently unreliable and required human intervention to analyze and to make corrections to the mappings generated. The manual creation of mappings could, however, lead to a set of development rules that could facilitate the creation of additional schemas in the future.

These tasks involved extensive consultation between members of the development team and experts from several concerned medical specialties, especially for "analysis of what information most succinctly and completely composed the patient care record across the source and target hospital information systems." The analysis of the data elements involved acquiring deep understanding of the meaning of each element in the source schema and its corresponding element in the target schema, as well as the associated differences in cardinality.

Sarnikar and Gupta (2007) presented a performance analysis of the above system in terms of information loss during the automated data translation process, relative to the coverage (amount of fields populated in the target schema using information from the source schema). Due to the presence of certain type conflicts and missing-data conflicts, a small amount of information was lost (<15%) in the presence of significant coverage values (>80%). Further, this was eliminated through the use of appropriate converters and filters (Gaynor, Gupta, Rawn, & Moulton, 2008; Gupta Martin, Avanavadi, & Sarnikar, 2007).

Industries and applications that are still at an evolutionary stage are frequently characterized by the existence of no standards or by the existence of too many standards, none of which carry broad acceptance. In the case of the healthcare arena, multiple standards currently exist, including HL7, EDIFACT, X12, ASTM, NCPDP, DICOM, and XDT (Dudeck, 1998). Further, as a reviewer of this article pointed out, the need for the transmission of medical data may be acute, sub-acute, or delayed. The electronic transmission of acute data (pre-hospital to emergency department) usually occurs in the case of healthcare providers who can use a common data set for their medical records. Sub-acute transmission could apply in situations involving hospitals and providers who use similar data elements, but not necessarily a similar platform. Delayed transmission, such as transmission of data across a national boundary, will need a standardized healthcare language, but not common data elements or platforms.

Based on the above discussion, we find that the use of cutting-edge computer and communications technology alone cannot accomplish the goal. Instead, large amounts of computational power and human expertise are needed to create the bridges across legacy healthcare information systems at this stage. Hospitals and other healthcare facilities in the U.S. have traditionally used medical and information technology personnel in the U.S. to undertake initial efforts in this area. Unfortunately, a vast majority of work remains to be done, and this cannot be accomplished, in terms of both time and costs, by the personnel available in the U.S. As such, one needs to explore non-conventional solutions that involve the use of resources from abroad.

Until the eighties and the nineties, large U.S. companies belonging to other sectors of the economy focused on doing all of their information technology work in the U.S. (Gupta, Seshasai, Mukherji, & Ganguly, 2007b). This was the traditional model, and the concerned management and technical personnel were satisfied with the pace of progress. Options for doing such work abroad, or by persons recruited from abroad for temporary work in the U.S., were frequently discarded on the basis that:

1. Only the persons currently associated with the work were familiar with the intricacies involved, thereby implying that such peculiarities were too complex or too confidential to be shared with others.
2. Organizational procedures or governmental regulations did not permit data and process information to be transmitted abroad or shown to foreign nationals.
3. The concerned work was too important for the success of the company, and the option of saving costs on this particular application was miniscule in comparison.
4. The work could not be performed by persons working in Asia because the difference in time zones made it impossible for them to interact with domain experts in the U.S.

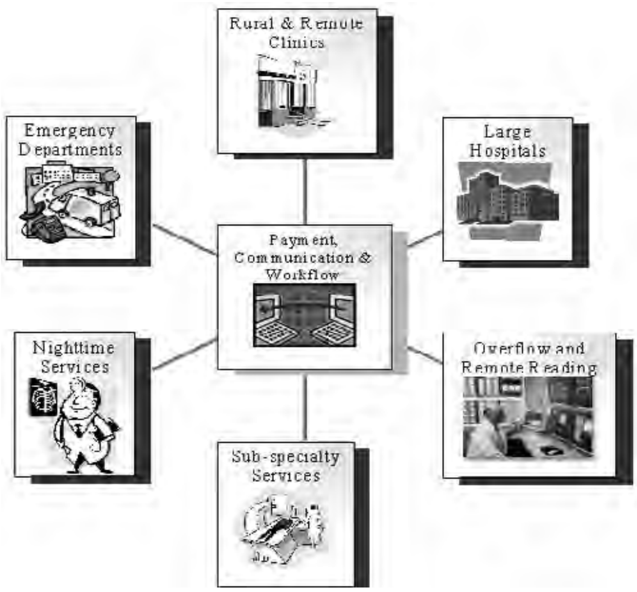
The above situation was dramatically altered by the Y2K dilemma. Management and technical personnel could no longer plead for six more months to complete a project. The date, December 31, 1999, was a very hard deadline, and the conversion of information systems had to be completed by then: no exceptions, indeed. This inflexible scenario forced the companies to become flexible. They permitted parts of the conversion work to be done abroad, as well as to employ persons with foreign qualifications and experience. The conversion from national currencies to the common currency, euro, had a similar impact in Europe. The unqualified success in both cases forced companies to depart from their arrogance in maintaining status quo.

A similar compelling need currently exists in the case of management of healthcare records. Conventional database systems are clumsy, costly, and time consuming. The integration of information in such systems, as well as the gradual incorporation of newer concepts, requires the healthcare industry to seriously consider the use of the hybrid model, involving the use of human resources in the U.S., human resources abroad, and state-of-the-art information technology. The success of the banking industry, the insurance industry, and several other industries too relies heavily on ensuring the privacy and the security of data belonging to their customers. Yes, glitches do happen from time to time. In 2004, information on 20 million credit card holders was compromised at a credit card processing facility in Tucson, Arizona. This particular facility was subsequently acquired by another company. But this unauthorized disclosure was not used as the basis to cease this type of application altogether. Instead, it should serve as the motivator for human experts, both in the U.S. and abroad, to develop more robust applications that can be used by more industries.

REMOTE DIAGNOSIS

Remote diagnosis is both an outsourcing and an insourcing phenomenon. For many years, medical records and medical images from patients and healthcare practitioners in Latin American countries, as well as from other countries in the world, have been reviewed by doctors at Massachusetts

Figure 3. A service delivery model for teleradiology (adapted from Kalyanpur, Latif, Saini, & Sarnikar, 2007)



General Hospital in Boston and by a number of other leading hospitals in the U.S. The Arizona Telemedicine Program (ATP) is a pioneer in terms of medical professionals located in Tucson, Arizona, providing expert advice to patients located elsewhere in the state, in neighboring states, and in other countries. ATP provides teleradiology, telepathology, and teleoncology services to patients in hospitals, in prisons, and in other settings (Weinstein et al., 2007). A significant number of the patients, who seek remote diagnostic advice, are from Navajo Nation and from other Native American nations in Arizona and neighboring states of the U.S.

On the outsourcing side, medical personnel in other countries are looking at medical records of patients in the U.S. The specialty that has witnessed the most attention is teleradiology (Pollack, 2003). Teleradiology involves the electronic transmission of radiological images, such as X-rays, computed tomograms, and magnetic resonance images, across geographical locations via telephone lines, satellite connections, and wide area networks. It enables a single radiologist to serve multiple hospitals concurrently, even ones in other continents. Further, it enables the image to be interpreted by an alert physician working a day shift rather than a radiologist who has been up all night (Weinger & Ancoli-Israel, 2002; Firth-Cozens & Cording, 2004).

Telemedicine is the delivery of healthcare services in situations where the physician and the patient are not at the same geographic location; it is a broad term and includes teleradiology, telepathology, and teleoncology. Telepathology involves the use of video microscopy at the patient's location and a pathologist's workstation at the physician's location. Teleoncology refers to the use of remote technology to address different aspects of cancer care.

For the purposes of studying "remote diagnosis," we will focus primarily on teleradiology for four reasons. First, the area of teleradiology has attracted wide attention in the media (e.g., Pollack, 2003). Second, this article focuses on outsourcing rather than insourcing, and the other specialties are characterized more by insourcing than by outsourcing. Third, within outsourcing, we are focusing on offshoring issues and are looking at applications that transcend national boundaries, not just local or state boundaries. Fourth, the teleradiology scenario allows an objective assessment of the potential risks and opportunities for individual radiologists in the U.S., as well as for the broader medical community in the U.S.

The growth in teleradiology is being driven by four major forces. First, there is a significant shortage of radiologists, because of a significant number of radiologists retiring from practice and training programs not keeping pace with growing demand (Sunshine, Maynard, Paros, & Forman, 2004; Bhargavan & Sunshine, 2002). Second, the aging population and the advent of newer imaging technologies are leading to annual increases in imaging volumes; for example, a 13% increase in the utilization of radiological imaging was observed among Medicare beneficiaries (Maitino, Levin, Parker, Rao, & Sunshine, 2003). Third, the increased use of imaging technologies in trauma situations has led to a corresponding need for round-the-clock radiological services in hospital emergency rooms (Spigos, Freedy, & Mueller, 1996). Fourth, changing regulations and guidelines have contributed to the need; as an example, the Health Care Financing Administration (HCFA) requires that overnight coverage be provided by certified radiologists, rather than by residents or trainees, in order to be billable (HCFA Medicare Program, 1995).

Typically, the radiology group outsources its night calls to a teleradiology provider and pays the latter for preparing the preliminary report. The insurer is billed for the final report that is prepared by the radiology group the following morning. The service delivery model depicted in Figure 3 includes mechanisms for communications, workflow, and payments.

Teleradiology offers several advantages:

1. A single professional can support multiple hospitals concurrently via teleradiology links to a central reading facility (often the radiologist's home).
2. Remote locations with radiological scanning, but no on-site radiologist, can be supported leading to improved patient care (Franken et al., 1995; Lee et al., 1998).
3. The productivity of the radiologist can be enhanced by bringing the images to the radiologist, rather than vice versa, thereby eliminating commuting time and delays.
4. The work can be optimally assigned among multiple radiologists in large hospitals.
5. Greater availability of subspecialty consultations results in better patient care (Kangarloo et al., 2000; Franken et al., 1997; Sickles et al., 2002).
6. Residents (junior doctors) covering night shifts in academic hospitals can use teleradiological services to ensure correct diagnosis and to seek confirmation.
7. The increasing disparity in the patient-to-radiologist ratio, especially during off-peak hours, can be effectively addressed by offshoring teleradiology services.

The increasing availability of technologies that replace invasive screening procedures (virtual colonoscopy replacing actual colonoscopy) means enormous increases in patient volume. Further, defensive medicine increasingly employs tests to guard against missing even the most unlikely diagnosis. The use of head CT in the ED under circumstances when the chance of an abnormal reading is extremely small is one example. It remains commonplace to get a head CT done if the patient has expected meningitis before doing a lumbar puncture, even though the literature indicates this is typically unnecessary. While this example of defensive medicine is not gratifying to mention, it represents the current reality. It also provides another reason why the workload in the radiology department has increased and will continue to increase further.

Teleradiology providers must conform to the guidelines of the Health Insurance Portability & Accountability Act (HIPAA), and are required to implement adequate privacy and security practices, as Protected Health Information (PHI) and Electronic Protected Health Information (EPHI) are transmitted over public networks on a regular basis. HIPAA requires that "covered entities execute contracts that consist of specific provisions for protection, use and disclosure of health information" (Hilger, 2004). The Privacy Rule deals with all forms of patients' protected health information, whether electronic, written, or oral, while the security rule covers only protected health information that is in electronic form, including EPHI that is created, received, maintained, or transmitted. The security rule does not prescribe any specific technologies; being technology neutral, it allows the HIPAA-covered entities to choose solutions based on their specific requirements. Technical safeguard standards include stringent guidelines for Access Control, Audit Controls, Data Integrity, Person or Entity Authentication, and Transmission Security.

The biggest hurdle to the rapid deployment of teleradiology services is the credentialing process. The U.S. requires statewide licensing requirements and board certifications; as such, a teleradiologist based in Australia must be registered to practice in all the relevant states in the U.S., so to look at radiological images from hospitals in these states, as well as pay appropriate fees to these states on an annual basis. Canada does certification at the national level for radiologists. And in Europe, some of the members of the European Union allow still greater flexibility. The current U.S. regulatory and credentialing structure was designed for a physical presence of medical professionals and needs to be adapted for the evolving technologies and procedures. Recently, some states have modified credentialing laws to allow out-of-state radiologists to perform remote diagnosis. Further, several federal and military healthcare organizations in the U.S. have licensure laws that enable them to render services independent of state and national boundaries. However, such privileges have not been extended to the private sector.

Other obstacles to the growth of teleradiology are:

1. limited availability of reliable Internet connections, especially in remote locations;
2. limited availability of trained technicians;
3. traditional billing and reimbursement procedures that vary by country and state, such as Medicare not paying for services rendered from abroad;
4. variations by nations and states, as well as underlying ambiguity, in medical malpractice liability laws (Gantt, 1999); and
5. the need for incorporating new encryption methods while transmitting image data (Cao, Huang, & Zhou, 2003).

Other related aspects of radiology have been discussed by several researchers (Bradley, 2004; Graschew, Roelofs, Rakowsky, & Schlag, 2006; Hayward & Mitchell, 2000; Jacobson & Selvin, 2000; Kalyanpur, Weinberg, Neklesa, Brink, & Forman, 2003; Kalyanpur, Neklesa, Pham, Forman, & Brink, 2004; Levy & Yu, 2006; Maitino et al., 2003; Mun, Tohme, Platenbery, & Choi, 2005; Takahashi, 2006; Weinger & Ancoli-Israel, 2002).

Over time, the concept of using both onshore and offshore radiologists will grow in terms of overall numbers of radiological images analyzed, as well as in terms of the breadth of the cases studied. Further, we expect the trends in both insourcing and outsourcing to continue. Parts of some medical diagnostic and allied applications will be performed abroad because of lower costs, quicker response, and load balancing. Conversely, more patients from abroad will seek professional advice from medical experts in the U.S. Overall, it appears appropriate to gradually lift barriers that currently impede outsourcing and insourcing activities; most of these barriers are in the former category.

MONITORING AND ENHANCEMENT OF SAFETY

Timely information on adverse drug effects can save lives and reduce healthcare costs. Previous studies show that more than two million adverse drug reactions occur yearly and are responsible for an estimated 100,000 deaths (Lazarou, Pomeranz, & Corey, 1998; Gurwitz, Field, Avorn et al., 2000; Fontanarosa, Rennie, & DeAngelis, 2004). Some systems exist for identifying drugs with serious adverse effects, but they have had limited success (Kopec, Kabir, Reinharth, Rothschild, & Castiglione, 2003; Ray & Stein, 2006). Between 1997 and 2005, the MedWatch system in the U.S. identified 15 drugs with toxic side effects, taking an average of 5.9 years for the identification phase and the subsequent drug withdrawal phase. In general, after the introduction of a drug into the market, the process of eliciting and analyzing information from patients is weak, especially when problems arise during extended use of the drug (U.S. Department of Health and Human Services, 1999; Brewer & Colditz, 1999; Okie, 2005). The problem with Vioxx, for example, was only uncovered during controlled clinical trials (Bombardier, Laine, Reicin et al., 2000). And there is still no system, either in existence or under discussion, for addressing this need at a global level.

In order to address these issues, the Institute of Medicine (2006) presented a report on "The Future of Drug Safety" and made the following recommendations:

1. increase the FDA's authority to ensure sponsor compliance with standards and regulatory requirements, especially those related to packaging and distribution;
2. establish separate performance goals for safety, in addition to existing goals for speed of approval;
3. ensure proper communication of the drug approval/testing status to consumers and medical practitioners through effective package indicators and advertisements; and
4. improve the facilities, available resources, and organization structure of the FDA.

Towards these goals, a prototype Community Pharmacy Safety Network (CPSN) was developed. Pertinent raw data are spread over the computer systems of multiple organizations including: (1) the one who performed the original drug development work, (2) the one that produced the drug, (3) the one that conducted the clinical trials, (4) the FDA in the U.S. and equivalent government agencies in other countries, and (5) the one that prescribed the medication. In addition, pharmacies contain information on the buyer of the drug, on what date, and in how much quantity. The problems involved in integrating these types of information from diverse sources were discussed in a different context earlier in this article; additional details are available in recent papers by Kalyanpur, Parsia, and Hendler (2005), Corcho and Gomez-Perez (2005), and Cristani and Cuel (2005). The problems become even more complex in the present case because of the need to access information from multiple countries and cultures.

The prototype system, including the key modules, is depicted in Figure 4. Detailed information on the system architecture and allied issues are available in Gupta, Crk, Sarnikar, and Karunakaran (2007a) and Gupta, Woosley, Crk, and Sarnikar (2007c). With proper infrastructure and incentives, pharmacists and pharmacy technicians would be designated agents for collecting raw information on the patient's medication history, including the adverse reactions experienced by the patient.

Development of the prototype system revealed several issues and opportunities. First, some drugs are given as samples by physicians to patients, and significant effort would be involved in incorporating such information into the overall system. Second, individual patients buy drugs from multiple pharmacies; in view of the current guidelines for privacy of patient records, it is very difficult to link records concerning the same patient from different pharmacies. Third, the procedures differ very significantly across countries. Fourth, analysis of the information requires the use of sophisticated data mining technology, with the help of (human) domain experts and (human) data mining experts. Such experts are already pressed for time in the U.S.; they are expensive too. It therefore seems appropriate to explore if this type of work could be done abroad. For example, one could envisage the creation of a global center of excellence for this particular field in Mexico, close to the U.S. border, so that one could benefit from the less expensive rates in Mexico in conjunction with the feasibility of experts from the U.S. visiting such a center on a frequent basis.

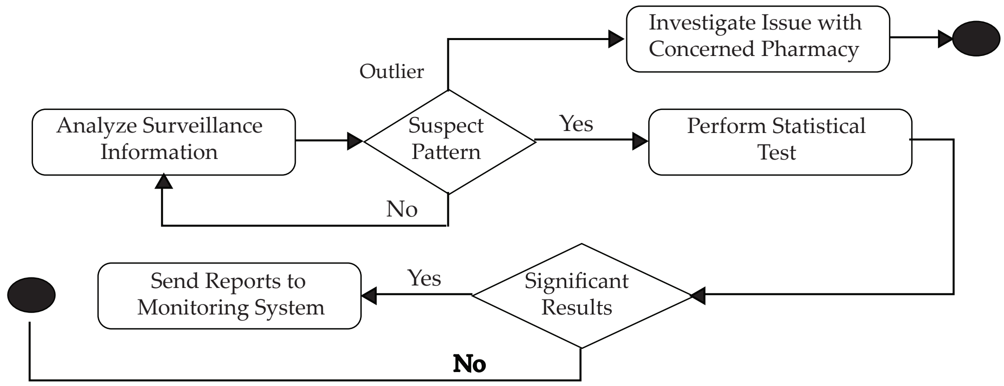
Gopal (2007) and her associates have employed an entirely different approach to assimilate information from patients, especially related to the side effects of alternative medicines. Their approach focuses on the mining of information from chat groups and other online repositories of information voluntarily provided by the patients, such as message boards, blogs, and listservs. They utilize proprietary search and aggregation techniques to distill raw data into structured information that answers critical questions. Their approach, again, utilizes a combination of computer power and human expertise.

DISSEMINATION OF THE LATEST HEALTHCARE INFORMATION

The ideas presented in this section are currently geared more towards medical education and medical research, rather than the provision of improved patient care. The current version of the prototype system enables users to search for current and previous literature, how-to articles, and other educational items. In the future, the enhanced Web site will assist healthcare providers by providing immediate lookups for symptoms and diagnosis. This would not only aid practitioners by giving them access to the latest medication data available, but also reduce treatment times. Further, based in part on a suggestion from a reviewer of this article, access to a human expert will be provided for the purpose of providing additional advice and support on specific cases.

Medical information has been maintained in books, journals, and specialty magazines. Now, a growing number of people turn to the Internet to retrieve healthcare-related information, and they do so from a variety of sources, most of which are run by commercial entities. The next area of growth will be sites that focus on specific fields of medicine, contain data culled from scholarly publications, and are operated by eminent specialists in the field. One such site is being developed for the field of gastrointestinal motility; it builds upon the concept of existing healthcare information sites with the intention of serving the diverse needs of laypeople, medical students, and experts in the area. The site, called Gastrointestinal Motility Online, leverages the strengths of online textbooks, which have a high degree of organization, in conjunction with the strengths of journal collections, which are more comprehensive, to produce a knowledge base that can be easily updated, is comprehensive, and can provide accurate and high-quality information to users. In addition to implementing existing Web technologies such as Wiki- and Amazon-style commenting options, Gastrointestinal Motility Online uses automatic methods to collect information from various heterogeneous data sources to create coherent, cogent, and current information for the diverse base of users.

Figure 4. Surveillance process for medical drugs (adapted from Gupta et al., 2007a)

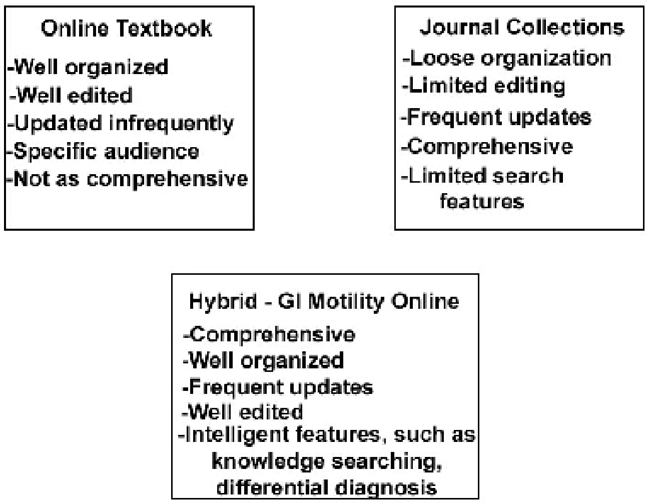


Gastrointestinal motility is a very small part of the vast field of medicine. Books such as *Harrison's Principles of Internal Medicine* serve as the main source of information in the field of medicine including gastrointestinal motility (Kasper et al., 2005). Most of these books now also have electronic versions. More recently, electronic texts sites such as Wiki, eMed, WebMD (http://www.webmd.com/), and UpToDate (http://www.uptodate.com/) have evolved and are rapidly gaining popularity. Because these works are designed to provide a broad overview of the field of medicine, they only provide a very superficial treatment to a topic such as gastrointestinal motility. More detailed information about gastrointestinal motility disorders may be found in medical journals. Many journals that were previously in paper format now come out both in paper and electronic formats. Searchable electronic archives, such as PubMed (http://www.pubmedcentral.nih.gov/), now place a plethora of information into the hands of researchers and physicians. However, such searches are very time consuming and inconvenient. Sites like AccessMedicine (http://www.accessmedicine.com/) serve as search engines that attempt to place the most suitable information on a medical topic in a user's hand.

As shown in Figure 5, Gastrointestinal Motility Online is a hybrid between standard textbooks and review articles (Au & Gupta, forthcoming). It seeks to centralize and present the information in a scalable manner that is customized to the user's information requirements. The user base includes: laypersons, patients, medical students, biomedical scientists, physiologists, pathologists, pharmacologists, biomedical students, researchers, pharmaceutical personnel, house staff, specialty fellows, internists, surgeons, and gastroenterologists.

Creation of the gastrointestinal motility knowledge repository started with calls to key gastrointestinal experts inviting them to submit a chapter, in electronic form, for inclusion in this knowledge repository. The titles and themes of these chapters were determined through discussions involving the concerned authors and the editors for this project (Dr. Goyal and Dr. Shaker). The inputs from the contributing authors were reviewed by the editors and by others. Under the aegis of an unrestricted grant from Novartis Corporation, the two editors worked closely with the staff of Nature Publishing Group on a number of tasks that ultimately led to the creation of the Web site, http://gimotilityonline.com. This site may serve as a model for user-driven, scalable, and interactive medical information at a single site for other specific medical topics. These sites

Figure 5. Gastrointestinal motility online is a hybrid of online textbooks and journals



can then be interlinked to cover the broad field of medicine. Since GI Motility Online is a hybrid that includes textbook-type material as well as authoritative up-to-date reviews and interactive features, it poses many new problems and opportunities. Currently, all updates must be initiated manually. Automated content generation or extraction from other publications is not feasible, due to the stringent need to maintain relevance and quality. This applies to addition of new material, editing of existing material, and deletion of parts of existing material as new test results become available.

In the next part of the endeavor, the goal is to enable machine-assisted updating of the material in the gastrointestinal knowledge repository. Given the large number of articles published weekly and the difficulty in ascertaining relevance and quality, a number of automated tools will be used to optimize the updating process. One technique that will assist in the maintenance and updating of the site is presented in Sarnikar, Zhao, and Gupta (2005). This method selects articles ranked by relevance using a combination of both rule-based and content-based methods, using the following principles:

1. Profiles are modeled in the form of rules.
2. The purpose of rule-based profile use is to identify a subset of documents of interest to a user.
3. Each role has a set of predefined rules associated with it.
4. Rules specify knowledge sources to access (for example, nursing journals for nurses).
5. Rules can specify knowledge depth and knowledge breadth.
6. Rules can specify semantic types of primary importance to roles.

Profiles are used in the gastrointestinal motility context to separate information into categories—for example, new clinical findings vs. basic science. Articles could be assigned a category and a weight, given categorization rules based on Unified Medical Language System (UMLS) synonym lists and the categories sign or symptom, diagnostic procedure, therapeutic or preventive procedure, and disease or syndrome semantic types. These tools can form the basis for an RSS XML news feed or to efficiently assemble relevant articles for use by the editors or Web site administrators. While these tools will aid the editor, there is no replacement for the role of humans in selecting and classifying information.

Ontologies and semantic networks are necessary prerequisites to the development of and classification of information repositories. Ontologies serve many purposes including to: reuse and share domain knowledge, establish classification schemes and structure, and make assumptions explicit. They also allow analysis of information and complement the stricter terminology that is used in straightforward text searches, with or without synonyms. Examples of ontologies in use today include the National Library of Medicine's Medical Subject Heading (MeSH), disease-specific terminologies such as the National Cancer Institute's PDQ vocabulary, drug terminologies such as the National Drug Data File, and medical sociality vocabularies such as the Classification of Nursing Diagnoses and the Current Dental Terminology. In Gastrointestinal Motility Online, the ontological hierarchy will be used to make distinctions between parts of the gastrointestinal tract and the different sections of the stomach and the esophagus (Kumar, 2005).

One of the keys to developing an automated system is the set of ontologies presented in the UMLS semantic network that relies on the concepts built into the UMLS concept hierarchy. An overview of the UMLS is available at http://www.nlm.nih.gov/research/umls/presentations/2004-medinfo_tut.pdf.

THE UNIFIED MEDICAL LANGUAGE SYSTEM: WHAT IS IT AND HOW TO USE IT?

UMLS is an aggregate of more than 134 source vocabularies, including the classifications from such lists as ICD-10 and DSM: IIIR-IV. It represents a hierarchy of medical phrases that can be used to classify articles and textbook entries.

The system described in Sharma (2005) uses techniques of Natural Language Processing (NLP) to construct a semantic understanding that goes beyond text searching. Using the ATIMED (Automated Integration of Text Documents in the Medical Domain) system, the content and order of phrases are related lexically using a concept called Word-Net. Word-Net operates on the verbs, subjects, and objects of the sentences, comparing sets and subsets of subject-verb-object collections in order to determine relatedness to a desired topic. Sharma (2005) uses the following two sentences as examples: Dysphagia is a disease and defined as a sensation of sticking or obstruction of the passage of food. Dysphagia is related to obstruction of passage of food. Since both sentences use similar objects and subjects, and use the verb "is," the sentences would be deemed similar. However, the phrase "Dysphagia relates to obstruction of passage of food" would not result in potential match because the action verb is not similar (Sharma, 2005).

Developing a schema to accurately represent journal abstracts and determine the relevance of those abstracts is one method of exchanging contexts. Innovation in this domain allows Gastrointestinal Motility Online to maintain updated, consistent, quality references without requiring an editor to read all journal articles published immediately. Knowledge-mining tools are being developed to utilize this information as it becomes available to add fast, relevant access and other utility to the information repository. Advanced technologies to aid in the conversion and integration of articles and research into the mainstream science are being integrated and look to impact the breadth and speed of knowledge-base upgrades. These activities involve the use of medical and computer professionals, both in the U.S. and abroad.

The base site is hosted by Nature Publishing Group. As this site was being developed, it was found that commercial tools were available to handle the production of electronic journals and static textbook efforts like AccessMedicine (http://www.accessmedicine.com/) and WebMD. The gastrointestinal knowledge repository falls somewhere in between these two cases; accordingly, few off-the-shelf tools and algorithms were available for immediate use. As such, a significant fraction of the necessary material had to be generated and refined through experimentation.

An interesting addition to the above system is the addition of a "Gastrointestinal Guru," based in part on a suggestion from one of the reviewers. In specific cases where a person needs access to a human expert, the system will facilitate access to such experts who can provide support on an instantaneous basis. The situation is somewhat similar to the one we experience when we try to make a travel reservation online, experience difficulty, and feel relieved when we are able to connect to a human being, either by phone or online. However, the level of expertise and the degree of structure with respect to the desired knowledge are vastly different in the two cases. This difference is highlighted in Figure 6 (later in this article) and its accompanying text.

MULTI-PRONGED APPROACH

While the five scenarios discussed above are drawn from different aspects of medical practice, they have several aspects in common. In all cases, the advent of new information technologies is making a major impact on how the particular task or medical specialty is performed (Siau, 2003; Wachter, 2006). Further, in all cases, automation applies only to part of the effort. Human beings still need to be involved, though to varying degrees in the five examples considered. In some cases, a significant part of the work needs to be performed in very close proximity to the patient, whereas in others, the concept of remote tasks can be applied to a large extent. Finally, in some cases, the off-site work is medical in nature, whereas in others it is largely non-medical in character. While similar approaches have been followed in the healthcare industry to some extent in the past, the relevance and practical importance of this model in today's scenarios is more significant. This is happening for several reasons including the following:

- The technology that is available now did not exist earlier. A growing number of previously underserved, remote locations are increasingly able to access medical services through the Internet; and PACS systems are improving rapidly; data and image transfer methodologies are becoming less expensive, more effective, and more error-free. This is resulting in a corresponding need for embarking on international telemedicine endeavors, instead of regional collaborations.
- There is a growing awareness of the advantages of having interoperable health information systems, especially in addressing mass casualty situations, where fast and timely diagnosis, via telemedicine, attains paramount importance.
- The increasing incidence of persons moving across national borders for work or other reasons, as well as the continued trend towards globalization, are making national boundaries lose their traditionally strong importance. As such, one needs the ability to ensure the safety of citizens when they are traveling in foreign countries and taking drugs that were prescribed for them by doctors in the U.S., and to support allied functions. For example, the creation of new global drug efficacy monitoring systems could enable Americans with the same ethnicity or ancestral homeland to be grouped by predictable responses to drugs

based on findings by researchers in their native countries.

We consider in the following paragraphs the significance of the diverse examples highlighted throughout this article.

In the case of mammography, a technician needs to attend to the patient in order to take the mammogram; the doctor can be off-site, either in the same country or a different one; and the computer-based data mining algorithms will be executed on an off-site basis too. This is perhaps the earliest example in healthcare where the concept of doing part of the work on-site, part off-site, with the computer providing active decision-support capability, was mooted as the most accurate and the most cost-effective way.

In the case of integration of medical records in heterogeneous systems, either for emergency needs or for routine needs, computer-based techniques can be of significant help, but human experts are needed at the initial stage as well as on a continuing basis. Integration of major systems in other fields, such as logistics and manufacturing, is being increasingly done on an offshoring basis. Banks and financial institutions located in the U.S., Switzerland, and other countries were very reluctant in the eighties and nineties to let such work be performed abroad; by the late nineties, many of them accepted the offshoring concept, after they were satisfied that the evolving security and privacy protocols were adequate for their needs. The same is expected to occur for the integration of heterogeneous hospital information systems; we will consider the legal and regulatory aspects later in this article. In addition to experts in information technology, medical personnel from multiple subspecialties will need to be involved, both on-site and off-site, in order to integrate the concerned systems based on the specific characteristics of the concerned medical institutions.

In the current versions of teleradiology, the technician can be in the U.S. or another developed country, and the radiologist can be in India or another less expensive country; in addition, there is a second radiologist in the same state (or nation) as the patient who issues and signs off on the final report. Technology is used almost entirely for transmitting the image from the developed country to the less expensive one. Over time, technology could be used to partially analyze the images, to compare the image to an earlier one involving the same part of the body of the same patient, and even to compare the image with images of the same part of the body of other patients, in order to make a diagnosis and to evaluate how the symptoms may change over time.

In the case of monitoring for adverse drug effects, the MedWatch system needs to be augmented. Some of the new tasks need to be performed by pharmacists in the U.S. Other tasks, such as reconciliation of duplicate records, need to be performed using inexpensive manpower, wherever available, with support from computer-based techniques. Further, individuals in the U.S. are increasingly obtaining less expensive equivalent drugs from Canada and other countries. Such drugs must also be taken into account while designing any comprehensive system for monitoring adverse drug effects. Ultimately, this system will need to be implemented across multiple systems, as a harbinger of a global system. A growing percentage of clinical trials are now being conducted in India and other countries because of lower costs, availability of drug-naïve persons (individuals who had not taken other drugs in the past for addressing the same disease), and access to persons with different heritages. The ability to conduct these clinical trials at lower costs increases the probability that a drug company would decide to take a potential new drug from the lab to the clinical trial stage. This can also reduce delay in the launch of the new drug. However, this also implies transforming local systems for monitoring adverse drug effects into international ones. In such a case, both medical personnel and other personnel need to work from multiple countries.

In the case of dissemination of healthcare information, the initial endeavor focused on getting reputed experts from multiple countries to contribute material for inclusion in the evolving knowledge repository. The idea was to gradually support automated updates to such material on a continuing basis. So, if new results from a trusted clinical study became available, such results should be incorporated into the appropriate chapters. While part of this work can be done using computer-based techniques, the experience of the development team is that high quality and accuracy will only be accomplished if the suggested edits and updates were reviewed and approved by human experts. The use of domain experts and editorial personnel located in less expensive countries is more appealing, as it makes the overall endeavor more viable (see Table 1).

While improvements in Internet communication have made the multi-pronged approach described above possible, the lack of standardization in messaging protocols is a roadblock to the creation of a global healthcare model. We now describe how standards can be applied effectively to each of the five operational scenarios discussed, to reduce costs and improve clinical outcomes:

1. In the area of CAD mammography and teleradiology, the communication of radiological images and other data clearly depends on the standards used for creating, maintaining, and exchanging medical images (such as PACS and DICOM).
2. The problem on data exchange and integration from heterogeneous data sources can be solved by the effective use of standards such as HL7. Though the current scenario does not easily allow the adoption of a single data standard among all hospital information systems nationwide, using a standard message development framework as a mediating schema could eliminate some of the problems and make the system more portable and scalable.
3. The area of drug monitoring and post-market surveillance could also benefit from the use of standards. Using standards to create and store medication and adverse effects reports and experimental results sent from various participating agencies would create a much richer database allowing for better analysis and quicker response times.
4. Finally, while considering the issue of dissemination of medical information, the use of standards (not medical standards, though) for storing and displaying the information to the end users can increase the productivity and usefulness of search portals.

24-HOUR KNOWLEDGE FACTORY

Earlier in this article, we discussed the scenario of seeking immediate assistance from an expert in a particular specialty; the geographic location of that specialist was totally irrelevant. The same is true of situations related to some tasks related to mammography and radiology. Finally, in the other two examples of the integration of medical information systems and the creation of global drug monitoring systems, it would be appropriate for the concerned pieces of work to proceed on a continuous basis, around the clock. In all such scenarios, the paradigm of a 24-Hour Knowledge Factory bears relevance.

The University of Arizona has signed a three-party collaborative agreement with the Wroclaw University of Technology in Poland and the University of Technology located in Sydney, Australia. Under the aegis of this agreement, researchers at the University of Arizona can work from 9:00 a.m. to 5:00 p.m., Arizona time. At around 5:00 p.m., Arizona time, the research-in-progress can be transferred to fellow scientists at the University of Technology in Australia, who can work from around 9:00 a.m. to 5:00 p.m., Sydney time. At the end of the "research shift" in Sydney, the

Table 1.

Scenario	Tasks by Medical Personnel		Tasks by Non-Medical Personnel		Tasks by Computer-Assisted Techniques
	On-Site	Off-Site	On-Site	Off-Site	
CAD Mammography	X	X			X
Integration of Heterogeneous Healthcare Data Sources	X	X	X	X	X
Teleradiology	X	X			X
Monitoring of Adverse Drug Effects	X	X		X	X
Dissemination of Healthcare Information	X	X		X	X

professional work can be transferred to the Wroclaw University of Technology in Poland where researchers can conduct incremental activities over the next period of approximately eight hours, and can then transfer the evolving endeavor to the first set of researchers in the U.S. This process is akin to the passing of a baton in a relay race, with the notable difference that the baton is returned back to each participant exactly 16 hours after that participant transfers it to a colleague located on a different continent. We believe that this model will be gradually adopted by the healthcare industry, and further analysis of the historical and structural aspects will determine what subset of healthcare tasks can benefit most from the adoption of this evolving paradigm.

In general, the 24-Hour Knowledge Factory paradigm is appropriate for situations where the healthcare endeavor can be broken down into components, the underlying knowledge can be digitized, different individuals can potentially work on such components with minimal support from their peers, and the work-in-progress can be transferred at minimal cost from one collaborating center to another.

INTELLECTUAL PROPERTY AND LEGAL ISSUES

The performance of medical tasks in a collaborative fashion, on a regular basis, by individuals located across state and national boundaries, raises new issues. Who owns the intellectual property such as patents on new medical or drug inventions? Who can be sued for medical malpractice, and under which set of laws and regulations? How should the charges for medical services be apportioned? What are the corresponding avenues for seeking reimbursements from insurance companies? And what are the mechanisms for seeking redress if and when it becomes necessary? Besides these, there are also other related social and policy-related concerns such as quality control, and assurance and intensity of workflow across boundaries.

In the case of the United States, the FDA plays the dominant role at the national level on issues related to drugs. However, medical professional credentialing and registration are done almost entirely at the state level. As mentioned in the section on radiology, the radiologist can render an initial opinion from outside the particular state or country, but the final opinion is still issued by another radiologist who resides within the particular state and is licensed to practice there. The use of two radiologists, though providing quicker action, increases overall costs.

In the case of patents and intellectual property, there is a common feeling among patent holders around the world that others are exploiting your work. In the U.S., there is a feeling that companies in foreign countries are exploiting U.S. inventions and patents without authorization and payment of royalties. On the other side, there are people in India and China that feel the same way; there are instances of patents issued by the U.S. patent office on items of indigenous nature that have existed for thousands of years. This is somewhat akin to the situation where different states in the U.S. would render conflicting decisions on the same case, creating confusion. For example, until the 1970s, child custody cases were handled entirely at the state level. So in a case of divorce involving two parents residing in two different states, the first state might well give the custody of the child to the father (who resided in that state), and the second state would likely give custody of the same child to the mother (who resided in the latter state). Finally, in 1992 the Uniform Interstate Family Support Act (UIFSA) was drafted., According to this act, states have the power to reach beyond their borders for the establishment and enforcement of support orders. A similar type of action is now warranted in the healthcare domain.

Let us analyze the issue based on how laws, regulations, and norms have evolved over history. Three thousand years ago, all rules were at the village level. The village was the basis of the economy. If a person did something undesirable, the person could be ostracized from using the village well. Without water, the person could not survive. Therefore, the person had to plead with his or her peers. This was one of the mechanisms, then prevalent, to enforce conformity with the norms and mores of that era. As time progressed, the size of the geographic unit increased. In England, one saw the advent of the concept of the manor, typically a collection of a dozen villages, that functioned as a unit for economic and security purposes. The manor was replaced by still larger entities in the form of principalities, which were ultimately replaced by nation states. The lawmaking and enforcement evolved too, sometimes with overlapping provisions. For example, a person residing in Tucson today may be governed by up to four sets of regulations, of the City of Tucson, Pima County, the State of Arizona, and the United States of America, respectively. (In some areas, such as intellectual property, there may be a supranational layer as well, that is, the WTO's Trade Related Intellectual Property Agreement, which although not applied directly in the United States affects U.S. intellectual property law). Being governed by laws of the U.S. does not imply having to go to Washington, DC, to seek redress; benches of U.S. federal courts exist in most large and medium-sized cities in the United States.

Similarly, in the case of healthcare, the ultimate solution may be an international regulatory system that maintains offices in large cities around the world. This organization could deal with issues related to performing healthcare work across national boundaries. This could include credentialing, registration, medical malpractice, medical accounting, and reimbursement. Such an international regulatory system could be operated under the aegis of the World Health Organization.

Issues of trade and intellectual property are currently coordinated at the international level by the World Trade Organization (WTO) and the World Intellectual Property Organization, respectively. These organizations could serve as the nucleus for establishing streamlined mechanisms that would enable better coordination of emerging types of practices, in healthcare and in other disciplines, perhaps under the aegis of the WTO's General Agreement on Trade in Services. The Agreement on Trade Related Aspects of Intellectual Property is another mechanism of IP protection. Healthcare services will increasingly transcend national boundaries as efforts are made to perform them with speed, efficiency, and in the most cost-effective manner.

CONCLUSION

The traditional model of healthcare required medical personnel to be in immediate proximity to patients being attended to. This model will gradually be replaced, for a growing number of healthcare applications, into a three-faceted model that requires: some personnel to be on-site, other personnel to be off-site, and the use of evolving technologies to render support in a manner that is beyond the capabilities of the best medical personnel available anywhere in the world. Computers can look at millions of images of mammograms in very short periods of time to locate ones that match the key characteristics of the one currently in the clinic; such power is clearly beyond the capability of a single doctor or even groups of doctors. Off-site personnel can be located in the same state (such as physicians and surgeons of the Arizona Telemedicine program assisting doctors in clinics in Navajo Nation and in other Native American nations), in a different state or a different country. If the support is being provided from a different country, it could be in the same time zone (to provide good overlap) or in a different time zone (to provide complementary advice, especially advice from specialists, during the night in the patient's country). The time difference was initially perceived to be a hindrance; today, it is considered an asset, as it enables better usage of medical and other personnel in both countries. Initially, outsourcing will be embraced using the notion of two collaborating groups that are 10-12 hours apart in terms of time. Gradually, the model of three collaborating centers will be embraced. The use of this 24-Hour Knowledge Factory paradigm allows three centers located in three countries to continue work on a round-the-clock basis, with all the tasks being performed primarily during the day in the respective countries. New international systems must evolve to address the intellectual property, legal, accounting, and other issues related to the various forms of outsourcing.

Medicine is geared to assist mankind as a whole. The offshoring of medical services will benefit developed countries because it can lower overall costs, provide quicker response, and facilitate load balancing. Such offshoring will be advantageous to developing nations because it can widen the range of available medical expertise and enhance the knowledge of healthcare professionals in developing countries. At the same time, one must be conscious of the fact that there is a shortage of medical professionals both in developed and developing countries, and the diversion of such resources to address the needs of foreign patients can potentially aggravate the shortage in their respective home countries. These issues will be partially resolved by market forces. Over time, we will witness more cooperative endeavors involving on-site and off-site activities in the healthcare arena.

ACKNOWLEDGMENT

The authors acknowledge, with sincere thanks, valuable information, comments, suggestions, and assistance provided by many persons, including Shiu-chung Au, Harvey Meislin, Elizabeth Krupinski, Kurt Denninghoff, Rick McNeely, Richard Martin, Surendra Sarnikar, Yan An, Shawna Sando, David Branson Smith, Kit Cheong, Georgina Apresa, and Zak Campbell. Their insights have contributed to enhance the breadth and depth of this article.

Chapter 6.9
Strategic Maneuvering in Healthcare Technology Markets:
The Case of Emdeon Corporation

ABSTRACT

Healthcare technology markets have been recently identified as potential investment targets. Having survived a major environmental shock, the dot. com bust, firms in the healthcare technology industry are presently experiencing an impressive revenue growth. In this study, we investigate the strategies of Emdeon Corporation, a healthcare technology firm whose e-business model provides clues for achieving a sustained revenue growth and profitability. We trace the current sustainability of Emdeon's e-business model to a related diversification strategy that the firm's upper management has pursued via mergers and acquisitions (M&As). We also address the motivation behind current restructuring of Emdeon's e-business model. We argue that maturation of diversified e-business models leads to the transformation of individual segments into distinct entities focusing on specific technology markets.

INTRODUCTION

A growing specialization of e-business models has offered a variety of new services that create business value for the healthcare industry (Parente, 2000; Payton, 2003; Singh, O'Donoghue & Soon, 2002). These diverse services can encompass online execution of medical transaction processing, health information retrieval, and/or online enrollment to health plans, to name a few examples. Recent publications in the trade press have reflected a growing sense of optimism on the part of investors in e-business firms that serve niche technology markets. In particular, healthcare technology markets have been praised as potential investment targets (*New York Times*, 2006; *Wall Street Journal*, 2006). Investors presently focus on funding start-up companies that provide access to health-related information as well as offer Internet-based capabilities to compare quality and outcomes of healthcare services.

The gigantic size of U.S. healthcare industry presents many opportunities for technology firms that have a potential to improve value chains. According to the National Coalition on Health Care, the total healthcare spending in the United States reached $1.9 trillion or about 16% of the gross domestic product in 2004. The fact that healthcare is a data-rich industry creates opportunities for technology firms to make health data exchanges more efficient and reliable. The other distinctive characteristic of healthcare is that it is strictly regulated. In this regard, the value proposition of technology firms is evident in their capability to decrease complexity of medical-transaction processing and reduce the number of data-related medical errors.

U.S. healthcare organizations first began to build proprietary information systems in the 1960s (Collen, 1991). At that time, hospital networks were most prolific adopters of information systems given that they possessed sufficient capital bases to do so. Only recently has it become cost-effective for physician practices to embrace medical software systems. Mass adoption of broadband Internet and decreasing costs of worldwide delivery of digital materials offer opportunities for technology firms to interconnect hospital information systems and connect to software systems of physician practices.

In addition to improved affordability of information systems and technological advancements, healthcare institutions could potentially benefit from incentives offered by the regulatory agencies to digitize the exchange of health-related information. In the mid-2000s, the U.S. government intensified efforts to raise the adoption rate of electronic health record (EHR) systems. This technology enables caregivers to collect and circulate digitized patient data across the network of authorized healthcare providers (Goldschmidt, 2005; Ford, Menachemi & Phillips, 2006). The U.S. government plans to link individual EHR systems in a centralized network, allowing access to patient data on a national basis (Office of the National Coordinator for Health Information Technology, 2005). The planned centralization of EHR systems would be a massive undertaking on the part all the stakeholders of the U.S. healthcare industry. The increased quantity of digitized patient data would fuel further demand for medical-transaction processing services. Such a scenario indicates greater revenue-growth opportunities for the healthcare technology industry. Firms that are capable of building EHR systems, processing digitized data, and facilitating health-related decision-making would benefit from proliferation and centralization of EHR systems.

In the light of these important developments in the U.S. healthcare industry, we investigate the strategies of Emdeon Corporation, a healthcare technology firm whose e-business model provides clues for achieving a sustained growth of revenues and earnings in the emerging healthcare technology industry. Whereas e-business models built on a single source of revenue are dominant in this industry, Emdeon Corporation relies on a variety of revenue streams to sustain a leading market position. This case study explores the evolution of Emdeon's e-business model from a strategic management perspective. We trace the current sustainability and profitability of Emdeon's e-business model to a related diversification strategy that the firm's upper management has pursued through mergers and acquisitions (M&As). We also address the motivation behind the current restructuring of Emdeon's e-business model. The time period for this investigation spans 1998 to 2005.

We will discuss the literature on healthcare e-business models in the second section. Research method and data sources will be addressed in the third and fourth sections, respectively. In the fifth section, we analyze the evolution of Emdeon's e-business model. This model went through a number of development phases, which were reflections of the changes in the firm's strategy. In the sixth section, we offer conclusions in the form of lessons learned from Emdeon's strategic maneuvering in the emerging healthcare technology markets. These lessons point to the factors that contributed to the firm's sustained profitability in the observed period.

LITERATURE ON HEALTHCARE E-BUSINESS MODELS

There have been a number of academic and practitioner-oriented accounts that shed light on e-business model types that have emerged in healthcare technology industry. Given that e-business in healthcare is a recent phenomenon, this literature is at the early stage of development. The authors writing on this phenomenon largely investigate how healthcare technology firms add value to medical processes. The literature on trans-industry e-business models, on the other hand, has been plentiful. Timmers (1999, p. 2) advanced his definition of business models that is applicable for electronic environments: "A business model is defined as the organization of product, service and information flows, and the sources of revenues and benefits for suppliers and customers." Given that the focus of this article is on healthcare e-business models, we will focus on the current state of research on healthcare e-business models. In addition, we will selectively address research on general e-business models that complements our discussion on healthcare e-business models.

Parente (2000) distinguished four categories of healthcare e-business models: e-commerce portals, e-commerce connectivity, business-to-business (B2B) e-commerce, and business-to-consumer (B2C) e-commerce. In the first category, the author recognized that healthcare portals primarily obtained their revenue through advertising fees. Parente (2000) also acknowledged that healthcare portals offered information retrieval capabilities to both providers and recipients of healthcare services. Portals originated their value proposition through provision of up-to-date and in-depth medical information. Payton (2003) analyzed the features of a number of healthcare Web portals to identify needed enhancements for information services targeting consumers of health plans.

The second category advanced by Parente (2000) in his taxonomy of healthcare e-business models was e-commerce connectivity. This model was primarily supported by revenues originating from transaction-processing activities. Provision of online accessibility to electronic medical records (EMR) and delivery of information on quality and outcomes of healthcare services were the other revenue sources for e-commerce connectivity model. The e-business model of Emdeon Corporation was cited as exemplary for the e-commerce connectivity category. Parente (2000) emphasized that Emdeon's primary value proposition was based on minimal investments in information infrastructure by users of transaction-processing systems. The author also noted that the major hurdle for Emdeon in terms of advancing this e-business model was a low rate of acceptance of new technologies by healthcare organizations. Parente (2000) explained Emdeon's strategy of aggressive acquisitions of healthcare technology firms as a reaction to this impediment. Abrams (2004) conducted a cross-sectional analysis of M&As in the healthcare technology industry and concluded that e-commerce connectivity firms were behind a rise in spending on M&As in 2004. In particular, production of EMR solutions was an area posed for growth. Abrams (2004) noted that e-commerce connectivity firms benefited from an increasing interest, on the part of healthcare institutions, in adding Internet- and software-based components to their services.

Healthcare B2B and B2C e-commerce models function similarly to a general e-commerce model that facilitates efficient market exchanges of goods and services. Parente (2000) described a B2B e-commerce model that offered services unique to healthcare settings. Such B2B platform would facilitate procurement processes involving employers and health insurance companies. A firm deploying this e-business model would act as an agent for employers seeking competitive health plans for their employees. An agent firm would handle a variety of tasks, including assessment of alternative propositions and setting online accounts for individual employees. Singh et al. (2002) described benefits and shortcomings of B2B healthcare e-commerce models. In particular, they addressed cost savings that B2B models delivered to healthcare institutions which had procured medical supplies online. The authors also identified a number of key e-commerce firms specializing on sales of healthcare supplies. The value proposition of the healthcare B2C e-commerce model is based on facilitating online transactions between organizational sellers and individual customers. According to Parente (2000), this e-business model is represented in the healthcare industry by applications that support filling prescriptions online as well as remote management of health plans.

A number of research accounts that have focused on general e-business models have been influential in shaping our analysis of strategy development and implementation at Emdeon Corporation. In particular, taxonomies of Afuah and Tucci (2003) and Weill and Vitale (2001) have complemented findings of the literature assessed above by stressing importance of economic factors for successful exploitation of e-business models. The taxonomy of e-business models devised by Afuah and Tucci depicted various economic dimensions of e-business models: profit site, revenues, and pricing. Our study relies on the "traditional" approach when evaluating business value creation by emphasizing revenue generation and profitability of the firm. When discussing revenue sources, Afuah and Tucci noted that e-business models could rely on commissions, subscription and advertising fees in addition to production, markup and referral revenue bases. These insights are helpful in distinguishing the revenue bases for the e-business model of Emdeon Corporation.

While the distinctive feature of the e-business model taxonomy by Afuah and Tucci (2003) was revenue bases, Weill and Vitale (2001) illuminated several other dimensions of the e-business model. They recognized such dimensions as strategic objective, value proposition, critical success factors, and core competencies in addition to sources of revenue. Weill and Vitale identified these dimensions for each of their eight e-business models, including content provider, intermediary, virtual community, and value net integrator. The dimensions of core competencies and value proposition have also been useful for our analysis of strategy development and implementation at Emdeon Corporation.

Finally, the taxonomy of e-business models developed by Timmers (1999) shed light on the influence of electronic business environments on enterprise value-chain activities. Having placed a major emphasis on Internet instigated value chain modifications, the author distinguished such categories of e-business models as e-procurement, value-chain service provider, virtual business community, collaboration platform, and value-chain integrator in addition to six other categories. While the taxonomies of Weill and Vitale (2001) and Timmers offered a high-level view on various distinct e-business arrangements for value creation, we find it difficult to apply these taxonomies to the case of Emdeon Corporation. The taxonomy of Afuah and Tucci (2003) provided a clearer path for our discussion of strategy development and implementation at Emdeon due to the fact that we decided to focus on the dimensions of revenue generation and profitability when assessing the effectiveness of strategizing.

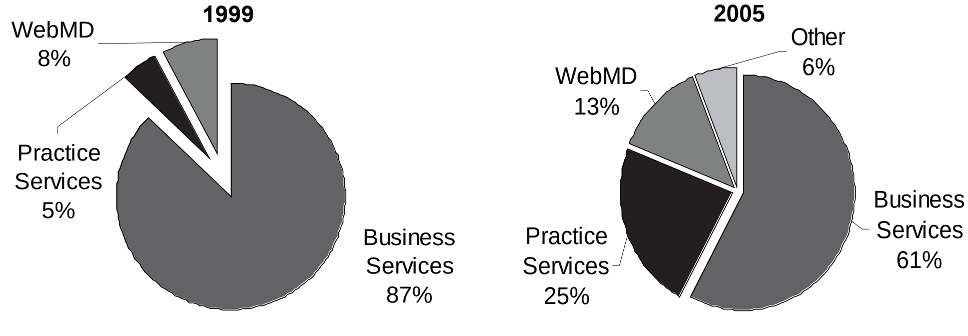
METHOD

This study primarily aims to explore competitive strategies in the emergent healthcare technology industry. We employ the case study approach to investigate the evolution of the e-business model of a healthcare technology firm. Benbasat, Goldstein, and Mead (1997) argued that the case study method could be used in information systems (IS) research for both exploration and explanation. Benbasat, Goldstein, and Mead (1997) noted that "a case approach is an appropriate way to research an area in which few previous studies have been carried out" (p. 370). The literature on e-business models in healthcare technology industry has not gained a critical mass yet. Healthcare technology markets have been undergoing a period of formation from the mid-1990s to the present day. Only recently, leaders have emerged in respective technology markets. We aim to trace the evolution of interactions between a leading firm in healthcare technology industry and pertinent client bases to identify lessons that we can learn from inception and implementation of a sustainable e-business model.

DATA

The data used in this research was primarily compiled from U.S. Securities and Exchange Commission (SEC) 10-K quarterly and annual reports provided by Hoover's Online. In particular, we collected the data on revenues and earnings in 1998-2005 as well as in the first quarter of 2006 for the individual segments of Emdeon's e-business model. SEC 10-K quarterly and annual reports from Hoover's Online also provided the data on the M&As that Emdeon completed in the period of study. The second source of research data was Standard & Poor's Market Insight database. We used analytical reports contained in this database to collect the data for the analysis of healthcare technology industry.

Figure 1. Emdeon's Annual Sales (Revenues) by Segments in 1999 and 2005



Note. From Securities and Exchange Commission 10-K annual and quarterly reports available from Hoover's Online database.

EVOLUTION OF EMDEON'S E-BUSINESS MODEL

Emdeon Corporation has evolved from a company that relied on a single source of revenue with 648 employees and $48.8 million of annual sales in 1998 to a leading multi-segment firm with 6,100 employees and $1,277 million of annual sales in 2005 (SEC Reports, 1998, 2005). Currently, the firm controls a 17 % share of the market for healthcare technology services (GICS Sub-Industry Profile, 2006). We argue that the key factor to achieved sustainability and market success has been a related diversification strategy that Emdeon carried out via M&As. This strategy has enabled the firm to build a sophisticated e-business model that relies on several robust sources of revenue.

Entry to Healthcare Technology Markets

Emdeon acquired electronic transaction-processing capabilities by purchasing ActaMed Corporation in 1998. In the next year, the firm made an IPO on the NASDAQ under the name of Healtheon. At that point, healthcare transaction processing services (Business Services according to Emdeon's terminology) constituted Healtheon's primary source of revenue, which accounted for 87% in 1999 (see Figure 1). The same year, Healtheon merged with WebMD Corporation aiming to expand into healthcare portal services (WebMD segment according to Emdeon's terminology). The addition of Medical Manager Corporation formed the other core competency: software development services (Practice Services according to Emdeon's terminology) targeting healthcare providers. Therefore, by pursuing a related diversification strategy, Emdeon laid a foundation for its e-business model that largely remains intact to the present day. Through the key acquisitions made in 1998-2000, Emdeon achieved the economy of scope effectively building a diversified e-business model that relied on multiple sources of revenue.

When Emdeon entered the market for medical portal services following the merger of Healtheon and WebMD Corporation in 1999, the portal services market was still in the experimentation phase. Elfenbein and Lerner (2003) outlined the two milestones for the early phase of development of portal services. The inception of portal services is traced back to 1994 when the users of the World Wide Web began to actively adopt the Internet browser. Portal services at that time attracted users through agglomeration of hyperlinks leading to the Web sites of interest, Web search capabilities, and proprietary content. In 1997, portal services entered a new phase of development, which denoted a boost in new content offerings such as online news and stock price information. Later, portal firms also expanded service offerings by adding such features as Internet-based auctions and electronic mail. According to Elfenbein and Lerner, Web portal firms primarily received revenue from two sources: fees for placing advertisements on portal Web pages and alliance agreements. In the portal services market, Emdeon chose to target a specific audience: providers and recipients of healthcare services.

In the 2000s, the Healtheon/WebMD portal has gained a noticeable position on the World Wide Web. A number of commentaries assessed the impact of this portal from a variety of perspectives. According to one commentary (Singh et al., 2002), the visibility level that Healtheon/WebMD portal achieved made it a much-discussed destination for online medical services (e.g., transcription). Another commentary (Damsgaard, 2002) pointed to the general popularity of Healtheon/WebMD portal. The author viewed this portal as successful, noting that the survival rate in the portal services market was very low. The model of portal management that Damsgaard advanced pointed to the importance of building a strong customer base and proactively responding to changes in the external environment.

Table 1. Emdeon's annual sales by segments in 1998-2005 (millions of dollars)

	2005	2004	2003	2002	2001	2000	1999	1998
Business Services	759	687	506	467	384	269	46	34
Practice Services	304	296	303	275	260	120	3	
WebMD	168	134	111	84	75	102	4	
Other	79	77	72

Emdeon Corporation entered the medical software market in 2000 when the firm acquired Medical Manager Corporation, whose most established unit was a practice management system. Emdeon pursued opportunities in an emerging technology niche that served physician practices. It is important to note that the market for software development services in healthcare at that point had reached maturation for large institutions. U.S. hospital networks began to deploy information systems as early as 1960s. Initially, hospitals invested their own resources in the development of such systems. For the most part, affiliated academic research centers provided the required computer resources and professional expertise (Collen, 1991). In the 1970s and 1980s, the number of software development firms serving U.S. hospitals considerably increased (Michell & Singh, 1996). By the early 1990s, the market for hospital information systems reached maturity in terms of both cumulative sales amount and number of firms offering information systems solutions. According to Michell and Singh, 491 firms offered such solutions to financial and business office operations of U.S. hospitals in 1991. In addition, 218 firms brought IS solutions designed to manage patient records to the hospital software market in the same year.

The Medical Manager set of applications targeted a different niche by offering practice management software to physicians. Its integrated software solutions served major business aspects of a doctor's office and consisted of clinical, financial, and patient data management modules. Prior to the acquisition by Emdeon, Medical Manager had been installed at 25,000 businesses representing 80 medical specialties, according to the 1999 SEC 10-K annual report of Medical Manager Corporation. Acquired software development capabilities produced $120 million, which accounted for 24% of Emdeon's total revenue in 2000 (see Table 1).

Emdeon gained an additional revenue stream from an unrelated segment: production and distribution of plastic materials. These materials primarily target customers in the healthcare industry. This segment was inherited from Medical Manager Corporation acquired for its software development line of products. For the two years following the acquisition, Emdeon tried unsuccessfully to divest this unrelated segment. This fact presents evidence that the firm focused on a related diversification strategy upon the entry to healthcare technology markets.

Strengthening a Diversified E-Business Model

For the three e-business segments, Emdeon pursued two strategies to advance its market positioning: economy of scale and economy of scope. The former strategy dealt with customer base expansion while the latter focused on quickly adding new technologies and services. Emdeon Corporation skillfully mastered the art of expanding its customer base as well as scope of technologies and services via M&As. Table A1 summarizes the history of M&As completed by Emdeon for the software development segment in 2000-2005. In the period of 2001-2003, Emdeon acquired 38 small software development companies that provided technology services to physician practices for the total amount of $24.9 million. This allowed Emdeon to reach the level of critical presence in the market of physician technology services.

Table A2 illustrates the dynamics of acquisitions made by Emdeon for the segment of electronic medical-transaction processing services. The first series of additions were made in 1999-2000. Emdeon acquired firms that had closely related e-business models, including Envoy Corporation, Kinetra, LLC (a joint venture of EDS and Eli Lilly), and MEDE America Corporation. The next wave of acquisitions for this segment, performed in 2003-2004, signaled a change in strategy. Emdeon sought and acquired targets that would expand its scope of technologies and services. The firm added print-and-mail services through the acquisition of Advanced Business Fulfillment, Inc. The addition of Medifax-EDI, Inc. provided a new capability for transaction processing services: real-time eligibility verification. In 2004, Emdeon acquired Dakota Imaging, Inc. and ViPS, Inc. to add capabilities in the areas of fraud detection and predictive modeling. At the same time, these acquisitions expanded the customer base of Emdeon. The addition of ViPS, Inc. resulted in entering a technology market serving healthcare government agencies and large insurance companies. The acquisition of Claims Processing Systems, Inc. brought in the clientele consisting of dental practices.

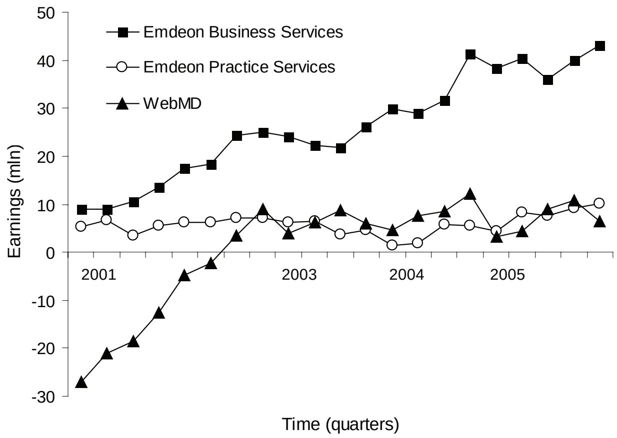
Emdeon faced a greater challenge for strengthening the portal services segment. This segment differed from the two other segments as it primarily relied on advertisement fees, and was a new e-business model at the time. Emdeon's portal services experienced losses for a number of years. The segment first became profitable in the third quarter of 2003 (see Figure 2). To this end, Emdeon made several acquisitions to provide enhancements to the portal's features as well as to diversify its customer base. Initially, portal services targeted online consumers of health information with such services as enrollment to health plans and health information retrieval. In 2001, Emdeon acquired Medscape, Inc. to penetrate a new customer base: providers of healthcare services. This development required addition of new portal features. Emdeon embarked on a series of acquisitions to offer additional Web site content: an online drug directory, online capabilities to compare costs and quality of healthcare providers, and online databases containing physician contact information and medical treatment guidelines. Table A3 displays the M&As that Emdeon pursued to carry out these changes.

Figures 2 and 3 display a steady growth of revenues and earnings for each segment. The M&As that Emdeon executed in 1998-2005 resulted in achieving sustainability and profitability of its e-business model.

Organizational Restructuring

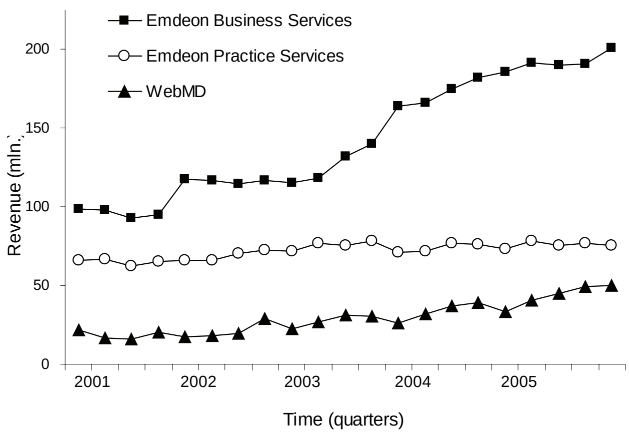
In the period of 2001-2005, Emdeon aggressively acquired companies that would fit the profiles of its three e-business segments: online medical-transaction processing, software development and portal services. Currently, the largest fraction of revenue for Emdeon comes from the transaction-processing segment. Development and sales of specialized software targeting healthcare providers make up the second largest source of revenue. The portal services segment generates the smallest amount of revenue. Changes in the breakdown of

Figure 2. Emdeon's quarterly earnings before interest by segments in 2001-2006



Note. From Securities and Exchange Commission 10-K annual and quarterly reports available from Hoover's Online database. Quarterly sales and earnings data by business segments prior to year 2001 are not available because Emdeon Corporation started to distinguish sales and earnings by business segments for quarterly reporting only in year 2001.

Figure 3. Emdeon's quarterly revenues by segments in 2001-2006



Note. From Securities and Exchange Commission 10-K annual and quarterly reports available from Hoover's Online database. Quarterly sales and earnings data by business segments prior to year 2001 are not available because Emdeon Corporation started to distinguish sales and earnings by business segments for quarterly reporting only in year 2001.

revenues by segment and distribution of revenues by segment over the observed period are displayed in Figure 1 and Figure 3 respectively.

Having built a sustainable e-business model, Emdeon embarked on a new strategy: organizational restructuring. In 2005, the firm spun off its portal services division under the name of WebMD Health Corporation. Realized profitability and a greater revenue growth rate in the recent years made this development possible. As evident in Figure 3, a revenue growth of the portal services segment enjoyed a healthy rate. The earnings of WebMD Web sites have been positive for a number of years as shown in Figure 2.

WebMD Health Corporation has been very active in pursuing M&As. The firm added Summex Corporation in July 2006 to supply information about wellness and health education programs, effectively expanding its array of services. In addition, WebMD made an announcement about its intention to purchase Medsite Inc., whose e-business model offered services in the areas of interactive medical education and physician recruitment. WebMD evidently continues the tradition of its parent, Emdeon, aiming to expand its market share and diversify its array of services through aggressive M&As.

CONCLUSION

The healthcare technology industry is dynamically evolving. Having survived a major environmental shock, the dot.com bust, some firms in this industry are experiencing an impressive revenue growth. The industry currently enjoys a 21.8% revenue growth based on the 12-month period compared with a 13.4% growth for the rest of the market[1]. The firm in our study, Emdeon Corporation, emerged as a market leader in the healthcare technology industry by being able to adjust quickly to evolving market conditions. The key to the firm's success was its e-business model, which relied on multiple sources of revenue.

To enter healthcare technology markets, Emdeon Corporation pursued a related diversification strategy. In the span of three years, Emdeon made key acquisitions that formed distinct revenue segments of its e-business model: electronic medical-transaction processing, software development and portal services. The first lesson learned from Emdeon's experience is that a related diversification strategy creates a competitive advantage upon the entry to emerging niche technology markets.

Emdeon implemented a related diversification strategy by the means of M&As to achieve the economies of scope and scale quickly. Although Emdeon has entered a number of strategic alliances, the firm invests more aggressively in acquiring companies. The second lesson learned from Emdeon's experience is that firms in emerging niche technology markets can use M&As to sustain revenue growth and to increase market power.

Emdeon's upper management made a major strategy shift by spinning off one of the segments, portal services. Having secured a great deal of market power for this segment, Emdeon currently focuses on strengthening market positioning of the other segments. This change in Emdeon's organizational structure points out that the firm's e-business model has reached a certain level of maturity. The lesson learned from Emdeon's restructuring strategy is that maturation of diversified e-business models in niche technology industries leads to the transformation of individual segments into distinct entities focusing on specific technology markets.

Chapter 6.10
M-Health:
A New Paradigm for Mobilizing Healthcare Delivery

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Steve Goldberg
INET International Inc., Canada

ABSTRACT

Medical science has made revolutionary changes in the past decades. Contemporaneously, however, healthcare has made incremental changes at best. The growing discrepancy between the revolutionary changes in medicine and the minimal changes in healthcare processes is leading to inefficient and ineffective healthcare delivery and one if not the significant contributor to the exponentially increasing costs plaguing healthcare globally.
Healthcare organizations can respond to these challenges by focusing on three key solution strategies, namely, (1) access – caring for anyone, anytime, anywhere; (2) quality – offering world-class care and establishing integrated information repositories; and (3) value – providing effective and efficient healthcare delivery. These three components are interconnected such that they continually impact the other and all are necessary to meet the key challenges facing healthcare organizations today. The application of mobile commerce to healthcare, namely, m-health, appears to offer a way for healthcare delivery to revolutionize itself. This chapter serves to outline an example of adopting mobile commerce within the healthcare industry, namely, in the area of a wireless medical record. In particular, it discusses an appropriate, feasible mobile solution to enable hospitals operate effectively and efficiently in today's competitive and costly healthcare environment as well as meet all the necessary regulatory requirements. The lessons learnt from these case study data should be of interest to both practitioners and researchers since they will outline realistic and feasible solutions to enable hospitals to incorporate a wireless/m-commerce solution as well as highlighting key areas for further research in this important area of high-quality, effective, and efficient healthcare management.

INTRODUCTION

Currently the healthcare industry in the United States as well as globally is contending with relentless pressures to lower costs while maintaining and increasing the quality of service in a challenging environment (Pallarito, 1996, pp. 42–44; Wickramasinghe & Silvers, 2003, pp. 75–86). It is useful to think of the major challenges facing today's healthcare organizations in terms of the categories of demographics, technology, and finance. Demographic challenges are reflected by longer life expectancy and an aging population; technology challenges include incorporating advances that keep people younger and healthier; and finance challenges are exacerbated by the escalating costs of treating everyone with the latest technologies. Healthcare organizations can respond to these challenges by focusing on three key solution strategies, namely, (1) access – caring for anyone, anytime, anywhere; (2) quality – offering world-class care and establishing integrated information repositories; and (3) value – providing effective and efficient healthcare delivery. These three components are interconnected such that they continually impact the other and all are necessary to meet the key challenges facing healthcare organizations today.

In short then, the healthcare industry is finding itself in a state of turbulence and flux (Wickramasinghe & Mills, 2001, pp. 406–423). Such an environment, we believe, is definitely well suited for a paradigm shift with respect to healthcare delivery. Therefore, in this chapter we address the issue of wireless solutions for healthcare delivery and management.

First, we discuss the findings from INET's study on mobile Internet (wireless) technology in healthcare by Ontario Hospitals in Canada. We use these findings as a launching place to review a rigorous way to accelerate healthcare delivery improvements. Next, we outline some preliminary evidence for using a standardized mobile Internet (wireless) environment in healthcare. For example, INET International is advocating the use of a wireless healthcare portal to validate the possible reduction in IT infrastructure costs. A portal may reside on a wireless PDA device as single point of contact for clinicians to obtain immediate patient data (radiology reports, lab results, and clinical findings). This wireless portal may also improve patient care outcomes with access to the best available clinical evidence at the point of care. We shall also describe the current status of a standardized mobile Internet (wireless) environment in terms of technology requirements, security readiness, and IT management practices. In addition, we will also outline some of the key challenges that a hospital's IT department, medical units, administration, and clinicians will face regarding a wireless project and provide some reasonable solutions to these challenges. Finally, we shall outline the key steps necessary for a hospital to transition from proprietary information systems to a three-tier Web-based architecture.

INETS STUDY IN MOBILE INTERNET TECHNOLOGY IN HEALTHCARE

INET International Inc. delivers rigorous e-business acceleration projects in large corporate, government, and healthcare organizations. The organization focuses on custom Mobile, Internet, Intranet, Extranet (INET), and wireless solutions. It was founded by Steve Goldberg in 1998 and it leads a Wireless Technology Consortium (WTC) to collect evidence on the best way to use wireless technology to accelerate healthcare delivery improvements. These applications are designed to improve patient care, reduce costs, increase healthcare quality, and enhance teaching and research.

Over a period of 2 years INET has been conducting research that has been directed at how to apply mobile Internet wireless technologies' low-cost advantages to evolve a wireless healthcare portal. A portal is a single point of contact for healthcare providers and handheld technology applications (HTA) to access and process various data pertaining to patients such as: (1) patient-specific data (i.e., patient ID, radiology reports, lab results, clinical findings, and research data); (2) medical knowledge (primarily from evidence-based medicine training and journals); (3) clinical guidelines (i.e., association guidelines such as the Association of Radiologists clinical practice publications); and (4) reimbursement rules and data (i.e., Ontario Health Insurance Plan, known as OHIP). This research has shown that mobile/wireless solutions for healthcare can achieve four critical goals of (1) improving patient care, (2) reducing transaction costs, (3) increasing healthcare quality, and (4) enhancing teaching and research.

Improving Patient Care and Increasing Healthcare Quality

In the final report compiled by the Committee on the Quality of Healthcare in America (AIM, 2001), it was noted that improving patient care is integrally linked to providing high-quality healthcare. Furthermore, in order to achieve a high quality of heathcare the committee identified six key aims, namely, (1) healthcare should be safe – avoiding injuries to patients from the care that is intended to help them; (2) effective – providing services based on scientific knowledge to all who could benefit and refraining from providing services to those who will not benefit (i.e., avoiding under use and overuse); (3) patient centered – providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions; (4) timely – reducing waiting and sometimes harmful delays for both those receiving care and those who give care; (5) efficient – avoiding waste; and (6) equitable – providing care that does not vary in quality based on personal characteristics.

Most of the poor quality connected with healthcare is related to a highly fragmented delivery system that lacks even rudimentary clinical information capabilities resulting in poorly designed care processes characterized by unnecessary duplication of services and long waiting times and delays (AIM, 2001). The development and application of sophisticated information systems is essential to address these quality issues and improve efficiency, yet healthcare delivery has been relatively untouched by the revolution of information technology that has transformed so many areas of business today (Wickramasinghe & Mills, 2001, pp. 406–423; Wickramasinghe & Silvers, 2003, pp. 75–86). This, then, certainly justifies the need for e-business solutions for healthcare delivery; however, from various applied research scenarios (Goldberg et al., 2002a, 2002b, 2002c, 2002d, 2002e), we can see why mobile solutions appear to be superior since they enable even better care for patients with the added advantage of significant cost savings. Physicians themselves are excited by the possibilities offered by mobile solutions as the following quotation discussing benefits to radiologists exemplifies:

"The demands on radiologists in today's fast-paced and cash-strapped hospitals are tremendous," says Dr. Brian Yemen, radiologist at Hamilton Health Sciences. "The possibility of transmitting radiology reports between hospitals and physicians on-demand is exciting. It will mean less time and travel for busy doctors, but more importantly, it will mean faster turnaround and quicker results for patients."

A mobile Internet wireless solution uses a personal digital assistant (PDA) device at the point of patient care. Such handheld technology applications are simple to use and require little, if any, training. Furthermore, they can significantly reduce change management costs which are usually dominated by technology education. Typically, the PDA devices and application require very little training unlike most PC-based e-health alternatives where even simple skills like typing prove to be challenging hurdles for physicians and other users to overcome. This means that not only do physicians have the information they need in a timely fashion but they also are not restricted by typing or other activities that are not directly going to benefit the patient's encounter. In Canada, most manufacturers and IT national resellers have found no need to set up educational practices to support over 1 million PDA users. Currently, Canadian retail stores provide the bulk of the customer service requirements, such as, product pricing, availability, promotions, and product warranty. Usually, the product warranty process replaces defective PDA devices with a new or refurbished unit within hours or the next business day with minimal inconvenience to users.

Cost Reductions: Wireless Technology May Reduce IT Infrastructure Costs by 84%

- Integral to the set up of such a mobile solution is the wireless healthcare portal. This portal can dramatically reduce IT infrastructure project costs. For example, the government of Ontario, Ministry of Health and Long-Term Care is planning to spend $150 million to develop a turn-key IT solution for 6,400 physicians. By using wireless technology it is possible to reduce this IT infrastructure cost to $24 million by leveraging hospital IT infrastructure investments. The preliminary cost estimate is $1,259/year/physician over 3 years. Table 1 outlines the cost estimates/ year/physician for each component.

Thus, the findings summarized above from the research conducted by INET demonstrate not only does the mobile/wireless solution support improving patient care, but it also is a cost-effective solution. Furthermore, not only can cost savings be enjoyed by leveraging off existing infrastructure, but the wireless solution also lends itself to rapid healthcare delivery improvements as well as the ability to deploy healthcare improvements within short time cycles as discussed below.

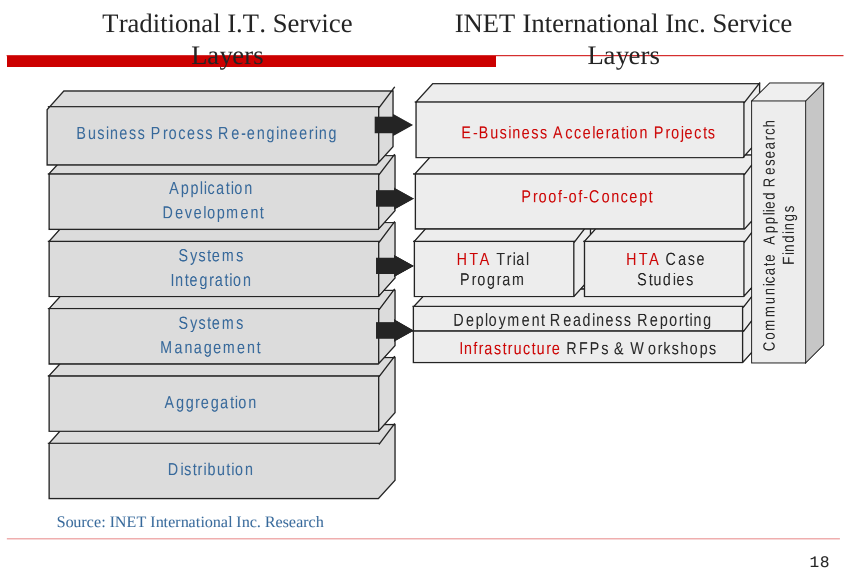
Achieve Rapid Healthcare Delivery Improvements

By adopting a mobile/wireless healthcare delivery solution, it is possible to achieve rapid healthcare delivery improvements, which impacts both the costs and the quality of healthcare delivery. This is achieved by using an e-business acceleration project which provides hospitals a way to achieve desired results within a standardized mobile Internet (wireless) environment as shown in Figure 1.

Table 1. Cost estimates

Component	Total Cost	Comment
Mobile Internet (wireless) Infrastructure Support	$60	Annual
Mobile Internet (Wireless) Infrastructure Upgrade	$100	Amortize Over 3 Years
PDA Device	$133	Amortized Over 3 Years
Cell Phone/Data Cable/Modem	$66	Amortized Over 3 Years
Wireless Communication Costs	$420	$35/Month – transmits 25 to 50 patient records/day
Physician Wireless Portal	$480	$40/Month – assume four handheld technology applications

Figure 1. E-business accelerated project



Integral to such an accelerated project is the ability to build on the existing infrastructure of the hospital. This then leads to what we call the three-tier Web-based architecture. In such an environment, tier 1 is essentially the presentation layer, which contains the Web browser but no patient data is stored within this layer, and thereby ensuring compliance with international security standards/policies like HIPAA. Tier 2 then provides the business logic, including but not limited to, lab, radiology, and clinical transcription applications; messaging of HL7, XML, DICOM, and other data protocols; and interface engines to a Hospital Information Systems (HIS,) Lab Information Systems (LIS), Radiology Information Systems (RIS), as well as external messaging systems such as Smart Systems for Health (an Ontario Healthcare IT infrastructure project). Finally there is the tier 3 architecture which consists of the back-end databases such as Oracle or Sybase.

Deploying Healthcare Improvements within Short Time Cycles

A mobile Internet (wireless) infrastructure may achieve rapid technology deployments to individual practices, small clinics, and healthcare networks at a very low cost. For example, for $35/month a physician can have wireless access to a Radiology Information System (RIS) to retrieve diagnostic imaging (DI) reports. With a minimum cost these RIS systems may easily and securely access reports from the hospital, multiple hospitals (using Smart Systems for Health) or interface into other diagnostic imaging (DI) clinics as a single point of contact. The objective is to improve patient care by getting DI results faster to patients (through referring physicians). Once the solution achieves approval for general release, it has the possibility of being deployed to 3,000 to 4,000 physicians within short time cycles so that, for example, clinicians using a mobile Internet (wireless) connection are able to hook into an existing hospital infrastructure as in the case of the Ontario hospitals where they use the Hamilton and Toronto downtown hospitals' IT infrastructures.

Teaching and Research

The provision of the best available clinical evidence at the point of care is playing a pivotal role in medical research and training (www.cochrane.org). Today, a physician-led research center (www.cebm.utoronto.ca/projects/index.htm) is conducting an applied research project on the impact on mobile Internet (wireless) technology to help clinicians with the following:

- Consistently translate high-quality clinical evidence into practice.
- Obtain the information they need from the right resources.
- Engage in a process to replace the need to read 17 articles per day.

The challenges of using mobile Internet technology have been documented by this center. This includes the following:

- What kinds of information are most useful to clinicians?
- What is the most effective way of querying evidence-based resources?
- How do we format answers?

INET International Inc. applied research on a standardized mobile Internet (wireless) environment may provide some unique solutions. The solutions may include the following:

- Clinicians can participate in a rigorous e-business acceleration project to narrow information requirements into a few useful requirements. For instance, radiologists have identified and confirmed the importance of referring physicians getting imaging reports and results to patients faster.
- By harnessing a hospital's information systems (HIS) and standardized mobile Internet (wireless) environment a physician can gain access to patient-specific data (i.e., imaging reports). This may provide a new opportunity to evaluate how physicians can use current patient data to determine the best ways to query evidence-based resources. Also, researchers may extend the use of patient-specific data to nurse practitioners, home care providers, and patients to help develop the most effective way of querying evidence-based resources within a consumer-centric model.
- Finally, INET International Inc. research on a standardized mobile Internet (wireless) environment may help physician-led research centers select and aggregate Internet search forms and Internet "answer" formats from multiple resources into a single wireless personal digital assistant (PDA) presentation. Additionally, researchers can make rapid changes to Internet "answer" formats to accommodate user feedback. They work within this standardized environment to control iterative prototyping for the delivery of small and frequent proof of concepts and randomized trials. The use of release management and quality assurance tools enable the scaling of successful trials into wireless production systems for tens of thousands of healthcare providers and patients within a very short time cycle.

To summarize, based on the findings from the various research endeavors conducted by INET Inc. (Goldberg et al., 2002a, 2002b, 2002c, 2002d, 2002e), using a standardized mobile Internet (wireless) environment appears to be the simplest way to access the best-available clinical evidence at the point of care for everyone, anywhere, anytime at a very low cost. The achievement of superior quality cost-effective healthcare is uppermost on the agendas of most countries' healthcare initiatives.

We believe this can only be realized by adopting some type of the wireless solution.

THE MOBILE VISION

Having described the key benefits of a mobile/wireless solution, let us now turn to focus on how to set about actualizing such a mobile vision. We illustrate the possibilities by discussing INET's strategies and approaches.

Research Goal and Approach

Simply stated, the research goal is to use a standardized mobile Internet (wireless) environment to improve patient outcomes with immediate access to patient data and provide the best-available clinical evidence at the point of care. To do this, INET International Inc. research starts with a 30-day e-business acceleration project in collaboration with many key actors in hospitals such as clinicians, medical units, administration, and IT departments. Together they follow a rigorous procedure that refocuses the traditional 1–5 year systems development cycle into concurrent, 30-day projects to accelerate healthcare delivery improvements. Figure 2 highlights the key success factors required in such an approach.

The completion of an e-business acceleration project delivers a scope document to develop a handheld technology application (HTA) proof of concept specific to the unique needs of the particular environment. The proof of concept is a virtual lab case scenario. A virtual lab operates within a mobile Internet (wireless) environment by working with hospitals and technology vendors. The final step is the collection of additional data with clinical HTA trials consisting of 2-week hospital evaluations.

E-Business Acceleration Project Outcomes

The first e-business acceleration project for healthcare was conducted for Hamilton Health Sciences (HHS) Diagnostic Imaging (DI) Department.

They followed a procedure to divide an HHS enterprise DI process into smaller mini-processes. This provided a new way for radiologist to enhance DI delivery in small manageable pieces and minimize risk to patients. Hence we can see that a critical step in the e-business accelerated project is often to reengineer existing processes to ensure they are as effective and efficient as possible.

During the first e-business acceleration project a DI sign-off report process was selected and a handheld technology application (HTA) proof of concept was developed.

The next step, HHS is planning an HTA trial to evaluate a low-cost, secure, and simple way for radiologists and referring physicians to access critical healthcare information at the point

Figure 2. Key success factors

Mobile Internet (wireless) Technology Key Success Factors For Health Care	
Physician-led	Widespread physician acceptance of handheld technology applications
Simple to Use	Personal Digital Assistance, Bluetooth, Java Cell Phones, Digital communicators
Low Cost	Convergence of wireless IP WAN and wireless IP LANs.

of patient care. The radiologist and referring physicians could retrieve and review a patient's DI reports using a wireless PDA device—getting diagnostic results faster to patients and thus enhancing quality as well as effective and efficient healthcare delivery.

A series of 2-week evaluations are planned for hospitals in Ontario and United States. This trial program is presented in Figure 3. Each hospital provides a different environment to evaluate the scalability of the DI sign-off report HTA. The aggregation of such 2-week evaluation outcomes provides hospitals evidence on key areas such as:

- Showing clearly how reduction in large-scale IT infrastructure project costs can occur.
- Demonstrating that the PDA is simple to use, requiring little or no training of clinicians.
- Clearly outlining how to achieve rapid healthcare delivery improvements.
- Demonstrating how to scale and deploy healthcare delivery improvement to clinicians within short time cycles.

Applied Research Challenges

Engaging in such a project, naturally, has several challenges. Initially technology vendors saw the immediate opportunities to engage in INET International Inc. Virtual Lab to work with Hamilton Health Sciences (HHS). The lab is a low-cost way for vendors to connect demonstration facilities and resources to conduct proof of concepts and clinical trials. However, growing the lab to 10 hospitals involves the formalization of a hospital procurement process that includes applied research, that is, a proof of concept and a trial program.

Traditionally IT operates within 1- to 5-year systems development life cycle to meet hundreds of end-user requirements. Whereas the e-business acceleration project process selects one or two requirements to deliver improvements in concurrent short time cycles. To expand the applied research of a rigorous approach to accelerate healthcare delivery improvements requires additional investment by hospitals, something that is clearly challenging.

Possibly the most significant impact of the virtual lab is the resolution of mobile Internet (wireless) technology challenges. The HHS applied research findings (lesson learned) provide a way to help wireless projects achieve the same results in a much shorter time cycle. HSS is an academic health sciences center whose primary role is healthcare delivery. It is one of the largest hospitals in Ontario, operating across four sites with approximately 8,000 employees and 1,000 physicians and thus the research findings from HHS are detailed and extensive and a useful resource to help any other wireless project in this area.

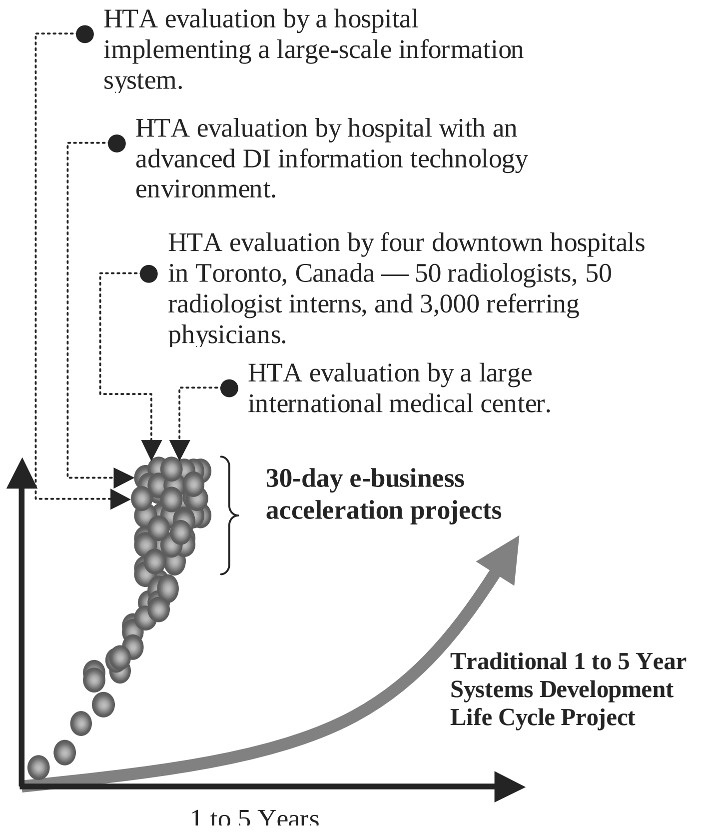
A Standardized Mobile Internet (Wireless) Environment

INET virtual lab also encounters unknown challenges when working with key actors in hospitals such as clinicians, IT departments, medical units, and administration. This is to be expected because each situation is unique and it typically happens during consensus building on HTA proof of concepts and clinical HTA trial programs. The virtual lab uses these challenges to identify, prioritize, and select the requirements for a standardized mobile Internet environment.

Ontario's Management Board Secretariat (MBS) is taking the lead in the use of a Three-Tier Web-Based Architecture, a standardized application environment to implement and scale applications for the Ontario Public Sector. Used as the starting point, this is the foundation to architect a standardized mobile Internet (wireless) environment for an Ontario hospital.

By design, the mobile Internet (wireless) environment is a very thin layer on top of a standardized application environment and represents

Figure 3. A wireless handheld technology applications (HTA) trial program



the extension of the tier 1 presentation layer. The purpose is to prevent time-consuming and costly tier 2 (business logic) and tier 3 (back-end database) development (see Figure 4 on this reading from the bottom up).

INET International Inc. started a wireless technology consortium in 2001 to collect evidence on the best way to define a standardized mobile Internet (wireless) environment. Every member works in collaboration to build a consensus on the IT management practices and IT professional services related to each component. The member's competency is validated through applied research on using mobile Internet (wireless) technology in collaboration with an Ontario hospital. The virtual lab is the basis of INET's applied research. INET uses case scenarios by running selected handheld technology application proof of concepts and trial evaluations. All unpublished data (Goldberg et al., 2002a, 2002b, 2002c, 2002d, 2002e) is available to INET International Inc. collaborations with business and physician-led research centers.

In 2001 the WTC members' roles and responsibilities are listed in Table 2, while Appendix 1 provides the necessary background information on all participating members.

The WTC acceptance process is currently under review. The process may include the following steps:

1. Identify vendor's IT management practice investments.
2. Map IT management practices and IT professional services to a mobile Internet (wireless) environment component(s).
3. INET assigns WTC responsibilities: WTC leaders, complete management qualifications, IT service transition plans and workshops. Build a consensus on a mobile Internet (wireless) technology certification program. Assist IT associations in training.
4. Each member meets or sets international management practice standards (based on ITIL Information Technology Infrastructure Library http://www.itil.co.uk/index.html). They participate in academic conference panels, present papers, and collaborate on applied research.
5. Participate in INET virtual lab proof of concepts and trial evaluations to validate a standardized mobile Internet (wireless) environment.
6. At any time INET International Inc. may reassign a WTC role, request a new member to apply to the WTC, or ask WTC to reengage the WTC acceptance process in step 1.

KEY CHALLENGES

The introduction of wireless into healthcare naturally brings with it many unique challenges which must also be addressed if success is to ensue in these initiatives. One of these challenges is concerned with security and privacy of highly sensitive patient data. In a healthcare setting, in the case of the mobile electronic patient record, typically the physician is accessing patient data from the hospital's Web services. The order information is transmitted is from the mobile device to a base wireless station, and from there, through the mobile communication infrastructure, to the wireless application gateway of the hospital. There are naturally many valid business reasons why all concerned parties—the patient,

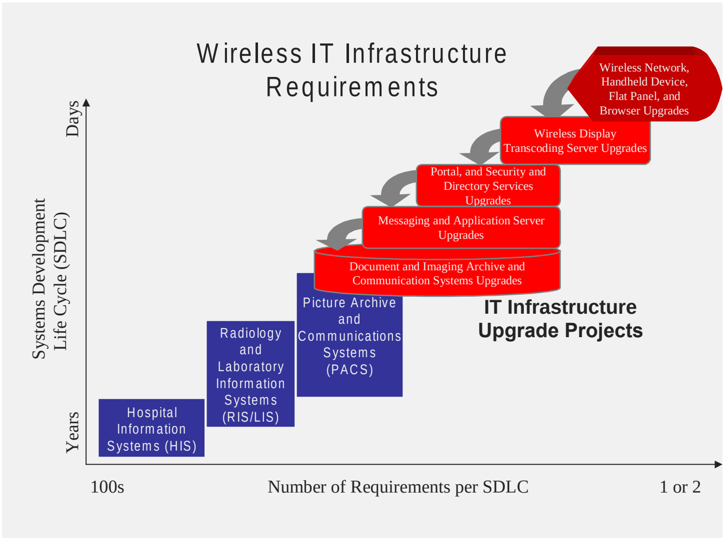
healthcare institution, and physician, to name a few—should expect the information exchanged during such a mobile transaction process to be secure. Specifically, parties should expect the data associated with a transaction to be *confidential* and delivered without violation of *integrity* or *authenticity*. Further, all parties should similarly expect *nonrepudiability*; neither the client nor the hospital should be able to deny the completion of the transaction if such a transaction, in fact, occurred.

Possible security vulnerabilities can occur at several points including: (1) between the physician and the mobile device; (2) between the mobile device and the mobile infrastructure operator; (3) between the mobile infrastructure operator and the wireless application gateway of the merchant; and (4) between the wireless application gateway and the Web services of the hospital. There are similarities and differences between a mobile and a fixed (those not using a mobile device) transaction with respect to security concerns. As in the case of a fixed transaction, *content* of a mobile transaction must be protected from unauthorized access and alteration whether it is in storage or being transmitted. However, protecting data that move is a bit more difficult than data that do not move since one has to worry about parameters that do not come into play in a fixed network, such as (a) location management, (b) mobility management, and (c) radio resource management.

Figure 5. (Source: Wickramasinghe & Goldberg, 2004, pp. 140–156)



Security and privacy are important considerations. In the United States, all healthcare institutions must be HIPAA compliant in this regard. Yet, while HIPAA details what is required, it does not discuss how this should be addressed. We believe that a sound approach to achieve a high degree of end-to-end security in a mobile/wireless environment is to develop a suitable mobile trust model using symmetric keys (Goldberg et al., 2002e). This will not only ensure HIPAA compliancy but will also ensure at least as secure an environment as its wired counterpart. We are confident that these security challenges can be addressed and then healthcare organizations can enjoy the full power and potential of their mobile/wireless solutions.

Security is not the only challenge, however. Other important challenges include compatibility issues and the ability to share information throughout the existing hospital networks. We believe this is less problematic because of the advantages inherent in constructing the healthcare portal. Furthermore, in the designing of the wireless, infrastructure directly builds on top of existing hospital infrastructure as can be seen in Figure 5.

INET's studies (Goldberg et al., 2002a, 2002b, 2002c, 2002d, 2002e) have shown that this approach appears to circumvent several problems pertaining to information sharing. Clearly though incorporating techniques such as information management and knowledge management would serve to enable even more efficient and effective use of all necessary information (Wickramasinghe & Goldberg, 2004). We also suggest that some business process reengineering would be required to ensure that processes are as effective and efficient as possible and make full use of the potentials of the wireless technologies.

DISCUSSION

"Today's hospitals demand zero tolerance for software defects and downtime. That's where Compuware comes into play," says Cathy Lippert, Distributed Systems Product Management Director, Compuware Corporation, Farmington Hills, Michigan. "Our tools can set a new pace for accelerating the testing and quality assurance processes for handheld-technology applications based on mobile Internet standards. This means lower costs, reduced risk, a shorter learning curve, and the confidence that applications can be scaled from one user to thousands of users."

In an effort to improve medical information systems within 30-day cycles and help establish international mobile Internet standards, the WTC is creating a virtual research lab in Ontario. The virtual lab will play a key role in setting new standards for the delivery of high-impact handheld technology applications to clinicians. "The WTC's establishment of a virtual lab designed to help establish global mobile Internet standards should rapidly accelerate the development of handheld applications across a broad spectrum of healthcare industries," says Matthew Hickey, director, enterprise solutions for Palm Canada. "Already, Palm handhelds are at the forefront of this revolution and we expect to continue pushing the envelope in terms of innovation and collaboration." "Our 2.5G iDEN technology allows the seamless transfer of information from wireless handheld devices to hospital servers," says Jawad Shah, manager of Wireless Data, TELUS Mobility, Scarborough, Ontario. "The virtual lab can examine the proper implementation of firewalls, authentication servers, biometrics, intrusion detection, virus protection, and virtual private networks (VPN) to assure that patient-sensitive data can be transmitted securely over the entire TELUS Mobility iDEN network." The preceding quotations from various qualified people in the field are presented to illustrate some key points. First, wireless is here to stay and this technology offers us many advantages. Second, healthcare requires a new way to manage current challenges and thereby provide cost-effective quality care to us all. Finally, the combination of wireless in healthcare appears to be a real solution. Clearly we are technically capable of delivering wireless solutions to healthcare institutions as we have outlined in this chapter. Now appears to be the opportune time to do so. We strongly believe that hospitals of the 21^{st} century should be wireless to some extent at least and a mobile healthcare delivery solution will facilitate the necessary revolutionary changes required by healthcare to contend with today's challenging environment.

CONCLUSION

Wireless technology advancements have made it possible for physicians to use handheld computers to produce diagnostic imaging reports on demand and within seconds. Along with improving access to medical information and the overall speed of healthcare delivery, mobile Internet wireless technologies can play a significant role in lowering IT infrastructure costs for hospitals and preventing disruption to healthcare delivery due to technology problems. The preceding has served to demonstrate that (a) we have the capabilities to offer wireless solutions and (b) wireless solutions will enable healthcare institutions to enjoy many advantages. By detailing the studies conducted by INET, we have shown how doable wireless solutions are in healthcare. Furthermore, we have highlighted the many benefits including cost savings and the ability to deliver a higher level of quality care. We have also endeavored to highlight the key challenges that any wireless initiative must address so that the full power and potential of such an iterative can be realized and thereby truly making mobile healthcare delivery a necessary component of any healthcare arsenal.

We close with a strong message about the importance of thinking of wireless as a necessity in healthcare delivery for the 21st century and we urge for more research in this area as well as for healthcare institutions globally to move forward in this direction. Finally, we also wish to underscore that the lessons learned from INET Inc.'s accelerated project approach have broader implications above and beyond the healthcare domain. Specifically, we believe that the e-business accelerated project techniques are useful to many wireless endeavors and we encourage researchers and practitioners in the field to explore these possibilities.

ENDIX I: BACKGROUND INFORMATION ON CONSORTIUM MEMBERS

1. **About INET International Inc.**
   INET International Inc. is a Canadian technology management consulting firm. Currently the firm is focusing on how to use wireless technology to accelerate healthcare delivery improvements and leads a wireless technology consortium. INET International is not on the Web. If you need additional information, please do not hesitate in contacting Steve Goldberg at sgoldberg@sprint.ca, or t: 905 889-2704.
2. **About TELUS Mobility**
   TELUS Mobility, combining the national wireless operations of Clearnet, QuébecTel Mobilité, and TELUS, provides a full suite of wireless services to more than 2.3 million clients across Canada. For more information, please visit us at www.telusmobility.com.
   TELUS Corporation (TSE: T, T.A; NYSE: TU) is one of Canada's leading telecommunications companies, providing a full range of telecommunications products and services that connect Canadians to the world. The company is the leading service provider in Western Canada and provides data, Internet Protocol, voice, and wireless services to Central and Eastern Canada. For more information about TELUS, visit www.telus.com.
3. **About Palm, Inc.**
   Palm, Inc. is a pioneer in the field of mobile and mobile and wireless Internet solutions and a leading provider of handheld computers, according to IDC (December 2000). Based on the Palm OS(R) platform, Palm's handheld solutions allow people to carry and access their most critical information wherever they go. Palm™ handhelds address the needs of individuals, enterprises, and educational institutions through thousands of application solutions. The Palm OS platform is also the foundation for products from Palm's licensees and strategic partners, such as Franklin Covey, Handspring, IBM, Kyocera, Sony, Symbol Technologies, and HandEra (formerly TRG). The Palm Economy is a growing global community of industry-leading licensees, world-class OEM customers, and approximately 170,000 innovative developers and solution providers that have registered to develop solutions based on the Palm OS platform. Palm went public on March 2, 2000. Its stock is traded on the NASDAQ national market under the symbol PALM. More information is available at http://www.palm.com.
4. **About Compuware Corporation**
   With fiscal 2001 revenues of more than $2 billion, Compuware Corporation provides business value through software and professional services that optimize productivity and reduce costs across the application life cycle. Meeting the rapidly changing needs of businesses of all sizes, Compuware's market-leading solutions improve the quality, ease the integration, and enhance the performance of distributed, e-business, and enterprise software. Compuware employs approximately 13,000 information technology professionals worldwide. For more information about Compuware, please contact the corporate offices at 800-521-9353. You may also visit Compuware on the World Wide Web at http://www.compuware.com.
5. **About NetManage**
   Founded in 1990, NetManage, Inc. (NASDAQ: NETM) delivers information access, publishing, integration, and support software and services that maximize a company's investment in existing information systems and applications. It provides an instant bridge to e-commerce. NetManage offers a significantly broader range of application integration software, host access software, centralized management, and live interactive support solutions than competitors. Only NetManage instantly transforms corporate information assets into powerful e-business solutions. NetManage sells and services it products worldwide through its direct sales force, international subsidiaries, and authorized channel partners. For more information, visit www.netmanage.com, send e-mail to pr@netmanage.com, or call 408.973.7171 (Pacific Time).

Chapter 6.11
Mobile Business Process Reengineering:
How to Measure the Input of Mobile Applications to Business Processes in European Hospitals

Dieter Hertweck
University for Applied Sciences Heilbronn, Germany

Asarnusch Rashid
Research Center for Information Technology Karlsruhe, Germany

ABSTRACT

There is an ongoing debate about the value of mobile applications for the optimization of business processes in European hospitals. Thus finding satisfying methods to measure the profitability of mobile applications seems to be of great importance. Prior research had its focus mainly on general value dimensions concerning the medical sector or the usability and design aspects of hospital information systems. Conterminous to that, the authors chose a strictly process-oriented approach. They modeled the requirements of future mobile systems as an output of a profitability analysis based on activity-based costing. The cost savings defined as the difference between former and future business processes were used as an incoming payment for an ROI analysis. In a nutshell, the authors present a case study that highlights the value of their analyzing method as well as the enormous benefit of mobile applications in the area of food and medical supply processes in German hospitals.

INTRODUCTION: INCREASED DEMAND FOR EFFICIENT PROCESSES IN HEALTH CARE

Apart from the long-term decline of the population, a great challenge in the contemporary discussion turns out to be the increasing aging of the population in European industrial societies. This raises various difficulties for our welfare systems and reveals the necessity of long-term adjustment to this development. Aging describes the process of composition of the population shifting for the benefit of elderly people.

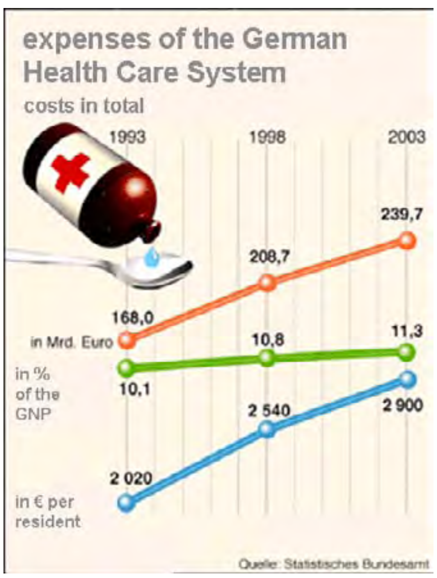
Thus, the decisive item is not the increasing number of the elderly but rather their increasing proportion of the population. For example as latest simulations for the development of the German population (Statistisches Bundesamt, 2003) reveal, the proportion of 65-year-old and older people will rise from 17.1 % today to 29.6 % in 2050. At the same time the percentage of geriatric people (80 years and older) will increase to 12 % which means a triplication.

This development causes serious problems in welfare and tax systems that are based on the income of a workforce. Less young people have to pay the pensions and health care of the elderly.

Furthermore, the productivity of our highly automated industry leaves an increasing number of people unemployed. So the real challenges of over aged European industrial societies will be to enhance the productivity of the existing education and health care systems.

And as productivity is defined as the relationship between output and input factors, there was an intensive discussion going on during the last 2 years about the input factor dimension. Even

Figure 1. Expenses of the German health care system



though the German health care system was able to perform quite well the last decades, from an input point of view the costs and resources to maintain the system were increasing dramatically (see Figure 1).

This development is not typical for the German health care system only; you will find similar developments in all Organisation for Economic Co-operation and Development (OECD) countries around the world as published at the OECD fact book (OECD, 2006).

One major initiative to stop this cost explosion was the release of a law for financing the clinical sector in 2002. According to this law, a hospital does not get paid for the duration a patient is being treated, but for the respective type of disease. The treatment of every illness is linked to a fixed price—documented in the Diagnosis Related Group (DRG)—the hospital is then paid by the health insurance companies. This system results in the effect that a hospital can only earn good money by improving the business processes in the treatment of the patient, without loosing quality. Since this time on, a big competition between hospitals and different clinical departments to enhance there business process productivity has taken place. Best practices achieving business processes improvements are defined as clinical pathways.

As a parallel to other new deregulation decisions invented by the government, new types of market players like, for example, the Rhön Clinical enterprise emerged. They act as business redeveloper, buying unproductive hospitals and now, by standardizing and optimizing their processes in relation to given DRGs to transfer them to profitable businesses.

This development has only just begun, but the trust in the potential of the business process optimizer is still unbowed, if you take a look to the 3 year curves of their stocks (see Figure 2).

Further potentials in optimizing business processes in the clinical sector are dependent on several issues like:

Figure 2. Chart of the Rhön clinical enterprise

- Deployment of best practices
- Availability of new technologies that enable high qualified staff to perform the processes in a new way
- Permanent will to benchmark and improve existing business processes

If you look on the infrastructural dimensions of business processes in hospitals today, you can still find a lot of weaknesses linked to the traditional clinical organization, like:

- A very low degree of computerization for support and administrational processes, deeply based in history where traditional administration leaders of the hospitals were not very powerful in comparison to their medical colleagues
- A very poor degree of existing IS integration between different hospital departments, which still causes a lot of medical problems and costs
- A very traditional hierarchical organization with powerful medicinal stuff, but seldom trained in economy
- A very restrictive type of regulation based on the influence of different interest groups and their negotiations in the past

On the other hand, good medical work needs a lot of different information just in time and close to the location, where the patient gets their treatment. From this point of view, one major success factor in business process improvement in the future will be based on technologies that are supposed to be able to transport a big variety of information from different data sources to the medical employee while they are treating their patients, analyzing their physical conditions, or support them with meals and medicine. This is a major reason why the elaborated use of mobile applications in hospitals will be essential for their future success in business

The focus of this paper will be showing you the economic potential of mobile applications, especially their capacity in leveraging the performance of supporting processes like meal and drug supply and how to measure these benefits.

BACKGROUND: THE ECONOMIC POTENTIAL OF MOBILE APPLICATIONS IN A CLINICAL ENVIRONMENT (RELATED WORK)

As mentioned before, it is perhaps, supposed to be a question of organizational survival if the hospitals in European countries are able to decrease there costs far to a level of where they are today. We also argue that only the invention of new, innovatively designed business processes will lead to this target.

But to what degree will and can mobile applications be part of value-added business processes? And how can we measure this value?

If we look at the related literature, we will find two different kinds of studies.

Studies that Deliver Theoretical Basics and Frameworks to the Topic of Value Generation of Mobile Applications

A good example for this kind of research was published by Nah, Siau, and Sheng (2005). Following their definition, value can be defined as: "the principles for evaluating the consequences of action, inaction, or decision" (p.85). The output of their study was a procedure modeled in Figure 3, which was meant to help creating a means-ends objective network including a distinction between basic and fundamental objects as shown in Figure 4.

The methodological way to gain these networks was based on interviews between researcher and employee in the field. A major result can be seen in Figure 4. The strength of this kind of research surely is the identification of relevant factors, which reveals the possibility of enhancing productivity of mobile applications for the whole enterprise.

On the other hand, their weakness can be seen in the fact that efficiency of an application system can only be measured in relationship to a supported business process, its core activities, and the output produced. A second weakness of their approach was more methodologically. The productivity model of the resulting means-ends objective network of the application system might be based on subjective cognitions, given by the interviewee during the interview situation, instead of time and cost savings measured in a real-world user scenario. A measurement of saved costs between the initial business processes and the redesigned one is not addressed.

Studies Focused on the Business-Oriented Design of Mobile Applications

This approach focuses on the question, what are the basic requirements or architectural patterns that drives the value of a mobile application system in relationship to supported business processes. In addition we can divide this related work in studies that start from an existing business process that

Figure 3. Procedures of value-focused thinking

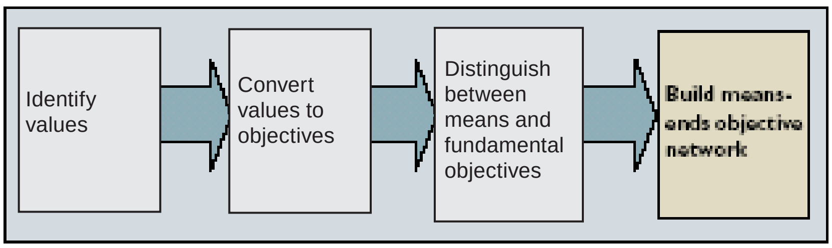


Figure 4. The means-ends objective network

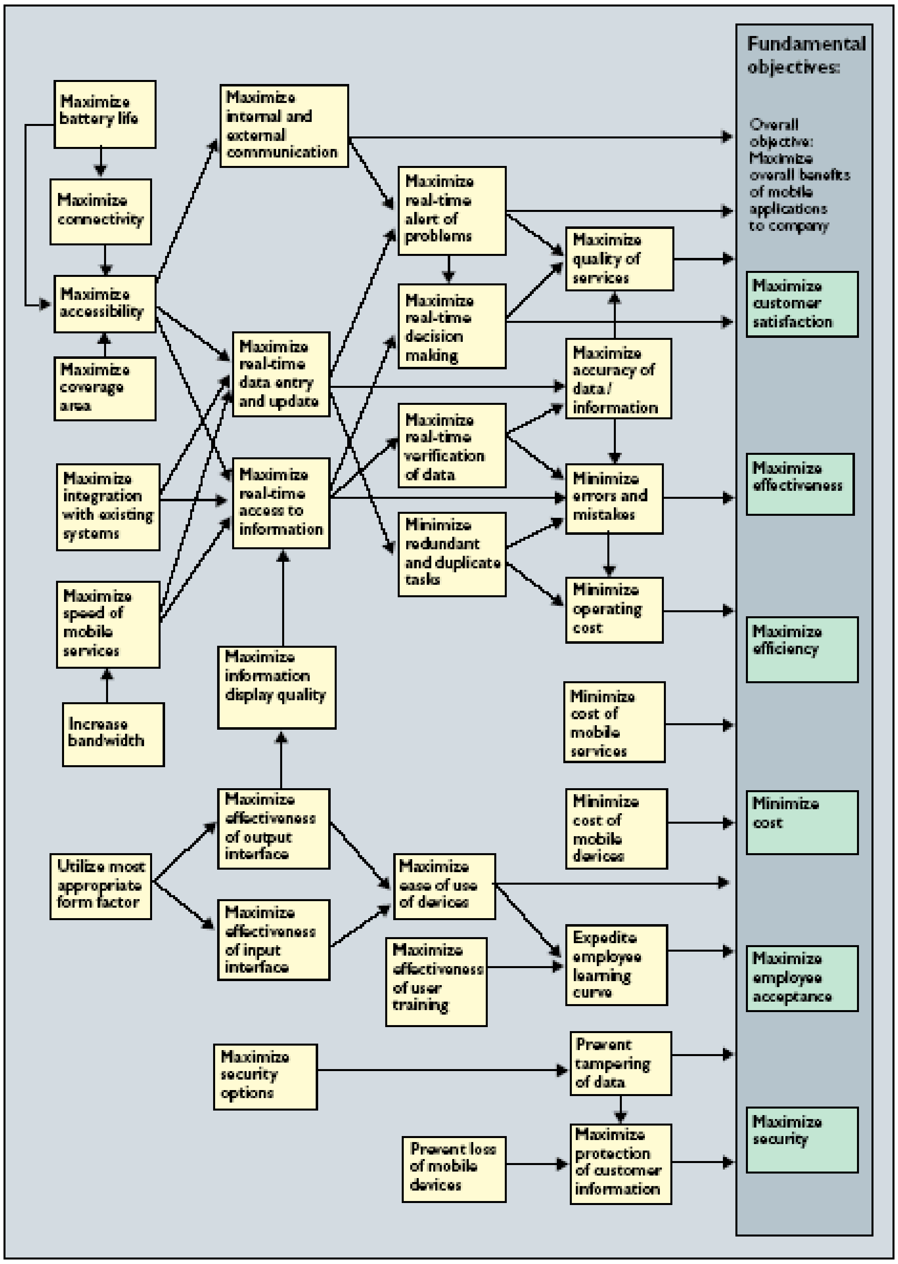

Figure 5. Delivered services by a mobile application (Shiffman 1999)

Delivered Service	Service Description
Recommendation	the determination of appropriate guideline-specified activities that should occur under specific clinical circumstances
Documentation	the collection, recording, and storage of observations, assessments, and interventions related to clinical care
Explanation	the provision of background information on decision variables and guideline-specified actions (e.g., definitions, measures of quality or cost) and the rationale that supports guideline recommendations, including evidence and literature citations
Presentation	the creation of useful output from internal data stores
Registration	the recording and storage of administrative and demographic data to uniquely identify the patient, provider(s) and encounter
Communication	the transmission and receipt of electronic messages between the clinician and other information providers
Calculation	the manipulation of numeric and/or temporal data to derive required information
Aggregation	the derivation of population–based information from individual patient data

has to be improved, and into studies that derive mobile application systems from target processes. There are various studies in the computer supported cooperative work (CSCW) area, which try to enhance the performance of existing business processes by supporting them with fitting mobile system architectures.

A typical research work in this area was published by Shiffman et al. (1999). He shows the benefits of different services (see Figure 5) delivered by a mobile application to a screening workflow for asthma deceases in child care. They described what kind of information management services should be delivered by a pen-based mobile application system to support decision-making workflows in a hospital. Although they get very deep into the interrelationships between system functionalities and the quality of business process support, they did not measure the resulting influence of the system in cost, time, and quality.

Another study from a more transaction network design perspective was published by Morton and Bukhres (1997). It focuses on the improvement of existing transactions in an ambulance scenario. Morton and Bukhres developed a network architecture that enables a hospital to use mobile applications successfully in the ambulatory service. A major challenge in this scenario is the fact, that a mobile host, for example, in an ambulance car could not be online all the time. So they developed an architectural solution, based on a so called base station agent (BSA) that is responsible for the monitoring of transaction of the mobile host during its execution. This architectural innovation developed from existing business processes by interviewing experts and measuring transaction time, which enables the ambulance to use mobile applications for accelerating their transaction times—a very successes critical benchmark in the area of lifesaving.

Different to Shiffman (1999), and Morton and Bukhres (1997), Wang, Van de Kar, and Meijer (2005) published a study that focuses on a mobile application system design, derived from a future target process. Their design methods are based on the collaborative business engineering (CBE) method from Hengst and De Vreede (2004), and tested for the design of a mobile online information system based on a PDA that supports the conductor on the railway delivering actual information and services to railway customers on the train. The output of their kind of research was a very good system design, derived from the requirements of the new, targeted business processes. Although their research design delivers the opportunity to do a business process benchmark between the performance of the current and the target process, an economically motivated measurement of the improvements was not operated in that research study either.

Conclusion: The Integrated Approach

Recurring to related researches as mentioned before, we were looking for a third way that started from an approach as published by Wang et al. (2005) for the necessary system design but also was combined it with a classical activity-based costing analysis. The aim of our approach was to gain data, which enabled us to measure the efficiency of the new designed and mobile application supported business processes. We found a suitable method named mobile process landscaping (MPL) developed by Köhler and Gruhn (2004) that supported our research in the mentioned way. MPL includes eight steps shown in Figure 6.

However, based on our long-years experience in the area of business process modeling at the Research Centre for Information Technologies (FZI) and a conclusion drawn in the unpublished doctoral thesis of Högler[1] (2006) we improved the MLP method and adapted it to the mobile business process development and profit analysis of a hospital nursing 300,000 patients a year.

We executed the analysis in the five major steps described in Figure 7:

Figure 6. Major steps of mobile process landscaping (MPL)

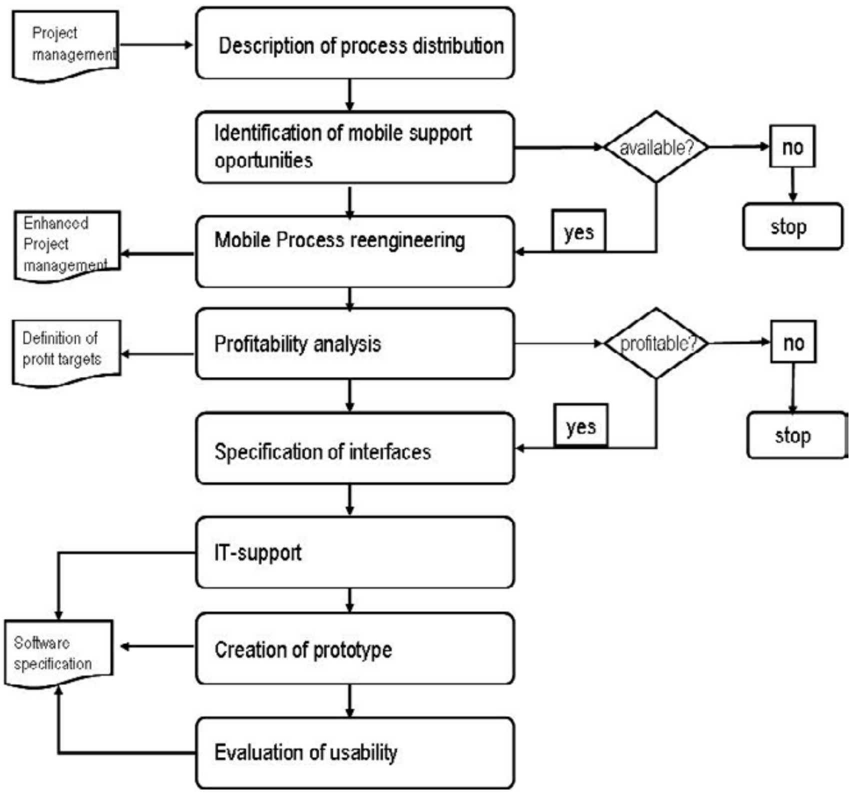

Figure 7. FZI mobile process reengineering approach

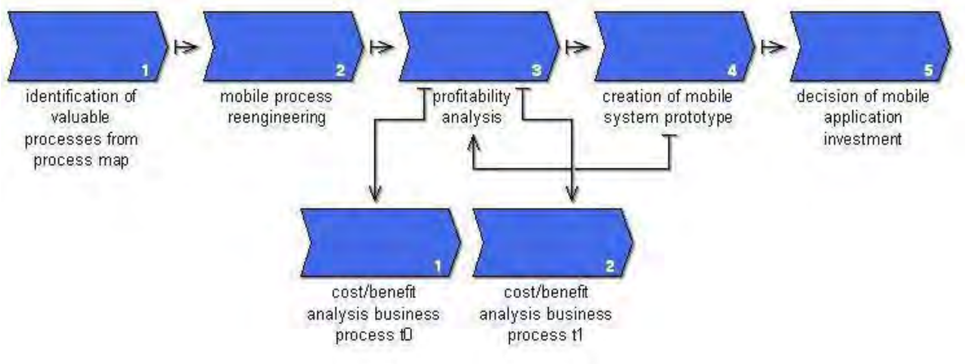

Step 1: Identification of highly valuable business processes in the business process map of the hospital (see Figure 8).

Highly valuable processes should have a significant cost-saving potential as well as a high degree of distributed activities, so that mobile application support may deliver a remarkable benefit. In our case these processes were easily to be identified, as they were delivered from external service providers, too. Benchmarks for meal and medical supply process performance were far ahead from the performance delivered in the observed hospital.

After quick-win business processes in the area of medical and meal supply had been identified as valuable, and the strategic decision made by the management to still internally deliver these services in the future, a second step in research had to be done—the analysis of the mobile potential of the identified supporting processes as well as the reengineering potential on an activity level (see Figure 7).

Step 2: Identification support opportunities on an activity level and the reengineering potential

The analysis of mobile potentials can be operated in two ways:

a. The first one will be *the identification of activities in an existing process, which could possibly be supported by mobile applications (improvement approach).* Typical indicators for supportable activities are:
   - the necessity of having access to actual information at a point work that is not yet connected to a network (information quality and delivery function), and
   - the necessity to improve existing data input procedures by delivering high qualitative information back to an integrated hospital information system electronically instead of manually (service quality function).

b. The second one will be *to reach predefined outputs of a needed service with totally new, less cost-intensive mobile business processes (reengineering approach).*

Especially the design of totally new business processes supported by mobile technologies in regard to their later implementation efforts, costs, and maintenance quality is a central research task the FZI has been working on for years now.

The application of steps 3 to 5 of the FZI Mobile Business Process Reengineering Approach

Coding	Coding and sequential analysis

(MBPRA), shown in Figure 7, will be described in the case study in chapter 3. It includes the operation of a profitability analysis, and the design of a mobile system prototype fitting into the reengineered business processes. Once the prototype will be able to reach serious savings of activity-based costs, the investment decision for the implementation of the whole system has to be made.

A major focus in our case study will be regarding the question of data quality, which is necessary for modeling and simulating business processes in a way that allows the delivery of detailed information about their cost structure and process performance.

CASE STUDY: MOBILE TERMINALS FOR DRUG AND MEAL SUPPLY

This study was carried out from January until June 2004 at FZI by order of Karlsruhe City Hospital, the largest hospital under public law in the vicinity of Karlsruhe with more than 1,500 beds and 14 clinical departments, handling approximately 300,000 patients per year. The departments are allocated campus-like to numerous buildings. In this study the hospital's processes of drug supply in the pharmacy of the hospital as well as meal supply in the kitchen were examined. Key stakeholders were nurses, physicians, pharmacists, assistant medical technicians (MTAs), assistant pharmaceutical technicians (PTAs), cooks, cooking assistants, diabetes consultants, haulage service, and the controlling and executive committee.

Used Methodology

As every model of reality is as good as its input, our profitability analysis of mobile business processes was highly dependent on the data quality. As long as time for delivery or processing of activities was supposed to be measured or informal stocks at the wards to be detected, it does make sense to use a mixture of traditional ethnographic and focused ethnographic approach (see Figure 10) as claimed by Knoblauch (2005). In our role as researchers we were involved as participants in the working process, which is not the case in focused ethnography, where the researcher normally acts as an observer. But all the other techniques we used were based on the ethnographic approach of Knoblauch.

The challenge was to gather high qualitative data and transfer it to linear cost models, like Lazarsfeld, Jahoda, and Zeisel (1933) practiced it in their early studies. We used the following data gathering methods:

- **Participating observation:** we worked together with nurses and a druggist as well as kitchen and health care staff for 8 days and night shifts to get a deep understanding of the business processes including the used resources and materials.

- **Inventories:** Inventories of the formal and informal medical stocks at the drug store and the wards
- **Inside interviews:** 34 non-closed expert interviews with different process owners in the hospital (nurses, pharmacist, IT operators, IT management, IS consultants, cooks, diet cooks, garbage man)
- **Outside interviews:** 4 non-closed expert interviews with experts from other hospitals that had just invented mobile systems in the same processes to validate their own gathered data.

Initial Situation/Preface

Previous to this study the hospital was faced with the choice of an investment and integration of mobile devices on wards and pharmacy. These processes were chosen from the process map, because they promised a high potential for optimization. In 2003 the project team "Mobile Computing" was founded by the head of the pharmacy, the chief information officer, and the chief executive officer. In a pilot project they started to develop and test a mobile system in the pharmacy and on two selected stations (oncology and nephrology, each with more than 20 beds) in cooperation with a software company. The aim of the Mobile Computing project was improving the drug supply by reducing administrative activities just as avoiding sources of error by the dint of mobile terminals and their integration into the supply workflow. At the time the study was performed, the Mobile Computing project was in the productive test phase. In case of a positive result, it was planned to roll-out the system on all stations. The study's objective therefore was to provide a basis of decision making about the roll-out by dint of an economic analysis.

In order to examine the portability of the mobile system the study was made up of two scenarios. The first scenario dealt with the processes of drug supply, where, within the scope of the Mobile Computing project, the possibility of comparing past and new situations in a real environment was given. In the scenario two processes of the meal supply were chosen to demonstrate the ability of the mobile system being extendable. In contrast to the scenario, one of the analyses was limited to the investigation of a business process without any mobile devices due to the fact that there was no test implementation of a mobile system for the meal supply. The analysis of the future processes (with mobile devices) had to be designed with experiences gained from interviews of other hospitals using mobile devices for meal supply already.

By implementing the mobile system, traditional paper-based processes were supposed to be adopted and optimized where exchanging information should be converted from paper-based to electronic-based processes as far as possible. Improvements in workflow by automating administrative jobs (e.g., validity check, sorting of forms, calculating order quantity, etc.) and minimizing sources of error were expected.

In scope of the drug supply the orders were previously taken at the station's PC or at the pharmaceutical rack using PDAs and sent to the enterprise resource planning (ERP) system and the pharmacy's IS via docking station. In the pharmacy, the orders could be processed directly on the PDA by a wireless LAN (WLAN) without the necessity of using paper-based media.

At the meals supply process the paper-based order form was displaced by the digital entry via mobile devices. If necessary, the chosen data could be linked to the patient's incompatibilities or objections. The software was to check up on all data on their plausibility automatically and to send alerts in the case of incomplete or false orders. In the kitchen, all steps for receiving and handling meal orders were automated. Based on the demand of ingredients, the kitchen's staff sent all orders to the supplier. Additionally, the patient nameplates were printed and cut to mark the meal tablets.

Objectives

Of highest interest in this study was the economic potential that could be gained by implementing mobile terminals in a hospital whereat the profitability of the mobile system for the chosen processes for the supply of drugs and meals described previously had to be measured. For this reason processes of the past and future situation were to be documented and compared in order to ascertain possible profit and loss.

Another target was the development of a methodology for the evaluation of economic potentials achieved by the integration of mobile devices into clinical and economical pathways as well as for its testing. For this purpose the general conditions for the use of mobile devices in hospitals had to be considered and the applicability of different kinds of mobile devices to be detected. Another question to be answered was where and how mobile terminals could be integrated in existing business processes. The analysis of advantages and risks that could occur during the roll-out of the mobile system was targeted as well.

Central questions that had to be addressed in the study were:

- How could costs and efficiency of supply processes be measured (with and without the support of mobile devices)?
- What advantages and risks could be expected during the roll-out of mobile systems?
- What profit and loss could result from implementing the mobile system?

Scenario 1: Drug Supply

In the hospital all medicaments like drugs, infusions, and so forth were delivered by the hospital's own in-house pharmacy. The pharmacy is in charge of ordering, producing (in special cases), storing, and delivering drugs to the hospital stations. Pharmacist, MTA, PTA, and warehouseman have to work together closely. The pharmacist is responsible for quality control and consulting services in case of questions about drugs (e.g., compatibility, unlicensed drugs, etc.) for the hospital's physicians and nurses. Furthermore he/she has to determine the demand for drugs and in special cases produce special pharmaceuticals and infusion bags. Usually, wards order drugs every day.

Former Situation in Drug Supply

The processes of the former situation in the hospital's drug supply are presented in Figure 11. After the prescription had been inserted into the patient record by the responsible doctor, nurses ordered lacking medicaments by an order form. Before that, they had to walk along the medicine shelves on their wards and write down name and amount of the needed medicaments on a notepad. Afterwards they went over their notes and transferred them on the order forms mentioned previously. Due to the numerous classifications of medications (usual medication, infusion, dispensing, cytostatica, anesthetic, etc.) there were eight different types of forms available. The order form had to be signed by the responsible doctor and transported to the pharmacy finally by being thrown in the pharmacy's letter box, faxed, or in urgent cases by using pneumatic post.

In the pharmacy, the pharmacist first sorted the incoming order forms according to their type of form and to their posting station and checked the details on the order forms. Detected discrepancies had to be straightened out by telephone. In case of missing compulsory data (e.g., signature of the doctor) order forms were to be sent back to the station. In case of valid details drugs were collected and put in boxes together. Before delivery the drugs were registered in the ERP system of the pharmacy by scanning the barcode. The so called "Hol- und Bringdienst" ("catch and delivery service") performed the delivery to the stations. Additionally, nurses are able to fetch ordered drugs at the pharmacy counter.

Information was transmitted by paper-based information media like order forms and notepads as well as by fax, letter box, pneumatic post, telephone, and the staff itself (nurses, pharmacist).

Weak points in the former situation could be identified in several processes. Inefficient activities were the sorting of the order forms, queries by telephone because of non-explicit or uncompleted details, the recording of the anesthetic, output, and sale to hospital staff member as well as orderings from drug maker and wholesaler.

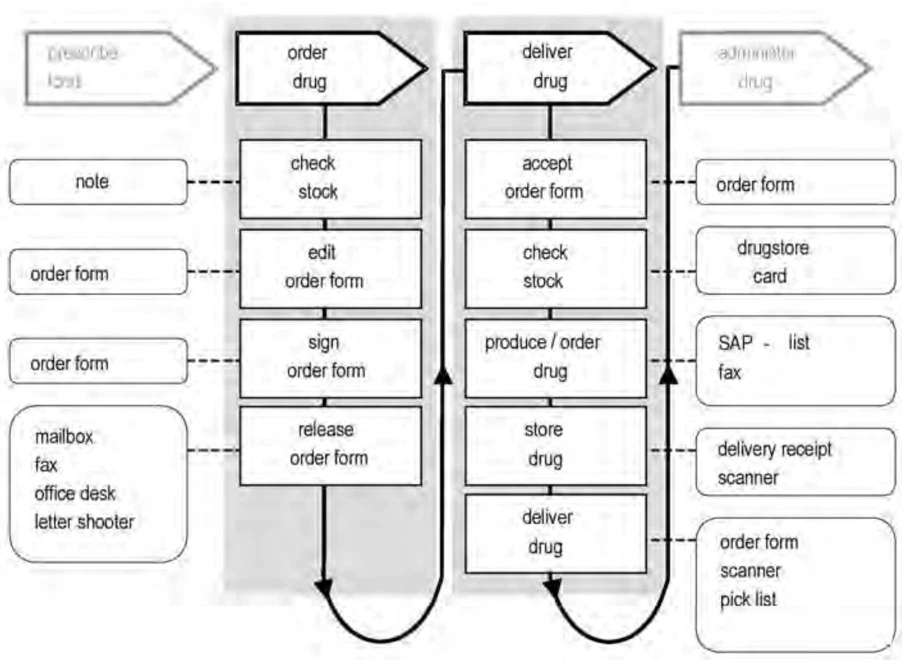
Using pneumatic post (ca. 40-60 times per day) required several time-consuming activities such as loading and unloading the sleeves. Furthermore the pneumatic post system often revealed little reliability and additionally caused high costs for maintenance (see Figure 12 and 13).

The material costs contain those for paper and printing, order forms, occupancy costs for archival storage of order forms, and of thrown away drugs because of the drugs were out of date/expired. The term factor represents the frequency of the respective activities per day. Costs can be calculated by multiplying labor costs by factor.

Present Scenario with Mobile Devices in the Drug Supply

In the present scenario processes of ordering drugs (see Figure 14 and 15) are supported by PDA (personal digital assistant) and by a Web-based order entry system. Nurses now walk along the drugs shelves on their station and fill out the order form directly on a PDA without any use of notepads. With the barcode scanner extension nurses just need to scan the barcode of the drug's package and choose the amount by pull-down menu. In order to save time, the barcodes labels itself are stuck on the shelves' front side, so that there is no more need of taking the drug packages out. Via docking station at the station's computer the order forms are directly transmitted to the ERP

Figure 11. Processes of the drug supply in the hospital (former situation)



system of the pharmacy. A Web front end enables nurses to check, correct, and activate the order. The responsible doctor merely has to check the Web-based order form and sign with his/her personal password to ratify its validity.

The team of the pharmacy now gains access to the order form in an electronic way. By computer and PDA they can view and work on all order forms on the display. Due to the pharmacy's WLAN connectivity the staff has ubiquitous access without any need to sort the order forms. The staff can walk along the shelves of the pharmacy and collect all ordered drugs. By scanning the barcode on the drug package the delivery items are automatically registered.

Review of the Process Improvements in the Drug Supply

The mobile system offered numerous forms of relief and advantages. It is possible to remedy the deficiencies of the former situation without IT support and to avoid disadvantages of stationary computer systems. Communication costs (telephone conversations) between pharmacy and station could be limited by eliminating unreadable handwriting and incomplete details. In the pharmacy numerous activities could be automated or usefully supported.

Because of several circumstances the field of application was limited in some issues. For example, ordering and delivering anesthetic had to be excluded from the mobile system, as dealing with anesthetic had to use paper-based documentation by statute. Another area where the mobile system was discussed to be applied was the pharmacy's stock control. But as the use of drugs could not be registered exactly (e.g., returned drug packages, which were partially used and no more needed), improvement of stock control by the mobile system was not possible either, nor was it to be expected that the amount of drugs that had to be disposed for exceed of expiration date could obviously be reduced.

Scenario 2: Meal Supply

In the hospital there exists one kitchen that supplies personnel, patients, and their dependants with meals. Patients get meals three times per day. One day before each meal, for example, lunch, nurses on the stations ask patients about their wishes for lunch the next day and transmit the orders to the kitchen. Thus, the kitchen's staff is able to plan and organize every meal up to 24 hours before.

Former Situation in the Meal Supply

Without the implementation of a mobile system, the supply of meals is a slow process (see Figure 16), afflicted with different kinds of errors. Orders are taken on the basis of menus and forwarded to the kitchen via meal vouchers. In the past these vouchers had been sorted, checked superficially, and afterwards were read in with a special PC-linked scanner. The associated software counted the orders per station and furthermore checked the vouchers' plausibility. Having gathered all orders the production schedule for the next day was printed and handed out to the cooks.

Future Scenario with Mobile Devices in the Meal Supply

On the basis of a new mobile system, the traditional paper-based processes can be adopted and improved (see Figure 17). The orders will be taken at the station's PC or directly at the patient via PDA. The name of the patient is chosen out of a patient administration system, linked to the chosen meal and via PC or docking station sent to the ERP system and the kitchen. If necessary, the chosen data can be linked to the patient's incompatibilities or objections. The software will check all data on their plausibility automatically and send alerts in case of incomplete or false orders. Additionally, it will check the patient's administration software in order to verify which

patients have left the hospital or have changed the station.

Review of the Process Improvements in the Meal Supply

These meal vouchers as well as false orders and insufficient deliveries emerge as the most important cost drivers within the old system. For example, it takes up a great deal of time to complete the meal vouchers, to arrange and to correct them as well as to import the vouchers into the system; errors emerging are redundant or needless orders that can not be cancelled. Further cost drivers are coordinative telephone calls between kitchen and hospital stations that have to be ascribed to the relocation or early release of patients, for example. 80-100 telephone calls per day are necessary due to short-term changes of orders.

These cost drivers add up to approximately 720,000 € each year for ordering activities between the kitchen and all stations of the hospital. This sum includes material costs like order vouchers and wasted meals due to mistakes as well as personnel costs for placing and taking the daily order.

With the help of the mobile system described previously, many of the former cost drivers in meal supply could be eliminated. Having implemented the mobile system, further costs for materials will only arise from the production of tablet cards and non-preventable false deliveries of meals. Non-preventable situations are, for example, when it is not foreseeable after which meal a patient will be released the next day or whether a meal can be taken after a surgery.

In Figure 18 and Figure 19 the costs accruing in the kitchen due to the old IS are listed.

The costs for materials compound of actualizing the software and the contract for maintenance of costs for paper and those for spare meals which can be ascribed either to preventable or non-preventable wrong orders.

Aside from retrenching working expenses, the mobile system also provides an obvious surplus in quality. In contrast to the former system, the patients' incompatibilities like, for example, allergies or possible objections can now be considered with much less effort. Figure 20 shows the personnel costs of the meal supply supported by the mobile system.

Figure 15. Cost of personnel for drug supply (present situation)

Synchonize PDA	1	5	2,56 €
Total costs of drug delivery (pharmacy)			23,94 €

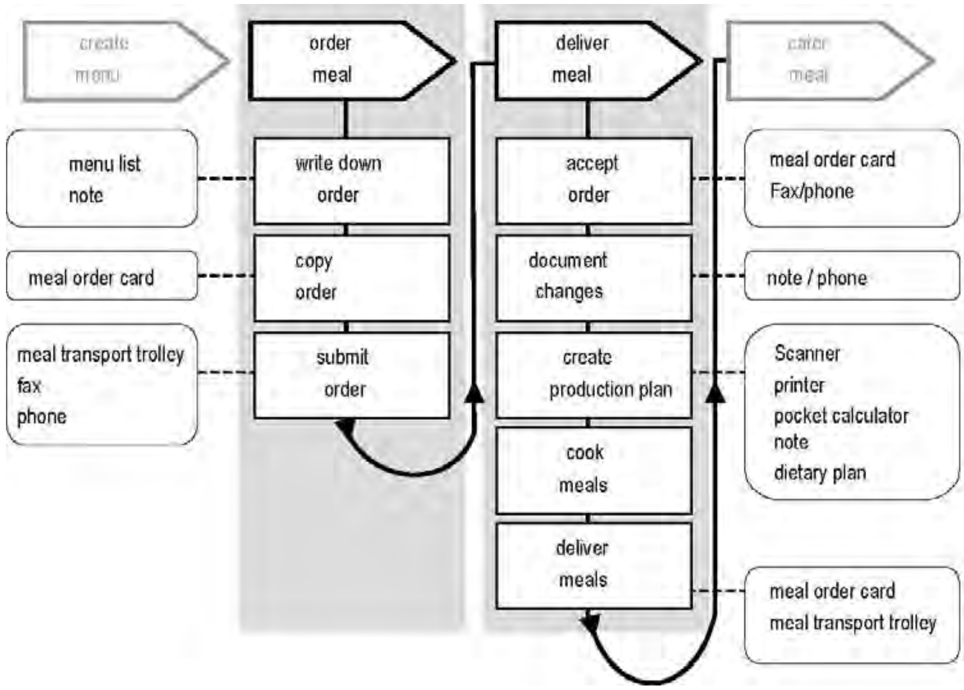
Economic Results

Process improvements were performed iteratively in several steps. During the process improvement, ideas and visions of staff members were considered and the experience gained in cooperative hospitals as well as in Mobile Computing projects in other lines of business were taken into account. Approved methodologies and rules for process improvement by Greiling and Hofstetter (2002, p. 96 et sqq.) were included. The profitability was calculated by the *net present value* (NPV) method (see Figure 21), where n means the time horizon of the project and t numeralizes the years. The term *discount rate* refers to a percentage used to calculate the NPV and reflects the time value of money at an actual average between 3% and 6%.

By dint of the methodology current and target processes of the traditional and the mobile system were modeled and documented, their costs and use in terms of activity-based costing were determined and compared within the scope of a profitability analysis.

The costs for the optimized drug and meal supply are scheduled in Figure 22. Just as in the drug supply, the one-of expenses for the mobile

Figure 16. Processes of the meal supply in the hospital (former situation)



system comprise of costs for investment and the non-recurring operating expenses. There is also a strong emphasis on staff's training activities to guarantee a maximum acceptance by the staff and a smooth IS implementation.

The investment into the mobile system and the scanner alternative gets profitable at least within one year (see Figure 23 and Figure 24), based on the assumption that operation expenses are lowered strongly and risks narrowed down. The discount rate is chosen on 10% by an initial investment of 200,000 €. In contrast the payback period is reached within 3 years time, if the implementation of the mobile system is not followed by an appropriate reengineering of the relevant processes. These facts can be ascribed to the integration of autonomous subsystems by mobile devices as well as to the removal of errors. Besides, parallel processes result in the decrease of labor time. Additionally, the mobile devices enable the controlling department to gather more and reliable data for the measurement of costs.

CONCLUSION

In comparison to the big amount of money, the European telecommunication industry has invested in Universal Mobile Telecommunications System (UMTS) and third generation (3G) mobile infrastructure; there still is a very slow adoption of mobile application in different domains, which might result from a lot of different reasons. Two major reasons surely apply: (1) lack of methods to demonstrate and measure the value creation potential of mobile business applications, and (2) the lack of potentially best practices and use cases in different domains.

If we go back to methodologies for measuring the value of mobile-supported business processes, we might be able to demonstrate that it is possible to show the benefits by business process modeling, design, and simulation methods, followed by an activity-based costing and traditional investment appraisal.

Figure 17. Processes of the meal supply with the mobile system (future situation)

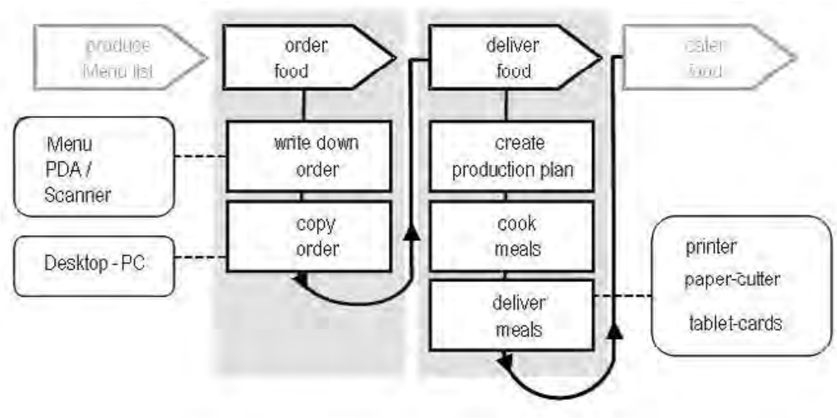


Figure 18. Material costs for meal supply (traditional scenario)

Invest (indispensable)	amount	unit price	Total costs
Software update (license paper based system)	1	3.100 €	3.100 €
Software update (installation)	1	5.200 €	5.200 €
Software update (training costs)	1	1700 €	1700 €
Additional operation costs (per year)	amount	unit price	Total costs
Software material costs	1.336.746,00	0,018 €	23.968 €
Software maintenance contract costs	1	911 €	911 €
Waste of meals	29.975	4 €	120.000 €

However, to do this in a proper way, there was a lot of effort necessary, for example, ethnographic studies and field work for the time of about 2 weeks, participating in the drug and meal supply processes, and recording and analyzing data.

On the other hand the quality of the resulting process model with time and cost data is strongly dependent on the quality of input. But if we look at the investment done in total and the potential savings, the time for research was worth its money.

The process-oriented research approach derived from the MPL method was able to deliver useful results. It was a further enrichment in comparison to research methods that focus on mobile system design (Wang et al., 2005) only, or on abstract means-ends objective networks that describe general value dimensions of mobile applications (Nah et al., 2004).

The business processes that had been chosen from the process map of the hospital turned out to be very fertile for optimization with mobile applications. An ROI of an investment of 200,000 € in mobile systems could be paid back in a time frame of 1 (progressive calculation) or maximum 3 years (conservative calculation).

Hospitals stand to benefit in different ways from implementing a mobile system: There is a high ROI and efficiency gain caused by the use of

mobile terminals. The restructuring of processes can reduce running time and thus the workload of health care and administrative personnel. By minimizing the number of errors that do occur during the recording and editing of orders, expenses for the drug and meal supply processes can be reduced, too. Information processing can be automated by the use of mobile electronic systems, thus the waste of material, labor time, and storage space for files (actually an important expense factor) can be significantly decreased.

Another remarkable improvement caused by the new mobile system is the extraction of very detailed information that can be used by the controlling department for the measurement of process performance, process costs, and occurring errors. Furthermore, by setting data in relation to patients, applications can be developed to

Figure 21. Formula of the net present value according to Grob (1999)

$$NPV = \left(\sum_{t=1}^{n} \frac{\textit{Cash Flow}_t}{(1 + \textit{Discount Rate})^t}\right) - \textit{Initial Investment}$$

share patient-oriented information including high traceability and a high transparency in supply processes. For example in drug supply a mobile system can provide new possibilities for enhancing the medication: The hospital's pharmacy now plans to enhance the existing mobile system to a unit dose system, in which every patient gets their individual medication, beginning at the bed-side prescription by PDAs to the patient-related packaging and ending at the patient-related billing.

Nevertheless, economic potentials can be reduced significantly by the wrong choice of mobile terminals. This fact was revealed by the analysis of the barcode scanner alternative. Though the same processes are supported, the scanner alternative proved to be a less appropriate solution. Although barcode scanner costs half the price of PDAs, they cannot verify the input quality of data, nor display inconsistency checks or warnings. Furthermore, they are not able to alert staff members in case of patients' incompatibilities against drugs or meals. All input can only be checked at the wards' PC. This means, that in case of occurring problems, data has to be recollected again. Comparing the drug supply process scenario operated by the PDA or scanner supported alternative, it becomes clear that barcode scanners lead to additional expenses and to an increasing personnel workload.

In the context of the drug order and supply processes it has not become clear yet if the implementation of intelligent mobile devices can result in measurable advantages in comparison to the implementation of a scanner-supported scenario. This phenomenon is based in the short spatial distance between the ward PCs and the drug cupboards.

But it would make no sense to operate these processes without the PDA system, as it has no measurable negative effects and all different processes can be supported by one system. This

lowers the break in barriers for the staff members, who have to be trained only in one system with only one kind of mobile device.

If we go further in the business process map of the hospital, we surely will find other business processes that could be supported by the available mobile system, like, for example, the coordination process for the hospitals laundry.

Once the system's use is established among staff members, the next step might be to support medical business processes, too, if it ends up in a higher efficiency. But before doing that, business process performance analysis will be essential. Nowadays there already exists mobile applications for medical business processes, like decision support systems, e-learning, and telemedical communication systems. One of the prominent mobile systems in Germany is the Stroke Angel system (Holtmann, Rashid, Weinhardt, Gräfe, & Griewing, 2006) in which paramedics use PDAs in emergency ambulance vehicles in case of a stroke to send information about their patient to the targeted hospital. Medicals in this hospital can begin their analysis and make preliminary preparations.. Furthermore, paramedics fill out checklists by PDAs that enable hospitals to make a

more precise analysis and collect data for improving the emergency management. Up to present there exists no business process performance analysis, neither of the rescue service nor of the emergency units, in hospitals.

A lot of German hospitals are still not able to tell you how much a treatment belonging to a given and predefined DRG costs. Modeling the existent business processes and enriching them with process costs and time data will be a major first step of improvement—the utilization of mobile applications for performance leverage the second.

Otherwise a hospital might go bankrupt by delivering services in a high quality but to very uncompetitive costs. For example, if a hospital is very famous for its kidney surgery and is planning to enhance it without knowing the cost/benefit structure it is possible to cause serious trouble if the profit contribution is negative, as happened to a competitor of the clinic we had research on.

However, to introduce mobile business process modeling, simulation, and redesign together with activity-based costing will be a major contribution of European hospitals to reduce the costs of their health care systems. Supporting or redesigning distributed clinical processes with mobile applications will be substantial items. This should be an inspiring signal for the telecommunication companies in OECD countries to become an informed partner for the health care sector with fitting mobile information applications and consultancy services.

Chapter 6.12
E-Health Dot-Coms' Critical Success Factors

Abrams A. O'Buyonge
Creighton University, USA

Leida Chen
Creighton University, USA

BACKGROUND OF THE BUSINESSES

The increasing use of the Internet by consumers gave rise to an information boom to health-care consumers. Not only could the Internet be used as a communication tool to provide information that would allow patients to make informed decisions, but it could also be used to generate revenue for investors. The dot-com boom of the late 1990s exploited this opportunity, targeting the health-care system, a $1.7 trillion market in the United States alone. Overall, the health-care system is wasteful and costly (Itagaki, Berlin, & Schatz, 2002), and as a result, health-care IT was touted as the magic pill for cutting costs. The Internet boom of the late 1990s saw the emergence of e-health: the delivery of health services and health information through the Internet and Internet-related technologies (Eysenbach, 2001). Leading the many entrepreneurs and venture capitalists who stepped in to seize a piece of the health-care industry cake were WebMD Corp., an online provider of medical information for doctors and consumers in Elmwood Park, New Jersey, and DrKoop.com, an Austin, Texas-born company that later moved to Santa Monica, California, and began doing business as Dr. Koop LifeCare Corp.

Dr. C. Everett Koop, the former U.S. surgeon general, had spent over 6 decades in the medical profession. He envisioned the Internet as an opportunity to change the health-care delivery system in order to empower individuals to take charge of their own health care (Musselwhite, 2002). With this vision and his reputation as an advocate for health-care reform, along with the help of two budding entrepreneurs, Don Hackett and John Zacarro, the trio opened a business-to-consumer Internet portal: DrKoop.com. The portal was designed to provide health information to consumers in areas such as chronic illness, food and nutrition, fitness, and medical breakthroughs. At the beginning, the Web site was an overwhelming success, receiving a million hits per month after 2 years of operation, and about 4 million unique visitors per month at its peak. The portal included a personal medical-records system that facilitated the cross-referencing of medications for interactions, as well as the storage of medical reports that could then be accessed by both patients and physicians.

DrKoop.com's public woes began in February 2000 when its auditor, PricewaterhouseCoopers, issued a "going concern qualification," an ominous warning that highlighted the precarious financial situation the Internet-based health service was in Cleary (2000). By the end of 2000, DrKoop.com was still struggling, and in the first 9 months of 2001 alone, the company's losses were nearly 3 times its revenue. According to the Securities and Exchange Commision (SEC) filings, from January 1999 until the service's liquidation in September 2001, DrKoop.com's losses stood at $193.6 million, dwarfing the $41 million revenue generated during the period. At the site's peak in July 1999, DrKoop.com's stock rose to $45.75 per share on the NASDAQ, but was worth $0.12 at the time of bankruptcy filing. In July 2002, Vitacost.com, a privately held online seller of nutritional supplements, paid a paltry $186,000 in cash for DrKoop.com's assets, which included the brand name, trademarks, domain names, the Web site, and the e-mail addresses of its registered users.

WebMD, originally called Healtheon/WebMD, was founded by Jim Clark, who also founded Silicon Graphics and Netscape. Clark's vision was to connect insurance companies, doctors, and patients over the Internet in order to lower costs and reduce paper trails. Rather than building its own products and services, Healtheon used its highly valued stock to finance acquisitions of leading companies in the industries it targeted. In 1999, it acquired WebMD.com and OnHealth, both leading health portals, giving it access to the consumer health market (Salkever, 2000). Though WebMD lost $6.5 billion on revenue of $530.2 million in the first 9 months of 2001, it still continued to expand long after DrKoop.com had dropped off the radar screen. For the fiscal year ending in December 2003, WebMD reported revenues of $964 million, an increase of 10.6% on the previous year's revenues, which totaled $871.7 million. Of the 11 health-care mergers and acquisition deals in the first 7 months of 2004, valued at $900 million, WebMD was the leading acquirer (Abrams, 2004). Two of WebMD's high-profile acquisitions in 2004 were the $160 million cash purchase of ViPS, a privately held provider in Baltimore, Maryland, of information technology to the government, Blue Cross-Blue Shield, and other health-care insurers; and the $40 million acquisition of Dakota Imaging Inc., a private company in Columbia, Maryland, that offered automated health-care claims processing technology.

As industry leaders, WebMD and DrKoop.com faced competition from both health-care information portals (such as HealthGrades.com, MDConsult, ZoeMed.com) and online pharmacies that provided consumers with one-stop shopping for medications and medical information (Walgreens.com, drugstore.com, Webvan.com). The threat from the health-care information portals, nevertheless, was minimal due to their limited brand recognition and information coverage. In the online pharmacy sector, however, Walgreens.com gained a substantial market share by combining the best of both worlds: complementing its physical stores located throughout the country by offering online customer service, convenience, and real-time access to a health library that provided comprehensive information on prescription drugs, insurance, and health issues.

Strengths	**Weaknesses**
• Large footfall • Growing financial strength • Aggressive acquisition strategy	• Large restructuring charges • Acquisition-driven strategy • Investors unsure of strategy
Opportunities	**Threats**
• Shed unprofitable alliances • Drive core strength and diversify • Excess cash to pursue acquisition • Self-directed health-plan market	• Low demand from practitioners • Increasingly innovative competitors • Power shift in the market

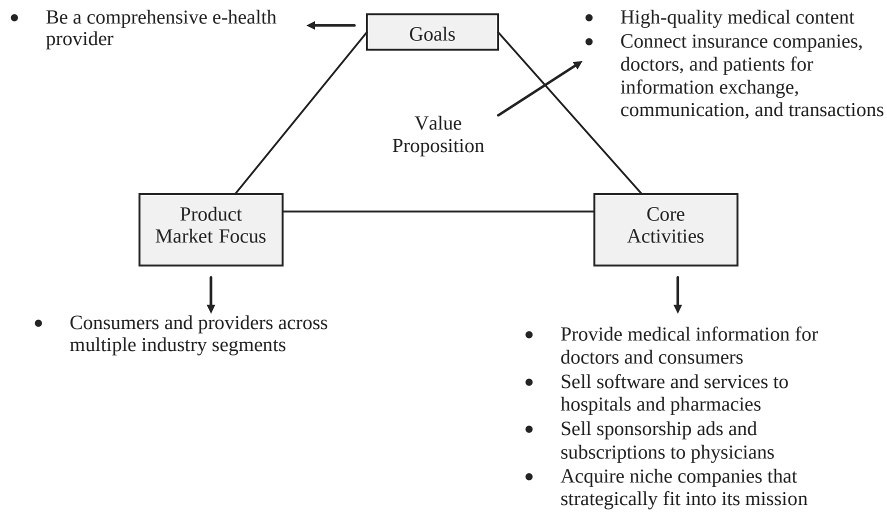
DESCRIPTION OF THE BUSINESSES

Products and Services

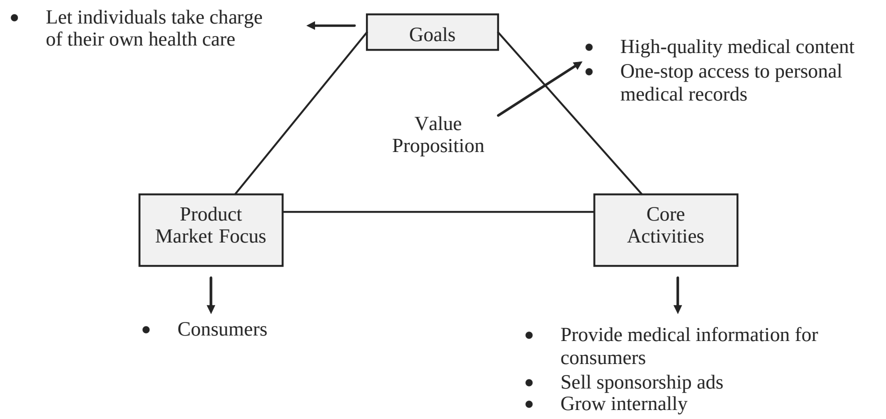
DrKoop.com's vision for its online venture was a Web-based health-care information portal on which individuals and their doctors could have one-stop access to personal medical records, prescription history, medical exam results, and general health-care information (Itagaki et al., 2002; Musselwhite, 2002). According to Musselwhite, the venture's marketing strategy was to differentiate itself as "the premier healthcare information website," and would accomplish this via the four *C*s: content (which would be the driver), community (bringing people together to discuss issues pertaining to health), cool tools (such as Drug Checker), and commerce (enabling people to purchase drugs online from strategic e-commerce partners such as Drug Emporium) (p. 6). In order to generate revenue, DrKoop.com sold advertising rights to health-care-related companies that would pitch sales and promote their products to the portal's users and communities. Unfortunately, DrKoop.com failed to implement checks and controls on advertising, and some of the companies began making promotional claims that were not always substantiated.

WebMD's products and services, on the other hand, were more diversified with the overall objective of facilitating information exchange, communication, and transactions between consumers, physicians, and health-care institutions. Through a series of mergers and acquisitions, WebMD was able to offer a wide variety of health-related

Figure 1. Value proposition frameworks for WebMD and DrKoop.com



WebMD



DrKoop.com

products and services, including health-care information to consumers and physicians, billing and transaction processing for physician practices and hospitals, and handheld services (Itagaki et al., 2002).

Management and Business Models

DrKoop.com was plagued with management problems from the start. None of the founders had business experience, but with less than $1 million of lifetime revenue, DrKoop.com still raised $84.4 million in its initial public offering (IPO). The company swelled from a handful of employees to 200 after the IPO, and an 80,000-square-foot office was acquired in a long-term lease. At a time when competition was fierce, advertising revenue alone could not support operational expenses, but the corporation continued its free-spending practices. Employees' in-house massages cost $9,000 per month, and free, catered Friday lunches cost $15,000 each week, contributing to a monthly burn rate of $7 million (Hawkins, 2001). The company signed a 3-year, $58 million agreement with Disney's Go Network to be the exclusive provider of health-care information on that network (Musselwhite, 2002). This was later followed by a 4-year agreement with AOL for a whopping $89 million to be featured on the AOL Web site, a sum that surpassed the IPO capitalization. Such evidence of capital mismanagement sent the wrong signals to investors, who began to question the viability of DrKoop.com. The business model envisioned by the company—a health-care information portal whose content would attract users, and in which advertisers would be attracted to the users—soon began to crack. By April of 2000, DrKoop.com was trailing its two major rivals in visitors per month and was spiraling into the dot-com abyss. In July, two class-action lawsuits were filed against management alleging the withholding of financial information for the purpose of inflating its stock price. The lawsuit was bolstered by other questionable actions by executives, including the selling of shares before the end of a 6-month holding period, which gave the impression of insider profiteering. Subsequently, two top executives, the chief operations officer and the chief financial officer, were forced to resign. In August, the stock fell below $1 a share and the downward trend never reversed. Public trust and investor goodwill on DrKoop.com were dealt a final blow with more reports of unethical practices. The company had received revenue from a pharmaceutical firm for referring patients for clinical trials, undisclosed commissions were received on health products and services sold through the Web site, and companies had paid money to be listed exclusively in some sections of the Web site, thus misleading customers (Noble, 1999).

Unlike DrKoop.com, WebMD adopted a comprehensive business model, targeting both consumers and providers across multiple industry segments. WebMD began a multibillion-dollar shopping binge from the start, acquiring several firms specializing in medical-related ventures such as electronic medical-claims processing, medical software, medical information, charge capture, physician practice management, and so forth. As the company's financial report shows (see Table 1), revenues from all areas were growing at a healthy pace. WebMD's revenues were expected to top $1 billion in 2004, and after several years of systematic cost cutting, operating earnings were expected to rise to at least $150 million (Tsao, 2004). The strength, weakness, opportunigy, threat (SWOT) analysis from Datamonitor (WebMD Corporation, 2004; see Table 2) indicates a favorable competitive environment for WebMD's continued growth. Using the value proposition framework (Crossan, Fry, & Killing, 2002), the goals, product market focus, core activities, and value propositions of both WebMD and DrKoop.com are compared in Figure 1. Compared to Dr.Koop.com, WebMD has more diversified product market focus and core activities. As a result, WebMD has been able to achieve more enhanced and sustainable value propositions.

LESSONS LEARNED

Apart from the irrational exuberance exhibited by investors, the success or failure of dot-coms can be attributed to other factors. Itagaki et al. (2002) identified four critical factors that predict the success or failure of e-health companies: a compelling value, an unambiguous revenue model, competitive barriers to entry, and the organizational structure for cost control. These factors can be matched to the traits described by Walters (2002): the "lots of money, but no vision" dilemma; the "business-as-a-website" approach; the burn rate; and the speed trap. The following sections discuss how these critical factors played out in the cases of WebMD and DrKoop.com, and the lessons that can be learned.

A Compelling Value or Vision: In the end, both WebMD and DrKoop.com succeeded in providing valuable, easy-to-understand, and useful health-care information to patients and physicians. However, DrKoop.com began to deviate from the original vision and mission, focusing on internal growth and fast-tracking to the IPO without adequate planning for the aftermath, a trap that befell many of the dot-coms that are now virtually extinct. WebMD developed a clear vision (to be a comprehensive e-health provider) and stuck to it, focusing on diversifying assets in order to augment its value. As of July 2004, WebMD Health provided the content for two of DrKoop.com's high-profile customers, the health channels for MSN and America Online, and had teamed up with the federal government to make consumer health information more widely available via the Department of Health and Human Services (HHS) channel on the WebMD Health portal (Henkel, 2004).

The lesson here is that instead of quickly rushing to the IPO, companies should first have a clear vision of where they want to be, a long-term strategy on how to get there, and the realization that agility is the key to survival in the fluid e-commerce marketplace. DrKoop.com lacked a long-term strategy and was forced to take poorly calculated risks. As a result, the stock price plummeted, massive layoffs soon followed, and in a desperate move to save the sinking ship, the company began engaging in questionable practices.

An Unambiguous Revenue Model and Avoiding the Business-as-Web-Site Approach: DrKoop.com built a technology infrastructure that relied heavily on an unproven revenue model and did not have alternative strategies for generating revenue. As a result, expenses soared and, with increased competition, Web-site traffic declined. WebMD, on the other hand, aggressively diversified its revenue sources via strategic mergers and acquisitions of firms in health-related industries. Consequently, WebMD began generating most of its revenue from the sale of software and services to hospitals and pharmacies (Bulkeley, 2003).

The lesson here is that companies should have a viable plan and alternative sources of revenue instead of putting all their eggs in one basket. WebMD's growth from a health-information portal to a comprehensive e-health site enabled the company to effectively deter the threat from substitute products and services. By expanding its offerings to both patients and physicians, and aggressively seeking business opportunities that are in sync with its corporate strategy, WebMD continues to thrive in the volatile e-commerce marketplace.

Competitive Barriers to Entry and Avoiding the Speed Trap: Both WebMD and DrKoop.com were able to create high-quality medical content, utilizing experts to ensure that the information was accurate. DrKoop.com went a step further by branding itself using the identity of a prominent physician. However, by aggressively pursuing a getting-to-market-first approach, DrKoop.com was lean on contingency planning and was thus not able to deal with the shocks that soon followed, such as the droughts of funding and declining customer demand fueled by competition. WebMD, however, was favored by economies of scale: Its large size and comprehensive services made it a dominant force and, in essence, was an entry barrier to competitors. By focusing on expansion, capturing new markets, and buying niche companies that strategically fit into its mission, the company was able to shield itself from competition and market downturns.

The lesson from this is that companies should be alert and ready to adapt to change, or perish. WebMD expanded its base by building relationships with its customers (physicians and general-health-information consumers), industry partners, and the government. Even though fast market penetration has competitive advantages, companies should also exercise patience, ensuring they have a solid and well-tested business model and contingency plan before they set sail into the expanse of the e-commerce market. Competitors who wait and take advantage of the new and improved technologies and business processes often surpass first movers in this dynamic technical and business environment. Marketing gurus emphasize the importance of capitalizing on the first-to-market advantage, but the history of e-commerce has taught us that competitive advantages created by IT were often unsustainable and could be easily duplicated by competitors (Porter, 2001).

Organizational Structure for Cost Control and Controlling the Burn Rate: Cost control was the nemesis of many dot-coms, including WebMD and DrKoop.com. The pay-per-click revenue model was fragile and unpredictable. Companies that did not have alternative revenue sources soon realized that their expenses could not be met. Within the first 6 months following the IPO, DrKoop.com spent $50 million while raising revenues of only $8 million. DrKoop.com's extravagance, with little consideration for earning a profit, further contributed to its demise. WebMD's struggle with cost control was complicated by the arduous task of harmonizing operations among the many business units it owns, but it had accumulated cash reserves that have enabled it to grow.

The lesson here is that management should not abuse its investors' trust by spending irresponsibly. Costs should be controlled and, in essence, aligned to revenues so that expenses do not spiral out of control. The surviving e-businesses spent funds wisely because they recognized that in the e-marketplace, the bargaining power of customers is very strong and demand is ever changing.

The dot-com boom was short lived, and following the bubble burst, many of the dot-coms never recovered. For a time, DrKoop.com seemed to defy the odds, but eventually it succumbed as well. WebMD managed to ride the tide and is now on its way to profitability. In this article, we have explored the factors that were critical to the failure and success of DrKoop.com and WebMD, respectively, and discussed some of the lessons learned. As can be gleaned from the demise of DrKoop.com and the continuing growth of WebMD, success in Internet commerce cannot be realized without a compelling value and vision, a clear-cut and effective revenue-generating strategy, cohesive and effective organization, and a cost-control system. Profit is not the goal but the requisite for any business, thus any dollars spent for creating and keeping customers should be measured and tracked against incremental revenue. Executives must watch the cash flow, income, and loss statements closely, and make changes where necessary to ensure that unnecessary expenses are curbed.

KEY TERMS

Business-to-Consumer (B2C): An e-commerce business model that facilitates transactions between a company and a consumer, as opposed to a transaction between companies (called B2B) or a transaction between consumers (C2C).

E-Business: Any financial or non-financial transaction involving an electronic process using the Internet or Internet technologies e.g. creating a map with directions on Mapquest.com.

E-Commerce (electronic commerce): The buying and selling of products and services by businesses and consumers over the Internet. E-commerce involves a direct financial transaction in the electronic process using Internet technologies. E-commerce encompasses business-to-business or B2B (Cisco), business-to-consumer or B2C (Amazon.com), and consumer-to-consumer or C2C (eBay).

E-Health: The use of emerging technologies, especially the Internet, to improve or enable health and healthcare-related services. The Journal of Medical Internet Research defines e-health as "an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies" (Eysenbach, 2001).

Handheld Services: The use of hand-held devices, such as Personal Digital Assistants (PDAs) and Pocket PCs, as an extension of workstation resources through the use of client/server based software for access and synchronization in conjunction with wireless access service provider. Handheld services are used for electronic prescribing, real-time drug references, scheduling, charge capture, etc.

Pay-per-Click: A search engine advertising strategy that allows for companies to bid for a website ranking based on the price they are willing to pay per click-through (when a visitor clicks on a Web ad as a result of keywords used when performing the search, e.g. on Google.com). The client chooses the keywords to appear on his website when a search is performed.

Portal: An electronic environment that provides a secure, single point of interaction with diverse information, business processes, and people, personalized to a user's needs and responsibilities. Examples of web portals include About.com, MSN, and Yahoo.

Chapter 6.13
Healthcare Network Centric Operations:
The Confluence of E-Health and E-Government

Dag von Lubitz

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

ABSTRACT

Healthcare has yet to realize the true potential afforded by e-health. To date, technology-based healthcare operations are conducted chaotically, at a wide variety of nonintegrated fronts, with little or no long-term strategy, and at a tremendous and ever increasing cost. This chapter proposes that in order for healthcare to ever reap the full benefits from e-health, it is imperative for the development of a doctrine of healthcare network centric operations. Otherwise, millions if not billions of dollars will be spent on a futile chase of the definitions of how and when the computer, healthcare provider, and healthcare administrator interact most efficiently and at least expense. The concept of a doctrine, "conceptual platform," that outlines the consequent, goal-oriented way forward, and integrates all constituent elements into a smoothly operating whole, is utilized to great effect in the military. Drawing upon the strategies and techniques employed by the military to develop a network centric doctrine, the chapter outlines the essential components necessary for the establishment of the doctrine for healthcare network centric operations (HNCO), and in so doing not only highlights the integral role played by information computer and communication technologies (IC^2T) but also the pivotal role of policy makers and governments. In fact, HNCO underscores the important yet rarely acknowledged confluence of e-health and e-government.

INTRODUCTION

The rules of competition are changing as a result of the growth of global markets, the increased speed of business transactions, the technological revolution, and continued change in customer expectations. The growth, integration, and sophistication of information computer and communication technologies (IC²T) are changing our society and economy. Consumers and businesses have been particularly quick to recognize the potential and realize the benefits of the Internet and Internet-facilitated computer networks. The resultant "e-revolution" changed many aspects of the traditional "way of doing business," facilitated substantial changes in internal and external management styles, enabled increased efficacy of virtually all production stages and operations, and helped to extend the customer reach. As e-commerce or the application of IC²T to business matures, more attention is being placed on maximising its potential benefits to all areas of society. Two areas where much focus is now being placed regarding the use of IC²T to improve access to information and provide better access to services include public institutions and governments and healthcare.

E-government is defined as the use of IC²T to provide citizens and organizations with more convenient access to government services and embrace interactions within governments (government-to-government), between governments and citizens (government-to-citizen), and between governments and businesses (government-to-business) (Turban, King, Lee, & Viehland, 2004). An analogous definition holds for e-health, which involves the use of IC²T to provide all participants within the healthcare domain with better access to information and services (Wickramasinghe, Geisler, & Schaffer, 2005).

IC²T are without doubt the source and the platform of one of the greatest transformations of society since the invention of print and permit-free flow, access, and exchange of information, and the development of universal means of contact among humans. In practical terms, these technologies offer the possibilities for vast improvement of efficiency and cost reduction in business, provide a platform for dissemination of high quality education, facilitate healthcare delivery, and limit the potential for conflict. Already today, the impact of the increasingly more intensive IC²T use can be measured in the way local, national, and global political, economical, or social transactions are conducted. Yet, with the growing employment of IC²T in daily operations, it is also apparent that neither the optimal pattern of use has been developed (we need look no further, for example, than the productivity paradox (Haag, Cummings, & McCubbrey, 2004; Jessup & Valacich, 2005; Laudon & Laudon, 2004; O'Brien, 2005), nor a philosophy guiding such use has been contemplated despite the emerging chaos that threatens the future growth of the field. The impeding state of chaos is exemplified by the collapse of e-businesses in the 1990s (Affuah & Tucci, 2001; Kalakota & Robinson, 1999; Stiglitz, 2003; Wickramasinghe & Sharma, 2004). The need for optimization and doctrine development is most evident in the arena of healthcare that, at the moment, is the most costly budgetary item in the world's economy (McGown, Overhag, Barnes, & McDonald, 2004; Reinhardt, Hussey, & Anderson, 2002; Stats & Facts, 2002; von Lubitz & Wickramasinghe, 2005a; Wickramasinghe & Ginzberg, 2001; Wickramasinghe & Mills, 2002).

Irrespective of the particular healthcare system adopted by a country, governments will always be one of the major influencing forces and key actors of the healthcare stage. It should therefore be a logical extrapolation that e-government and e-health should share a significant overlap. One might even go to the extreme and suggest that e-health, especially for countries which only have a public healthcare system, is in fact a subset of e-government. And yet, the two are rarely if ever discussed together. This confluence between e-health and e-government is best highlighted in the doctrine of healthcare network centric operations (HNCO). We believe that by acknowledging this confluence, more effective policies and protocols can be developed which will facilitate the adoption and diffusion of HNCO and in turn will lead to more effective and efficient healthcare delivery.

In healthcare, despite their relatively late arrival, computer-based technologies will play the major role in management of services at all levels. Yet, while the concept of "e-health" brings the promise of improved economy, increased efficiency, greater equality, and wider range and availability of services, the increasingly diverging goals and philosophies, disparity in the emerging approaches, and frequent incompatibility or limited nature of the available or developed electronic platforms mitigate against such optimistic future. Moreover, the tendency to convert precise terms describing individual components of "e-operations" (operations or activities where IC^2T have been applied to make them electronic) into often meaningless "household" terminology adds superficial linguistic grandeur to quite non-glamorous and very common-sense notions, and transforms the latter into profoundly sounding expressions of a trivialized credo. The misconceptions serve to produce chaos that, in turn, diffuses the true value of the "electronic" in the context of healthcare, reduces its impact, and, consequently, delays its most significant contribution toward elimination of spatial and temporal barriers, and energized operational facilitation.

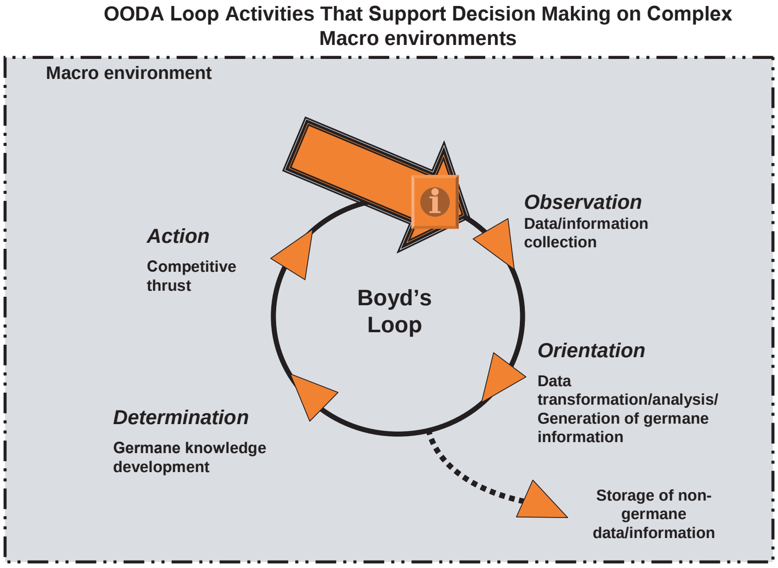
Presently, existing networks and e-health initiatives in healthcare represent distinctive and disconnected entities whose operation is, essentially, platform-centric, that is, concentrates on the operations of a single system (platform) without any regard for the operational interaction among different systems (a "system of systems" or systems network, see von Lubitz & Wickramasinghe, 2005a, b, c, 2006). The consequent fragmentation and broad incompatibility of individual efforts has, in turn, a major influence on the access range to and sharing of high quality information existing among (or even within) the existing individual systems (ibid). For these reasons, despite providing very significant advantages to the local users (Wickramasinghe & Ginzberg, 2001; Wickramasinghe & Mills; 2002), the overall impact of the electronic information systems on either national or international healthcare operations continues to be relatively limited (von Lubitz & Wickramasinghe, 2005a) and nor does it provide the promised superior quality of care (Institute of Medicine, 2001).

Healthcare operations are conducted in a complex operational space. The limitations of a platform-centric approach in such environments are compounded by the fact that the limited (or inadequate) information extraction, gathering, and manipulation capabilities of individual systems are amplified by their frequent lack of interoperability (von Lubitz & Wickramasinghe, 2005a, b, c, 2006). Such limitations severely degrade the possibility of integrating inputs of complex, highly relevant data both from a wide variety of relevant (clinical data banks, for example) as well as seemingly nonessential sources (e.g., political, economical, geographical, ethnographic data pools) and has been the justification for taking a systems approach (Checkland & Scholes, 1990; Churchman, 1968). Environmental complexity of healthcare operations is often magnified by the presence of multiple actors (agencies, governmental bodies, global organizations, etc.) performing within the same space but using a wide variety of independent and non-intercommunicating platform-centric tools. As a consequence of the resulting chaos, the attainment (mission) of healthcare goals (objectives) is uncertainty, rather than information-driven (von Lubitz & Wickramasinghe, 2005c).

HEALTHCARE NETWORK CENTRIC OPERATIONS (HNCO)

The *network-centric approach* stands in direct apposition to platform centricity (Alberts, Garstka, & Stein, 2000; Cebrowski & Garstka, 1998; von Lubitz & Wickramasinghe, 2005a, b, c, 2006). Its underlying conceptual framework is drawn

Figure 1. Boyd's (OODA) Loop depicting how the processes for making critical decisions can be framed in terms of the four key stages of orientation, observation, determination, and action.



Note: The loop revolves both in time and space, and that termination of each revolution (Action stage) modifies the environment with which the Observer interacts, and imposes a new set of "unfolding circumstances" that generate "outside information" and shape the subsequent "Orient" and "Decide" stages. (Adapted from von Lubitz & Wickramasinghe, 2005a, 2005b, 2005c)

from the pioneering work of Boyd (1987), who synthesized decision making, interaction with and control of a fast paced and unpredictably changing environment into a loop-like process (OODA Loop) (Figure 1) (Boyd, 1987; von Lubitz & Wickramasinghe, 2005b, c, d, 2006). Decision making in complex macroenvironments, particularly those characterized by a very rapid revolution cycle and a vast array of multispectral information inputs, is the primary beneficiary of the practical applications of Boyd's Loop. Application of Loop methodology allows for the interpretation of the environment of multidimensional action space (in this case, healthcare) as a set of simultaneous and intertwined events that characterize the space, and are both influencing and are influenced by the actor (e.g., a healthcare organization, clinician, or disease). Boyd's Loop-based thinking forces the actor into continuous extraction and synthesis of pertinent information and germane knowledge. Without such extraction / synthesis, information chaos and overload will rapidly ensue and force the operator into subjective selection of *seemingly* relevant inputs and disregard of other inputs *that appear, at the time of the analysis, to be inconsequential* (von Lubitz & Wickramasinghe, 2005c, 2006; von Lubitz et al., 2004). The ensuing responses to the objective pressures will thus derive from increasingly subjective data interpretation, leading to suboptimal decision making and the ultimate danger of catastrophic errors.

Application of Boyd's Loop and the associated continuous extraction and analysis of high quality information from the environment of the "operational space" provides yet another major advantage: the development of "information superiority" and the reduction of "information asymmetry" relative to the environment.

Each environment contains a complete set of data (information) that describe it. By extracting this information, the actor shifts the knowledge of the given environment from fully unknown (i.e., the environment containing all information that is hidden from the observer) to fully known (the observer uncovers the entire information content of the environment). In the process of uncovering the informational content of the environment, the actor shifts information asymmetry (from environment contained to actor extracted) in his favour and, at the same time, attains the state of "information superiority" (the actor knows progressively more about the faced environment, while the density of the unknown information contained within the environment diminishes during the extraction process). Hence, the highest possible rate of the shift of information asymmetry in favour of the actor and the maximum reduction of time needed for the attainment of valid information superiority are the principal goals of the actor acting in a complex, dynamically evolving environment. Both actor-biased information asymmetry and information superiority are also the principal countermeasure to the "information chaos" or information overload (Lehto, 1991; Prietula, Feltovich, & Marchak, 2000; Tole, Stephens, Harris, & Eprath, 1982) — elements that also characterize many aspects of today's healthcare (Arellano & Weber, 1998; d'Alessandro & Kreiter, 1999; Geiger, Merriles, Walo, Gordon, & Kunov, 1995).

In summary, information superiority provides asymmetric operational advantage not only assures complete control of the direction and tempo of all activities in a collaborative yet highly coordinated manner, but also facilitates attainment of the objective in the most effective and economical way possible.

The state of information superiority can be attained only through the effective use of IC^2T — a critical architectural element of doctrine of "network-centric warfare" created and currently implemented by the U.S. Department of Defense (Stein, 1998). The approach calls for the development of interconnected information grids creating a multilayered, robust network that facilitates information sharing among all participants within the operational space (Arellano & Weber, 1998; d'Alessandro et al., 1999). Drawing upon these ideas and the underlying logic of Boyd's OODA, a doctrine for healthcare network-centric operations has been proposed recently (von Lubitz & Wickramasinghe, 2005a), of which the principal element is the creation and employment of an effective integrated worldwide collection/dissemination/exchange IC^2T grid that will allow free flow of standardized/structured data/information among worldwide actors within the healthcare space necessary to allow the development of global information superiority state.

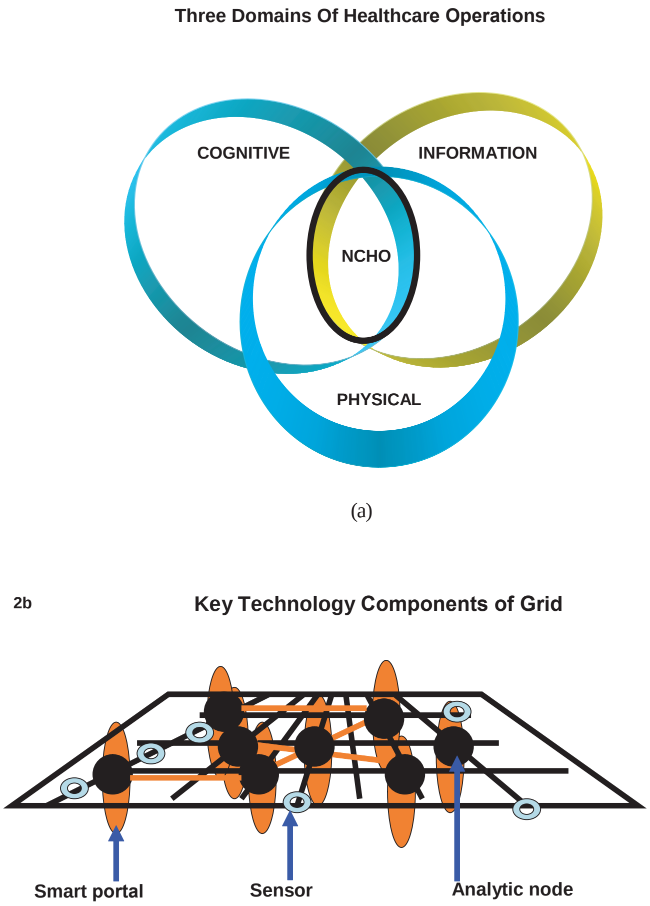
The doctrine of HNCO is thus defined as:

unhindered networking operations within and among all three domains that govern all activities conducted in healthcare space and are based on free, multidirectional flow and exchange of information without regard to the involved platforms or platform-systems and utilizing all available means of ICTs to facilitate such operations. (von Lubitz & Wickramasinghe, 2005a)

The three distinct domains of networkcentric operations are very closely interrelated, and the space within which the domains overlap provides physical and conceptual infrastructure within which all activities are conducted (Figure 2a):

- **Physical domain:** the target that the healthcare intends to influence directly or indirectly. In addition to the most obvious goal of eliminating disease, other aspects of healthcare, for example, research and its policies, fiscal issues, political environment of healthcare, provider personnel, and patient education, belong to this domain. The data/information/knowledge within physical domain relate to its *present rather than future state* and are the easiest to collect. Cumulatively, the physical domain

Figure 2. (a) The relationship among the operational domains in health care. Network-centric health care operations (NHCO) exist only in the territory where all three domains overlap; (b) The critical components of WHIG, including the smart portal, analytic nodes, and sensors (Adapted from von Lubitz & Wickramasinghe, 2005a, 2005b, 2005c, 2005d)



(b)

represents *the current state of healthcare reality.*

- **Information domain:** consists of all elements needed to generate, store, manipulate, disseminate/share/transform information, and disseminate/share the product of such transformation as knowledge in all its forms. All sensory inputs gathered are gathered within the information domain with the sensors representing a wide variety of entities (people and devices.) The output of the sensors may have a wide variety of forms/sensitivity (e.g., basic research data, diagnostic data from individual/multiple patient encounters, electronic health records, etc.) The information existing in this domain may not fully represent the current state of reality. However, all knowledge about that state emerges from and through the interaction with the information domain, and all communications about that occur through interactions within this domain. The information domain is particularly sensitive to incursions that may affect the quality of information contained within the domain. Hence, it must have appropriate security measures that prevent hostile intrusions in any form.

- **Cognitive domain:** constitutes all human factors that affect healthcare operations, such as education, training, experience, personal engagement (motivation), "open-mindedness," or even intuition of individuals involved in relevant activities. All these represent highly intangible quantities that are difficult to measure but form the basis for the selection of right timing, right place, and right effect of all actions undertaken within the healthcare. Even in the presence of well developed decision support systems provided by the information domain, deep situational awareness is created and decisions are made within the cognitive domain.

The technological backbone of network-centric healthcare is the World Healthcare Information Grid (WHIG) (von Lubitz & Wickramasinghe, 2005a, b, c, 2006) which utilizes Web and related Internet technologies, for example, HTML, TCP/IP, Web, JAVA, XTML, and so forth (Eysenbach, 2001; Eysenbach & Diepgen, 1998; Glaser, 2002; McGown et al., 2004; PricewaterhouseCoopers, 2003; Sharma & Wickramasinghe, 2004a; Sieving, 1999; Umhoff & Winn, 1999; Wickramasinghe & Ginzberg, 2001; Wickramasinghe & Mills, 2002). Figure 2a depicts the WHIG with its three distinct yet interconnected domains, each made up of interconnecting grids while Figure 2b identifies the key elements of the grid with its smart access portals, analytic nodes, and intelligent sensors (von Lubitz & Wickramasinghe, 2005b). Implementation of principles based on ASP (application software provider) philosophy and fusing them together with the concept of smart portals allows direct worldwide access to the WHIG that is essentially independent of the technology existing at the user site and that opens network-centric healthcare operations to practically all involved entities — whether individual healthcare providers or national/international bodies providing healthcare governance, monitoring, and policy development.

FUTURE TRENDS: IMPLICATIONS FOR POLICY MAKERS AND GOVERNMENTS

WHIG provides the technology backbone of HNCO; however, for WHIG to function as intended, providing pertinent information and germane knowledge in a seamless, effective, and efficient fashion to a decision maker anywhere anytime, various protocols and procedures must be developed at a global level. Without such standardization even the simplest of functions, such as the exchange of documents and other procurement information, connectivity, and e-commerce enabled benefits, become problematic while the critical goal of decreasing information asymmetry becomes unattainable. Unfortunately, standardization is woefully lacking in too many areas of healthcare let alone e-health. Given the global nature of WHIG, it is here that global bodies, such as the World Healthcare Organization (WHO) in conjunction with governments and policy makers, must develop policies, procedures, and standards that will enable the seamless functioning of WHIG. We identify four key areas that must be addressed:

1. **Information computer communication technology (IC^2T) architecture/infrastructure:** The generic architecture for most e-health initiatives is similar to that required by WHIG. However this infrastructure that consists of phone lines, fiber trunks and

submarine cables, T1, T3 and OC-xx, ISDN, DSL and other high-speed services used by businesses as well as satellites, earth stations and teleports must be available globally.

A sound technical infrastructure is an essential ingredient to the undertaking of e-health initiatives by any nation. Such infrastructures should also include telecommunications, electricity, access to computers, number of Internet hosts, number of ISPs (Internet service providers) and available bandwidth and broadband access. To offer a good multimedia content and thus provide a rich e-health experience, one would require a high bandwidth. ICT considerations are undoubtedly one of the most fundamental infrastructure requirements.

Networks are now a critical component of the business strategies for organizations to compete globally. Having a fast microprocessor-based computer at home has no meaning unless you have high bandwidth based communication infrastructure available to connect computers with the ISP. With the explosion of the Internet and the advent of e-commerce, global networks need to be accessible, reliable, and fast to participate effectively in the global business environment. Telecommunications is a vital infrastructure for Internet access, hence also for e-commerce. One of the pioneering countries in establishing a complete and robust e-health infrastructure is Singapore which is in the process of wiring every home, office, and factory up to a broadband cable network which will cover 98% of Singaporean homes and offices (APEC, 2001; A report prepared for Asia Pacific Foundation, 2002a).

It is estimated that over 70% of world telephone lines are in countries with 15% of the world's population (Parker, 1998). The average number of telephone lines in industrialized countries is one for every two persons as compared to 13 lines per thousand people in emerging economies such as India and China (ibid). A sound technical infrastructure is a key ingredient to the future economic health of any given nation and should be a priority for all governments.

For example, in the Asia-Pacific region (APEC, 2001; Beal, 2000; Oxley & Yeung, 2001; A report prepared for Asia Pacific Foundation, 2002a; A study report on Thailand, 2001; Turpin, 2000), there are a number of "digital divides," not only between the richer and poorer countries, but divides between urban and rural populations and between more and less educated or affluent groups. Although the number of female Internet users in a number of countries in the region is catching up quickly with those of male users, women are less present when it comes to the actual use of the new technologies. Furthermore, in many of these countries, women make up the majority of the rural population, which is often marginalized in areas of telecommunication infrastructure, education, and training. Therefore, governments should formulate national IC^2T and e-commerce strategies that help to ensure universal access for all socioeconomic groups. A number of prerequisites for access to IC^2T include education and training, local content, sociocultural awareness, and a stable social, economic, and political environment. Appropriate technologies need to be developed to address the needs of disadvantaged communities.

2. **Building human capital/resources:** The disparity between educational standards of developed and developing nations in the world is significant (Roquilly, 2002; Sharma & Wickramasinghe, 2004a, b; UNCTAD, 2002). In order for healthcare network-centric operations to fully maximize the potential afforded by WHIG significant enhancement of human capital through education and

training is required. Many of the developing nations through investment and foreign aid need to concentrate on developing human capacity, and increasing basic access to IC^2T, as well as rapidly increasing the presence and access to the Internet. Moreover, the governments of disadvantaged countries must also exercise significant international pressure to lower costs of hardware and software while, at the same time, contemplating to form larger multinational user blocks capable of effective implementation of ASP principles. E-commerce adoption in general requires improved e-commerce knowledge and skills, and improved language proficiency (especially in English as it is as the recognized principal technology / commerce language). For example, governments in many countries have started to introduce basic education in digital literacy in primary and secondary schools. Such training courses should be constantly updated as new innovations and practices emerge very rapidly in this field. Institutions responsible for human resource development of e-commerce personnel should provide appropriate incentives for e-commerce courses to be kept up-to-date. Increasing the number of programs or activities for human resource development for IC^2T and especially Internet use will only be effective if the education and training matches the changing needs of the industries concerned. It is important to note that only medical specialists require medical training but all people globally who need to interact with WHIG must have basic familiarity, training, and proficiency with use of IC^2T. Once again much of the onus falls on governments to set the agenda and priority for such an emphasis.

3. **Fostering consumer trust:** Consumers are also concerned about a number of dimensions of trust; trust in the security of value passed during electronic transactions with organizations that are "virtual" in a disconcertingly ineffable way and trust in the privacy of personal data arising from electronic transactions (Fjetland, 2002; Ghosh & Swaminath, 2001; Panagariya, 2000; Roquilly, 2002). Other than in North America, Japan, and integrated Europe, the infrastructure for e-commerce is not in place for effective e-commerce transactions. The key reason for slow penetration has been the scale of investment in infrastructure, and the small volume of transactions over which to amortize (Dutta, 1999; A report prepared for the Asia Pacific Foundation, 2002b).
The security issue in particular is perceived as very important across the Asia-Pacific region, and the majority of SMEs, for instance, have a fear of electronics. This is primarily due to the low level of technology diffusion and awareness making it a psychological barrier for SMEs as confirmed in various reports (APEC, 2001; Beal, 2000; A report prepared for the Asia Pacific Foundation, 2002b). Many of these SMEs do not have technical expertise, and are not convinced that the technology standards, such as encryption, will protect them. Thus, SMEs are not willing to use electronic payment systems.
Given such a general lack of trust in developing nations with using e-commerce, it is likely that the trust issue will be a significant factor in e-health initiatives given the general sensitivity of healthcare information. Once again government and national bodies must make every attempt to foster trust. This will not be an easy task since in many developing countries people have a low level of trust for governments, corruption tends to be significant, and especially in rural areas, people tend to be very superstitious and leery of "modern methods." However, in many instances WHIG and healthcare network

centric operations will offer these groups of people the best healthcare alternatives and thus significant effort must be made to build and foster trust.

Ethical concerns are inevitably related to healthcare operations based on network centricity. The notion of the governmental bodies having ready access to healthcare information of the citizens is among the major concerns in the U.S., and similar reservations are also voiced in Europe. The possibility of security breaches, similar to those that recently affected millions of credit card customers in the United States, demands a very stringent layer of protective layers that will assure prevention of commercial misuse of healthcare data. The seriousness of such intrusions is emphasized by the dynamic development of molecular biology and genetics that allow early determination of the likelihood to develop long-term debilitating diseases at the later stages of life. Misappropriation of such information may then affect the subsequent chances of employment, nature and availability of health insurance, and even acquisition of credit. While laws preventing such discrimination already exist in several Western countries, their enforcement is not simple and the fear of clandestine stratification into "health risk" classes whose quality and freedom of life is directly related to the long-term risk is a threat that needs to be addressed with utmost vigor now. At a less threatening, albeit far more practical level, the problems of the responsibility for the delivery of healthcare also need clarification.

Among the major obstacles to the development of an efficient national telemedicine network in the U.S. is the difficulty of assigning responsibility for treatment conducted across state borders. The dilemma becomes even more pertinent when healthcare expertise is projected across national borders. While there is no doubt that the rule of the "best medical practice" ought to be the prevailing one, the best practice has different definitions in different countries and what is considered the standard of care in one country may not be so in another. There is thus a clear need to develop generally accepted standards of delivery and the current acceptance of the concept of "evidence-based medicine" may offer the most useful foundation for further deliberations of such standards. These are but two of several problems that already either influence or are about to influence e-health in all its forms. The magnitude of network centricity and its global nature will add even greater urgency to the need for their effective operational rather than merely political or legislative solution. At a purely technical level, while network centricity strengthens the efficacy and economy of global healthcare, it may also have an impact on access to it. Ideally, network-centric operations will support a continuously broadening access to high quality healthcare across the entire globe. In practice, however, there is a chance it may support improvements there where the level of the preexisting technology and sophistication in its use are already high while leaving those who lag behind, yet needing rapid improvement of even basic healthcare in the same position they are now — desperately struggling to satisfy the most elementary healthcare needs of the local population. It is thus evident that introduction of network centricity and the creation of WHIG require a fundamentally different approach to the one currently practiced: they can be made functional only when a state of intense, multilateral, and determinedly synergistic collaboration exists between corporate and governmental entities not only at the national but, even more importantly, at the international level. Ultimately, transparency, international synergism, and adherence to the highest ethical standards of operations will be among the most instrumental factors to convince the users (i.e., both deliverers and recipients of healthcare) that network centricity in healthcare offers tangible benefits that have been unattainable prior to the implementation of the concept.

4. **Creating synergies between national and regional economic blocks:** For WHIG and HNCO to be fully functional, it is vital that synergies are created between national and economic blocks. For example, in similarity to the EU, all countries in the Asia-Pacific region should improve access to IC^2Ts, design the necessary legal and institutional frameworks to educate the governments, businesses, and civil society to more efficiently use IC^2Ts in their daily practices, and create an environment for further development of IC^2T use in general and in particular with a focus on healthcare. There is a tremendous need to support the integration and interoperability of regional e-commerce initiatives through various international and regional economic blocks such as the Asia-Pacific Economic Cooperation (APEC), North American Free Trade Agreement (NAFTA), and the European Union.

   Another critical aspect that requires significant consideration to enable and facilitate the required synergies is that pertaining to legal and ethical issues. In general the Internet community has developed its own distinctive culture and a great part many of these behavioural norms function outside the realm of International Law given the current maturity of International Internet Law (Commission of the European Communities, 2003; De Ly, 1992, 2000; Nielson, 2000; Polanski, 2005; Polanski & Johnston, 2002). Given the sensitive nature of much of the information contained with healthcare interactions, this poses a significant problem and major stumbling block for the adoption of HNCO. This is clearly an area that requires significant discussion and will form the center of future research; we mention it here only in passing to note that it remains as yet a key area that needs to be addressed

CONCLUSION

It is beyond the scope of this chapter to discuss the details of the technology configuration of WHIG or provide guidelines for practioners. Interested readers can refer to other research (von Lubitz & Wickramasinghe, 2005a, 2005b, 2005c, 2005d; von Lubitz, Wickramasinghe, & Yanovsky, 2005) for details. The primary focus here is to highlight the key role for governments if we are to ever realize the full benefits of e-health.

The idea of WHIG and HNCO is to span many parties and geographic dimensions. To enable such a far reaching coverage, significant amounts of document exchange and information flows must be accommodated. Standardization is the key for this. Once a country decides to undertake e-health initiatives and become a "WHIG member," standardization policies, protocols, and procedures must be developed at the outset to ensure the full realization of the goals of e-health. The transformation to e-health by any country cannot be successfully attained without the deliberate establishment of standardization policies, protocols, and procedures which play a significant role in the adoption of e-health and the reduction of many structural impediments (Panagariya, 2000; Samiee, 1998). Fortunately, the main infrastructure of WHIG is the Internet which imposes the most widely and universally accepted standard protocols such as TCP/IP and http. It is the existence of these standard protocols that has led to the widespread adoption of the Internet for e-commerce applications.

Access to the technologies of e-commerce is defined by the WTO (World Trade Organization) as consisting of two critical components: (1) access to Internet services and (2) access to e-services (Health Insurance Portability and Accountability Act, 2001); the former deals with the user infrastructure, while the latter pertains to specific commitments to electronically accessible services. The user infrastructure includes number of Internet hosts and number of Web sites, Web users as a percent of the population as well as ISP availability and costs for consumers, PC penetration level, and so forth. Integral to user infrastructure is the diffusion rate of PCs and Internet usage. The United States and the United Kingdom have experienced the greatest penetration of home computers (Samiee, 1998). For developing countries, such as India and China, there is, however, a very low PC penetration and teledensity. In such a setting it is a considerable challenge then to offer e-health, since a large part of the population is not able to afford to join the e-commerce bandwagon. Countries, thus have to balance local call charges, rentals, subscription charges, and so forth, otherwise the majority of citizens will find these costs a disincentive. This is particularly significant for developing and emerging nations where access prices tend to be out of reach for most of the population. Upcoming new technologies hold the promise to increase the connectivity as well as affordability level and developing countries will need to seriously consider these technologies. In addition to access to PCs and the Internet, computer literacy is important and users must be familiar not only with the use of computers and pertinent software products but also the benefits and potential uses of the Internet and World Wide Web (ibid).

The key challenges regarding e-health use include (1) cost effectiveness that is less costly than traditional healthcare delivery; (2) functionality and ease of use: that is, they should enable and facilitate many uses for physicians and other healthcare users by combining various types and forms of data as well as be easy to use; and (3) they must be secure. One of the most significant legislative regulations in the U.S. is the Health Insurance Portability and Accountability Act (HIPAA) (2001).

Given the nature of healthcare and the sensitivity of healthcare data and information, it is incumbent on governments not only to mandate regulations that will facilitate the exchange of healthcare documents between the various healthcare stakeholders but also to provide protection of privacy and the rights of patients (Dyer, 2001). Some countries, such as China and Singapore, even control access to certain sites for moral, social, and political reasons while elsewhere transnational data flows are hindered by a plethora of regulations aimed at protecting domestic technology and related human resource markets (Ghosh & Swaminatha, 2001; Gupta, 1992; Samiee, 1998). Irrespective of the type of healthcare system; that is, whether 100% government driven, 100% private or a combination thereof, it is clear that some governmental role is required to facilitate successful e-health initiatives.

HNCO also serves to underscore the inextricable connection and intertwining of e-health and e-government which to date has rarely been researched let alone acknowledged. Moreover, for HCNO to become adopted successfully, it requires governments to develop policies and protocols which will in turn facilitate its usability. We identify four key areas that will have an important impact on the development of the necessary policies and protocols as IT education, morbidity, cultural/social dimensions, and world economic standing as elaborated upon below. It is interesting to note that these areas also impact the development of numerous e-government initiatives (Turban et al., 2004), once again highlighting the inextricable link between e-health and e-government.

- **IT education:** A sophisticated, well educated population boosts competition and hastens innovation. According to Michael Porter, one of the key factors to a country's strength in an industry is strong customer support (Porter, 1990). Thus, a strong domestic market leads to the growth of competition which leads to innovation and the adoption of technology enabled solutions to provide more effective and efficient services such as e-health and telemedicine. As identified earlier, the health consumer is the key driving force in pushing e-health initiatives. We conjecture that a more IT educated healthcare consumer would then provide stronger impetus for e-health adoption.

- **Morbidity rate:** There is a direct relationship between health education and awareness and the overall health standing of a country. Therefore, a more health conscious society, which tends to coincide with a society that has a lower morbidity rate, is more likely to embrace e-health initiatives. Furthermore, higher morbidity rates tend to indicate the existence of more basic health needs (World Health Organization, 2003) and hence treatment is more urgent than the practice of preventative medicine and thus e-health could be considered an unrealistic luxury and, in some instances, such as when a significant percentage of a population is suffering from malnutrition related diseases, is even likely to be irrelevant, at least in the short term. Thus, we conjecture that the modifying impact of morbidity rate is to prioritize the level of spending on e-health vs. other basic healthcare needs.
- **Cultural/social dimensions:** Healthcare has been shaped by each nation's own set of cultures, traditions, payment mechanisms, and patient expectations. While the adoption of e-health, to a great extent, dilutes this cultural impact, social and cultural dimensions will still be a moderating influence on any countries e-health initiatives. Another aspect of the cultural/social dimension relates to the presentation language of the content of the e-health repositories. The entire world does not speak English, so the e-health solutions have to be offered in many other languages. The e-health supporting content in Web servers/sites must be offered in local languages, supported by pictures and universal icons. This becomes a particularly important consideration when we look at the adoption and diffusion of evidence-based medicine as it will mean that much of the available evidence and case study data will not be easily accessible globally due to language barriers.

Therefore, for successful e-health initiatives it is important to consider cultural dimensions. For instance, an international e-commerce study by International Data Corp. indicates that Web surfing and buying habits differ substantially from country to country (Wilson, 1999) and this would then have a direct impact on their comfort to use e-commerce generally and e-health in particular, especially as e-health addresses a more fundamental need. Hence, the adoption of e-health is directly related to ones comfort with using the technology and this in turn is influenced in a major way by cultural dimensions. Also connected with cultural aspects is the relative entrepreneurial spirit of a country. For example, a study (Hofstede, 1984) indicates that in a cultural context, Indians score high on "uncertainty avoidance" criteria when compared to their Western counterparts. As a result, for example, Indians do not accept change very easily and are hostile towards innovation. This then would potentially pose a challenge to the starting up of e-health initiatives whose success depends on widespread adoption for their technological innovations. Thus, we conjecture that fear of risk and absence of an entrepreneurial mindset as well as other cultural/social dimensions can also impact the success of e-health initiatives in a given country.

- **World economic standing:** Economies of the future will be built around the Internet. All governments are very aware of the importance and critical role that the Internet will play on a country's economy. This makes it critical that appropriate funding levels and budgetary allocations become a key component of governmental fiscal policies so that such initiatives will form the bridge between a traditional healthcare present and a promising e-health future. Thus, the result of which would determine success of effective e-health implementations and consequently have the potential to enhance a country's economy and future growth.

A healthy society is in the interests of all governments. As labor costs increase and productivity is critical to economic development, a healthy population is naturally able to contribute more significantly to increasing GDP. Coupled with the fact that healthcare remains the most expensive item for any government, it behooves governments to make healthcare a top priority on their agenda. The doctrine of HNCO serves to outline a coherent and systematic approach for harnessing the full potential of IC^2T for healthcare and the ability to realize the promises of e-health. However, if this is to occur, e-health must become a top priority on all government agendas. Moreover, governments must go further than just acknowledge the importance of e-health to focusing their energies and efforts to address the key impediments we have identified and that currently preclude the ubiquitous adoption of HNCO.

The World Economic Forum's Global competitiveness ranking measures the relative global competitiveness of a country. This ranking takes into account factors such as physical infrastructure, bureaucracy, and corruption. It is a simple extrapolation of the combination of these factors to postulate that the combination of a weak physical infrastructure with high levels of bureaucracy and corruption will constitute a significant impediment to the establishment of successful e-health initiatives. Surely, network-centric healthcare operations will not change these realities. On the other hand, the possibility for a rural healthcare provider working in an even most oppressive political and economical environment to enter WHIG and benefit from the combined global healthcare expertise will be without doubt a step in the right direction. And many steps in the right direction will ultimately help to redress the level of current inequalities in access to the most fundamental right of all humans across the globe — health.

ABSTRACT

Advances in healthcare information technology have enabled new models for electronic delivery of healthcare services. In this article, we present the case of electronic delivery of radiological services and describe the market-based and technological factors that have led to the development of Internet-based service models for flexible delivery of radiological services. Specifically, we describe the technical, regulatory, and security issues that affect teleradiology and propose a service delivery model for providing cost-effective and flexible radiological services.

INTRODUCTION

The continued wide-scale adoption of information technology in the healthcare industry is facilitating the electronic delivery of healthcare related services. Following the integration of medical infrastructure with information and communication technologies (ICT), patient-facing, and inter-organizational healthcare services can now be delivered using Internet-based applications and e-commerce platforms. In order to understand the factors influencing the evolution of e-commerce models in healthcare services, we present the case of global teleradiology.

Teleradiology refers to the electronic transmission of radiological images such as x-rays, computed tomograms (CT's), and magnetic resonance images (MRI's) across geographical locations for the purposes of interpretation and consultation. The digital radiological images are typically transmitted using standard telephone lines, satellite connections, or wide area networks (WANs). Teleradiology is an empowering technology and a facilitator for enhanced medical care. It enables a single radiologist to simultaneously provide services to several hospitals independent of their location and allows the exploitation of global time differences to provide emergency night coverage by personnel in a different time zone working a day shift. Additionally, the quality of care delivered by an alert physician working a day shift is far superior to that provided by a radiologist who is up all night. In addition, teleradiology also enables the delivery of subspecialty opinions to remote locations, where otherwise expertise is not available. In this article, we describe the current state-of-art in teleradiology, the benefits of the clinical practice of teleradiology, and the technical, regulatory, and security issues related to teleradiology. We begin by discussing relevant work in healthcare e-commerce and subsequently the evolution of global teleradiology.

E-Commerce in Healthcare Services

In the past decade, several new businesses have developed that deliver healthcare related services over the Internet. They can be broadly classified into four different forms of e-health business (Parente, 2000). These include portal, connectivity, B2B, and B2C applications. Portal, connectivity, and B2C commerce in healthcare typically involves either the provisioning of information to consumers via advertising supported Web sites, or the Web-based ordering services for prescription drugs (Zehnder, Bruppacher, Ruppanner, & Hersberger, 2004). In B2B e-commerce, the healthcare industry is mostly focused on the procurement and supply of medical devices and equipment (Arbietman, Lirov, Lirov, & Lirov, 2001; Smith & Correa, 2005). The exchange of services has been mostly limited to non-medical services such as billing and claims processing.

The exchange of medical services over the Internet has received little attention both in the industry and in academic literature. However, recent advances and developments in the healthcare industry and medical information technology are now enabling several new models for delivery of medical services over the Internet (Siau, 2003), primary examples of which include telemedicine and teleradiology. In addition, initiatives on data standardization and standardization of quality are also driving the development of outsourcing-based models in the healthcare industry (Segouin, Hodges, Brechat, 2005). Following the development of enabling technologies and the emergence of favorable market factors for medical service outsourcing, the outsourcing of medical services is now a major topic for discussion and research (Wachter, 2006). Among the first applications of medical service outsourcing and offshoring is the teleradiology service, and is now practiced by firms like NightHawk (http://www.nighthawkrad.net/), virtual radiologic (www.virtualrad.com), teleradiology solutions (www.teleradsol.com), etc.

Although the concept of teleradiology was first tested and clinically utilized in the late 1950's (Gershon-Cohen & Cooley, 1950), the high cost of transmission and the variability in digital imaging protocols limited the widespread adoption and application of teleradiology applications. However, the rapid progress in digital communication technologies and the development of efficient Internet-based software for image transmission, storage, and display in the 1990s has significantly reduced the technical barriers to teleradiology adoption. In addition to the previous developments, the universal adoption of the DICOM standard, as required by the ACR-NEMA (American College of Radiology and the National

Electronic Manufacturers Association), has enabled the wide spread adoption of teleradiology applications.

Global Teleradiology

Today, teleradiology has become both global and online. The precedent for globalization of teleradiology was set by the information technology services industry, which has pioneered the concept of the global office where the work "follows the sun" (i.e., divisions in different time zones are connected over a WAN to provide a 24-hour workforce without the need for having individuals to work a night shift at any location). Extended to teleradiology, this means that the interpreting radiologist for a given hospital can potentially be located anywhere on the globe and day-night time differences can be exploited to staff the emergency room (ER) night shift. A paper published by Kalyanpur, Weinberg, Neklesa, Brink, and Forman (2003) from Yale University showed that this was both technically and clinically feasible (Kalyanpur et al., 2003).

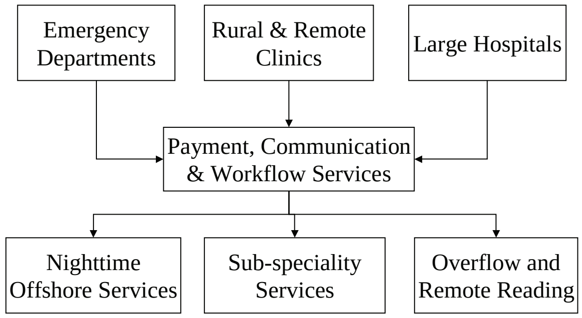
Several market-based factors such as staffing shortages (Sunshine, Maynard, Paros, & Forman, 2004), increases in imaging volumes (Bhargavan & Sunshine, 2002), new technology, and insurance and regulatory changes have also contributed to the growth and development of teleradiology. We briefly describe these factors next.

- **Radiologist Staffing Shortage:** A significant shortage of radiologists became apparent in the U.S. toward the turn of the millennium, with a large cohort of senior radiologists retiring from practice and training programs not having grown adequately to keep pace with the increased needs (Sunshine et al., 2004). In many other parts of the world, a similar shortage of trained/skilled radiologists exists. As might be expected in a time of staffing shortages, it is the night shift in the community hospital that is typically hit the hardest, although academic departments also stand to benefit from having their off-hours/overflow work done remotely by faculty based offshore (Kalyanpur et al., 2004).
- **Increase in Imaging Volumes:** The rapid evolution of faster imaging technologies such as multi-slice CT, faster MRI scanners, and sequences, coupled with an ageing population in the U.S. has led to a consistent per year increase in imaging volumes in recent years. A recent survey of radiology utilization in Medicare population indicates a 13% increase in the utilization of radiological imaging (Martin et al., 2003).
- **Increase in Trauma Imaging Utilization:** The development of newer applications of CT in the emergency setting has necessitated a large increase in 24-hour radiologist coverage at hospital emergency rooms (Spigos, Freedy, and Mueller, 1996). In addition, the Health Care Financing Administration (HCFA) requires that in order for the services to be billable, overnight coverage for radiological services has to be provided by a fully trained and certified radiologists, rather than residents/trainees (Federal Regulation 60: 63124). This has resulted in a large increase for overnight radiologist services.

A Service Delivery Model for Teleradiology

Recent advances in information and communication technologies such as Web services and workflow technologies enable new extensions to teleradiology that facilitate the delivery of radiological services across various time zones and geographical regions. The foremost application of teleradiology is in the emergency setting. In emergencies, teleradiology facilitates a prompt response by bringing the emergently performed images to the off-site radiologist that allows for

Figure 1. A service delivery model for teleradiology



timely diagnosis and the timely administration of appropriate treatment.

However, using secure Internet-based communication mechanisms and workflow technologies, several new applications of teleradiology can be developed. An overview of the service delivery model is presented in Figure 1. A key feature of the model is an e-commerce platform consisting of payment, communication, and workflow services. Under typical current arrangements for emergency teleradiology, the radiology group outsources its night calls to a teleradiology provider, somewhat like a locum relationship. The radiology group then reimburses the teleradiology provider at a predetermined rate for the preliminary emergency report provided by the latter and then bills the insurer for the final read that the former performs. By integrating a workflow system with the remote teleradiology service, all the previous payment, billing, and routing services can be automated.

In addition to automating the billing, payment, and routing services, an Internet-based service delivery model enables the delivery of radiological services to emergency departments, large hospitals, and remote rural clinics. We further describe these application areas next.

- **Emergency teleradiology services:** Teleradiology within the U.S. led to the development of the "nighthawk" concept wherein a radiologist is able to simultaneously provide services to multiple hospitals via teleradiology links to a central reading facility (often the radiologist's home). This enables a single radiologist to simultaneously staff the night shift at multiple hospitals. The process is cost-effective to hospitals, as the need to recruit night shift personnel is minimized.
- **Radiology to remote locations:** Teleradiology also enables the provision of radiological services to remote locations where the technical infrastructure for radiological scanning exists, but a radiologist is not available on site. Field studies indicate that teleradiology implementations at rural hospitals have been highly successful and cost-effective in providing radiological services even in real-time situations and have lead to improved patient care (Franken et al., 1995; Lee et al., 1998).
- **Optimization of workflow:** Teleradiology also increases the efficiency of a radiologist by ensuring that he or she spends the most part of his or her time delivering quality care to the maximum number of patients.

This is achieved by bringing the images to the radiologist rather than vice versa, thereby saving physician commuting time and increasing the range and reach of the radiologists' expertise. Within large radiologist groups servicing multiple hospitals and imaging centers, teleradiology also permits the optimal distribution of work based on need and the availability of radiologists.

- **Subspecialty consultations**: Teleradiology enables the wider availability of subspecialty consultations wherein images of a specific body region/modality need to be referred to the radiologist with expertise in the interpretation of that type of study. Past studies indicate that opinions of subspecialty radiologists obtained through teleradiology have resulted in significant improvements in the quality of patient care (Franken et al., 1997; Kangarloo et al., 2000).

Technical Requirements for Teleradiology

The key components of a teleradiology system include a picture archiving and communications system (PACS), a radiology information system (RIS), and a reliable and secure high-speed connectivity between the remote sites. These put together with standards for imaging and systems/procedures for security and contingency practices complete the technical aspects of teleradiology. These are further discussed in the following sections.

Picture Archiving and Communications System

An efficient Web-based PACS is the cornerstone of a clinical teleradiology practice. PACS is the information system used for the acquisition, storage, communication, archival, viewing, and manipulation of radiological images and related data. We provide a brief discussion on each of these components next.

- **Acquisition devices:** Acquisition devices are modalities with digital output capabilities or devices such as frame grabber and digitizers that convert the analog output from imaging modalities to a digital format.
- **Storage:** The storage components in a PACS system include both short-term as well as long-term archival solutions. This allows radiologists to have easy access to relevant prior studies for comparison. Typical radiological images range from 0.5MB to 4 MB or higher in size and depending on the number of images storage requirements can run to several gigabytes of storage per month. Since long-term archives do not require instant accessibility, optical disks or tape drives could be used for this purpose. The duration for which images need to be stored is dependent on the image type and varies from organization to organization. In the emergency setting, images are not usually stored for longer than 30 days. However, if outpatient imaging is being performed where comparisons are required, longer periods of storage may be necessary.
- **Communication:** PACS requires high-speed connectivity to enable rapid transfer of images to viewing workstations over LAN and WAN (the latter is what constitutes teleradiology). Transmission of images is based on protocols of imaging standards called DICOM. Transmission of non-image data like text uses HL7 standards. We further discuss DICOM and HL7 in later sections.
- **Software:** Image viewing and manipulation software are most often an integral part of PACS. Image viewers can be on a diagnostic workstation, review workstation, or could be done utilizing a Web-based module. Diagnostic workstations are high-end systems with high-resolution flat panel displays while

standard desktop PCs can be used as review workstations or as Web viewers.

- **Image Compression:** Given the large file size of typical radiological images, an important feature required facilitating rapid image transfer and throughput in teleradiology is compression. Compression algorithms used may be industry standard like JPEG 2000 or could be proprietary to the vendor. It has been noted that compression settings of up to 10:1 can be tolerated in clinical teleradiology without the compromise or loss of clinically relevant data, for review of CT images (Kalyanpur, Neklesa, Taylor, & Daftary, 2000). In the case of plain radiographs, even higher settings may be tolerated.

Radiological Information Systems

RIS is often a subsystem of hospital information system (HIS), but can also be a stand-alone entity and may or may not be connected to PACS. While PACS mainly deals with images, RIS/ HIS deals with data associated with patient demography, studies, and reports. RIS is often what guides the workflow of a teleradiology practice. Though RIS was used as a report generation and distribution tool earlier, commercially available RIS packages currently have integrated many features like voice recognition, staff scheduling, work distribution, invoicing, etc. At teleradiology solutions, a RIS has been developed by an in-house software development team to meet the requirements of an offshore teleradiology practice.

Connectivity Requirements

An ideal connectivity solution for teleradiology providers includes dedicated commercial broadband connection. The high-speed connections allow teleradiology service providers to serve clients half way around the globe, with report turnaround times comparable or even superior to the ones from local radiologists. A single radiologist working from home may use DSL connectivity, provided adequate throughput is confirmed prior to clinical use. For example, a single ultrasound image would take about 2 seconds to transfer over a typical DSL connection; however, larger plain film images can take between 1 and 4 minutes to transfer. Apart from bandwidth, one would also require other networking components such as routers, firewalls, VPN concentrators, and intrusion detection and prevention systems.

As the service being provided is a clinical service, typically in the emergency setting, a high level of communication between the site of origin and interpretation of the images is mandatory. This involves the utilization of fax systems capable of handling high volume data, direct telephonic contact and video and teleconferencing facilities.

Data Standards

DICOM is the industry standard used for transfer of radiological images between different hosts claiming conformance. DICOM is a standard developed by a joint committee set up by American College of Radiology (ACR) and National Electrical Manufacturers Association (NEMA). HL7 (Health Level Seven) is the standard for the exchange, management, and integration of electronic healthcare information like clinical and administrative data. Using HL7 compatible software streamlines the workflow considerably. For example, if PACS and RIS of a teleradiology practice are HL7 enabled, as soon as a new study is received by the PACS, a new order can be created on the RIS using patient demography and study details from the DICOM file, thereby eliminating duplication of work.

Securing Patient Data

Teleradiology providers are covered under the Health Insurance Portability & Accountability Act (HIPAA) and therefore need to implement adequate privacy and security practices as protected health information (PHI) and electronic protected health information (EPHI) are transmitted over public networks on a regular basis. While offshore teleradiology providers are not required to comply with HIPAA laws, the HIPAA act requires that "covered entities execute contracts that consist specific provisions for protection, use, and disclosure of health information" (Hilger, 2004). The privacy rule deals with all forms of patients' protected health information, whether electronic, written, or oral, while, the security rule covers only protected health information that is in electronic form, including EPHI that is created, received, maintained, or transmitted.

With the availability of a large number of commercial off the shelf network security solutions and technical safeguards, building and managing a secured network are relatively easy to implement. However, unauthorized access to patient data due to administrative breaches are difficult to monitor and implement, and hence the bulk of the HIPAA privacy rules have to do with administrative and physical safeguards. These breaches can only be prevented by educating employees about privacy and security practices followed by the organization and ensuring that these practices are implemented.

The security rule does not prescribe any specific technologies--being technology neutral allows the HIPAA covered entities to choose solutions based on their specific requirements. Technical safeguard standards include access control, audit controls, data integrity, person or entity authentication, and transmission security. Our in-house developed RIS solution (Tele-RIS) is used as a case in point here to illustrate/demonstrate how it complies with the above standards.

Access control mechanisms are used to ensure that a person or software can only access and modify resources for which the person is granted authorization. Access controls standard require the implementation of several features such as unique user identification, automatic logoff, and data encryption procedures. In addition, the following functionality also needs to be implemented:

- **Emergency access procedure:** This implementation specification requires a covered entity to establish procedures to retrieve EPHI during emergencies. Tele-RIS has a provision for adequate backup for power or network outages, but in case of a total outage, a backup procedure for the entire workflow from order entry to report distribution is well defined. Operating from different geographical locations also helps in dealing with contingencies.
- **Audit controls:** Are useful for recording and examining information system activity, especially when determining if a security violation occurred. Any addition, deletion, or remarkable modification on Tele-RIS is logged for audit purposes.
- **Data integrity:** Data could be altered during transit or in storage. "EPHI that is improperly altered or destroyed can result in clinical quality problems for a covered entity, including patient safety issues" (Health Insurance Portability & Accountability Act). This could happen by both technical and non-technical sources. A user can change the data, accidentally or maliciously. Tele-RIS addresses this problem using audit logs and techniques like versioning and digital signing.
- **Person or entity authentication:** Authentication involves confirming that users are who they claim to be. Tele-RIS uses a username/password combination for authentication. Many applications now incorporate the use of biometrics for authentication.
- **Transmission security:** This standard requires a covered entity to "Implement technical security measures to guard against unauthorized access to electronic protected health information that is being transmitted

over an electronic communications network" (Health Insurance Portability & Accountability Act).

Barriers to Adoption

Although teleradiology provides several benefits and can result in improved patient care and the technology exists for the large scale implementation of Internet-based radiological services, several barriers exist in the healthcare services industry that prevent the wide adoption of Internet-based radiological and medical service delivery. We briefly discuss these factors next.

- **Technology:** Although the technological capability to enable the delivery of medical services exists, the availability of the technology and trained technicians to operate them is a major barrier to wide-scale adoption. For example, the availability of reliable Internet connections in remote locations is a major barrier to the successful implementation of teleradiology and telemedicine projects. For a detailed discussion on the technological barriers to telemedicine, please refer to Paul, Pearlson, and McDaniel (1999).
- **Credentialing:** A major impediment to the rapid adoption of teleradiology services is the credentialing process. In addition to state-wise licensing requirements and board certifications, a hospital appointment for the consulting radiologist with the client hospital is necessary for providing radiological services. The current regulatory and credentialing structure is designed for a physical presence-based delivery model of radiological services, and needs to be redesigned for remote radiological or medical service delivery to develop.
- **Malpractice liability:** The medical malpractice liability laws differ from state to state and its implications to the practice of telemedicine are not clear. In addition, malpractice claims could also arise from improper use of equipment and errors in data transmission. For a detailed discussion on the legal issues related to the practice of telemedicine and teleradiology, the reader is referred to Gantt (1999).
- **Billing and reimbursement:** Although teleradiology consultations are now eligible for reimbursement under Medicare, HFCA rules limit the eligibility to patients who reside in a designated health professional shortage area (HPSA). In addition, regulations exist that prevent the billing of Medicare claims outside of United States, thus preventing the offshore reading services for Medicare related cases.
- **Health Insurance Portability & Accountability Act:** The confidentiality and security of patient information when transmitted across public networks is of major concern during the implementation of teleradiology solutions. Adequate safeguards need to be implemented in order to prevent unauthorized access to patient information at both local and remote locations. In addition to textual data, new encryption mechanisms need to be implemented to secure image data while maintaining their reliability (Cao, Huang, & Zhou, 2003).
- **Availability and work-satisfaction:** The availability and work-satisfaction of radiologist is a major factor in determining the success of teleradiology services. While a recent study of teleradiology satisfaction indicates a positive job-satisfaction for radiologists (Krupinski, McNeill, Haber, & Ovitt, 2003), the long effect of teleradiology on job satisfaction of radiologists needs to be evaluated.

CONCLUSION

In this article, we describe the state-of-art in teleradiology and present a service delivery model for providing cost-effective and flexible radiological services. The proposed model can enable the delivery of radiological services to several hospitals independent of their location and allows the exploitation of global time differences to provide emergency night coverage in emergency departments. In addition, we also describe the technical, regulatory, and security issues related to teleradiology and discuss barriers to the adoption of Internet-based teleradiology services. We conclude that while the technological capability exists to enable the remote delivery of radiological and other medical services, several legal, regulatory, and operational barriers remain that prevent the wide-scale adoption of Internet-based radiology and medical services.

Chapter 6.15
A Metric for Healthcare Technology Management (HCTM):
E-Surveying Key Executives and Administrators of Canadian Teaching Hospitals[1]

George Eisler

ABSTRACT

Among key drivers of healthcare reform in Canadian society are the challenges faced by the rapid rate of technological change and its impact on organizational performance in terms of efficiency, cost-effectiveness, and innovation in business and operational processes. However, despite the noted significance of the impact of technological change on healthcare organizations, the challenge of healthcare technology management (HCTM) has received only scattered and marginal attention in the technology management (TM) literature. The lack of formalization in HCTM construct, attributes, and measures motivated an empirical study to develop a metric for HCTM. This metric was then used to assess HCTM practices in teaching hospitals across Canada. The project began with an analysis of developments to date in the fields of Management of Technology and Management of Medical Technology. An extensive literature content analysis generated a set of definitions and attributes of the conceptual TM construct, which was eventually extended to

HCTM. A measuring instrument was developed through a formal design process involving expert panel review, pilot testing, instrument refinement, and field-testing to extract and measure HCTM performance indicators. Administration of this metric with the help of the Association of Canadian Academic Health Organizations via a Web-based survey of senior healthcare administrators provided insights into the HCTM status of Canadian teaching hospitals and its relationship with organizational performance.

INTRODUCTION

Amazingly, the history of digital computing and automated information processing technology has unfolded before us, for only a brief period of no more than several decades. In the last decade, we began to witness a gradual convergence of computing, telecommunications, and Web-based networking technologies, augmented by high-speed global access to an explosion of information on the Internet and increased global competition (Geisler, 2000; Ramanathan, 1990; Ulhoi, 1996). A key challenge with this trend is to unravel how management of technology innovation can impact business and operational performance of healthcare organizations in today's environment.

Business strategists, analysts, and researchers as well as economists have pointed to technology innovation as a catalytic change agent in the structure of industries and competition. Indeed, technological innovation can shift the competitive balance within an industry and create opportunities for growth. A technology management (TM) problem arises when business strategy does not fully incorporate technology-based threats and opportunities. Countries around the world are recognizing that the competitiveness of their private sector industries in the global market depends on their attention to TM. Technology has become a competitive tool in national and corporate survival, especially in an environment of global and more intense competition (Perrino & Tipping, 1989; Sharif, 1994). The issues are similar in the public service arena in that, "public expectations for the level and quality of government services… have grown while satisfaction with their fulfillment has steadily declined. In the past few years, it has become evident that cutting fat, eliminating waste, and preventing abuse is not nearly enough. Government needs to rethink its methods and restructure its approach to public services." As identified by Canadian healthcare CEOs, the task of managing healthcare organizations and systems is particularly complex, demanding that healthcare executives master many different skills, including government relations, community liaison, human resources, finances, patient care, research, and teaching. Communication skills, culture management, creativity, shared leadership, and alliance building rank among the top (Armstrong, Brunelle, Angus, & Levac, 2001). Healthcare technology management, therefore, adds one other dimension to these challenges.

In this paper, we review the extant literature with an attempt to link the more established field of Management of Technology (MOT) to emerging fields of Management of Medical Technology (MMT) and Healthcare Technology Management (HCTM). HCTM research domain and questions, focusing on the lack of alignment between healthcare technology strategies and healthcare systems goals and objectives, are first reviewed. Next, we outline the significance of HCTM research and attempt to link the published literature on MOT, MMT, and HCTM. We then discuss the methodological approach and statistical techniques used in the study. In analyzing and reporting the findings, we attempt to provide insights into characteristics and comparative performance of Canadian healthcare organizations and address key questions raised by this research with respect to aggregate views and perspectives of senior teaching hospital executives on HCTM. We close the paper with concluding remarks and directions for future studies.

LITERATURE REVIEW

In recent years, there has been increasing attention on the need to diffuse HCTM practices and expertise in developed as well as developing nations. The World Health Organization (WHO), for example, had alluded to serious shortcomings in the performance of health systems around the globe (World Health Organization, 2000). WHO's attempts to introduce components of a HCTM-like system in the late 1980s into countries and regions around the world had not been very successful.

HCTM Research Domain and Questions

The lack of a working HCTM model or framework and the shortage of TM training, knowledge, and expertise among workers in developed as well as developing countries were identified as serious limitations. Without an accepted and proven HCTM model, TM component functions and activities, such as technology planning, life cycle management, technology assessment, and performance assurance had no lasting infrastructure support and impact. Even outside the healthcare sector, these deficiencies with respect to TM point to the crucial need to align technology strategy and business strategy in organizations across many business industry sectors (Kaounides, 1999; Neumann et al., 1999). The strengthening, linking, and aligning of technology planning and business planning in healthcare is the essential purpose of HCTM. In light of this, our research concentrated on the status of HCTM among Canadian teaching hospitals. Specifically, key questions to be addressed included:

1. What is HCTM? What is the status of HCTM practices in Canadian teaching hospitals?
2. What attributes constitute successful TM activities in industries other than the healthcare sector? How can these attributes be applied to Canadian teaching hospitals to improve services without increasing costs?
3. What primary factors are adopted by hospital executive teams in practicing HCTM efficiently, cost-effectively, and in response to trends in hospital governance, infrastructure, resource limitation, health informatics leadership and culture, as well as changing medical and technological capabilities?

In an attempt to provide some valid and reliable answers based on empirical data collection and evidence gathered from the literature, we first operationally restate these questions into a series of more specific investigative queries. In this sense, the following questions serve as specific research aims or project objectives:

- How can TM and HCTM be conceptualized? What are these constructs and how do we define them operationally? More specifically, what are key and specific dimensions and indicators of the HCTM construct and how can these be determined empirically?
- How can HCTM performance indicators be measured? How can these measures be aggregated, grouped appropriately, and developed into a reliable and valid instrument for easy and convenient administration on the Web (as a Web-based survey instrument)?
- What is the level of HCTM capacity in Canadian teaching hospitals?
- Where are potential "weaknesses" and "specific performance gaps" among HCTM measures as applied to Canadian teaching hospitals?

Study Rationale and Significance

This section addresses the legitimacy of transferring TM lessons from other industry sectors to healthcare and hospital management, focusing on the concept of strategic TM and the importance of technology innovation. It also discusses the challenges of sustainability, cost, and quality of healthcare and incentives for technological innovation in healthcare.

The complexity of the healthcare environment, the multitude of forces that shape technology decisions, and the uniqueness of the healthcare environment are part of the justification for the promotion of the academic discipline of HCTM as separate and unique from MOT in general. Compared to other industry sectors, such as banking, housing, and transportation, the healthcare environment is seen not only as more complex, but also more emotionally charged (Eisler, Sheps, Satuglu, & Tan, 2002; Geisler & Heller, 1996). This environment is characterized not only by the complexities inherent in the development and maintenance of a seamless system spanning the continuum of healthcare delivery, but also by the complexity of relationships between provider organizations, service and product vendors, third-party payers, funders, and insurers, patients (consumers), the general public, regulators, researchers, and educators. In a 2005 *Communications of the ACM* publication, Tan et al. (2005) pointed to characterizing the present day healthcare and services delivery systems as "Complex Adaptive Systems". The need to understand the strategic TM concept in such a modern, complex system environment is clearly warranted.

The healthcare industry is an industry in transition, driven by such factors as changing population demographics, changing technology, and changing economic conditions. These pressures have resulted in changes to structure, process, financing, and human resource management. These challenges are driven by attempts to ensure timely access to quality and cost-effective healthcare services facilitated by technological innovation. Healthcare systems in Canada, the U.S., and other OECD countries are expected to continue on a road of cost reduction and quality improvement. Among OECD members, many countries regard cost control as a paramount policy aim (Gray, 1992). In Canada, federal and provincial governments are responding to such data as that provided by the Conference Board of Canada[2]. The Board projects that the proportion of Canada's population over the age of 55 will increase 10% per year for the next 20 years, rising from 22% to 32% of the population. Public health expenditures are projected to rise correspondingly from 31% in 2001 to 42% in 2020 as a share of provincial government revenue, representing an annual growth in healthcare costs of 5.2% over that period, of which 1.7% are attributed to demographic changes, that is, aging and population growth. Adjusted for inflation, per capita spending on healthcare is projected to increase by 58% while per capita spending on all other government services is projected to increase by only 17% over the next 20 years. Given these economic predictions, a debate about the role of technology is taking place against the backdrop of the incentive structures in publicly-funded, not-for-profit, for-profit, and mixed healthcare environments. It is, therefore, significant at this juncture to do a study to assess the status of HCTM in Canadian teaching hospitals.

Technology can play a vital strategic role in healthcare, as it does in other knowledge-based service industries like banking, entertainment, and other professional and technical fields. This is particularly true for information technology (IT) and communications technology, which can contribute significantly to improved management, cost effectiveness, customer service, and support. These applications have strategic implications, creating opportunities for new services, or for delivering existing services in new ways. It is for these reasons that the BC government has maintained IT and tele-health applications on its list of priorities at a time of severe cost reduction responses to the economic situation (British Columbia Ministry of Health Planning, 2002).

MOT, MMT, and HCTM

The field of MOT has been developed as an academic specialty in the arena of bio-medical engineering and sometimes cross-disciplined between business and IT engineering based on an evolving concept about the role of technology in organizations. Technology and its management have long been seen as critical factors to an organization's success and survival, particularly in competitive environments (Badawy, 1996; Morton, 1991; van Wyk, 1988). In public sector environments, MOT concepts are equally relevant because they help organizations to provide better service within available resources, to optimize organizational objectives, such as seamless access and quality, and to address special needs, societal problems, or political goals.

In the past, many industries saw IT as playing only supportive roles, thereby contributing simply to overhead costs. In short, these technologies were not seen as central to corporate goals and objectives. Today, new perspectives are being championed: Emerging technologies are seen as significant core enabling assets with major strategic implications for business survival and success. The power of integrative and converging technologies is blurring the boundaries between administrative and core business assets. Many CEOs now believe that such enabling technologies, if managed appropriately, can contribute significantly to the achievement of organizational objectives. As well, they may change fundamentally the way an organization functions and the way it relates to its industry sector, its sponsors, suppliers, and, perhaps most importantly, its customers and clients.

A common case example is that of the Internet and related Web Services. Many companies, realizing the power of the Internet, have set up shop online. From a marketing perspective, such unpredictable and rapid technological development creates a volatile technology push on the input side of organizations. For example, companies such as CVS Pharmacy and Rite Aids have gone online to protect their chain stores from losing customers to its growing list of competitors that have virtual storefronts. On the output side, customers expect reliable, consistent, safe, effective, and efficient services. The convenience of online shopping means that they can change their royalty to companies more easily and faster than queuing up at the retail store counter waiting to pay for their purchases. To these e-consumers, the technology and its applications should be seamless. The challenge then is for executives, in the face of increasingly difficult internal and external constraints, to employ management strategies to enable the organization to continuously transform the turbulent technology input into a customer-focused and appropriate output (Tapscott, 1996; Tapscott & Caston, 1993). According to McGee and Thomas (1989), what has been missing "is a comprehensive view of how technological change can affect the rules of competition, and the ways in which technology can be the foundation of creating defensible strategies for firms." Driven by the need to compete more aggressively and efficiently in global markets, new ways of doing business has emerged, including shared responsibilities and programs restructuring, buyouts, and takeover campaigns, and various forms of online collaborative and joint venture arrangements. Studies have indicated that levels of companies' investments in technology may explain international differences in productivity and in shares of world markets.

In contrast to the disciplinary tradition of MOT, Canadian healthcare researchers have yet to pay attention to the more recent work on MMT. In an attempt to develop a new intellectual space, Geisler and Heller (1998a, 1998b) were among the first to suggest the application of the TM construct to the healthcare field. The scope of MMT advocated by Professor Eli Geisler encompasses both clinical and administrative technologies (and functions) of the healthcare system. The premise is that owing to economic pressures, the health services delivery system is in crisis unless it can further, and more substantially, benefit from the increasing role that technology has played. It is, therefore, argued that proper and better management of medical technology is critical in overcoming the challenges faced in future healthcare. Even so, the terminology and constructs in the MMT field are still poorly understood due to varied interpretations of the individual components of these constructs and the lack of commonly accepted definitions of the constructs. Before measures for these constructs can be established, Geisler (2000) argued that clear definitions and indicators have to be determined.

THE HCTM Construct

"Health", as defined by the WHO, refers to a state of total physical, mental, and social well-being, not just the absence of disease or infirmity. It is now recognized that population and individual health has many determinants not traditionally associated directly with the healthcare system. Correspondingly, the concept of "healthcare technology" includes applications of know-hows, methods, tools, and techniques that influence the environment, health information dissemination, healthy lifestyle, care protection, and disease prevention. It goes beyond technologies applied in modern acute care systems or for direct medical care. In this context, it applies broadly to facilities, information, devices, processes, and drugs, from the simplest to the most complex, along the entire continuum of healthcare. Technologies that may contribute to quality or sustainability of healthcare systems could be associated with direct patient care, infrastructure, or business processes. It seems, therefore, appropriate to refer to the management of these various and diverse forms of technologies as HCTM.

Notwithstanding, our content analysis of current MOT literature leads to the conclusion that there still is no commonly accepted definition of the TM construct, much less the HCTM construct. On the one hand, Anderson (1993) infers that the lack of agreement on a definition might be a barrier to the growth of the TM concept even though it is expected that a set of favored definitions will emerge over time. On the other hand, there has been some agreement that MOT is a multi-faceted discipline, linking engineering, science, and management concepts and theories in a holistic, systematic, and integrative fashion, and that TM should shape and support organizational strategic goals and objectives.

Following a comprehensive review of the literature across several industry sectors, we found that the multi-faceted TM concept yields a number of general but important observations (Eisler, 2002): (1) TM forms the basis for a technology strategy; (2) TM is characteristic of a technology-ready organization; and (3) TM encompasses the responsibilities and capabilities of the chief technology officer (CTO).

1. TM forms the basis for a technology strategy; the technology strategy is based on:

- The competitive environment, the organization, and technology; consideration of firm-specific factors, environmental factors, and customer preferences; creation of strategic advantage, technological expertise, the decision-making process, and organizational capabilities; comprehensive rethinking and readjustment of job descriptions, information systems, organizational structure, incentives, and decision-making processes; and
- Corporate objectives identified; organizational structure is one of the most important issues; policies hold together a decentralized, virtual workplace with direct access to global information; in addition to flexible organizational structures, management emphasizes information flow, incentives, and different performance assessment schemes;

centralization versus decentralization is one of the single biggest organizational issues.

2. TM is characteristic of technology-ready organizations; technology-readiness strategy is characterized by:

- Top management vision, foresight, and entrepreneurial spirit; leadership is the most critical aspect; commitment to knowledge acquisition rather than product development; alignment with strategic planning and integration of related functions; management must know what it wants, given the difficult-to-quantify costs and benefits of new technologies and attributes like flexibility; set the goals, understand the product/market interactions, being clearly aware of resources, constraints, and risks;
- Decisions and attitudes are based on analysis of competitive position, market intelligence, technical preferences of customers and internal capabilities; focus on the customer replaced organization-centered approaches; emphasis is on market pull rather than technology push;
- Management systems focus on an integrated enterprise; coordination across functional boundaries has priority over efficiency-driven divisions within functions; cross-functional approaches facilitate convergence of divergent views between technical- and marketing-oriented individuals; full and meaningful worker and customer participation in the production process is assured; and
- Process management has replaced product management; focus is on flexibility, adaptability, responsiveness, and effectiveness rather than efficiency and costs; competitive advantage comes from technology and strategy, not from savings in labor costs; able to change, to adapt, and to avail itself of new opportunities; effectiveness is considered with efficiency.

3. TM encompasses the responsibilities and capabilities of the CTO; characteristics of the CTO include:

- Being responsible for visionary leadership, organization, funding, alignment with objectives, bridging between and among operational units, planning, resource allocation, development of standards, rapid reorganization when necessary, leading adoption and implementation of fundamental organizational change; must also be steward of inter-networked leadership, be close to the business front line, and build an invisible enabling infrastructure;
- Assures that promises made on behalf of technology are kept; builds a viable, productive, and flexible technology asset base; gets back to basics and delivers the goods; takes responsibility for managing technology-driven organizational change, for learning what can be done and how to apply it, and for acting as a change champion; and
- Capabilities include managing in an environment of decentralized decision making with a high level of inter-functional coordination; must have commitment, technical competence; capable of skills to effect and manage change; conversant in business and organizational matters, as well as with technical information; understands the importance of systems that provide a competitive edge and the need for systems that support the goals of the organization.

RESEARCH METHODOLOGY

The study reported here was conducted in three phases. Phase I, content analysis, concentrates on identifying the constructs and related critical MOT capabilities and attributes. Phase II, the instrument development, emphasizes the selection of items, expert panel review, and metric refinement and validation. Phase III, the national survey, involves the administration of the field-tested instrument via a Web survey of hospital executives.

Phase I: Content Analysis

A rigorous content analysis was used to develop and contribute to a definition of the TM construct and to identify related critical MOT capabilities and attributes. Lewis (1993) refers to the methodology of "content analysis" as a "common technique employed in the social sciences to draw inference from text; it is executed by objectively and systematically extracting attributes from written communication and by analyzing those extracted parts". Essentially, a broad and comprehensive review of both published and unpublished sources forms the basis of this methodology[3].

Definition of the TM Construct

The database of 255 articles and dissertations was searched for the sampling unit "defin*" (for definition) in its abstract or full text, to locate discussions of the definition of "technology management". Thirty such articles were found, which were in turn scanned to eliminate those that did not in fact discuss or contain a definition, leaving seven articles. Although only one dissertation contained the root word "defin*" in its abstract, eight more dissertations with discussions about the definition were located by detailed reading of 47 dissertation abstracts.

A summative definition of the conceptual TM construct emerged from this exercise:

Technology management can be defined as a holistic and integrated application of engineering, science, and management capabilities to strategic life cycle management of new and relevant product and process technologies in order to shape as well as accomplish the goals and objectives necessary for organizational success.

From this definition, a schematic diagram for the TM Framework emerged, as shown in Figure 1. Organizational success in healthcare could, for example, be expressed as improved patient care within given resources or as protection of the principles of the *Canada Health Act*.

Phase II: Instrument Development

TM is a complex, multi-faceted process with interlinked activities, clearly containing more than one indicator. Following an abstraction ladder approach to metric development, the goal was to create a hierarchy of major dimensions, of variables that described the dimensions, and of indicators that gave shape to the variables. The measurement instrument itself was constructed from an exhaustive list of individual attributes, which were the result of the literature content analysis.

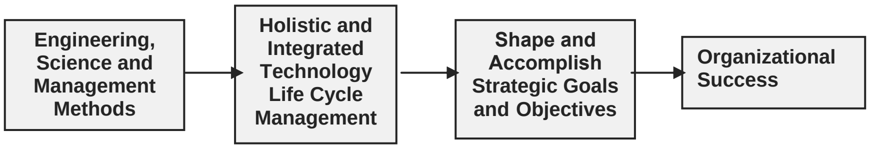
A long list of indicators was initially formed. These were grouped and regrouped iteratively until an intuitively sensible and comprehensible list of 26 indicators emerged. The list of indicators was far more detailed than similar reported attempts in the literature, although it became apparent that the indicators could be grouped into variables comparable in name to ones referred to in the literature.

The Pilot Test

Using the Delphi approach, senior healthcare administrators and management consultants were asked to rank and validate the attributes of the HCTM construct from the perspective of Canadian teaching hospitals with a focus on the responsibilities at the corporate or executive level. This pilot process constituted an expert panel review and a more specific content validity assessment.

In order to qualify as expert, an individual had to have been involved in healthcare management at senior levels for more than 10 years. Their collective professional backgrounds were to cover

Figure 1. Technology management framework



technical, administrative, and patient care arenas. They were provided with a draft survey and were asked to critique it from the perspectives of clarity and understandability. These experts were also asked to recommend unambiguous descriptors for the state of implementation of each statement category in the survey. The positions held by these experts at some point in their career were: Deputy and Assistant Deputy Minister, CEOs, VPs, and CIOs of hospitals, Directors and Executive Directors of Canadian health industry organizations.

The experts were informed about the national character and the expected target audience of the study. They were presented with the prototype questionnaire including 42 indicators, and were asked to:

- Complete the survey keeping any familiar large healthcare organization in mind:
- Identify if and how specific statements should be altered;
- Add statements that they thought were important but not included;
- Express concerns they may have about the appropriateness of the three main domains and the categories within each domain of the survey; and
- Identify examples of additional real and practical evidence or indicators that could be used to support statements about the extent of implementation in the various categories (strategic plans, job descriptions, budgets, etc.).

At this stage, the objective was to test the comprehensiveness and comprehensibility of the metric.

The Field Test

For further refinement of the HCTM metric, a field test was undertaken, incorporating feedback from the pilot study. It was targeted at institutions that would not be included in the survey of teaching hospitals. Senior managers of four regional referral organizations, who represented a variety of administrative responsibilities, participated.

The CEOs of four medium-size BC health service organizations provided the e-mail addresses of their executive teams and the individuals reporting to the executive team members (VPs, CEOs). A total of 64 senior managers, representing eight different areas of responsibility, received a cover letter serving as the consent form designed and based on recommendation of the respective Human Investigative Committees (HICs) as well as the survey instrument. With 33 responses from 64 individuals on the e-mail list, overall response rate was 52% and varied between 43% and 64% for the four participating institutions. As in the pilot test, respondents were asked to comment on content, wording, and structure of the instrument. No changes to the instrument were suggested. The importance of the HCTM topic itself was confirmed by a consistently high average rating from each organization. On the 6-point Likert scale, average ratings for each organization ranged from 5.6 to 5.9, where 5 means “great importance” and 6 means “very great” importance.

In addition to the Likert ratings for each indicator, a single measure was established to capture each respondent's perception of the "gap" between the ideal extent of implementation (reflected in a rating of 6 on the Likert scale) and perceived extent of implementation (1 to 6 rating) for each of the 26 indicators. Gap scores were weighted using the respondent's assessment of the importance of the respective indicator.

The result is a new variable (Gap Score) calculated by the formula:

$$GS = (6 - E) \times B,$$

where

GS = gap between ideal and perceived implementation
6 = ideal implementation rating
E = rating for perceived extent of implementation
B = rating for the perceived benefit/importance of implementation

A Gap Score (GS) was therefore calculated for each respondent. The term (6 – E) can be interpreted as an indication for "room for improvement", as an E score of "6" would indicate full implementation. The factor B becomes a weighting factor relative to the perceived importance of the item. For example, perceived full implementation of an indicator would yield a gap score of zero: $GS = (6 - 6) \times B = 0$.

A rating of "1" (meaning: not at all) for implementation would yield the highest gap score if the indicator was also rated as "6" for importance (meaning: very great): $GS = (6 - 1) \times 6 = 30$.

The possible range for gap scores was, therefore, 0 to 30. An average gap score (average of responses from a particular organization) of less than eight for an indicator was interpreted to mean that this indicator had been implemented to a high level and would not require additional attention for improvement. This could be either because the indicator had been well-implemented (rating of 5 or 6) or because the importance was rated lower than other indicators (4 or less). Field test results indicated that the resulting metric and the gap score measure seemed to capture differences in perception between senior managers from different organizations with some consistency.

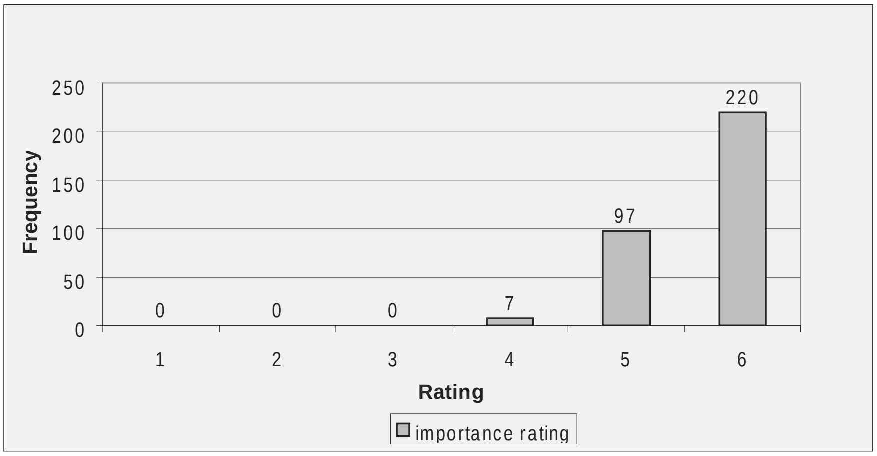
As summarized in Table 1, responses from organizations 1 and 2 did not result in an average gap score of less than 10 for any of the 26 indicators in the metric. Results of the pilot test on the individual indicators (numbered 1 to 26) for computing average gap scores are shown below. For example, organizations 1, 2, and 4 had average gap scores of 15 to 19 on 8, 10, and 6 indicators respectively, while none were recorded at the higher gap score for organization 3.

One could also interpret Table 1 as indicating that, compared to organization 3, organizations 1 and 2 are not performing well in the eyes of their senior managers. Also, senior managers in organization 4 have a less consistent view of their organization's performance. organization 3 seems to have reached a high level of HCTM

Table 1. Distribution of indicators by gap score range

Average Gap Score Range (high, low)	**Indicators**			
	Organization 1	**Organization 2**	**Organization 3**	**Organization 4**
6 - 10 (low)	none	none	1,3,10,11,12,13,14, 20,21,22,24	2,3,4,6,10,14,16,2 5
15 - 19 (high)	4,8,15,19,20,21,26	3,4,11,13,17,18,2 1,23,25,26	none	9,13,18,19,23,26

Figure 2. Topic importance rating



performance. Coincidentally, organization 3 was nationally recognized for its quality management system.

Phase III: National Survey Administration

The resulting survey design was influenced by the choice of a Web-based delivery system. The survey was presented in a logical sequence according to the overall model laid out for participants in the cover letter. Given that the target audiences for the survey were highly experienced and knowledgeable individuals, it was deemed unnecessary and probably not helpful in this study to scramble the sequence of the statements.

The Executive Committee of the Association of Canadian Academic Health Organizations (ACAHO) had enthusiastically endorsed this research and acknowledged its importance. Executive members, the CEOs of some of Canada's largest teaching hospitals, shared the view that HCTM approaches in the Canadian healthcare system could and needed to be strengthened. Their support and active promotion of this project presented an invaluable opportunity to attract participation from senior managers in Canada's teaching hospitals. Following the decision of the ACAHO's Executive Committee, which included the CEOs of six of Canada's largest healthcare organizations and ACAHO's Executive Director, to sponsor this survey, letters were sent to the CEOs of member organizations asking for their organization's participation.

The list of ACAHO member organizations was compared with the list of organizations ranked by a number of "technology intensive beds" from the Canadian Health Assotiation guide. This list indicated that ACAHO member organizations provided a national target audience of the majority of highly technology intensive organizations. It was felt that the senior managers of these organizations were best positioned to assess HCTM practices in Canada.

The Web-Survey Procedure

E-survey was chosen in this study because:

- Senior hospital administrators are expected to have access to Web-based technology.

- The spirit of the HCTM topic warrants an application that would better serve the customers; speed of data collection, convenience for the recipients, ease of data handling and online data analysis are among the key influencing factors on making this choice.

Interestingly, the most time-consuming aspect of the process was determining and iteratively correcting hundreds of e-mail addresses. The process of developing and posting the survey on the Web involved a number of additional steps. The e-survey content was developed as a MS Word document, including all associated notes and rating scales. The Web pages with forms to accept data input were designed with Dreamweaver 4.0 Web design software.

The decision to design the Web-survey tool rather than to use purchased software was based on the ability to design a more professional look and the need to create data files of submitted responses that could easily be exported directly into MS Excel program for convenient storage and rapid analysis. The e-survey was tested internally and

externally before it was posted live on the British Columbia Institute of Technology (BCIT) server via the BCIT School of Health Sciences Web site. It was sent electronically with the cover letter allowing convenient links to the e-survey URL to hundreds of senior managers for whom e-mail addresses had been secured and verified.

Finally, a "thank-you" page was generated and sent automatically upon receipt of a survey response to the Web server. Participating organization and individuals were assured of the privacy of their identities and that any published reports would not identify and link organizations, individuals, or responses.

RESEARCH RESULTS

Owing to space limitation, issues of instrument validity, consistency, and reliability are only highlighted here prior to discussing the study results[4].

First, content validity was optimized through the iterative process in which the instrument was developed. Content analysis informed the metric development and expert opinions in pilot and field test stages refined the instrument.

Furthermore, validity and reliability of the metric was strengthened through:

Table 3. Gap score differences between clusters 1 and 2

Indicator	Difference	% Difference	Cluster 1	Cluster 2
7	0.61	6.54	9.33	8.73
22	0.80	7.46	10.73	9.93
10	1.24	13.15	9.43	8.19
9	1.53	13.53	11.31	9.77
25	1.89	14.26	13.25	11.36
17	2.00	15.85	12.62	10.62
8	2.34	16.03	**14.60**	12.26

4	5.71	48.15	11.87	**6.15**
3	7.29	56.42	12.92	**5.62**

- Supporting the instrument development process with a comprehensive literature review and content analysis (face/content validity);
- Refining the metric based on initial faculty suggestions and on comments and suggestions received from experts in the two-stage pilot and field testing (content validity);
- Clustering items on the instrument following expert panel review on its content as well as on comprehensibility, understandability, clarity, and structure of the instrument (construct validity);
- Factor analyzing responses during repeated testing of the instrument for key dimensions (construct validity); and
- Triangulating the results via a comparison of findings with a performance review of the same institutions using a completely different metric, which was conducted completely independently (concurrent validity).

Last, the Cronbach's alpha coefficient was also computed to determine internal consistency of the metric. It was applied to each of the dimensions resulting from the factor analysis. The reliability of the instrument was assessed for each of the indicators according to the factors established by the factor analysis. Reliability was high for all indicators with alpha ranging from 0.79 to 0.94.

Survey Responses

Thirty-three ACAHO member organizations were invited to participate in this project. The offices of the CEOs invested considerable energy in putting these lists together. In the end, approximately 850 individuals in 28 organizations received the survey; of these, 324 individuals responded, representing an average response rate of approximately 38% per participating institution with a range of 24% to 58%.

As noted, owing to privacy and confidentiality concerns, participating organizations were coded from 1 to 33. This is how the individual organization will be identified for the remainder of the discussion. For example, organization 1 submitted 36 responses, reflecting a 33% response rate relative to the number of senior managers who received the survey. Of these respondents, six executive members had patient care responsibilities (VP Nursing, VP Medicine, etc.) and seven did not (VP Finance, VP Support Services, etc.). Of the responding managers reporting to VPs, eight had patient care responsibilities and 15 did not. The respondents were first asked to rate the importance of the topic of the survey (1 indicates "not at all", 2 indicates "very little", 3 indicates "little", 4 indicates "some", 5 indicates "great", and 6 indicates "very great"). As indicated in Figure 2, 317/324 = 98% rated the topic's importance as great or very great. No respondent rated the importance at less than 4 (some) on the 1 to 6 rating scale.

One of the key questions to be answered by this research was the ability of the metric to differentiate between organizations relative to their HCTM approach. As no significant differences in gap scores between the categories of respondents were found, it indicated that all responses from the same organization could be grouped for the purpose of testing for significant differences between organizations. The 20 organizations that supplied five or more responses were included in this part of the analysis. Based on ANOVA and the resulting p-values, significant differences ($p < 0.001$) was found in the way in which senior managers across the 20 organizations perceived the state of HCTM in their organization. This suggests the need to further investigate the possibility that senior managers with direct patient care responsibilities responded differently from those that did not have direct patient care responsibilities. The same applies to the question of whether executive team members (VPs, CEOs) would respond differently from those senior managers reporting to VPs.

Table 4. Indicator distribution

Gap score quartiles	Cluster 1 indicators	Cluster 2 indicators
6.0 - 8.4		**3,4,12**,10,
8.5 - 11.0	12,10,22 1	6,14,11,24,6,1,9,13,22,18,20,26,17,21
11.1 - 13.5	9,14,24,16,11,4,6,5,20,3,21,25,2,1 2	,15,23,25,19,8
13.6 - 16.0	18,15,13,23,**8**,**19**,**26**	

Factor analysis was applied to identify variables that reflect some common underlying factor or dimension. Table 2 shows three underlying factors (or "latent variables") on which the 26 indicators "loaded": (a) strategic management; (b) management of change and innovation; and (c) organizational management.

Cluster analysis was used to group "like" hospital organizations based on their responses ("like" based on indicator gap scores) to optimize the comparison and identification of differing HCTM practices and capabilities. A practical three-cluster solution resulted out of the 20 organizations with more than five responses:

- Cluster 1: Organizations 1, 2, 3, 5, 6, 7, 9, 11, 13, 14, 17, 18, 19
- Cluster 2: Organizations 4, 8, 10, 12, 16
- Cluster 3: Organizations 15, 20

Testing for significant differences in-between clusters indicated that there was a statistically significant difference ($p < 0.01$) between the cluster mean gap scores for each of the three dimension variables. Since cluster 3 consisted of only two institutions with comparatively fewer responses, further comparative analysis was focused on the differences between clusters 1 and 2. The significant differences between the two clusters of organizations, based on senior managers' perception, are influenced by some variables more than others.

Table 3 lists the 26 variables in the survey in the order of the percent difference between cluster 1 and 2 mean gap scores. As illustrated, it shows that the average gap scores for each and every indicator were lower for cluster 2 organizations. Percent differences range from 6.54% to 56.62%. The two indicators 3 and 4 with the highest percent difference were also the ones with the highest variability on a national basis.

The data revealed what constituted the major difference among managerial responses between the two clusters of organizations. On the one hand, cluster 2 managers rated their organization very highly (low gap score) in the following three areas:

- Indicator 3: Executive member formulates technology strategy
- Indicator 4: Executive member administers/ manages technology strategy
- Indicator 12: Senior management promotes organizational vision/direction

On the other hand, cluster 1 managers rated their organization particularly low (high gap scores) in the areas:

- Indicator 8: Technology linked to customer needs
- Indicator 19: Organization has strategies to respond to change
- Indicator 26: Performance due to technology management evaluated

Table 4 portrays the distribution of indicators in the four quartiles of the gap score range.

Apparently, cluster 1 managers rated none of the indicators in the lowest quartile of gap scores compared to four indicators for cluster 2 managers. In contrast, seven indicators were rated in the highest quartile for cluster 1 as opposed to none by cluster 2 managers. It is interesting to note that indicators 8, 19, and 26 were also the ones that were deemed to need the most attention based on the overall national average. They also top the list of indicators needing attention in cluster 1 organizations. The largest differences in reported perception based on implementation ratings and gap scores between cluster 1 and cluster 2 managers related to indicators 3 and 4 of our HCTM model.

It can be concluded that the resulting metric is able to distinguish between differences in perception by senior managers about their organization's HCTM standard. Significant differences between clusters of organizations can be identified consistently across all three dimensions of the HCTM construct. In particular, the perceived presence of "Chief Technology Officer" roles in the organization seems to contribute strongly to the differences in mean gap scores between clusters. Other "strategic management" and "change management" variables seem to be perceived as being implemented to a greater extent in cluster 2 institutions. Improvements seem to be possible along all three dimensions.

The Hay Group Study

As indicated, the purpose of studying HCTM status is to assess its impact on health organizational performance in terms of alignment of IT goals with the strategic business goals and objectives of the organization. For a private sector organization, this may be expressed as competitive advantage, market share, profit, return on investment, or other such measure. What would be the metric that would indicate organizational "success or survival" of our study hospitals? What difference would it make that one cluster of hospitals seems to manage technology better than another cluster?

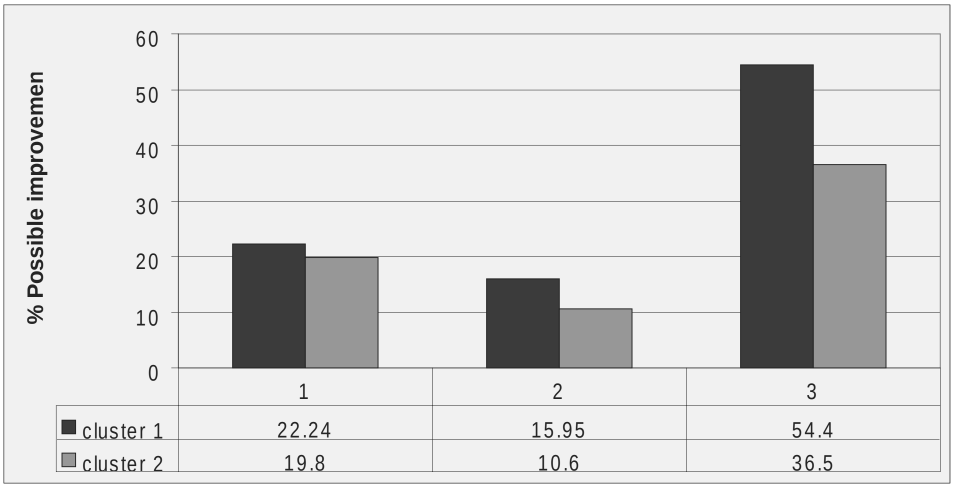
Fortunately, ACAHO provided independently generated information about operational efficiency and clinical efficiency of the same study hospitals (and others not included in the study) on a confidential basis. The Hay Group in Toronto compiled the data in an annual report entitled Benchmarking Comparison of Canadian Hospitals. The Hay study was commissioned by the hospitals in an effort "to improve the efficiency, effectiveness and quality of their care processes". The comparisons were based on CIHI hospital separation data, on accounts and statistics reported to Ministries of Health, and other data provided by the hospitals.

In order to determine if there was any association between the HCTM performance of the two clusters of hospitals identified in this study and other measures of performance, the Hay study outcomes for the same two clusters were analyzed. The following two summary measures, as defined in the report, were used:

- The measure for the overall clinical efficiency of a hospital is the percentage of inpatient days that can be reduced if a hospital were to achieve benchmark levels of performance. The smaller the percentage, the more efficient the hospital.
- The measure for the overall operational efficiency of a hospital is the potential reduction in operating cost to the 25th percentile performance, including direct care, administrative, and support functions. Subject to some caveats, the hospital with the smaller potential reduction can be considered more efficient with respect to the areas examined in these comparisons.

If an average gap score of 6 (over all responses and all indicators for each organization) was considered as the benchmark target, the potential HCTM improvement could be calculated and

Figure 3. Hay study comparison



expressed in terms of potential percent reduction. This measure was used in the comparison. As demonstrated in Figure 3, the Hay study comparison results provided independent validation of our findings with respect to organizational performance of the two clusters of hospitals studied and, at the same time, provided support of the concurrent validity of our HCTM metric.

CONCLUSION

Altogether, there has been recurring and increasing interests between both the academic and practitioner communities about the potential impact of HCTM on healthcare organizational performance. Like the management of other key strategic resources, such as health human resource and financial resource management, HCTM should and could become a more easily understood concept and its impact more conveniently assessed. In the past, the role of IT in healthcare has been poorly understood. Technology innovation, in particular, has sometimes been portrayed as a key contributor to escalating healthcare costs, as an expensive clinical tool that is primarily driven by some key decision maker's interest, or as a "hype" promoted by a vendor with few benefits but many empty promises. If it really is to support the goals and objectives of the healthcare system, IT in healthcare has to be better managed. This study contributes to a more systemic approach to understanding and even measuring the impact of IT in healthcare and has generated new knowledge about appropriate HCTM practices in teaching hospitals.

The study used a cross-sectional survey involving cluster sampling. The target sample was representative of senior administrators in the Canadian healthcare system as it comprises executive team members of the 40 largest Canadian teaching hospitals. Selected individuals from this group responded to a newly developed HCTM metric. Factor analysis and cluster analyses were the two key statistical inference methods applied to the resulting data set. Major clusters of respondents were those associated with individual organizations. These responses were analyzed to identify systemic differences in HCTM practices among different clustering organizations. For in-depth analysis of the data, the Analysis of Variance (ANOVA) technique was applied. It assumed that respondents from within each organization could be treated as one cluster. Unfortunately, field test analysis was inconclusive on this question due to limited sample size. Yet, the outcome of this study provided new thinking on HCTM, a theoretical contribution to the advancing fields of MOT and MMT. It also recognizes and bridges a multi-disciplinary science base with the broad modern concepts of healthcare, technology, and management.

This study, however, did not develop a new definition for the construct "technology". Rather, the perspective of technology as an *extension of human and organizational ability* was adopted from the literature. Based on an extensive literature content analysis, the study does propose a new definition and a theoretical model for the HCTM construct. The major critical dimensions of the HCTM metric include: (a) strategic management factors; (b) management of change and innovation factors; and (c) organizational management factors. Interestingly, two indicators (Indicators 3 and 4 of our metric) focus on the function of a chief technology officer (CTO) were found to be the largest differences in reported perception based on implementation ratings and gap scores between high performing and low performing teaching hospitals. Indicator 3 states: "A designated member of the executive team is responsible for the formulation of the organization's technology strategy" while Indicator 4 states: "A designated member of the executive team is responsible for the administration and management of the organization's technology strategy." This result strongly confirmed the message from the literature about the necessity of executive attention and leadership for HCTM. Along with providing leadership, coordination, and facilitation, the responsibilities of the CTO include such activities as gatekeeping, advocacy, funding, sponsorship, policy and procedure development, promotion, capacity building, and overseeing the technology management system. Not all hospitals have a CTO, in which case the responsibilities discussed here are either taken up by the CEO or, more likely, delegated to someone else such as the chief financial officer or chief operations officer. This person's job is to understand the strategic business issues, the customers, and the technology. She or he should be an effective leader and command the respect of his or her employees, managers, and peers. Our finding implies that a good CTO is key to differentiating among clustering organizations as to their HCTM status.

Another set of indicators that were shown to be critical for poor performing hospitals and presented the highest need for improvement on a national, system-wide basis is the set of Indicators 8, 19, and 26. Indicator 8 states: "Technology is linked to clearly identified customer needs and priorities." Indicator 19 states: "The organization has strategies to respond flexibly and rapidly to technological change." Finally, Indicator 26 states: "The organization's performance as a function of TM activities is routinely evaluated and benchmarked." A high gap score on Indicator 8 implies a lack of ongoing access to information about current and future needs and priorities of customers and staff. Indicator 19, similarly, addresses how quickly the organization responds to shifts in technological trends. A high gap score here implies that the organization ignores "market pull" strategies as part of its customer-relations policy, essentially going along with a "technology push." Product development times, innovation cycles, and overall cycle times for putting ideas and innovations into practice are longer than expected relative to industry norms. Lastly, a high gap score for Indicator 26 implies a lack of systematic performance reviews for different aspects of HCTM. These might include their impact on overall organizational goals, objectives, and customer service, including, for example, annual performance evaluations of the executive fulfilling the CTO role. Apparently, our results tell us that poor performing hospitals must pay particular attention to these factors.

Moreover, these results are very similar to the issues raised regarding patient safety and how it is to be enhanced given the recent dramatic increase in literature on this topic. TM and HCTM principles identified here are almost identical to the governance requirements in high reliability industries (aviation, nuclear power, etc.) which are also technologically intensive. Indeed, lack of thoughtful adoption and use of technology is a major factor identified in the patient safety literature. Thus, the lessons learned from this research could have a direct bearing on approaches to enhancing patient safety in healthcare settings.

In summary, our findings indicate that there are key differences in HCTM sophistication among Canadian teaching hospitals. Major differences occur in areas of strategic technology management, followed by change management, and, to a lesser extent, organizational management. The perceptions of senior managers are not significantly influenced by their area of responsibility relative to patient and non-patient care, or by their position in the reporting structure. Improvements are needed generally in all areas addressed by the HCTM metric. A further question relates to the impact of HCTM sophistication on organizational performance and success. This study was able to explore, to some extent, the relationship between clinical and operational efficiency and HCTM performance. It did not address the more strategic impact of HCTM performance on customer satisfaction and customer service levels relative to customer needs.

Future Research

This study built on earlier research in the areas of MOT and MMT. An outcome of this study is the enhancement and the expansion of the current research agenda for the MOT and MMT disciplines. Research in this area should be focused on development of more specific measurement items, refinement of the measures and applications of these measuring tools. For example, an expanded application of our HCTM metric is to go beyond teaching hospital settings.

Another stream of research could further explore the metric relative to particular health systems issues at national, provincial, and institutional levels of management. While knowledge could undoubtedly be expanded in each of these facets, some examples of priority research questions for HCTM metric refinement include:

- Who are the customers in healthcare, what are their needs, and what order of priority is attached to those needs?
- There has been mixed success with the HCTM as a *tactical* resource, what particular challenges arise out of *strategic* HCTM?
- While senior managers in teaching hospitals provided their perspectives on HCTM; how can IT contribute to clinical and operational efficiencies, quality and levels of care, and customer satisfaction?
- The study results are based on perceptions of senior managers. How can follow-up case studies be designed to compare perceptions with reality?
- Case studies would also be useful with respect to the real, rather than perceived, differences between some cluster 1 and cluster 2 hospitals. To what extent are CTO functions explicitly established, given the large difference in perception between the clusters on this point?
- The Web-based survey approach was very successful. Language and design decisions, however, did impact on response rate. Participants had to complete all questions. They had to choose a rating between 1 and 6. Some would have preferred an “N/A” or “don’t know” category. Translation into French might have generated more responses from Quebec.

Moreover, the metric could be used to probe into the strengths and weaknesses of an individual institution. A case study with full management and staff participation would allow further statistical validation of the instrument. The motivation for undertaking this study was that in Canada's healthcare organizations, technology was not managed well enough, neither tactically nor strategically. The CEOs of some of Canada's largest teaching hospitals expressed support for this notion when they agreed to promote and support this study among their peers. Of the 324 surveyed senior managers, a vast majority of 317 confirmed the importance of HCTM for Canadian healthcare managers by rating it as "great" to very great (between 5 and 6 on a 6-point scale), the remaining managers rated it as being of "some" importance (rating 4).

Finally, other key research questions emerging from this study are issues related to the definition and identification of customers, customer groups, and customer needs in healthcare. Organizations like teaching hospitals are faced with competing customer interests (provincial services, community services, research, and education services). Resource planning of any kind, human, technology, or financial, is difficult under circumstances where the primary customers and their needs are not well-defined. Lately, with the emergence of e-health, a whole new scenario of customer/consumer relationships is unfolding with significant implications for providers and agencies of healthcare services (Tan, 2005).

Chapter 6.16
Applying Strategies to Overcome User Resistance in a Group of Clinical Managers to a Business Software Application:
A Case Study

ABSTRACT

User resistance is a common occurrence when new information systems are implemented within health care organizations. Individuals responsible for overseeing implementation of these systems in the health care environment may encounter more resistance than trainers in other environments. It is important to be aware of methods to reduce resistance in end users. Proper training of end users is an important strategy for minimizing resistance. This article reviews the literature on the reasons for user resistance to health care information systems and the implications of this literature for designing training programs. The other principles for reducing resistance (communication, user involvement, strategic use of consultants) are illustrated with a case study involving training clinical managers on business applications. Individuals responsible for health care information system implementations should recognize that end user resistance can lead to system failure and should employ these best practices when embarking on new implementations.

INTRODUCTION

Traditionally, health care has lagged significantly behind other industries in the use of information technology (Parton & Glaser, 2002). The use of computers in health care has up until recently been primarily to automate the business and administrative functions. Today, a variety of pressures are forcing the health care industry to invest more money and effort into using information technology in clinical settings. New legislation to protect privacy and confidentiality of medical information encourages the development of electronic medical records (US Dept of Health and Human Services, 2002). Concerns over medical errors have led to an increased interest in clinical decision support systems and computer-based physician order entry (Bates et al., 1999; Leapfrog Group, 2000). These developments will lead to more need for direct use of computers by health care providers who are used to manual processes for the same tasks. In addition, many clinicians are now assuming managerial positions in health care where they will be expected to use traditional business applications as well (Merry, 1999). Not only are these new managers not used to automating some of these tasks, but as clinicians, they have not seen use of the computer as part of their professional role. As a chairman of a clinical department once said, “What do I have a secretary for?”

The reluctance to use the new systems may be perceived as resistance, or in fact there may be real resistance to the changes that information technology makes in the clinical work processes (Worthley, 2000). In either case, administrators, information technology personnel, or clinicians charged with promoting the use of information technology in the health care environment may encounter more resistance than is found in other environments, so added to the issues of training end users that are common across a variety of settings, health care project managers also need to be aware of methods to reduce resistance in end users (Kaplan, 1997).

User resistance is a common occurrence when new information systems are implemented within a health care organization. There is also a sizable amount of literature on health care system implementations to explain and give insight into some of the reasons behind this resistance and to suggest strategies for overcoming it (Ash et al., 2000; Jiang et al., 2000; Lauer et al., 2000; Lorenzi & Riley, 1995; Lorenzi et al., 1997, 2000; McNurlin & Sprague, 1998; Worthley, 2000). The principles advocated in these studies can be used to develop a variety of end user training programs in health care settings. We will discuss this literature and the implications for design of training programs and will illustrate the application of these principles with a case study that involved training clinical managers on business applications.

POSSIBLE EFFECTS OF USER RESISTANCE

When computers were first introduced into the health care setting, the technical issues were the most important to address, but as Lorenzi et al. (1997) discuss, now that many technical issues have been solved the managerial, organizational and “people” issues are equally, if not more, important. Worthley (2000) attributes the failure of many system implementations to the failure to properly address user resistance. He discusses five different forms that resistance can take: sabotage of computer equipment; employees being absent or late to work; “badmouthing” the system, not using the new system and continuing to use the old system; and data tampering (Worthley, 2000, p. 170).

REASONS FOR USER RESISTANCE

Kaplan (1997) discusses some of the causes of resistance to information systems. She mentions “user-centered” theories, which “consider resistance to be due to factors inherent in users, such as their lack of knowledge or their reluctance to change" (Kaplan, 1997). Other researchers have also identified resistance to change as a significant source of implementation problems (Ash et al., 2000; Brown & Coney, 1994; Jiang, Muhanna & Klein, 2000; Lorenzi & Riley, 2000; Yaghmaie, Jayasuriya & Rawstorne, 1998).

In addition to resistance to change, both Lorenzi and Riley (1995) and Worthley (2000) discuss some other reasons for user resistance:

- Fear of loss of prestige and status in the organization due to not knowing the new information systems (Lorenzi & Riley, 1995; Worthley, 2000)
- Pressure to develop new skills (Lorenzi & Riley, 1995)
- Pressure of higher performance expectations (Lorenzi & Riley, 1995)
- Fear of loss of social interaction with other workers (Worthley, 2000)
- Historical reasons, such as a previous bad experience with an information technology effort (Worthley, 2000)
- Benefits may not be clear to the user (Ash et al., 2000).

STRATEGIES FOR A SUCCESSFUL INFORMATION SYSTEMS IMPLEMENTATION

Based on this literature review, the following were recurrent themes as strategies to overcome user resistance:

- *Communication* - Several researchers name communication as one of the most important strategies for a successful systems implementation (Jiang et al., 2000; Krishnan, 1999; Lauer et al., 2000; Lorenzi & Riley, 1995; Worthley, 2000).
- *User involvement* – Ives and Olson (1984) found as a result of reviewing over 20 articles that "participation leads to increased user acceptance and use by encouraging realistic expectations, facilitating the user's system ownership, decreasing resistance to change, and committing users to the system."
- *Clarification of benefits* - A strategy discussed by Ash et al. (2000) "is to make sure the system provides immediate benefits to users." Ash et al. suggest that telling the user what the short and long term benefits will be for that individual user will motivate a person to use the system more than telling the user what the overall benefits of the system will be for the organization.
- *Role of consultants* - Consultants can be beneficial in information systems implementation by filling in the experience and knowledge gaps of their clients (Bauman, 2001). By being an outsider, they are not involved in office politics and their decisions are based on what is in the business' best interest, not the best interest politically (Bauman, 2001). Very often a credible outside consultant can get a user to adopt new practices that internal managers have tried unsuccessfully to implement.
- *Training* - Training has been one of the main topics researchers have emphasized as essential to successful information systems implementation (Ash et al., 2000; Jiang et al., 2000; Lauer et al., 2000; Lorenzi & Riley, 1995; Lorenzi et al., 1997, 2000; McNurlin & Sprague, 1998; Worthley, 2000). Both Lorenzi and Riley (1995) and Worthley (2000) advise the use of the "just-in-time" training concept when training users on a new information system. This means that training should occur just prior to implementation. They also suggest training the users in the order they are going to use the system. There is a danger of training users too early and then finding that the users have forgotten

much of what they learned and/or are not as familiar with the product when the actual implementation occurs (Lorenzi & Riley, 1995). This means that the implementation schedule should be carefully monitored and the training plans should be revised if there is significant delay.

Lorenzi and Riley (1995) suggest that training address both technical content and attitudes. "Any training needs to be a combination of educating people in how to use the system plus building their enthusiasm for doing so" (Lorenzi & Riley, 1995). Lorenzi and Riley (1995) and Worthley (2000) discuss the importance of training manuals and online help. Complex systems may require special training, such as training in stages (Lorenzi & Riley, 1995). Breaking up the training will allow the users to get comfortable with one part of the system and may help to build confidence in learning the more complex parts (Lorenzi & Riley, 1995). Researchers have mentioned that physicians may require specialized training (Ash et al., 2000). Physicians "will rarely commit to group training sessions of any length" (Lorenzi & Riley, 1995) and "frequently like to be trained by other physicians" (Ash et al., 2000). One method that Lorenzi et al. (1997) suggest when training physicians on a new system is to design a training program that adapts to their current work styles. One idea is to use "training aids that are prepared on 3x5 index cards because most physicians are accustomed to keeping pertinent information in this manner" (Lorenzi et al., 1997).

CASE STUDY

We applied these principles in designing a training program in the use of the Microsoft Excel application to clinical managers of an outpatient medical clinic. Although all of the principles discussed above in regard to major systems implementation are not applicable to the small case study, many of them are. In addition, many of the same reasons for resistance can be found with small business applications as with large informational technology implementations. Below we describe the background to the request for assistance, the application of the principles in the design of the training program, and the outcomes.

BACKGROUND

Southern Medical Clinic (not its real name) is a multi-specialty group practice started in 1926. Currently, the clinic has been home to several of the physicians for over 20 years. One particular physician has been there for over 40 years, over half of the entire life of Southern Medical. Likewise, the support staff boasts many that have been with the facility for 25, 30, and even 40 years. In health care today such statistics are rare. Southern Medical clinic still operates as a multi-specialty, physician owned clinic. They still use paper medical records, they still house a completely handwritten master patient index, they have a paper card catalogue of all the patient charts, and they even make paper copies of all insurance remittances. For such a facility to continue to thrive, it must not only let technology in the door, but also embrace what technology has to offer, yet it is also to be expected that with such a stable staff there may reluctance to do things differently from the way they have always been done. Southern Medical Clinic has overcome much resistance already. All of the practice management, accounting, HR, claims filing and payroll are electronic. Internet classes are held and spreadsheets have just replaced old handwritten forms. They will soon be scanning all remittance reports to a server, and one department is toying with the idea of electronic medical records. The board meetings now have physicians with pocket PCs and the preferred means of mass communication is e-mail.

The problem that formed the focus for the case study was the reluctance of the clinical department managers to learn to use Excel. The managers had been encouraged to use Excel for a variety of tasks, including documenting employee leave, which they currently monitored manually. They were provided with spreadsheets from the human resources department that they were expected to use. Although a few were interested in learning how to use the spreadsheets themselves, most of the managers were not extremely computer literate and appeared to prefer to calculate the leave manually and ask their secretaries to enter the data into the spreadsheet. Obviously such a practice has a greater opportunity for introducing error and is less efficient than directly entering and calculating the leave with the spreadsheet, yet the managers were not eager to change the system with which they were familiar. It was with this background that the clinic manager requested outside consultation and training for her staff.

APPLICATION OF PRINCIPLES FOR OVERCOMING RESISTANCE

The strategies in the literature review were applied to developing the training program. A strategy discussed by Bauman (2001) was to bring in outside consultants. The trainer did not have any affiliation with the health care organization and did not know any of the clinical managers in the training classes. When preparing the training program, an effort was made to make sure that the users would see the personal benefits of using the program as advocated by Ash et al. (2000). To accomplish this, the training program included examples of some current processes that the managers performed manually and the managers were told that the goal of the training was to work on automating them. Some of the benefits of using the software were emphasized and the managers were told how they would be able to use the software as soon as they went back to work. Another strategy that was incorporated into the training program was based on Lorenzi and Riley's (1995) suggestion to break up the training into stages. There were three training sessions scheduled and each session progressively covered more complex material. Lorenzi and Riley (1995) discussed how breaking up the training in stages will allow the users to get comfortable with one part of the system and help to build confidence in the users when they are faced with the more complex parts.

Prior to taking the Excel training the department managers were required to pass a proficiency test in basic computing and Microsoft Word. Out of the 18 health care managers in this organization who were eligible to take the Excel class, 12 enrolled and 11 completed the class. There were three sessions, each two hours long, completed over a three-week period, with multiple sessions given each week to accommodate small groups of the managers. The training groups were mixed as far as level of computer experience. An evaluation form was developed to get feedback on the teaching and to assess any resistance that the health care managers might have had towards learning and using Excel. The evaluation form was distributed at the end of the final training session. The instructor informed the managers that their employer would not see the individual evaluation forms.

Outcomes

The 11 health care managers completed the evaluation form about the Excel training class. On the whole they were very positive. Over 80% responded positively to nine of the 10 questions. The exception still was positive, in that eight of the managers felt the class was less difficult than they thought it would be and only one thought it was more difficult. What was particularly interesting was that all of the managers agreed that their interest in using Excel was increased (73% responded Agree and 27% responded Strongly Agree), and that they would use Excel in their work (55% Strongly Agree; 45% Agree). The respondents were very positive about the instructor, with all of them interested in taking another class with her. Approximately nine months after the training session, the actual extent of use of the software was assessed. Results showed over half of the trained managers were now using the software. Of those who were not, 18% did not have access to a computer. Twenty-seven percent of the original group of trainees were still resisting using the software.

DISCUSSION

Given the expectation of encountering resistance, it was surprising that during the class as well on the final evaluation this resistance did not appear at all. The training program was designed and developed in an effort to minimize user resistance and appeared to have done so. When designing the Excel training program, the one overall goal, from the perspective of the organization, was for the managers to produce a sick and vacation report in Excel. This is a report that all of the managers were required to do and all were performing this report manually. In the first class managers were told that the sick and vacation report was the overall goal and they responded positively. During the classes, there were conversations about reports and processes that they perform manually and discussions about how they could use Excel to automate some of those other processes as well. The basics of Excel were covered in the first class. In the second and third class, on the focus was working the leave report. Showing the managers how Excel could help automate a time consuming manual report helped to motivate them to use and learn Excel. By being an outsider to the organization, the instructor was not encumbered by any relationships with the users. The users knew that how they did in the training classes was not going to affect how they are evaluated or perceived in their jobs. Thus, using outside consultants to provide a different perspective and increase credibility, designing the program to illustrate personal benefits, and focusing the training on gradually building up confidence in use resulted in very positive evaluations from a group of users perceived to be resistant to learning new technologies.

Although it would be gratifying to think that the attention to evidence-based good practices in instructional design were solely responsible for the positive outcomes, there are other explanations. It is possible that the most resistant users did not take the class, since a third of the eligible managers did not take advantage of the training opportunity. In addition, sometimes users' lack of confidence using a computer system can be perceived as resistance to the system. It may have actually been the clinical managers' lack of confidence using Excel that was perceived as resistance. The training classes may have helped to build their confidence and they realized it was not as difficult as they thought it would be.

CONCLUSION

As health care systems begin to implement new information technology, end user resistance is likely to become increasingly common. There are a variety of reasons for the resistance, but there are also strategies that have been shown to minimize it. These strategies include communication, user involvement and training, with specific focus on increasing user confidence. These strategies can be used with large-scale implementations and can be incorporated within the training programs themselves. Individuals responsible for health care information system implementations should recognize that end user resistance can lead to system failure and should employ these best practices when embarking on new implementations.

APPENDIX: LESSON PLAN FOR EXCEL TRAINING SESSION 1

Introduction

- Define what Microsoft Excel is and what it is used for.
- Excel is a spreadsheet application that allows you to perform quick and accurate calculations on data that are entered into a worksheet. Using Excel also helps to avoid errors and present data in a professional format.
- Discuss how Excel can be beneficial to them in their daily jobs.

Objectives for Session 1

- Learn how to open and create an Excel workbook.
- Be able to identify the components of the Excel screen.
- Learn how to use the menus and toolbars to perform commands in Excel.
- Be able to enter text and values in a worksheet.
- Learn how to close and save an Excel file.

Assignment

- In class, we will create a calorie counter worksheet. This will involve the students entering text and data. They will have a brief introduction to simple formulas. We will use the auto sum function and average function in this assignment. Next session will cover formulas in more detail.

LESSON PLAN FOR EXCEL TRAINING SESSION 2

Introduction

- Question and Answer section from last session
- Review of what we covered in the last session
- Discussion of formulas in Excel

Objectives for Session 2

- Learn how to perform calculations in Excel by the using shortcut formulas and by entering formulas.
- Be able to edit and delete data in Excel.
- Be able to cut, copy, and paste in Excel.
- Learn how to move cells around in Excel using the drag and drop method.

Assignment

- In class, we will begin work on a sick and vacation report that will allow them to apply skills learned from the previous lessons. The report will include entering text, values, and formulas. The objective is for them to use the worksheet in their jobs to keep up with the sick and vacation hours for each of the employees in their department.

LESSON PLAN FOR EXCEL TRAINING SESSION 3

Introduction

- Question and Answer section from last session
- Review of what we covered in the last session
- Discuss number formatting in Excel and how that can change the way values are displayed.

Objectives for Session 3

- Learn how to apply number formats.
- Learn how to format cells using the formatting toolbar.
- Be able to delete and insert columns and rows.
- Be able to change the width of a column and the height of a row.
- Learn how to use the undo function to undo your mistakes and the redo function in case you change your mind and want to redo the action.
- Be able to move between worksheets.
- Learn how to add, delete, and rename worksheets in a workbook.
- Learn how to get help from the office assistant and other resources in Excel.

Assignment

- We will continue to work on the sick and vacation report.

(See Worksheet on following page.)

Excel Training Class **Evaluation Form**

Please circle the response for each that best reflects your opinion. Please write any additional comments or suggestions on the back of this form.

1. The instructor covered too much material in each session.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

2. The sequence of course content facilitated learning about the subject matter.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

3. The Excel class was less difficult than I thought it would be.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

4. The instructor was friendly and easy to talk to.
   ***Student Comment: Helped above class subject for me*.**
   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

5. The instructor delivered the course content clearly.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

6. This class met your objective for what you wanted to accomplish in this training.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

7. I learned more about Excel than I expected.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

8. This course increased your interest in using Excel.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

9. I will use Excel in my work.

   Strongly Agree   Agree   Neutral   Disagree   Strongly Disagree

10. If you had the opportunity, would you take another class from the instructor?
    Yes   No

This work was previously published in Journal of Organizational and Ender User Computing, Vol. 16, No. 4, edited by Mahmood, pp. 37-54, copyright 2004 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of medical informatics, which include maintaining high ethical standards and ensuring that sensitive medical information remains private. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters also address mining biomedical literature, standardization of health and medical informatics, and fuzzy logic in medicine. Overall, contributions within this section ask unique, often theoretical questions related to the study of medical informatics and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1
"Do No Harm": Can Healthcare Live Up to It?

Nat Natarajan
Tennessee Technological University, USA

Amanda H. Hoffmeister
Cookeville Regional Medical Center, USA

ABSTRACT

The healthcare sector is a very important one in many countries and faces numerous quality and performance problems of great significance to all citizens who live there. Although there are many performance parallels between healthcare and other sectors, there are also numerous special issues and terminology, as well. Recent publications on medical errors have put the spotlight on the issue of safety in healthcare. There are opportunities for the healthcare sector to learn from other industries where many techniques and practices for preventing errors have already proved their worth. It is important and beneficial to encourage healthcare specialists to learn from other sectors the concepts, best practices, and tools for preventing errors and improving safety. This chapter addresses the key issues and challenges relating to the management and transfer of such knowledge and places them in the context of quality and knowledge management.

INTRODUCTION

Public spending on healthcare in Germany, France, Canada, UK, US, Australia, and Japan is at least 5% of their respective Gross Domestic Products (GDPs). In the US, UK, Australia, and Canada major health reforms have been proposed (*The Economist*, 2003). The total spending (public and private) in the healthcare sector in the US accounts for roughly 14% of its national income. In the US, the federal and state governments are the largest payers for healthcare services. The last decade has witnessed increasing attention to the healthcare-related issues such as widening coverage for access to healthcare, cost containment, quality of care, and regulation. These issues have been debated in legislative, academic, and professional forums. Issues concerning safety and quality have recently been in the public limelight. Recent publications have increased public awareness of safety or lack thereof in healthcare systems. They are the Institute of Medicine's (IOM) study titled *To Err is Human: Building A Safer Health System* (Institute of Medicine, 2000) and the follow-up report that was triggered by it, *Report of the Quality Interagency Coordination* (QuIC) *Task Force to the President* (Quality Interagency Coordination Task Force, 2000). The second report of the IOM, *Crossing the Quality Chasm: A New Health System for the 21st Century* (Institute of Medicine, 2001) goes beyond safety and identifies other areas where the need for improvement is urgent. Safety is viewed as one of the dimensions of healthcare performance. Effectiveness, patient-centeredness, timeliness, efficiency, and equity are the other dimensions. One of the ten recommended principles to guide the design of health systems is that safety should be system property (Institute of Medicine, 2001). The patient safety issue is not confined to the US. In the UK, a report published in June 2000 estimated 840,000 incidents and errors occur in the National Health Service (NHS) every year (BBC News, 2001).

QUALITY MANAGEMENT IN HEALTHCARE

The traditional approach to quality management in healthcare has relied on licensure, certification and accreditation, and the use of chart review methods. Over the years, a number of organizations have been involved in the development and deployment of these structural quality assurance mechanisms. Most notable are the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), Commission on Professional and Hospital Activities (CPHA), Regional Medical Programs (RMPs), Experimental Medical Care Review Organizations (EMCROs), Professional Standards Review Organizations (PSROs), and Peer Review Organizations (PROs). In one sense, these organizations form the backbone of the regulatory structure of the healthcare industry. Thus, the traditional quality management was externally driven. The positive aspect of this system is that it provides safeguards to the public in terms of standards of healthcare and minimal competence of the healthcare professionals and ensures at least minimal participation of those professionals in quality management activities (Williamson, 1991). Its shortcomings are that it uses the negative incentive of punishment in the cases of non-compliance, and the underlying premise seems to be that sanctions are needed to ensure quality. It does not promote learning. It also involves a lot of paperwork, absorbing time and effort while achieving only modest improvements.

In the last 15 years or so, there have been many instances where the healthcare organizations have used the principles that underlie the industrial quality control model (Chesanow, 1997). These are the principles of total quality management (TQM) and continuous quality improvements (CQI) that have been successfully implemented in the manufacturing sector.

Briefly, these principles can be summarized as follows (Berwick, Godfrey & Roessner, 1990a): (1) productive work is accomplished through processes; (2) sound customer-supplier relationships are absolutely necessary for sound quality management; (3) the main source of quality defects is problems in the process; (4) poor quality is costly; (5) understanding the variability of processes is a key to improving quality; (6) the modern approach to quality is thoroughly grounded in scientific and statistical thinking; (7) total employee involvement is critical; (8) quality management employs three basic interrelated activities: quality planning, quality control, and quality improvement.

There have been many case studies of applications of CQI in healthcare (Carey & Lloyd, 1995). However, the concepts and tools of CQI did not always find acceptance among healthcare administrators and providers. Skepticism such as: “How do we define and measure quality, which is a more subtle concept in healthcare?”, “Isn’t quality mainly a matter of the physician making the correct decision?”, “Where is the uniform product in medical care when every patient is different?” were expressed.

It is difficult to generalize about the effects of TQM in healthcare from isolated examples. Fortunately, the National Demonstration Project (NDP) on Quality Improvement in Healthcare provides a collection of experimental projects whose purpose was to study if the TQM model will work in the healthcare setting (Berwick, Godfrey & Roessner, 1990a). The NDP brought together 21 experts in quality management to work with a leadership team in 21 healthcare organizations represented by health maintenance organizations (HMOs), hospitals, and group practices in the US. The experts (who were from major US companies, consulting firms, and universities) were to offer their expertise in transferring quality management concepts and tools to these organizations that were willing to try them out. The participating organizations were to report on the results eight months later. Even though not all of the 21 teams completed the projects and reported back, the experiences of all of them contributed to the following important lessons learned (Berwick, Godfrey & Roessner, 1990b): (1) quality improvement tools can work in healthcare; (2) cross-functional teams are valuable in improving healthcare processes; (3) data useful for quality improvement abound in healthcare; (4) costs of poor quality are high, and savings are within reach; (5) involving doctors is difficult; (6) training needs arise early; (7) non-clinical processes draw early attention; (8) healthcare organizations may need a broader definition of quality; (9) in healthcare, as in other industries, the fate of quality improvement is first of all in the hands of leaders.

Despite these important insights that were gleaned from these projects, as acknowledged by the initiators of the project, there were two major gaps that were associated with these projects (Berwick, Godfrey & Roessner, 1990b). First, only a few project teams addressed core clinical processes such as physician decision-making, diagnostic strategies, and medical treatments. This seems to be in agreement with other research findings on the application of TQM in healthcare (Shortell, Levin, O’Brien & Hughes, 1995). Most teams worked on business and service support processes such as appointment waiting times, Medicare billing, patient discharge processes, and the hiring and training of nurses. Here the problems were similar to the quality problems in other industries. Interestingly enough, not even one of the teams measured success in terms of improved health status of the patient! Another gap was that the projects did not try to change the organizational cultures. Clearly, both these gaps have to be addressed in any effort to reduce or eliminate medical errors.

ERRORS IN HEALTHCARE

It is instructive to consider some findings about the occurrence and the impact of errors in healthcare. These stylized facts bring home in a compelling way the significance and the enormity of the tasks that lie ahead in the prevention of these errors. According to the IOM report (Institute of Medicine, 2000):

- Preventable adverse events (see the following below) are a leading cause of death in the United States. When extrapolated to the more than 33.6 million admissions to US hospitals in 1997, the results of two studies (involving large samples of hospital admissions, one in New York and the other in Colorado and Utah) imply that at least 44,000 and perhaps as many as 98,000 Americans die in hospitals each year as a result of medical errors. Deaths due to preventable adverse events exceed the deaths attributable to motor vehicle accidents (43,458), breast cancer (42,297) or AIDS (15,516).

- The rate of healthcare errors is far higher than the error rate in other industries. In one study of intensive care units (ICU), the correct action was taken 99.0% of the time, translating to 1.7 errors per day. One out of five of these errors was serious and/or potentially fatal. If performance levels even substantially better than those found in the ICU (for example, 99.9%, a 10-fold reduction in errors) were applied to the airline and banking industries, it would still equate to two dangerous landings per day at O’Hare International Airport and 32,000 checks deducted from the wrong account per hour (Leape, 1994)! In these industries, such error rates would not be tolerated.
- Errors occur not only in hospitals but in other healthcare settings, such as physicians’ offices, nursing homes, pharmacies, urgent-care centers, and care delivered in the home. Unfortunately, very little data exist on the extent of the problem outside of hospitals. The IOM report indicated, however, that many errors are likely to occur outside the hospital. For example, in a recent investigation of pharmacists, the Massachusetts State Board of Registration in Pharmacy estimated that 2.4 million prescriptions are filled improperly each year in the state (Agency for Healthcare Research and Quality, 2003b).

Errors in healthcare do not lend themselves to commonly agreed-upon definition and classification. This poses a challenge in the design and implementation of measures to prevent them. For instance, according to IOM, an **error** is defined as the failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim. However, QuIC (Quality Interagency Coordination Task Force, 2000), in order to address all the relevant issues, has expanded the IOM definition as follows: An **error** is defined as the failure of a planned action to be completed as intended or the use of a wrong plan to achieve an aim. Errors can include problems in practice, products, procedures, and systems.

Medical error is defined through adverse events. An **adverse event** is an injury caused by medical management rather than the underlying condition of the patient. An adverse event attributable to error is a “**preventable adverse event**.” **Negligent adverse events** represent a subset of preventable adverse events that satisfy legal criteria used in determining negligence, i.e., whether the care provided failed to meet the standard of care reasonably expected of an average physician qualified to take care of the patient in question (Institute of Medicine, 2000).

Medical error is an adverse event or near miss that is preventable with the current state of medical knowledge. Note that consideration of errors is broadened beyond preventable adverse events that lead to actual patient harm to include “near misses,” sometimes known as “close calls.” A **“near miss”** is an event or situation that could have resulted in an accident, injury, or illness, but did not, either by chance or through timely intervention. The broader definition of error allows learning from close calls as well as from incidents leading to actual harm (Quality Interagency Coordination Task Force, 2000). Such learning has proved to be very valuable in other industries, such as aviation and nuclear power. It is also worth noting that not all adverse errors are preventable. **Unpreventable adverse event** is defined as an adverse event resulting from a complication that cannot be prevented given the current state of knowledge.

The implication of these definitions and classifications is that a single approach to error reduction and prevention is not fruitful. Different types of errors call for different approaches.

Error Prevention in Other Industries

Error prevention strategies in other industries have been part of an overall strategy for process improvement. The important features of these strategies can be summarized as follows:

1. *They have emphasized the control of the variation in the process.* Sets of tools that help to monitor, identify, and eliminate the root causes of process variations were utilized. How the responses of management can reduce or amplify the variation in the process was understood by considering the common and special causes of variation. The important lesson was that only management could and must do something about common causes of variation. Control charts were used to monitor process stability and signal the presence of special causes of variation. It must be pointed out that in Complex Adaptive Systems (CAS) like healthcare one has to carefully distinguish between meaningful variation resulting from innovation and variation which leads to waste (Institute of Medicine, Appendix B, 2001).
2. *Processes were simplified; standards were developed, documented, and adhered to.* One of the principles of lean manufacturing is to simplify the process and make it transparent to the workers (Womack, Jones & Roos, 1990). Simple and visual signals like *kanban* cards and a system of lights are used in the pull system of Just-in-Time (Schonberger, 1986). Errors can be easily detected and prevented in a visual factory. Standardization of work methods — which implies reduction of variation — is considered an important aspect of *kaizen* or continuous improvement. Once a process is improved using tools like the Plan Do Check/Study Act (PDC/SA) cycle, it is documented for future use. Standardization encompassed all aspects of the process. For instance, a system like the 5S encompassed housekeeping and promoted safety in the work place (Shaw & Gillard, 1996). Food production and service is an industry where safety is of paramount importance. As part of its efforts to enhance the safety of food supply system in the US, the Food and Drug Administration (FDA) has mandated Hazard Analysis and Critical Control Point (HACCP) systems as a prevention standard**.** HACCP systems represent a systematic approach to the identification and control of the biological, chemical, and physical hazards that are reasonably likely to occur in a particular food in a particular production process.
3. *Inexpensive but effective solutions were used to design errors out.* Poka-yoke or error proofing is a powerful, simple, and often inexpensive technique for eliminating mistakes from occurring in the first place or to provide early warning that a mistake is about to occur. The basic ideas behind mistake-proofing were first developed and applied by Shigeo Shingo under the rubric of Zero Quality Control (Shingo, 1986). Shingo felt that defects have to be prevented by preventing the mistakes that cause them. And this has to be designed into the elements of the process, i.e., into the equipment, procedures, the operating environment, and training of the employees. Of late, the principles of mistake-proofing have also been applied to service processes. An application in healthcare is the use of indented trays in surgical procedures to prevent surgeons from leaving any particular instruments inside the patient!
   It is important to note that, in services, often the customer is an active participant in the

service creation and delivery processes. Customer mistakes can occur at the stages of: (1) preparing for the service encounter; (2) during the encounter; and (3) post-encounter resolution (Chase & Stewart, 1995). This has important implication for application in healthcare — mistake-proofing efforts must be directed not only at the equipment and employees of the providers but customers of healthcare as well. For example, if you are a patient in a hospital, consider asking all healthcare workers who have direct contact with you whether they have washed their hands (Agency for Healthcare Research and Quality, 2003a). There is great potential for the application of mistake-proofing in healthcare.

4. *Automation, information, and simulation technologies were used to reduce and prevent defects.* It is well known that computer-based automation in manufacturing has led to increased process consistency enabling much tighter tolerances to be met. For instance, robots can weld and paint more uniformly than humans. Information technology has been used in service industries to improve quality and customer service, e.g., by Ritz Carlton hotel chain (Bounds, 1996). Simulation and modeling has also proved to be very valuable in providing insights about the functioning of processes. Flight simulators are routinely used in aviation for training and education. Healthcare organizations can learn from the military as well. The healthcare profession can use computer simulation and military-based teamwork training as a means of training. Human factors engineering and ergonomics is incorporated into the design of processes and systems in industries such as nuclear power. By designing jobs, machines and operations that take into account human limitations, human errors can be prevented or reduced (Rooney, Heuvel & Lorenzo, 2002).

5. *Trained and empowered employees implemented error prevention methods. They often worked in a multi-disciplinary team structure.* There was a cultural shift. Process improvement was no longer the responsibility of management alone. Employees were now responsible for not only doing the job but also improving it. The leadership in the organization provided the support. Employees were encouraged to report on errors and devise solutions. In some of the companies that implemented Just-in-Time (JIT), the workers were given the authority to stop the line to prevent defects from being passed down stream. Once the line was stopped, problem-solving teams were formed on the spot to address the problem (Suzaki, 1987). The aviation reporting system, which the IOM and others have suggested as a model that healthcare should emulate, depends on the collection of as much information as possible about close calls as well as errors that actually resulted in harm. In the aviation industry, the identity of those who report and those who are involved in the incident are protected. This encourages people to report errors and makes the information available quickly.

6. *Organizations have benchmarked their processes to identify and close performance gaps in critical processes.* The best-in-class processes — which were not necessarily in the same industry — were benchmarked. For instance, the activities of pit crews during pit stops in the motor racing circuit have been studied to benchmark worker changes on assembly lines (Walleck, O’Halloran & Leader, 1991). Granite Rock, a building materials supplier, has benchmarked its concrete mix delivery process with Domino’s pizza delivery process (Bounds, 1996)!

7. *Process improvement strategies focused on multiple dimensions of process performance*. The Six Sigma approach that was pioneered by Motorola in the 1980s and now being utilized by many manufacturing and service companies aims at *simultaneous* reduction of defect rates, cost, and cycle time in the process (Bounds, 1996). Six Sigma has been applied to manufacturing and non-manufacturing (service and business) processes (Chassin, 1998). Linking costs to quality and cycle times is a relatively new concept in healthcare (Castañeda-Méndez, 1996).

What is Different About Healthcare?

There are some characteristics of the healthcare industry that distinguish it from other industries. Although the managerial processes in the healthcare industry are similar to those of other industries, the prevalent norms, culture, practices, and the regulatory framework can promote or hinder efforts to improve safety. These characteristics also influence the extent to which the best practices for error prevention in other industries are relevant and transferable to the healthcare sector.

1. Healthcare systems are very complex systems in terms of its constituent elements (e.g., patients, physicians and other healthcare professionals, purchasers of healthcare, payers, insurers, regulators, accrediting and licensing bodies, healthcare administrators, and professional groups), the web of relationships between them, and the knowledge, skills, and technologies that are utilized (Institute of Medicine, 2000). These groups have their own definition of errors and quality in healthcare. The interests of some of these groups are also in conflict.
2. It is difficult in healthcare systems to establish precise linkages between the inputs and the resulting outcomes (Garvin, 1990). Therefore, it is not always possible to study and model the delivery of clinical care as a "process" as it is done in manufacturing. The outcomes in terms of patients' physiological and psychological states lag — sometimes in years — the treatments they receive. The outcomes are also dependent on the cooperation and the compliance of patients themselves. In this sense, healthcare systems are quite different from other industries such as airlines, nuclear power, and food supply where safety is a critical issue. Hence, it becomes quite difficult to implement the principle that quality gurus like Dr. Deming have emphasized — quality can be improved only by improving the process. Lack of process knowledge could also be one of the factors that lead to litigation being viewed as the only recourse in the case of adverse outcomes. In fact, many legal cases in healthcare involve scrutiny of the underlying clinical processes in the courtroom.
3. In healthcare, there is an information asymmetry between the care provider and the patient. The professional judgment of the caregiver determines the nature of the clinical care that is provided. Thus, the patient often cannot judge the quality or the safety of clinical care that he or she is receiving. In this respect, healthcare may not be very different from other professional services (e.g., accounting, legal, education) where such asymmetry exists and professional judgment influences the outcomes. Nevertheless, it underscores the difficulties in developing and monitoring quality and safety standards for clinical practices. This makes the healthcare market one in which the consumers do not have the requisite information about quality, safety, and utility to make informed choices. Thus consumers cannot adequately

exert their power in the market place — as it happens in other industries — to bring about changes in healthcare providers.

4. In many healthcare institutions, there are dual lines of authority — one involving the medical staff and the other the administrative staff. This complicates decision-making concerning design and implementation of safety improvement projects. In other industries, the managerial core has control over the technical core.
5. Healthcare organizations are concerned about litigation in the context of tracking and reporting medical errors. This inhibits the relevant information from being shared within and between healthcare organizations. Legal constraints on access to and sharing of information relating to patients also prevent the dissemination of the information, which could be useful in preventing errors.
6. In other industries like the automotive, large customers routinely exert pressure on their suppliers for continuous improvements in quality and costs. This is just beginning to happen in healthcare as large group purchasers want the healthcare organizations to improve their performance, but this has not become standard industry practice so far.
7. Mechanisms and institutions for research and dissemination of research on safety in healthcare are still in a developmental stage (Institute of Medicine, 2000; Quality Interagency Coordination Task Force, 2000). The difficulties are compounded by the fact that advances in clinical knowledge, medications, and technologies in healthcare are taking place very rapidly.
8. There are powerful subcultures in healthcare organizations based on occupation and specialization, e.g., physicians, nurses, and pharmacists. Their interests and functional orientations do not facilitate a systems approach to the promotion of safety (Zabada, Rivers & Munchus, 1998).

Prospects for Improving Safety in Healthcare

In the 1990s, many healthcare facilities and health plans placed an increasing emphasis on improving healthcare quality. Since 1999, it has become a requirement for managed care plans that contract directly with Medicare (Scott, 1998). However, these programs have not sufficiently addressed the problem of medical errors.

There are a number of factors that reduce the effectiveness of existing programs to prevent medical errors (Institute of Medicine, 2000). Performance measurement and improvement programs within healthcare organizations do not directly address the problem of medical errors. Programs that have been specifically developed to prevent medical errors often operate in isolation. Efforts by external organizations to monitor errors also face limitations. For example, JCAHO has experienced significant difficulty in securing hospitals' participation in its "sentinel events" reporting system because of concerns about legal vulnerabilities or punitive actions. A number of different programs exist to detect adverse health events, although no one system is designed to detect the full scope of medical errors. Systems designed to hold organizations or individuals accountable for bad outcomes are commonly limited by underreporting of adverse events.

Clearly, the quality improvement programs within healthcare organizations could be enhanced or adapted to address errors. However, there are serious obstacles such as: (1) a lack of awareness that a problem exists; (2) a traditional medical culture of individual responsibility and blame; (3) the lack of protection from legal discovery and liability. This causes errors to be concealed; (4) the primitive state of medical information systems, which hampers efficient and timely information collection and analysis;

(5) inadequate allocation of resources for quality improvement and error prevention throughout the healthcare system. No insurer pays hospitals for safety initiatives, no matter how beneficial they are. And in most hospitals, revenues are declining as private and government insurers try to cut reimbursements; (6) inadequate knowledge about the frequency, causes, and impact of errors, as well as effective methods for error prevention; (7) a lack of understanding of systems-based approaches to error reduction (such as those used in aviation safety or manufacturing); (8) there are even greater barriers to error reduction in non-hospital settings, where the general absence of organized surveillance systems and lack of adequate personnel hinder local data collection, feedback, and improvement.

The IOM report and the action agenda developed by QuIC will go a long way in addressing these barriers. The QuIC report identified the actions that have already been taken and will be taken to reduce medical errors. They included, among others, plans of Department of Defense (DoD) to implement a new reporting system in its 500 hospitals and clinics serving approximately 8 million patients. This confidential reporting system will be modeled on the system in operation at the Department of Veterans Affairs and will be used to provide healthcare professionals and facilities with the information necessary to protect patient safety. DoD providers will inform affected patients or their families when serious medical errors occur.

The Food and Drug Administration (FDA) will develop new standards to help prevent medical errors caused by proprietary drug names that sound similar or packaging that looks similar, making it easy for healthcare providers to confuse medications. The agency will also develop new labeling standards that highlight common drug-drug interactions and dosage errors related to medications.

The Department of Veterans Affairs is considered as one of the nation’s leaders in patient safety, having instituted patient safety programs in all of its healthcare facilities serving 3.8 million patients nationwide. The Veterans Administration (VA) healthcare system will form an innovative alliance with NASA to develop a medical error reporting system similar to the system NASA has operated successfully for the Federal Aviation Administration (FAA) since 1975. Aviation errors are reported by pilots, air-traffic controllers, mechanics, and all others involved in air transportation, to the Aviation Safety Reporting System (ASRS).

In 2001, the Department of Defense (DoD), investing $64 million, began the implementation of a new computerized medical record, including an automated order entry system for pharmaceuticals, that makes all relevant clinical information on a patient available when and where it is needed. It will be phased in at all DoD facilities over three years.

The QuIC member agencies, including DoD, Veterans Administration (VA), and the Agency for Healthcare Research and Quality (AHRQ), began a collaborative project with the QuIC Task Force and the Institute for Healthcare Improvement (IHI) to reduce errors in “high hazard areas,” such as emergency rooms, operating rooms, intensive care units, and labor and delivery units.

Information Technology

The federal government has played a pivotal role in the application of information technology to healthcare. It has some of the earliest research on computerized patient records, studies evaluating the impact of computer reminder systems on laboratory testing errors, and research on the effect of computers on drug ordering. VA and DoD are recognized national leaders in the implementation of electronic medical records and decision-support tools.

QuIC can have an impact through its participants’ activities in the area of electronic records and order entry. Most healthcare providers currently work with handwritten patient notes, which are often difficult to read, not readily available, incomplete, and prone to alteration, destruction, and loss. Structured, electronic order entry systems that require complete data entry remove ambiguities that arise from incomplete information or illegible writing. Real-time decision support is a powerful technological tool for error proofing. Decision-support systems can intercept errors, such as interactions between incompatible medications and the prescription of drugs to which the patient's electronic medical record notes an allergy. Bar-coding of medications and use of robotics in dispensing medications can ensure that the appropriate medication is provided to the right patient at the right time.

Information technology can also play a very important role in preventing errors in the delivery of clinical care itself. Electronic medical records and interactive decision-support tools have the potential to allow healthcare providers timely knowledge of a patient's health history and improve clinical care. Often physicians are overwhelmed with the changes in the knowledge base and find it hard to keep up with the literature — now they can turn to information technology for help. New England Medical Center has done work in the areas of Decision Support Systems (DSS) and Expert Systems (ES) that help physicians in making accurate diagnosis in emergencies and in selecting the best course of treatments for individuals and groups. Choices are developed by ES in the form of decision trees which incorporate individual risk preferences and special medical conditions (Grossman, 1994).

STEPS IN THE RIGHT DIRECTION

- One hospital in the Department of Veterans Affairs uses hand-held, wireless computer technology and bar-coding, which has cut overall hospital medication error rates by 70% (Agency for Healthcare Research and Quality, 2003b). This system is to be implemented in all VA hospitals. VA has an exemplary patient safety program, and the DoD is developing one that is modeled after that of VA.
- The specialty of anesthesia has reduced its error rate by nearly seven-fold, from 25 to 50 per million to 5.4 per million, by using standardized guidelines, protocols and simple mistake-proofing devices, redesigning and standardizing equipment (Agency for Healthcare Research and Quality, 2003b).
- In the UK, a missed diagnosis that almost resulted in the death of a three-year-old spurred her parents to set up a charity to develop a computer system to prevent such mistakes. The online system, called ISABEL, is free to all doctors. The rapid system uses pattern recognition software to search for information in pediatric textbooks, once it is given the symptoms. It even builds in other doctors' experiences of making mistakes (News Telegraph, 2002).
- The VA/Stanford simulation center for crisis management in healthcare at Palo Alto, California, uses a simulator that can execute all the physiological functions and mimic many complex and realistic clinical crisis scenarios. Instructors can alter these scenarios. By simulating an actual patient during surgery as much as possible, doctors can get quick feedback on if they injected the wrong drug, made incorrect interpretations and other errors. In the future, such simulators are likely to be part of medical education (Institute for Healthcare Improvement, 2000).
- SSM Healthcare became the first winner of the Baldrige award in the healthcare sector (National Institute of Standards and Technology, 2003). Sister Mary Jean Ryan, the CEO of SSM for last 17 years, said she once failed to report her own error in medicating a patient, so SSM has created a "blame-free"

zone for reporting not only errors but near-misses. "Half the reported incidents lead directly to system improvements," she said (Broder, 2002).

- General Motors (GM), which has 1.25 million people in its health plans, is the largest private purchaser of healthcare in the US. It is working with partners in the healthcare industry to teach them principles of lean organization such as standardized work; workplace organization and visual controls; error proofing; employee process control; planned maintenance; and reduction of variation (Shapiro, 2000). Some hospitals have tried to be proactive in adapting such best practices from manufacturing by implementing patient-focused care teams analogous to manufacturing cells (Taylor, 1994).
- "The Medical Center of Ocean County has embraced an approach that has put the facility in Brick, New Jersey, on the cutting edge of medication system developments" (Darves, 2002). The new system involves using pharmacy technicians both on nursing units and in the emergency department and implementing Just-in-Time (JIT) delivery of medications to replace the traditional 24-hour cart system. Patient safety has improved, time savings have accrued, and nurse and patient satisfaction has increased.
- In an important development in the dissemination of comparative data, the federal centers of Medicare and Medicaid have developed a massive database, including in it every one of the 17,000 Medicare and Medicaid-certified nursing homes in every state in the US. This data is now available online (Medicare, 2003) and also on a toll-free telephone number, 1-800-MEDICARE (Medicare, 2003). For the first time, objective comparisons on several quality measures and inspection results can be made. It also provides individual nursing homes a database to benchmark, learn, and improve quality of care.

Other than the initiatives spawned by the above-mentioned federal agencies and taskforces, a number of other non-governmental programs have also been launched. For instance, the Leapfrog group was formed by the Business Roundtable in 2000. Leapfrog is a coalition of more than 135 public and private healthcare organizations and a voluntary program which has as part of its mission "… to help save lives and reduce preventable medical mistakes by mobilizing employer purchasing power to initiate breakthrough improvements in the safety of healthcare and by giving consumers information to make more informed hospital choices" (Leapfrog Group, 2003). It has focused on three patient safety practices that it believes have the potential to save lives by reducing preventable medical mistakes in hospitals. They are: Computer Physician Order Entry, Evidence-Based Hospital Referral, and Intensive Care Unit Physician Staffing. The group gathers data from hospitals on their status with regard to these practices and makes the information available to the consumers and communities.

The American Society for Quality (ASQ) is partnering with the National Patient Safety Foundation (NPSF) to offer solutions for reducing errors and increasing patient safety. Successful applications of methods such as Six Sigma will be shared in the events organized by them. ASQ is also influencing public policy in this area. It has presented a paper to the congressional health policy staff advocating the wider adoption of proven quality methods in an effort to reduce medication errors (American Society for Quality, 2002).

In the UK, where the National Health Service (NHS) is the major provider of healthcare, the National Public Safety Agency (NPSA) has been created. It is a special health authority created in July 2001 to coordinate the efforts of the entire country to report, and more importantly to learn from, adverse events occurring in NHS-funded care. The NPSA will collect and analyze incident and other patient safety information and provide timely and relevant feedback to healthcare organizations, clinicians, and other healthcare professionals, and patients (National Patient Safety Association, 2003).

While these success stories and developments contribute to the application of knowledge management systems to improve patient safety, a word of caution may be in order. The success stories may indicate what has worked in specific instances, but given the nature of the industry not too much is going to be heard about failures. The knowledge about what does not work may be lacking.

In one sense, the task of transferring best practices is made easier in the case of healthcare. In the 1980s, when the manufacturing sector in the US faced a crisis with respect to product quality and competitiveness, not many role models and forums for sharing best practices were available. The Baldrige Award was set up to address that gap. But today, there is no shortage of knowledge or the mechanisms to disseminate that knowledge. The Baldrige framework has been extended to the healthcare sector. Award winners such as SSM Healthcare can serve as role models. There are many other state and local quality award programs that provide avenues for sharing best practices. Within healthcare itself, organizations like the National Coalition for Healthcare, Institute for Healthcare Improvement, Leapfrog Group, and The National Patient Safety Foundation disseminate the best practices.

These forums and mechanisms are indeed necessary, but they are not sufficient to ensure the actual transfer of these best practices. For instance, it has been noted that the National Safety Partnership publicized a list of 16 proven and accepted best practices in medication safety. Many of them have been known for years but most are not used in a majority of hospitals. The case of the healthcare industry in Japan also reinforces this point. Despite having a manufacturing industry known for its world class quality management system, the healthcare system in Japan did not undergo a similar quality revolution (Wocher, 1997). The reasons for this are rooted in the institutional characteristics of the Japanese healthcare sector. According to Wocher, the Japanese healthcare sector lags far behind US in terms of efficiency, overall management, and the application TQM and CQI ideas (Wocher, 1997).

All this leads one to conclude that there has to be a "felt need" for industry-wide, effective prevention of errors, and improving patient safety. At the level of an individual healthcare organization, this "felt need" will be generated by a mixture of factors. They are: (1) the organizational leadership that is willing and able to overcome the internal obstacles; (2) economic incentives from the market place that affect the bottom-line; (3) external compulsions by the consumers, purchasers, payers, accreditors, and regulators; and (4) the leadership role and the role models of the federal agencies. Earlier discussion of the above issues suggests that, of late, there are encouraging signs that some traction for improving patient safety has been created by these factors. And that portends well for patient safety and knowledge management for patient safety as well.

Chapter 7.2
HIPAA:
Privacy and Security in Health Care Networks

Pooja Deshmukh
Washington State University, USA

David Croasdell
University of Nevada, Reno, USA

ABSTRACT

This chapter explores privacy and security issues in health care. It describes the difference between privacy and security in the context of health care, identifies sources of concern for individuals who use information technologies for health-related purposes, and presents technology-based solutions for privacy and security in health care networks. The purpose of the chapter is to provide an investigation of the sources of concern for regulations and technologies in the health care industry. The discussion is based on the Health Insurance Portability and Accountability Act (HIPAA) and its eight guiding principles. The chapter explores the implications of legal and regulatory environments driving HIPAA regulations, the need for privacy and security in health care networks, and information technologies used in the health care industry. Related ethical issues, current technologies for providing secure solutions that comply with the regulations, and products emerging in the market are also examined.

INTRODUCTION

Data communication infrastructures are changing how health information and health care is provided and received. People using tools such *as the Internet for health-related purposes — patients, health care professionals, administrators, and researchers, those creating or selling health products and services, and other stakeholders — must join together to create a safe environment and enhance the value of the Internet for meeting health care needs. Because health information, products, and services have the potential to both improve health and do harm, organizations and individuals that provide health information via the Internet have obligations to be trustworthy, provide high quality content, protect users' privacy, and adhere to standards of best practices for services in health care. People using telecommunications infrastructures in health care share a responsibility to help assure the value and integrity of the information by exercising judgment in using health care sites, products, and services.* Internet Health Coalition (2000)

The Health Insurance Portability and Accountability Act (HIPAA) has brought about significant changes in the procedures and practices within the health care industry. As newer information technologies are implemented in health care organizations, the challenge becomes to increase network connectivity and enable access to key information without compromising its confidentiality, integrity, or availability. With the advent of HIPAA regulations, health care organizations are required by law to have procedures in place to protect the privacy of patient information. This chapter addresses issues related to privacy and security of patient information in health care networks. It provides a background on HIPAA regulations, drivers for the need for privacy and security in health care organizations, the role of technology-based solutions, and the products available to the industry. The chapter includes a discussion of the ethical issues driving the design and implementation of information in support of HIPAA guidelines. The increased use of information technology in health care promises greater functionality and decreasing costs. While these factors point towards continued development of more robust applications, careful selection and implementation is necessary to ensure the security and privacy of patient information.

The evolution of networking technologies has enabled businesses to provide enhanced services, greater access to information, and higher levels of availability for both the service providers and the customers. While many industries have easily adopted internetworking technologies, others have been unable to do so because of the inherent complexities of their specific businesses. The health care industry is a prime example. Health care is a document-intensive industry that has faced significant challenges in migrating to the near "paperless" environments that many industries strive to achieve utilizing networking technologies (Cisco Systems, 2002). Furthermore, health care organizations work with highly sensitive data such as patients' personal health information. As such, health care organizations must be keenly aware of the privacy concerns and security risks of converting to electronic infrastructures.

BACKGROUND

Anyone seeking health-related information, products, or services has a right to expect that organizations and individuals who provide such information follow a set of guiding principles. If confidences are not kept, individuals will be less forthcoming with information, which in turn may impact the care they receive. Health information includes information for staying in good physical condition as well as for preventing and managing disease. It may also include information for making decisions about health products and health services and may be in the form of data, text, audio, and/or video. In addition, enhanced health information may be available through programming and interactivity (Internet Health Coalition, 2000). Managing health information in a technological world implies the persistent storage and potential dissemination of health-related data using data communication networks. Such environments have the potential to compromise both the security and privacy of the records maintained on these networks.

Although privacy and security are terms that are often used interchangeably, there is an inherent difference between the two concepts. The Merriam-Webster online dictionary (2003) defines *security* as:

The quality or state of being secure: as ***a****: freedom from danger:* ***SAFETY b****: freedom from fear or anxiety* ***PROTECTION*** *(1): measures taken to guard against espionage or sabotage, crime, attack, or escape.*

Whereas *privacy* is defined as:

The quality or state of being apart from company or observation: SECLUSION b: freedom from unauthorized intrusion <one's right to privacy>.

By combining the two terms, one can gain a complete picture of protecting information in context of the health care industry. Both security and privacy must be considered in order to adequately address the issue of safeguarding patient information (Fleisher, 2001). The Health Insurance Portability and Accountability Act (HIPAA), effective as of April 14, 2000, attempts to address privacy and security issues in the context of health-related activities. Accordingly, HIPAA defines *security* as:

The regulations which address the protection of data resident on provider computers or networks, as well as the protection of data while it is being transmitted to third parties. Primarily, security addresses the technical components related to the collection, protection, and dissemination of data. (HIPAA Standard164.530)

Whereas *privacy* is defined as:

The regulations, which address the protection of patient information in any format and by any user. Privacy necessitates providing an individual's health related information and disclosure of how and where that information is being used. (HIPAA standard 142.308) (Fleisher, 2001)

More simply stated, the security regulations address technical components of health care information, which are monitored by a Security Officer. Privacy regulations are more operational in nature and are managed by a Privacy Officer (Wilson, 2002).

Organizations are becoming increasingly dependent on data communication networks for their daily business communications, database information retrieval, and distributed data processing. The rise of the Internet and wireless communications has provided opportunities to connect to computers anywhere in the world. However, this capability has also increased the potential vulnerability of organizational assets. As a result, not only do organizations need to prevent their assets from threats such as fraud and theft but they also need to be concerned with the potential loss of consumer confidence from a publicly known security break-in. Other security concerns include potential losses from disruption of an application or natural disasters (Fitzgerald & Dennis, 2000).

SECURITY ISSUES IN THE HEALTH CARE INDUSTRY

In today's uncertain political and economic environment, many factors are driving the need for secure networks in the health care industry. A significant business challenge is to increase network connectivity and to enable access to key information assets without compromising the confidentiality, integrity, or availability of those assets. Some believe that using new technologies can assist with the process of securing patient information. According to Oracle Corporation, incorporating technology in hospitals will make the process of providing access to patient information more secure since all the data will be stored in one place (Couzin, 2001). This will reduce the risk associated with patient information "floating" around the hospital where it could potentially be accessed by multiple doctors, nurses, technicians, and administrators. In some of the solutions implemented by Oracle, doctors no longer need to spend valuable time filling out forms, tracking patient charts, or waiting to pick up X-ray or MRI results as these tasks are now automated through the use of technology (Couzin, 2001). While this has greatly increased the ease of use, it has also increased the vulnerability and security of the underlying content.

Conversely, the health care industry's steady move towards the computer-based patient record and the overall trend of delivering health care information using information technology in lieu of paper has raised anxiety regarding the security of that information. Issues related to the security of an enterprise network could create fear and uncertainty for health care executives. Securely sharing patient information over distributed regional networks that link multiple hospitals, clinics, and doctors' offices has become an issue of key importance in health care organizations (KBeta Security Web, 2001). For an organization to begin building a highly secure network, it must first understand the issue of security and why it has become such a priority in health care today.

To this end, network security has never been more important. For example, e-vandalism is occurring unnoticed in many of today's information-centric companies. Clandestine hackers and vandals not only steal a company's confidential information, but also damage its reputation in the process. The loyalty that companies have worked so hard to build could disappear if customers and business partners believe that their personal data is at risk (McMillan, 2002). The concern is thus magnified for health care enterprises trying to deploy network solutions.

Another factor driving the need for greater attention to security concerns is the move to sharing information with remote physicians. With the growth of outpatient care sites health care providers can no longer be content with just one local area network. In the past, doctors did not consider having the capacity to receive patient data in their homes. The ability of physicians to practice medicine remotely is becoming a competitive differentiation in the marketplace (Sarasohn-Kane, 2003). This practice is beneficial not only to the doctor in terms of flexibility and convenience, but also to patients who could be diagnosed and receive treatment virtually across time and physical space. Health systems and plans want to attract and retain the best physicians in the community by touting the ability to provide information anywhere and anytime a doctor needs it. The confidentiality of such information becomes paramount in the ability to conduct business.

These issues have also gained impetus as network intrusions by computer viruses have become more prevalent in recent years. The threat of new and more virulent computer worms and viruses has heightened the level of consumer awareness and concern about the use or misuse of personal health records. An IBM survey conducted in 1999 revealed that 33% of Americans would trust banks to handle their personal information properly, but only 23% placed the same faith in health care providers (Sarasohn-Kane, 2003). In a September 2000 Gallup poll, 77% of the respondents said the privacy of their personal health information was very important. Eighty-four percent were concerned that this information might be made available to others without their consent. Only 7% of the respondents said they were willing to store or transmit personal health information on the Internet and only 8% felt a Web site could be trusted with such information (Hunt, 1999).

Confidence in security measures is even more important given the push towards consumer-driven health care. Consumers' desire to access information about their own health has resulted in increased use of interactive medical networks such as the Internet and intranets. In part, the changes are due to the improving technological capability along with managed care organizations' desire for patient empowerment by asking patients to assume more self-management. Consumers' use of these networks has initiated the development of personal health information management software that may be a precursor to an electronic medical record owned by the patient. As a result, health care information is becoming more portable. Previously, the hospital literally owned patient records. In contrast today, multiple owners outside the hospital may be contending for it. The implementation of technical solutions has provided greater portability and convenience in the health care arena. At the same time, the demand for security is becoming even more imperative (Sarasohn-Kane, 2003). Copies of electronic files containing vast amounts of confidential information can easily be sent electronically over a network connection without any indication that the information was stolen.

Consumers want to control where their health information goes. Part of the enterprise's risk management analysis is to realize that we live in a litigious society. As such, it is prudent on the part of businesses to take every reasonable step to ensure the confidentiality of health care information. More trust in the health care system will help ensure better health outcomes through the use of technology.

PRIVACY ISSUES IN THE HEALTH CARE INDUSTRY

Health care providers maintain and share a vast amount of sensitive patient information for a variety of reasons. Such records are kept and shared for diagnosis and treatment of the patients, payment of health care services rendered, public health reporting, research, and even for marketing and use by media. While traditional paper-based systems have vulnerabilities, they also place some natural limits on the ability of information collectors to share and disseminate information. It is sometimes a challenge to locate paper records. In order to disseminate the information, someone must physically remove the records from the premises either by carrying, copying, mailing, or faxing the documents. These limitations create a double-edged sword. Although such systems may protect information from being disseminated for improper reasons, they may also obstruct the flow of information being shared for legitimate, health care-related purposes (Choy, Hudson, Pritts, & Goldman, 2001).

Health information can be easily located, collected, and organized with the migration of the health care industry toward electronic data collection, storage, and transmission. One major drawback is that sensitive and personal patient information can be sent to any number of places thousands of miles away with the click of a mouse button. Thus, some consumers may be afraid to take advantage of the technology because of privacy and confidentiality concerns. According to the Ethics Survey of Consumer Attitudes conducted by the Cyber Dialogue and the Institute for the Future for the California Health Care Foundation and the Internet Health Care Coalition in January 2000, more than 75% of the people surveyed are concerned about Web sites sharing information without their consent, thus impacting their willingness to use the Internet for health- related services (Goldman & Hudson, 1999).

Consumers are increasingly worried about the loss of their privacy, and have heightened concerns when it comes to their health information (Brewin, 2003). They worry that their health information may be used or disclosed inappropriately and leave them vulnerable to unwanted exposure, stigma, and discrimination, possibly leading to economic losses. Patients fear that their personal information will be used to deny them health insurance, employment, credit, and housing. With the increase in the use of technology and the ease with which information can be transmitted, there has undoubtedly been a considerable increase in the access of health care information. People who access such data without appropriate authorization are motivated either by profit or at times just plain curiosity (Goldman & Hudson, 1999). As a result, consumers sometimes take drastic steps to keep their health information private. According to one survey, almost one out of six U.S. adults has taken extreme steps to maintain the privacy of his or her medical information. Patients withhold information from their doctors, provide inaccurate or incomplete information, and doctor-hop to avoid a consolidated medical record. They go as far as paying out-of-pocket for care that is covered by their insurance, or even avoiding care altogether (Goldman & Hudson, 1999).

Such privacy-protection behavior, which consumers/patients do both offline and online, can result in a significant cost to their health. A study released by the Pew Internet and American Life Project found that 89% of Internet users who seek health information online are worried that others will find out about their activities and are worried that the Internet companies will give this information away. Eighty-five percent fear that insurance companies might change their coverage after finding out what online information consumers had accessed (Choy et al., 2001). By concealing information, patients risk undetected and untreated conditions. At the same time, the doctor's ability to diagnose and treat patients is jeopardized without access to complete and accurate information. Further, future treatment may be compromised if the doctor misrepresents patient information so as to encourage disclosure. This in turn can have a detrimental effect on the community, as without full patient participation upfront, the information collected will be unreliable for users downstream. Ultimately, health care initiatives that depend on complete and accurate information may be undermined (Goldman & Hudson, 1999).

LEGAL AND REGULATORY ENVIRONMENT

Regulatory factors are driving the current trend toward security and privacy standards in the transmission of health care information over enterprise networks. State and federal legislation, professional and standards organizations, and internal organizational risk management departments are driving the need for security measures. Many states, for example, regulate the use of electronic signatures and medical records. The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) addresses security and confidentiality issues in the Information Management section of its accreditation manual. Overlaying all these factors, however, is the greatest of all regulatory drivers: a recent federal law called HIPAA.

The Health Insurance Portability and Accountability Act, signed into law in the United States in August 1996, mandates the adoption of national uniform standards for the electronic transmission of health and patient information. The intent of HIPAA is "administrative simplification" and protection of patient privacy. HIPAA requires that the health care industry promote a national, uniform security standard for the secure electronic transmission of patient-identifiable information.

HIPAA is a turning point for the health care industry because it requires that the industry develop a set of national standards that will help bring the much-needed data-standard unity to health care transactions and provide assurance that confidential patient information will be safe or safer than paper-based patient records.

Although HIPAA does not mandate the collection or electronic transmission of health information, it requires that standards be adopted for any electronic transmission of specified transactions. To ensure protection of privacy, the law provides for confidentiality protections for information processed in accordance with the new standards. It requires organizations to focus on *Electronic Data Interchange (EDI) transactions for health plan enrollment, eligibility, claims payment, premium payment, coordination of benefits, and referral/authorization*. HIPAA also mandates p*rotecting confidentiality of individually identifiable patient information in an automated system*. It requires organizations to be able to demonstrate sound practices that protect patient confidentiality and security.

HIPAA security requirements are broad, covering any organization that generates or otherwise handles electronic patient records and other e-medical data. HIPAA requires the health care organizations to implement encryption, user authentication, and other security measures to safeguard the integrity, confidentiality, and availability of electronic data by mid-2003. Entities affected by this law include virtually all private and government hospitals, outpatient centers, nursing centers, Health Maintenance Organizations (HMO), Preferred Provider Organizations (PPO), insurance companies, firms providing clinical information systems for medical labs, providers of pathology, radiology, patient billing, and pharmacy records, medical software application providers, and even related Web portal companies (Yozons Technology, 2003).

Penalties for noncompliance to the law can be severe. The civil penalty for violating transaction standards is up to $100 per person per violation and up to $25,000 per person per violation of a single standard for a calendar year. The penalty for knowing misuse of individually identifiable health information can reach $250,000 and/or imprisonment for up to ten years. HIPAA has hit the nation's $1.3 trillion health care industry quickly by becoming the de facto security guideline for federal privacy standards regarding health care information. The privacy standards, which govern electronically Protected Health Information (PHI), went into effect as of April 14, 2003 and could create a legal nightmare for the health care industry, requiring a massive training effort and costing millions of dollars. There is also concern that litigation over a failure to adhere to HIPAA security standards may dampen the use of technologies such as wireless LAN systems in hospitals (Brewin, 2003).

Given the mandated HIPAA compliance, many organizations have been working overtime to ensure their organizations are aligned correctly. In order to examine the implications of HIPAA in the workplace, interviews were conducted with professionals responsible for information systems and telecommunication services in regional medical centers. The combination of HIPAA and the hospitals' endeavor to become HIPAA compliant has resulted in additional responsibilities for individuals such as the Privacy and Security Officers for their respective medical centers. On the whole, these professionals consider HIPAA to be a double-edged sword. In their opinion, to a large degree most hospitals and health care organizations have always been very sensitive to privacy and confidentiality of patient information. HIPAA has simply formalized some of those issues and ensured that the standards are being applied equally. The primary gap in the protection of patient information was seen at pharmacies as they previously shared patient information with various vendors. If a patient were to buy prescription drugs at the pharmacy, he or she might receive advertisements with information on drugs related to their condition. With the advent of HIPAA, pharmacies need to be monitored and are not allowed to share patient information with vendors without the consent of the patient. In addition, the electronic transaction of transmitting patient information to bill insurance companies needs to be supported by software that is HIPAA compliant.

IMPLICATIONS OF HIPAA IMPLEMENTATION

Overall HIPAA is believed to be a very positive thing, as patients find comfort in knowing that there are standards in place to safeguard their personal health information. Still, some patients have negative perceptions regarding how HIPAA affects the privacy and security of personal information. Most hospitals are very explicit when stating what happens with patient information and with whom such information is shared. However, such an expression, alluding to a more open process, has raised concerns among some patients who have only recently become aware of such standard practices of health care organizations. They believe that HIPAA has allowed health care organizations to share more information than they previously could. In effect, HIPAA has heightened peoples' awareness of issues related to information privacy and security. For many, these concern are issues that were previously unknown or of little interest. As such, efforts are being made to educate such individuals in order to make them feel more comfortable about the privacy of their information.

The security piece of the regulation mandates the implementation of security measures within health care organizations. These security measures were previously hard to implement because there was not much return on investment. With HIPAA, it has become easier to justify these requirements from a business standpoint. The security measures may contain a layered approach to securing the network. A plan needs to be in place to ensure that every single layer of the network has been "hardened" to make it secure. In addition, some medical centers have assigned different access capacities to their various staff members depending either on their location in the hospital or the privileges assigned to them. Further constraints have been implemented in order to manage and protect the IT resources. For instance, users may need to follow a specific format for their passwords in order to ensure that they are not easily decipherable. For systems containing clinical information used to make emergency decisions, some hospitals have implemented a "break the glass" procedure, in which, for example, if a password is not working in emergency situations, physicians are still able to get to the information. Extra audits and alerts are put in place so that if someone "breaks the glass," network administrators are automatically notified and upper management can be apprised of the related circumstances.

The processes associated with accessing records have also undergone changes as illustrated in the following scenario. If a physician examines one patient and consults with another physician on the case, the second physician may be unable to access the patient's records since he or she is not the "physician of record." In such a situation, the second physician could override the access blocks by agreeing to have their name appear in the audit report. If the second physician agrees, administrators can monitor records for inappropriate activities and follow-up with the physician to address access issues as needed.

There are obvious cost implications on the implementation of HIPAA. Organizations now need to maintain a fair-sized HIPAA contingency budget every year. There are costs such as traveling to understand more about HIPAA, man-hours, and employee education.

SOLUTIONS

Health care services and professionals are working toward providing environments that safeguard health-related information. In part, actions have been encouraged and set in motion as a result of HIPAA compliance efforts. Some solutions are enabled by information and communication technologies while others rely on standards of practice that have been advanced by the health care community. The eHealth code of Ethics, initiated in 2000, helps ensure that people understand the potential risks of managing their own health care and the health of those in their care. The eight guiding principles of the code work to ensure candor, honesty, quality, professionalism, responsible partnering, accountability, informed consent, and privacy of patient information (Internet Health Coalition, 2000) (Table 1).

In a similar vein, the Health on the Net (HON) Foundation (2002) Code of Conduct for medical and health Web sites addresses the reliability and credibility of information on the Internet. Specifically, it addresses the authority of the information provided, data confidentiality and privacy, proper attribution of sources, transparency of financial sponsorship, and the importance of clearly separating advertising from editorial content (Health on the Net Foundation, 2002).

ROLE OF TECHNOLOGY-BASED SOLUTIONS

In addition to guiding principles for behavior, health care enterprises are faced with a number of technical and operational challenges. Among these are the needs to operate more efficiently, to expand the scope of the enterprise, to provide greater access to information from a variety of locations and platforms including mobile/wireless, and to greatly improve the security and privacy of information. These challenges can, at times, seem contradictory. The responses to these challenges necessitate many different initiatives, including security planning, creation of wide area networks, and adoption of wireless/mobile platforms. In addition, the health care industry's ongoing, massive consolidation has resulted in the emergence

Table 1. Eight guiding principles of eHealth code of ethics (Internet Health Coalition, 2000)

e-Health Code of Ethics: 8 Guiding Principles	
Candor	▪ Disclose vested financial interests ▪ Disclose key information for consumer decisions
Honesty	▪ Present information truthfully ▪ No misleading claims
Quality	▪ Accurate, clear, current, evidence-based ▪ Readable, culturally competent, accessible ▪ Citations, links, editorial board and policies
Informed Consent	▪ Privacy policy and risks ▪ Data collection and sharing ▪ Consequences of refusal to consent
Privacy	▪ Prevent unauthorized access or personal identification of aggregate data ▪ Let users review and update personal data
Professionalism	▪ Abide by professional codes of ethics ▪ Disclose potential conflicts of interest ▪ Obey applicable laws and regulations ▪ Point out limits of online practice
Responsible partnering	▪ Choose trustworthy partners, affiliates, and links ▪ Maintain editorial independence from sponsors ▪ Tell users when they are leaving the site
Accountability	▪ Provide management contact info ▪ Encourage user feedback ▪ Respond promptly and fairly to complaint

of so-called Integrated Delivery Systems (IDS). These systems are designed for large, regional providers that need to share clinical and other information among numerous hospitals, clinics, home-care agencies, and other facilities. With the advent of multiple clinics and hospitals sharing data, a health care organization must contend with factors such as leased telecommunications lines and external circuits and services, rather than local services inside a building (KBeta Security Web, 2001).

From unauthorized users to disgruntled employees to cyber-terrorists, the threat to health care information systems cannot be taken lightly. Poorly written software, the demand for convenience over security, and overworked, undertrained IT health care professionals present substantial information systems vulnerabilities (Beaver, 2003). The HIPAA security rule is about information security best practices. Technology for secure networks includes tools such as firewalls, encryption, user authentication, and software that detects and reports network vulnerabilities and unauthorized activity (KBeta Security Web, 2001).

MANAGEMENT ISSUES

It is imperative to realize that technology is not the silver bullet that people have come to believe in and rely on. Simply relying on the technical solutions is not sufficient to ensure the security of the information. While cutting-edge network technology might be available to make networks secure, technology is only an enabler (KBeta Security Web, 2001). Other issues that need to be considered include ongoing information risk assessment, information security audits, disaster recovery, and business continuity plans (Beaver, 2003). Information security is a business issue as well. Organizational and cultural issues are paramount in making the technology fulfill its potential. The key is to impart a *culture of security and confidentiality* to an organization. As a corporate cultural issue, security and confidentiality integrate through diverse areas of technology, organization, and regulation. Security is an integrated approach in which an organization needs to have its entire management team involved in the decision-making processes. These processes should include key decision makers from multiple and varied departments such as legal, human resources, and operations.

Given the intersecting technical, organizational, and regulatory factors, it should be understood that security of enterprise networks is both an ethical as well as a cultural issue, requiring constant, iterative education and awareness. In order for information security initiatives to be effective, it is critical to not forget the end user. In fact, the human factor can be the weakest link in an information security program (Beaver, 2003). Organizations must reinforce employee awareness through an ongoing program of education, reward, and recognition. Individual user accountability is a critical component of network security. A system cannot allow, for example, several providers to use the same terminal simply by using the same password and logon for the sake of convenience.

Mobile computing applications and the use of wireless technologies in health care has seen a great deal of growth and expansion capabilities. From a security standpoint, the social changes are probably the hardest to implement. It is easy to have the firewalls and technologies in place, but it is harder as well as more important to manage the social aspect of such a change. If people leave their PC screen on and the others walking by can see the information displayed on it, then security doesn’t mean anything. Similarly, if people stick their passwords on post-it notes on their screens, then the security measures become meaningless. Maybe security will change with biotechnology, and people won’t have to remember multiple passwords while they simply remember to bring their thumb to work.

The information owners must determine security risks, impact, and the severity of a potential compromise. Additionally, the information owners should be responsible for determining a balance between the costs and benefits of security for their particular organization. Organizational risk is an aggregate factor and must be determined collectively by all of the information owners within and throughout the organization. Securing an organization's information assets is ultimately an upper management responsibility and must be managed from the top down from a business perspective. Health care managers must understand the business impact of information risks and the implications involved if systems are not secured. To protect themselves from legal liabilities, health care organizations need to show due diligence in attempting to implement best practices in this regard.

IMPLICATIONS AND CONCLUSIONS

In the end, it is necessary to understand that there is no such thing as 100% security. However, it is vital that reasonable measures be in place to reduce the chances of unauthorized access of confidential information. With HIPAA privacy regulation compliance mandatory since April 14, 2003, health care providers need to ensure that their systems meet the federal health privacy policies. Although the law allows for incidental disclosures of information, providers covered by the rule are expected to put reasonable safeguards in place to protect their patients' information. This means that sign-in sheets may be used in a doctor's reception areas but patients should no longer be asked to write down their conditions because other patients could see the sheet. In an emergency room, the large white boards listing patient names and conditions should be moved to areas out of public view. In hospitals, patient charts should be turned to face the wall so people walking by cannot read them. New computer software allows doctors' offices to identify patients by full name or just by initials, just in case others might catch a glance of a PC screen. Most hospitals have new policies regarding the release of information regarding a patient's condition. Such information was once routinely provided to family, friends, clergy, and reporters who called. Under the new rules, hospitals must give patients a chance to opt out of any hospital directory. No information, even that a person is a patient in the hospital, may be released without the patient's consent. Even if a patient agrees to being included on a general patient listing, hospitals may release only limited information without specific patient authorization and only if a caller asks about a patient by name (Meckler, 2003).

Technologically, the continued growth and acceptance of the Internet, widespread growth of wireless devices with greater functionality and decreasing costs of technology solutions all point towards continued development of more robust software applications. These developments may improve adoption of technology, but careful selection and implementation are necessary to ensure the security and privacy of patient information. Eventually, organizational policies, technical solutions, and regulatory guidance should improve the acceptance of e-technology and increase its value to the health care organizations. With greater security of patient information, health care organizations can build patient trust by protecting confidential patient information. This trust between the patient and the provider in turn will lead to improvement in the overall quality of health care.

Chapter 7.3
Medical Ethical and Policy Issues Arising from RIA

Jimmie L. Joseph

David P. Cook
Old Dominion University, USA

INTRODUCTION

New technologies can lead to social upheaval and ethical dilemmas which are unrecognized at the time of their introduction. Medical care technology has advanced rapidly over the course of the past two decades and has frequently been accompanied by unforeseen consequences for individuals, the medical profession and government budgets, with concomitant implications for society and public policy (Magner, 1992; Marti-Ibanez, 1962).

Advances in information technology (IT) during the last decade and a half are now impacting the medical profession, and the delivery of medical advances, in ways that will impact public policy debates for the foreseeable future. The World Wide Web (Web) makes information that was once the eminent domain of medical professionals available to average citizens who are increasingly demanding medical treatments from the leading edge of medical technology. For example, CenterWatch (www.centerwatch.com) provides a wealth of information concerning clinical trials and offers a conduit by which patients can become involved in such studies. The availability of such information has also led to patients suffering from life-threatening diseases not part of such clinical trials to request special access to potentially life-saving therapies. As a result, the Web is increasing the complexity of answering public policy questions surrounding what medical technologies to make available to the public, who will be eligible to receive new medical treatments, and at what cost.

BACKGROUND

In medicine, it has traditionally been the medical practitioner who has possessed the greater breadth and depth of information and knowledge in the provider-patient relationship (Magner 1992; Porter 1992; Robinson 1931). This condition, where one party has more information in a transaction than another party or parties (relative to the transaction), is known as information asymmetry. The existence of information asymmetry, in many transactions, has created the need to develop public policies to protect the interests of parties with less information (Akerlof, 1970; Hellwig 2001; Nayyar, 1990).

The risk of false advertising, the presence of disclaimers for contests, the existence of lemon laws for cars, and insider trading laws all attest to the need for societies to establish guidelines to handle the ethical issues which can arise from information asymmetry. Public policy has been designed to protect medical services consumers from the potential deleterious effects of information asymmetry (Akerlof, 1970; Hellwig, 2001; Milgrom & Roberts 2001). Specifically, it has dictated that doctors and other medical professionals be licensed in the nation, state or province in which they practice (Davies & Beach, 2000; Digby, 1997; Fournier & McInnes, 1997). Laws governing the practice of medicine, and what is acceptable and legal in the course of treatment and medical experiments have been developed. Oversight boards have also been established to ensure healthcare providers offer care in accordance with standards of care (Fournier & McInnes, 1997). Such precautions are intended to increase patients' confidence in the care being provided, even under the yoke of information asymmetry. The precautions do not reduce or eliminate the presence of information asymmetry.

A commonly held belief is that information parity, and information access that moves parties in transactions toward parity, is the cornerstone for the elimination of the ethical quandaries introduced by information asymmetry (Akerlof, 1970; Diamond, 1984; Hellwig, 2001). Until recently, medical information has presented two problems for the lay person: accessibility and comprehensibility (Ghalioungui, 1963; Marti-Ibanez, 1962; Magner, 1992; Porter, 1992; Robinson, 1931).

Accessibility refers to the opportunity to find, as well as the ease and convenience associated with locating, information. Medical journals are expensive, and prior to online libraries, many university libraries prided themselves on the expansiveness of their collections of journals. For a patient with a medical problem, or a family problem, a primary constraint was the ability to locate and access the salient medical information dealing with the problem. If the patient did not live in a town with a medical school, he or she would have to depend on the local library's often sparse repository of medically-related offerings to search for relevant information. Generally, assuming the patient could identify an appropriate source of information, it was not locally available (Digby, 1997; Matthews, 2000). This would necessitate relying upon the availability of interlibrary loan or a trip to the library that held the sought-after text or journal. More likely than not, however, the affected patient would not have the ability to reference such medical resources. Most commonly, the patient's knowledge of medical treatment options was limited to that offered by a medical care provider, word-of-mouth, or from popular press publications. Historically, lack of information accessibility has been a powerful protector of information asymmetry.

Even if patients could locate and access relevant medical information they were still faced with the problem of comprehensibility. Medical journals are written for an audience with a minimum understanding of biology, chemistry, physiology, anatomy, biochemistry, and pharmacology. There is a requisite base of knowledge for understanding medical texts and journals, and much medical literature is written for an audience with specialized knowledge of a particular field of medicine. For the lay audience, such literature is virtually indecipherable.

With the practically insurmountable twin problems of accessibility and comprehensibility, patients received most of their medical information through the filter of the physician. Few physicians could be considered members of the *avant garde*. Consequently, patients were more than likely to learn only of medical therapies with which their physicians were familiar (Marti-Ibanez, 1962; Porter, 1992; Robinson, 1931). Thus, information on progressive treatments not approved for use, or uncovered by medical insurance, would not be widely disseminated to the general public through physicians. Further, licensed physicians familiar with such treatments would face numerous legal hurdles to providing information regarding experimental or unapproved medical therapies.

DEVELOPMENTS THAT HAVE REDUCED INFORMATION ASYMMETRY

In the twentieth century, information on many medical and scientific advances was made available to a large cross-section of the population via print and electronic mass media. However, the availability of such media outlets did not significantly alter the level of information asymmetry between the patient and the medical practitioner. First, national oversight of media outlets limited their ability to report on medical treatments and breakthroughs not licensed in that particular country (Barry & Raworth, 2002). Perhaps, just as importantly, mass media tend to report on items of broad interest to their constituents. Esoteric medical discoveries of interest to a minute segment of the population were less likely to garner much media attention. This dynamic has shifted radically since Tim Berners-Lee's creation of the World Wide Web in the 1990s. With this innovation, the barriers to information symmetry in medical information have eroded, albeit imperceptibly at first.

The Web facilitates global access to medical information without regard to national laws or availability of treatment. The filter on medical information provided by physicians (i.e., national governments, regional health boards and media censors) was removed, and patients could access information at a rate nearly commensurate with their physicians'. Patients are made aware of new and developing medical treatments rapidly via such online outlets as CenterWatch and ClinicalTrials.gov (www.clinicaltrials.gov). ClinicalTrials.gov is a service of the U.S. National Institutes of Health. Numerous Web sites are also dedicated to alternative medical therapies for a variety of illnesses. Yahoo! Health provides a starting point for identifying potential alternative medicine resources (dir.yahoo.com/Health/alternative_medicine). Individuals are thus free to decide which medical innovations interest them, and then seek information on them.

The information availability barrier to information symmetry has been significantly reduced, leaving the difficulty with comprehensibility as a challenge to information parity. The Internet and Web, however, allow motivated individuals to locate multiple presentations of information on the same medical innovation in an effort to identify an intelligible (to them) presentation of the information. E-mail, online chats, text messaging, personal computer (PC) based video conferencing and inexpensive long distance through voice over IP (VOIP) facilitate the ability of communities of consumers sharing similar medical conditions to pool their intellectual capital in an effort to interpret the extant information on a medical innovation and to reduce that information to the lowest common denominator of intelligibility. Wikis constitute a powerful tool by which all kinds of, including healthcare, information is being disseminated. A plethora of healthcare topics ranging from the flu to HIV are available. One of the advantages of wikis is the fact they are developed and edited by online communities of users. Consequently, even conceptually difficult and technically rigorous knowledge bases can be interpreted and presented in a non-technical manner understandable to a broad readership. As a result, the second barrier to information symmetry continues to be reduced.

Technology has created a reduction in asymmetry (RIA) between the medical professional and the patient. Where the patient in the office of a medical professional once considered the practitioner before him to be the expert on the treatment of a condition, it is now feasible for the patient to have more information on the available treatments than the attending physician. The rapid advance of medical innovations and the volumes of information associated with each make it virtually impossible for a physician to be an expert on the entire spectrum of possible treatment options. Further, many medical therapies are experimental and will not find their way into mainstream medical care or even be approved for use for years. While a physician may have a passing familiarity with such therapies, it is unlikely he or she will have a strong motivation to become expert on them. A patient with a particular malady, however, not only has great incentive to research that condition and all treatments, including those that may currently be unapproved or categorized as experimental, but the Web also provides a means by which he or she can do so.

Online communities for particular maladies offer their sufferers a means of support in coping with their illnesses. Arguably, such communities provide a variety of informational and emotional support. ProHealth's ArthritisSupport.com (www.arthritisSupport.com) provides an example of such an online community. It provides a full range of information and support for sufferers of both osteoarthritis and rheumatoid arthritis in the form of online chats, message boards, coping tips, clinical trial and drug information, physician selection, as well as information related to disability claims. The existence of such communities demonstrates the power of the Web to bring patients with similar interests together for their mutual benefit in terms of support and a reduction in information asymmetry.

NEW RESEARCH ISSUES

The supposition of information asymmetry research (e.g., in economics and finance) is that the efficiency of markets can be improved by diminishing the level of asymmetry in transactions (Akerlof, 1970; Milgrom & Roberts, 2001; Payne, 2003). Further, research and public policy is predicated on the commonly held belief that information parity, and information access that moves the parties towards parity, is the cornerstone for the elimination of the ethical quandaries introduced by information asymmetry (Akerlof, 1970; Cowles, 1976; Diamond, 1984; Hellwig, 2001). However, movement toward information symmetry in the patient-provider dyad creates a number of issues that have implications for public policy makers, a sample of which is discussed here.

A significant issue with patients having unfettered access to medical information is that the information available online is not limited by geopolitical boundaries. The Web provides information on pharmaceuticals, treatments, innovations, technologies and facilities that may not be approved for use in the patient's home country or region. Large numbers of patients who desire and demand locally unavailable treatments place pressure on policy makers to examine the possibility of making such treatments available, perhaps prematurely. In some cases, pressure may mount to make a treatment available even if the long-term effects and efficacy of the treatment are uncertain.

Policy makers are placed in the position of determining whether to relax standards by which treatment options are evaluated prior to their release for public consumption. Already, we have seen mechanisms put into place to make investigational new drugs (IND) available to certain patients on an emergency, individual, or compassionate basis. The Regulatory Affairs Professionals Society (www.raps.org) is an organization dedicated to the health product regulatory profession with members from 50 countries involving industry, government, research, clinical, and academic organizations. Such organizations are intended to serve as a resource for information and education for those involved in the regulation of the healthcare sector.

Budgetary constraints frequently dictate the availability of medical therapies, particularly those that are new and expensive (Barry & Raworth, 2002; Schwartz et al., 1999). In nations with privatized healthcare, insurance companies may refuse to cover such treatments in favor of less expensive alternatives, or require the insured to pay a higher co-payment. In societies where healthcare has been nationalized, budgetary constraints are particularly troublesome since decision makers must allocate scarce medical resources either regionally or nationally. Consequently, even approved medical treatments may not be available in a particular area, or may be rationed (Barry & Raworth, 2002; Schwartz, Morrison et al., 1999).

Thus, if exogenous information enters the system and creates demand for a particular form of care, patients may seek a mix of healthcare alternatives unanticipated by medical boards. Conversely, citizens may not seek care in the volume expected by medical boards at particular locations. Consequently, resources may be over-allocated in one area, and under allocated in others. In situations where RIA leads patients to treatments which may be available in another country, the unanticipated current year expenditure to cover the extra-national treatment must come from existing budgets. Thus, funds budgeted for the current year for intra-national treatments are unavailable, and some must do without or a deficit will result. Additionally, allowing those on a long waiting list (or those excluded from the waiting list altogether) to jump ahead in the queue for treatment elsewhere, encourages those with low priority in the queue to find alternative treatment avenues.

Another serious issue may develop with patients' easy access to medical professionals in other countries. Scenarios exist where a locally unavailable treatment is available elsewhere and discussed with a patient. Patients may become well informed of the side-effects, efficacy, and benefits of a wide range of treatments not available to them; nonetheless, they will seek these treatments. When they learn of the treatments' unavailability they will demand the treatment be made available to them, or they may seek illegal means of acquiring the therapy. Online sources of certain medical services and therapies are a likely means by which to circuitously avail oneself of desired medical treatment or pharmaceuticals. E-pharmacies, for example, represent a possible conduit for the improper dispensing or illegal sale of drugs in a region or country. The challenge, here, resides in how to allow the online healthcare provider to continue to offer valuable services while ensuring the source is not abused.

The rapid rise of online communities, healthcare wikis, and other Web-based medical information sources leads to a number of important issues that need to be addressed. One such issue revolves around the accuracy of the information provided to patients via such conduits. How can we assure the veracity of the information? This is a particularly relevant question when considering user-developed informational sources such as wikis. In a wiki, the information's accuracy is assessed by the users themselves. Consequently, it is possible that conceptually difficult and technically rigorous information may be incorrectly interpreted and consolidated by users. Thus, the simplification of information may pose certain dangers to its potential consumers. Further, concerns exist with respect to online articles targeted toward specific drugs or medical therapies. How can a user of such information be assured of the information's quality? In traditional print media, we can rely, to some extent, upon an external review process. This quality check, however, is less certain in online arenas.

Another potential danger of the ubiquitous availability of medical information is information overload. What are the potential deleterious effects of information overload? It may be possible that this information overload may contribute to patients' increased confusion regarding medical conditions and available treatment modalities as opposed to alleviating such confusion. Many patients arguably make decisions concerning their healthcare, at least in part, based on the information they find online. Consequently, what is the legal culpability of the purveyors of such information when patients make decisions that are detrimental rather than beneficial to their medical care on the basis of said information?

Another relevant issue that must be addressed is the degree to which governments are responsible for controlling and disseminating available information to their citizenries. In what types of information campaigns should governments engage? The answer to this question may lie to some degree upon national cultures as well as the nature of the government in question. With the wide availability of information sources that link online users to mainstream medical modalities as well as those considered to be alternative medical modalities, some governments provide advice with respect to using such sources of information. For example, the National Center for Complementary and Alternative Medicine (www.nccam.nih.gov) in the United States provides links to its Web site visitors that explain complementary and alternative medical therapies in an effort to better educate medical consumers. The Australian government also maintains an internet presence to better educate its populace and to provide links to medical information through its Department of Health and Ageing (www.health.gov.au) as does the UK through the Health and Well-Being section of its DirectGov Web site (www.direct.gov.uk/HealthAndWellBeing/fs/en).

Since many governments attempt to provide their citizens access to relevant health-related information, two important issues arise: (1) at what point does government responsibility end and (2) are less educated or technically aware citizens exposed to increased information asymmetry. The first issue does not arise strictly from RIA, but does pose an interesting policy issue. The response to this issue will clearly vary depending upon the nature of country's society (e.g., socialist versus capitalist). The second issue also poses interesting policy implications that are directly related to information asymmetry.

If we assume that lower income and/or educational levels contribute to less access to Internet-based information technologies for individuals, then is it reasonable to assume that these individuals are subject to traditional levels of information asymmetry? Consequently, we can expect RIA gaps to vary widely across the citizens within and between countries. As a policy issue within a country, then, the problem that must be addressed is how to halt the growth of, and reduce, RIA gaps. How can a society reduce the educational disparity that results from differing socio-economic statuses? And, assuming such a disparity can be appreciably reduced, how can that society grant equal access to the internet-based information technologies that have contributed so much to RIA?

FUTURE TRENDS

Web technologies not only provide a means by which to increase information parity, but also represent a vehicle by which the scientific process may be compromised. Individuals participating in clinical trials can easily set up chat areas, news groups and email mailing lists to contact others in the same or similar studies. This allows participants to compare symptoms and progress, and may skew or completely thwart a medical study. Individuals in severe or chronic pain and those suffering from life threatening illness have great motivation to ensure they are getting the most efficacious treatment available. From the standpoint of public policy, however, this is problematic. While no one would argue that an individual does not have the right to seek the best treatment available for his or her disorder, altering the results of a clinical trial reduces the data available to determine what is best for an entire class of patients (Cowles, 1976; Digby, 1997; Matthews, 2000; Spilker & Cramer, 1992).

As Web access continues on its march toward ubiquity, the world's better-informed citizenry will, through their behaviors and desire for increasingly sophisticated medical therapies, place increased burdens on the health systems of their respective countries. Policy makers will continue to see citizens insinuating themselves into the process by which societies allocate their scarce medical resources. Debates about what medical technologies to make available, to whom, and at what cost which were once held in the relatively isolated environs of governmental and insurance provider offices are increasingly being influenced by the special interests of a diverse group of Web-savvy citizens. We can expect to see continued growth in the number and sophistication of the forums by which such special interests are expressed. Consequently, not only will policy makers have to continue to make difficult decisions about healthcare delivery, but will also have to do so under the unforgiving lamp of public scrutiny. This will place a burden on policy makers to provide mechanisms by which public concerns can be effectively factored into the decision-making process.

We are already seeing pressure mount to make medical therapies such as complementary and alternative medical treatments and promising treatments not yet authorized by the FDA available to citizens of the United States through authorized health care practitioners. This pressure has resulted in the introduction of such proposed legislation as the Access to Medical Treatment Act to the U.S. House of Representatives. Such proposed legislation is strongly supported by special interest groups such as the American Association for Health Freedom (www.healthfreedom.net). Another example of the interest in allowing better access to experimental drugs is demonstrated by the Abigail Alliance (www.abigail-alliance.org). This Web site is dedicated to providing patients with life-threatening illnesses access to potentially life-saving treatments. Further, foundations such as the LiveStrong Lance Armstrong Foundation (www.livestrong.org) are highly visible sources of support and information for sufferers of life-threatening diseases. The call to action is clear. Public policy decision makers must be prepared to deal with the cries of their citizenry. Dynamically assessing an increasingly complex information environment with ever-better informed medical consumers is necessary. It is not sufficient to react to demands for better access to medical care; policy makers must proactively develop coherent policies and information campaigns to facilitate the flow of relevant medical information and care.

CONCLUSION

This then is a microcosm of the problem facing public policy decision makers and society: Which is more important to society—individual medical treatment or the societal distribution of scarce medical resources? Is it in the public interest to allocate limited medical resources to those with the best information, or should medical professionals be trusted as better qualified to determine appropriate treatments and to prioritize patient access to medical technology?

RIA between patients and medical practitioners raises public policy issues which will affect the delivery of medical care for decades to come. It is unrealistic to think that persons or families facing grave illnesses will not seek all available information that may improve their lives or the lives of their loved ones. Whether it is paid by the patient, private health insurance or public funds from national insurance or nationalized healthcare, patients want the best and most efficacious care available. For most of these areas, RIA and increasing information parity reduces ethical, social and public policy issues. For the practice of medicine, however, RIA places physicians and governments in uncharted ethical and policy territory. An awareness of the issues that can be raised by RIA in this unusual circumstance can help the authors of public policy to prepare for social changes, and not be caught unawares.

FUTURE RESEARCH DIRECTIONS

IT facilitates communication and can de-layer the communications path between medical researchers and patients affected with a specific condition. Future research could examine the use of medical information bulletin boards, chat room and virtual communities by patients to exchange treatment results. As a means of determining motivation levels of patients, the research could survey patients to see what research they have done on their disease or condition.

Future surveys could explore medical researchers and their experiences with control groups contaminated by the sharing of treatment results. Further, examination of physicians who recommended/submitted patients to participate in medical research can be conducted. The physicians could track the frequency with which patients ask questions indicating advanced knowledge of the study. The information could be combined with study information on the types of diseases being treated and ages of the patients in the medical study.

Future research could investigate the degree to which non-hospital treatment centers assist in the dissemination of medical information. Many of these centers are staffed by nurses, not physicians, and may act as an additional layer of filtering for information to the patient.

A study of the correlation between Internet access speed and the questions posed to physicians could help in understanding the impact of broadband access on the RIA. Further, a correlation with income could disclose if a digital divide is forming in medical care. If information concerning medical studies and treatment options is readily available to those with computers and Internet access, but the same information is less readily available to non-computerized patients, medical studies may be weighted towards the wealthy and technically savvy.

Future research could explore the creation of a clearinghouse for researchers to report tainted studies. In this way, the medical and IT communities can determine the degree of medical research contamination. Ethics researchers can explore and debate the future of the physician-patient interaction, and how this will change as physicians lose their monopoly on diagnosis and treatment options. Public policy researchers can explore the legal options which may be necessary to ensure that medical treatments are equitably available. Public policy researchers can also examine the necessity of maintain laws which limit the discussions physicians can have with their patients, in the face of internationalization of medical technology information.

Future research could also explore other areas in which RIA produces greater ethical issues for one of the parties. As information technology becomes pervasive, it is likely that other fields will discover that RIA does not always lead to more efficient markets. This understanding will allow researchers to identify situations in which RIA leads to greater moral dilemmas, not a reduction in ethical considerations.

KEY TERMS

E-Pharmacy: A term that refers to the existence of an online pharmacy that offers medical care providers the ability to prescribe medications for patients online. These medications can then be delivered to patients without ever requiring them to leave the confines of their homes. In some, cases prescriptions can be filled without a physician ever having physical contact with the patient.

Ethical Issue: A situation where the decision maker is required to weigh values and employ judgment in reaching a decision. Frequently, this is a situation which is outside of, or different from, those with which the decision maker has previous experience.

Information Asymmetry: A situation in which one party has more information in a transaction than another party or parties, relative to the transaction.

Information Parity: As situation in which both parties in a transaction have equal information related to the transaction.

Information Accessibility: The opportunity to find, as well as the ease and convenience associated with locating, information. Often, this is related to the physical location of the individual seeking the information and the physical location of the information in a book or journal.

Information Comprehensibility: The ability to comprehend and utilize information once located. Comprehensibility, if the information is syntactically and grammatically correct, is often dependant on the preparation and training of the individual accessing the material.

Locally Unavailable Treatment: Medical treatment which may not be available in a nation or region for economic, regulatory or technical reasons. The treatment may also be limited by law or administrative actions.

Reduction in Information Asymmetry (RIA): Reducing the disparity in information between the parties in a transaction, relative to the transaction.

Chapter 7.4
Access Control for Healthcare

Yifeng Shen
Monash University, Australia

INTRODUCTION

Thanks to the rapid development in the field of information technology, healthcare providers rely more and more on information systems to deliver professional and administrative services. There are high demands for those information systems that provide timely and accurate patient medical information. High-quality healthcare services depend on the ability of the healthcare provider to readily access the information such as a patient's test results and treatment notes. Failure to access this information may delay diagnosis, resulting in improper treatment and rising costs (Rind et al., 1997).

Compared to paper-based patient data, computer-based patient data has more complex security requirements as more technologies are involved. One of the key drivers to systematically enhance the protection of private health information within healthcare providers is compliance with the healthcare information system security standard framework and related legislation. Security standards and legislation of the healthcare information system are critical for ensuring the confidentiality and integrity of private health information (Amatayakul, 1999). Privacy determines who should have access, what constitutes the patient's rights to confidentiality, and what constitutes inappropriate access to health records. Security is embodied in standards and technology that ensure the confidentiality of healthcare information and enable health data integrity policies to be carried out.

Based on the investigation of security standard and legislation, we can analyze and create basic security requirements for the healthcare information system. To meet the security requirements, it is necessary to deploy an appropriate access control policy and system within the organization. As discussed elsewhere (Sandhu, Coyne, Feinstein, & Youman, 1996), role-based access control (RBAC) is a promising technology for managing and enforcing security in a large-scale distributed system. In the healthcare industry, RBAC has already been adopted by the Health Level Seven (HL7) organization as a key access control standard (Blobel & Marshall, 2005).

HL7 was established in 1987 to develop standards for the electronic interchange of clinical, financial, and administrative information among independent healthcare-oriented computer systems. In June of 1994, HL7 was designated by the American National Standard Institute (ANSI) as an ANSI-accredited standards developer. HL7, in its draft Security Service Framework (Kratz et al., 2005) categorizes healthcare information security exposures in the following manner:

- **Disclosure:** Exposure, interception, inference intrusion
- **Deception:** Masquerade, falsification, repudiation
- **Disruption:** Incapacitation, corruption, obstruction
- **Usurpation:** Misappropriation

Although RBAC has been introduced to the latest version of HL7 (version 3) for strengthening the security features, it only includes those basic functions. Due to the complexity of the healthcare process, RBAC with only basic functions may not be sufficient. More context constraints need to be processed in addition to traditional RBAC operations.

The major contributions we have made in this article are:

- Illustrating the detailed design of a flexible and securer RBAC model for a healthcare information system based on HL7 standard;
- Introducing the basic elements of HL7 v3 and RBAC, which are necessary for us to realize our proposed model; and
- Analyzing the potential weakness of current HL7 standard and the basic RBAC model in terms of security and flexibility.

The rest of the article is organized as follows. The next section provides a general introduction and basic analysis of HL7 version 3. We then explain the RBAC concept model and describe our major work, and finish with our conclusion and future work.

HL7 VERSION 3

What is HL7?

Health Level Seven is one of several American National Standards Institute-accredited Standards Developing Organizations (SDOs) operating in the healthcare arena. Most SDOs produce standards (sometimes called specifications or protocols) for a particular healthcare domain such as pharmacy, medical devices, imaging, or insurance (claims processing) transactions. HL7's domain is clinical and administrative data (HL7, 2005).

HL7 is also a non-profit volunteer organization. Its members are the providers, vendors, payers, consultants, and government groups who have an interest in the development and advancement of clinical and administrative standards for healthcare services. In its achievements so far, HL7 has already produced HL7 Version 2 (HL7 v2) specifications (HL7, 2005), which are in wide use as a messaging standard that enables disparate healthcare applications to exchange key sets of clinical and administrative data. However, the newer specification HL7 Version 3 (HL7 v3), still under development, pertains to all aspects of clinical and administrative data in health services. Unlike its older version, HL7 v3 specifications are completely based upon the extensible markup language (XML) standards, and so have potential to win an instant acceptance by developers and vendors alike.

The target system during our research is based on HL7 v3, so only HL7 v3 will be described in this article.

The lack of data and process standards between both vendor systems and the many healthcare provider organizations present a significant barrier to design application interfaces. With HL7 v3, vendors and providers will finally have a messaging standard that can provide solutions to all of their existing problems.

HL7 v3 is based on a reference information model (RIM). Although RIM is not stabilized yet, once it is stabilized, it will be the most definitive standard to date for healthcare services.

The following section will highlight some key components of RIM.

Reference Information Model

RIM is the cornerstone of the HL7 Version 3 development process. An object model created as part of the Version 3 methodology, RIM is a large pictorial representation of the clinical data (domains) and identifies the lifecycle of events that a message or groups of related messages will carry. It is a shared model between all the domains and as such is the model from which all domains create their messages. RIM comprises six main classes (Beeler et al., 2005):

1. **Act:** Represents the actions that are executed and must be documented as health care is managed and provided.
2. **Participation:** Expresses the context for an act in terms such as who performed it, for whom it was done, where it was done, and so forth.
3. **Entity:** Represents the physical things and beings that are of interest to and take part in health care.
4. **Role:** Establishes the roles that entities play as they participate in health care acts.
5. **ActRelationship:** Represents the binding of one act to another, such as the relationship between an order for an observation and the observation event as it occurs.
6. **RoleLink:** Represents relationships between individual roles.

Three of these classes—Act, Entity, and Role—are further represented by a set of specialized classes or sub-types.

RIM defines all the information from which the data content of HL7 messages are drawn. It follows object-oriented modeling techniques, where the information is organized into classes that have attributes and that maintain associations with other classes. RIM also forms a shared view of the information domain used across all HL7 messages, independent of message structure.

HL7 v3 Security

The focus of HL7 security needs analysis on how systems communicate information using HL7 message. It is expected that healthcare application systems that implement HL 7 v3 will be required to have significantly more functionalities to protect the confidentiality of patient information and to authenticate requests for services than has been common in the past. The new functions may include, but are not limited to, limiting the right to view or transfer selected data to users with specific kinds of authorization, and auditing access to patient data, electronic signature, and authentication of users based on technologies more advanced than passwords. Version 3 will seek out and reference standards such as X.500 (Weider, Reynolds, & Heker, 1992) and RFC 1510 to support conveying the necessary information from one healthcare application system to another, so that these systems may perform the authorization and authentication functions. Version 3 will also seek out and adopt industry security standards that support conveying the necessary information from one healthcare application system to another, so that these systems may perform the confidentiality functions.

To meet the security goals, the HL7 Secure Transaction Special Group has created a security service framework for HL7 (Kratz et al., 2005). According to the scope of the framework, HL7 must address the following security services: authentication, authorization and access control, integrity (system and data), confidentiality, accountability, availability, and non-repudiation. The HL7 security service framework uses case scenarios to illustrate all the services mentioned above. All those case scenarios can help the readers to understand those services in a very direct way. However case scenarios are not detailed enough to be an implementation guide for the security services.

In this article we are going to design a flexible model for one key security service—access control. This model will extend the case scenarios to a very detailed level which can be directly used as an implementation guide for HL7 v3.

Figure 1. (

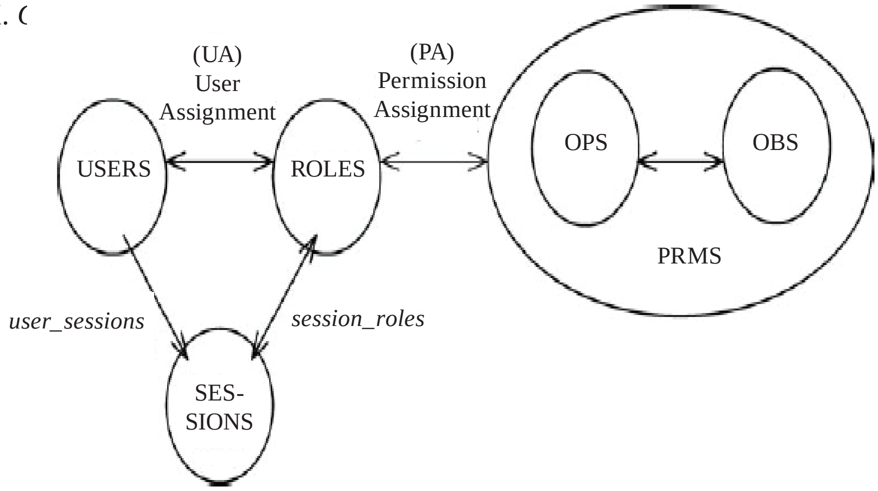

Figure 2. RBAC permissions with context constraints

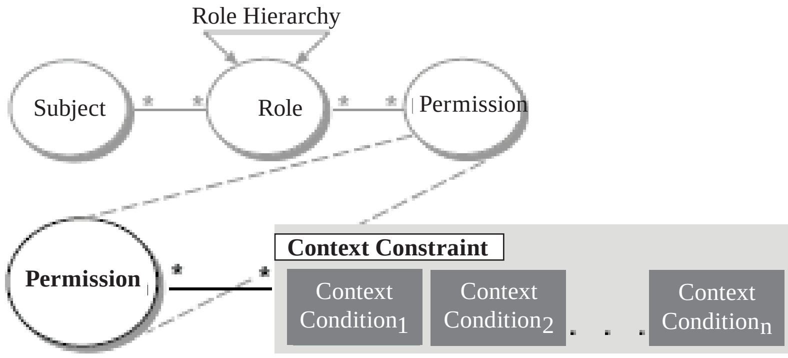


ROLE-BASED ACCESS CONTROL

RBAC has became very popular in both research and industry. RBAC models have been shown to be "policy-neutral" in the sense that by using role hierarchies and constraints (Chandramouli, 2003), a wide range of security policies can be expressed. Security administration is also greatly simplified by the use of roles to organize access privileges. A basic RBAC model will be covered in this section, as well as an advanced model with context constraints.

Basic RBAC Model

The basic components of the RBAC model are *user*, *role*, and *permission* (Chen & Sandhu, 1996). The user is the individual who needs access to the system. Membership to the roles is granted to the user based on his or her obligations and responsibilities within the organization. All the operations that the user can perform should be based on the user's role.

Role means a set of functional responsibilities within an organization. The administrator defines roles, a combination of obligation and authority in organization, and assigns them to users. The user-role relationship represents the collection of users and roles.

Permission is the way for the role to access more than one resource.

As shown in Figure 1, the basic RBAC model also includes *user assignment* (UA) and *permission assignment* (PA) (INCITS359, 2003).

The user assignment relationship represents which user is assigned to perform what kind of role in the organization. The administrator decides the user assignment relationship. When a user logs on, the system UA is referenced to decide which role it is assigned to. According to the object that the role wants to access, the permission can be assigned to the role referenced by the permission assignment relationship.

The set of permissions (PRMS) is composed of the assignments between operations (OPS) and objects (OBS).

UA and PA can provide great flexibility and granularity of assignment of permissions to roles and users to roles (INCITS359, 2003). The basic RBAC model has clearly illustrated the concept about how role-based access control works within an organization. However it may not be dynamic enough when the business process becomes very complex. Thus the idea of context constraints is introduced to make the RBAC model more useful.

RBAC Model with Context Constraints

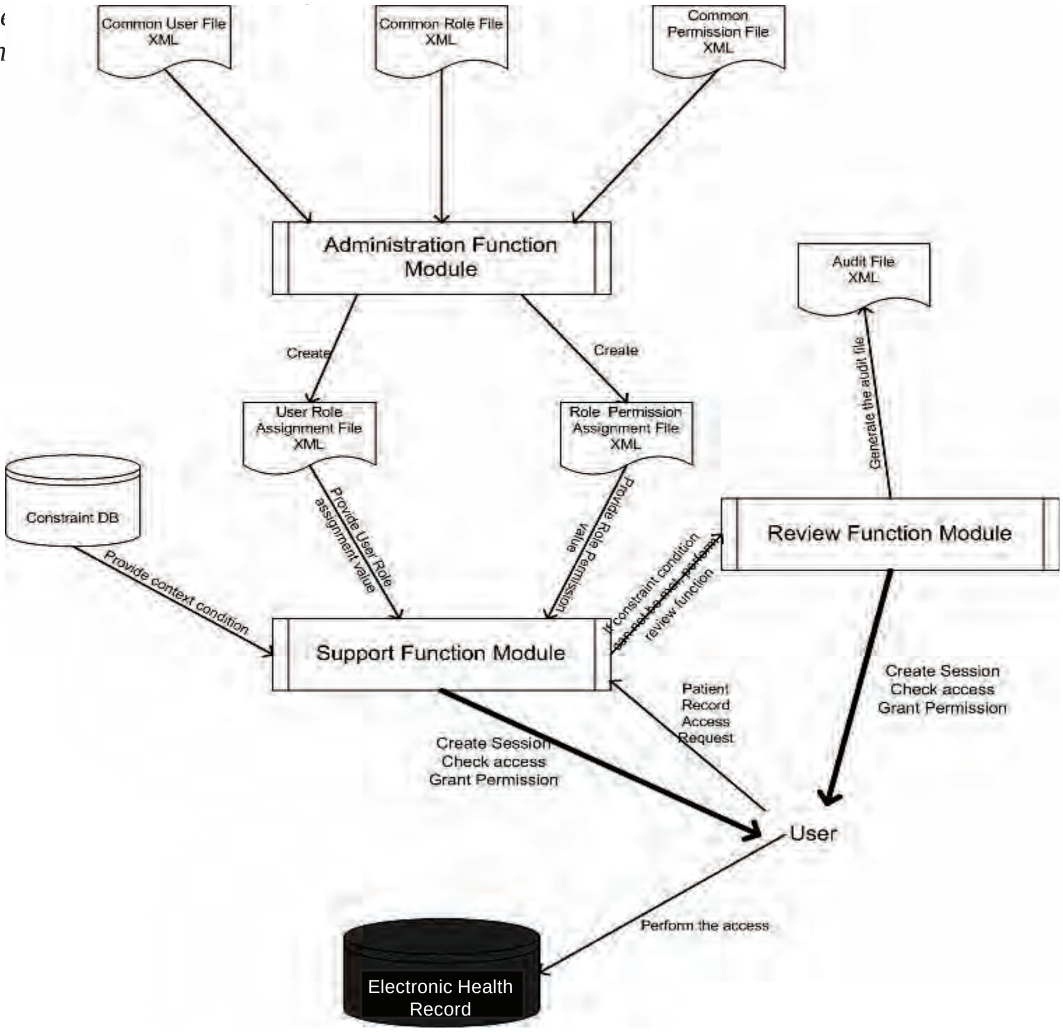
Traditional RBAC supports the definition of arbitrary constraints on the different parts of a RBAC model (Sandhu et al., 1996). With the increasing interest in RBAC in general and constraint-based RBAC in particular, research for other types of RBAC constraints has gained more attention (Bertino, Bonatt, & Ferrari, 2001). In this section we describe the context constraints in an RBAC environment.

A context constraint is an abstract concept. It specifies that certain context attributes must meet certain conditions in order to permit a specific operation. As authorization decisions are based on the permissions a particular subject/role possesses, context constraints are associated with RBAC permissions (see Figure 2).

The context constraint is defined through the terms context attribute, context function, and context condition (Strembeck & Neumann, 2004):

- A *context attribute* represents a certain property of the environment whose actual value might change dynamically (like time, date, or session-data, for example) or which varies for different instances of the same abstract entity (e.g., location, ownership, birthday, or nationality). Thus, context attributes are a means to make context information explicit.
- A *context function* is a mechanism to obtain the current value of a specific context attribute (i.e., to explicitly capture context information). For example, a function *date*() could be defined to return the current date. Of course, a context function can also receive one or more input parameters. For example, a function *age*(*subject*) may take the subject name out of the *subject*, *operation*, *object_* triple to acquire the age of the subject, which initiated the current access request, for example, the age can be read from some database.
- A *context condition* is a predicate that consists of an operator and two or more operands. The first operand always represents a certain context attribute, while the other operands may be either context attributes or constant values. All variables must be ground before evaluation. Therefore, each context attribute is replaced with a constant value by using the corresponding context function prior to the evaluation of the respective condition.
- A *context constraint* is a clause containing one or more context conditions. It is satisfied if and only if (iff) all context conditions hold. Otherwise it returns false.

Figur
health



A context constraint can be used to define conditional permissions. Based on the terms listed above, the conditional permission is a permission associated with one or more context constraints, and grants access iff each corresponding context constraint evaluates as "true."

As we can see, a context constraint can help the organization provide more flexible and securer control for the RBAC model.

Design a RBAC Model with Context Constraints for the Healthcare Information System Based on HL 7 Version 3

The access control model we are going to describe is a method to control access on a healthcare information system. It is developed to enhance the security and flexibility of traditional access control systems. The resource to be accessed in this article is limited to a patient's electronic health record (EHR).

The primary purpose of the EHR is to provide a documented record of care that supports present and future care by the same or other clinicians. This documentation provides a means of communication among clinicians contributing to the patient's care. The primary beneficiaries are the patient and the clinician(s) (ISO/TC-215 Technical Report, 2003).

System design will include two major phases:

1. **Components design:** Describes all the necessary elements that make up the system.
2. **Data flow design:** Describes all the processes that make the whole system work.

Components Design

As described in the previous section, the RBAC system must include the basic elements such as user, role, permission, user-role assignment, and role-permission assignment. All those elements will be associated with real values in our system design. Figure 3 illustrates the overall structure of the system.

- **User:** Anybody with authenticated identity can act as the user in the system. For example, after Tom successfully logs into the hospital's computer system with his user ID 19245678, he becomes the user of our system.
- **Role:** The set of roles can be retrieved from those functional roles that already exist in the current healthcare information system such as physician, pharmacist, registered nurse, and so forth. As the number of roles is limited in our system, we can store all the role information by simply using an XML file instead of a database. This file is named "Common Role File.xml."
- **Permission:** The scope of the permissions in our design will focus on those system operations (create, read, update, delete, execute, etc.). Similar to role information, we use another XML file with the name "Common Permission File.xml" to represent all the permission information.

As shown in Figure 3, the user, role, and permission file can be used as the basic input for the whole system. To generate user-role assignment and role-permission assignment relationship, we introduce the *administration function* module. This module is designed to create and maintain the user role assignment file and role permission assignment file.

The rules of user role assignment and role permission assignment are referenced from the security section of HL7 v3 standard (HL7 Security Technical Committee, 2005).

In addition to the administration function module, we also designed another two function modules: *support function* module and *review function* module. The support function module provides the core function of the system. It receives the access request from the user and makes judgment based on the input from different sources to decide whether the access can be granted. The detailed process will be described in the next section.

The review function module is an extension of the support function module. It is used for exceptional scenarios, such as emergent circumstances that do not satisfy the constraint condition. Every time the review function module is initiated, an audit file will be created to record all the necessary information of the exceptional case. In our system, the audit file is saved in XML format with the name " Audit File.xml."

The ultimate object the users want to access is the EHR. The existing database that stores all the EHRs can be used directly by our system.

Another database included in this system is the constraint database, which stores all the context attributes and context conditions. The context attributes and context conditions can be used as input for the support function module during the access control decision process.

In summary, the components can be categorized into three types based on the design:

- **Type 1 – Basic elements:** Role, User, Permission, User Role Assignment, Role Permission Assignment, Audit File. All these basic

elements are represented in XML format.
- **Type 2 – System functional modules:** Administration Function Module, Support Function Module, Review Function Module. All these modules provide the core functions of the system and are represented in real program.
- **Type 3 – Database:** EHR database and constraint database.

Data Flow Design

After all the components are defined, we will design the proper data flows to make the system work. The data flow design is based on the three functional modules previously discussed. Thus, we introduce three kinds of data flow in this article:

- data flow for administration function module,
- data flow for support function module, and
- data flow for review function module.

Data flow for administration function module

1. Administration function module reads the common user file, common role file, and common permission file. Those files contain all the user information, role information, and permission information respectively.
2. Based on the pre-defined user-role relationship/role-permission relationship, the administration function module creates a user role assignment file and a role permission assignment file in XML format.

Data flow for support function module

1. The user sends an access request to the support function module.
2. The support function module requests and receives role information about the user from the user assignment file.
3. The support function module requests and receives the permission which is assigned to the role. This can be retrieved from the permission assignment file.
4. Get context attributes and context condition information from the constraints database.
5. The support function module performs the "check access" function then grants the access permission to the user.
6. The user can retrieve the information from the EHR database.

Data flow for review function module

1. Sometimes the context condition cannot be met, however all the other conditions (permission assignment, user assignment) can be met and the user really wants to access the resource because of emergency. In this case, all authentication information will be forwarded to the review function module.
2. The review function module records all the necessary information and generates an audit file, then grants conditional access permission to the user.
3. The user can retrieve the information from the EHR database.

All the steps listed above for the data flow just give a brief description. More detailed steps are necessary when it comes to the system implementation phase.

CONCLUSION AND FUTURE WORK

Clinical information sharing between different healthcare information systems is the key factor to improve the quality of service. Health Level Seven is the data exchange standard for clinical information. In this article we first introduce the basic concept of Health Level Seven and role-based access control. Then we illustrate how to design a flexible role-based access control model for a healthcare information system based on Health Level Seven version 3. The design utilizes the existing access control feature of Health Level Seven version 3 and integrates context constraints to make the system more secure and more flexible.

In the future, the major work will be the development of those function modules and applying this model to a real healthcare information system to see how the security access control can be improved.

KEY TERMS

Electronic Health Record (HER): A longitudinal electronic record of patient health information generated by one or more encounters in any care delivery setting.

Extensible Markup Language (XML): A W3C initiative that allows information and services to be encoded with meaningful structure and semantics that computers and humans can understand.

Health Level Seven (HL7): One of several American National Standards Institute (ANSI)-accredited Standards Developing Organizations (SDOs) operating in the healthcare arena.

Permission Assignment (PA): Assigns permission to an authorized role.

Reference Information Module (RIM): The cornerstone of the HL7 Version 3 development process and an essential part of the HL7 v3 development methodology. RIM expresses the data content needed in a specific clinical or administrative context, and provides an explicit representation of the semantic and lexical connections that exist between the information carried in the fields of HL7 messages.

Role-Based Access Control (RBAC): A system of controlling which users have access to resources based on the role of the user.

User Assignment (UA): Assigns a role to a user.

Chapter 7.5
Securing Mobile Data Computing in Healthcare

Willy Susilo
University of Wollongong, Australia

Khin Than Win
University of Wollongong, Australia

ABSTRACT

Access to mobile data and messages is essential in healthcare environment as patients and healthcare providers are mobile. This is inline with the need of ubiquitous computing in everyday life. Mobile and wireless devices can assist in ensuring patient's safety by providing easy availability of the data at the point of care. Portability and accessibility of these devices enhances use of them in healthcare environment. However, data integrity and confidentiality of information in them need to be ensured to provide safe, effective and efficient healthcare. Mobile healthcare involves conducting healthcare related activities through using mobile devices such as a smart phone, Personal digital assistant (PDA), wireless enabled computer, iPod and so on. Mobile computing is suitable for healthcare as healthcare providers are mobile. These would be suitable for conducting patient's healthcare activities in emergencies, ward rounds, homecare, chronic disease management, conducting clinical trials, and so on. There are various projects using mobile devices to enhance patient's care. With the advancement of medical informatics, telemedicine and information technology, mobile data devices play an enormous role in healthcare system. In this chapter, we outline the need of mobile devices in healthcare, usage of these devices, underlying technology and applications, importance of security of these devices, securing mobile data communication

in healthcare through different security models and case examples of applications that we have developed, in particular (1) iPathology tool on iPod, (2) securing healthcare information using Pocket PC 2003, and (3) securing information on handheld devices. There were several incidents in the past due to the insecurity of mobile devices that can leak information to anyone who does not have access to the information. In this chapter, we will illustrate several techniques that we have developed to protect these malicious activities and how these are applicable for securing mobile data computing in healthcare.

INTRODUCTION

In recent years, a wide range of handheld devices have been introduced in the market. Pocket size handheld organizers, called personal digital assistants (PDAs), have evolved from offering simple services such as calendar, address book, and e-mail, to working as a powerful mobile network client that can be used to access corporate databases and be used as part of an e-commerce platform. The healthcare industry is not an exception with healthcare providers using various handheld devices for accessing information and for telemedicine purposes. These days, the mobile devices are also equipped with communication abilities, such as GSM/GPRS ability, WiFi 802.11a/b/g Wireless LAN or Bluetooth. Handheld devices are perfect for carrying information, such as multimedia information, on the fly. Users can enjoy the information while they are on their way to work, etc.

Securing such devices includes providing protection for wireless communication, stored data and against viruses and malicious codes, together with making provisions for preventing theft of the device. The more we become dependent on handheld devices, the more threatening the attack will be. Today the U.S. military is already relying extensively on such devices. These devices can be used for GPS, viewing maps of areas, interacting with other troop units and as (remote) sensors (such as those used against bio-warfare), etc. Moreover, the U.S. military is spending large amounts of money to expand the capabilities of such devices. Other applications in critical infrastructures can be expected. For example, today many firefighters and ambulance services rely on paper maps. In regions in the world that expand rapidly, there is a significant advantage to switch to handheld devices where maps are updated more frequently. Since several manuals are primarily available via the Internet, handheld devices will be used by technicians to repair machinery in nuclear power plants, airplanes, etc.

There are several major differences between a desktop computer and a handheld device including limited input methods, small screen size, lower range processor, and limited memory for the handheld device. These differences affect the design of applications that run on these devices. Palm OS and Pocket PC handheld devices do not have a keyboard. Although a third party keyboard, such as Palm Portable keyboard or Targus Stowaway keyboard, can be used, most users enter text to the device with a *stylus* which is then recognised by a character recognition program such as Palm *Graffiti* or *Microsoft Transcriber*. Other methods of input include using the on-screen keyboard, or typing text on a desktop PC that is connected to the PDA. Communication with the device is achieved by using the HotSync/Activesync that synchronizes the data with its copy that is stored on a desktop computer, using a communication port such as the serial port, the IrDA (Infrared Data Association) port, or the USB port.

Palm 1000 was introduced by 3Com in 1996. Devices running Palm OS have dominated the handheld market and currently having around 70% of the market share (Hansmann, Merk, Nickous, & Stober, 2001). Palm OS is also adopted by companies such as HandSpring and IBM with applications ranging from Palm OS native applications including Address Book and Date Book, to other applications that are available as freeware, shareware or commercial products from third-party providers, including fax software, calculators, and software development kits for developers. The second major operating system for handheld computers is Windows CE (or pocket PC) which takes almost the rest of the market share. The most recent version is known as Windows Mobile 2005, with its support to GSM/GPRS mobile phone connection, together with its ability to connect to Wireless LAN 802.11a/b/g and Bluetooth.

Our Contribution

In this chapter, first we review the background on handheld devices, together with their known weaknesses. Then, we proceed with the use of handheld devices in healthcare environment. Finally, we provide some case studies that we have done in the effort to securing such devices.

Background of Handheld Devices

In this section, we review the necessary background and knowledge in handheld devices.

PALM OS PDA

Storage on a Palm PDA includes RAM and ROM that reside on memory cards. A memory card can store 256 MB and is divided into a dynamic heap and multiple storage heaps that are used for providing runtime environment, and storing data and applications. Newer models of Palm PDA, starting from Palm m505, m515, and Tungsten, are equipped with SD (Secure Digital) expansion slots that could be used for Bluetooth or Wireless LAN 802.11b devices.

Palm OS and built-in applications are stored in the ROM while user's data and applications are stored in RAM which is always powered to allow persistent storage. Applications and users' data can be backed-up on a desktop PC, or to the backup expansion pack (for the new models).

Development Systems

There are several development systems for building programs for Palm OS with C and C++ being the most commonly used languages for Palm Computing platform. Other available languages are Basic, Java, and Assembly.

A newly created application can be tested on a Palm OS Simulator or a Palm OS Emulator before it is installed on a Palm device. Palm OS Simulator is only available on the Macintosh OS and requires the application to be linked with a Simulator library that allows it to run as an independent application. Palm OS Emulators are available for Windows, Mac OS and Unix systems. The Emulator imitates the Palm OS device and allows an application to run without requiring additional library.

Third Party Program Installation

There are a number of ways of downloading programs to a Palm PDA. Firstly, *HotSync* program can be used to download new applications during the synchronization between the Palm and a desktop PC. A second method uses a third party program such as *Pilot Install* (envi.com, online). Applications can also be downloaded using IrDA port or a Bluetooth connection. IrDA drivers for desktop PCs can send a file to another IrDA point and so an application can be sent to a Palm PDA. An application can also be attached to a mail. This requires connection to users' mailbox on their PC via a synchronization program and so in terms of difficulty is similar to downloading the program via the HotSync program. Downloading a program is also possible through a browser (either on-line or off-line browser), such as AvantGo.

Communication and Networking

Palm OS supports two types of data communication: *serial/USB* and *infrared*. The serial/USB communication is used to synchronize the Palm via a HotSync or be used to transmit or remove data through a serial bus. The Palm is equipped with an infrared transceiver and can *beam* data (such as contact details) to another Palm using appropriate communication protocols. This ability has been used to enable a Palm to remotely control another device or to print to an infrared printer.

A TCP/IP connection can be established when a Palm connects to the Internet via a modem or a cradle with a software that supports the PPP protocol. Palm OS provides two libraries for TCP/IP networks which are known as Palm OS Net Library and Internet Library.

Wireless Portal

Many handheld devices can only access Web pages that have specially formatted data to download. Webclipping and WAP are the two commonly used technologies that meet the limitations of small displays that are not capable of displaying regular multimedia Web sites. Although Web browsers such as ProxyWeb and PalmScape, are available for Palm, the two technologies above are usually preferred due to the size limitation of the device.

Palm.Net offers mobile Internet access for Palm device with ROM version 3.5 and above. This service is available in North America and allows users to connect to the Web through a connectivity gateway, operated by Palm.

WINDOWS CE DEVICES

Windows CE was introduced in 1996 to provide a common operating system for a range of devices including handheld computers, industrial controllers, embedded appliances and wireless communication devices. Windows CE has the same API as Windows 2000 and allows the programmers to use a subset of Win32 API development tools and languages including Visual Basic and Visual C++ targeted for CE devices. There are also special versions of the compiler, known as the Embedded Visual C++ and Embedded Visual Basic, that makes it easier to create programs.

Windows CE is not an on the shelf OS. Rather, a device manufacturer needs to configure the Windows CE operating system for the processor platform of his/her choice. The operating system is usually built into the device's ROM, although sometimes it is put in flash memory.

Windows CE devices support serial and USB communication for one-to-one communication, and network connection which can use one or many devices and more sophisticated protocols such as HTTP and file exchange protocols like remote access service (RAS). To support infrared communication based on IrDA protocol, the IrSock API has been added to the operating system.

The latest version of Windows CE is known as the Windows Mobile 2005 Operating System, which is equipped with GSM/GPRS mobile phone connection together with 802.11a/b/g Wireless LAN and Bluetooth support.

VULNERABILITIES OF PALM OS DEVICES

In the following, we illustrate the known vulnerabilities of handheld devices. Without losing generality, we only illustrate the vulnerabilities against Palm OS devices. Three types of attacks have been reported on Palm.

Eavesdropping Palm Infrared Connection

The Palm OS Infrared is vulnerable to data stealing attack. Two main reported cases include constructing a program called "NotSync" which enables a Palm to *steal* the password from another Palm via its IrDA interface (@stake, online), and an eavesdropping attack (Nutheesing, online).

Denial of Service Attacks via HotSync

Palm HotSync manager is used to synchronize data between a Palm and a desktop PC. The HotSync program has a network mode that allows remote synchronization via a modem, hence adding more flexibility to Palm.

It is shown (Knight, online) that setting HotSync in the Network mode can lead to a denial of service attack by sending a large amount of data followed by a new line which results in the Palm to crash.

Palm Virus and Trojan Horse

Similar to other operating systems, Palm OS is vulnerable to viruses and Trojan Horses. The first Palm OS virus, known as the "Liberty crack" (Harris, online), is written by one of the co-authors of the Liberty program. It is a destructive Palm application, disguised as a free version of the Liberty application, that deletes all of the programs stored on a Palm and then reboots the device. A more comprehensive survey of Palm OS weaknesses can be found elsewhere (Kingpin, 2001).

PROTECTION OF HANDHELD DEVICES VIA PERSONAL FIREWALL

We have created a personal firewall for Pocket PC 2003 handheld device. Our personal firewall will allow an authorized information to pass through the device, but an unauthorized information will not be able to enter the device. The technique that we used is by rewriting the Ethernet driver for Pocket PC 2003 device. We will illustrate our work in the following section.

Background

In such a pervasive connected environment, network security is critical to protect devices and the information they contain. Central to network security is the firewall, which acts as a barrier between an untrusted network and the trusted network (or device). Due to high-profile hacker attacks and proliferation of viruses, firewalls have become a fundamental security tool. At this stage, no security system can ensure with absolute certainty that all of the information will be protected all of the time. Firewalls are one of the most effective security tools that a network administrator can deploy to limit vulnerability.

A firewall is hardware or software that monitors the transmission of packets of digital information that attempt to pass through the perimeter of a network. A firewall can be described as a system for enforcing *access control policy* between two networks. A firewall can deny unauthenticated requests or requests with potential threats, while permitting authenticated requests, thus protecting the internal network. In most cases, firewalls are used to prevent outsiders from accessing an internal network. However, firewalls can also be used to guard one highly sensitive part of a private network against its other parts. Such sensitive parts are for payroll, payment processing, R&D systems, etc.

There are essentially three types of firewalls: (1) packet-filtering firewalls, (2) stateful firewalls, and (3) application-level firewalls. A packet-filtering firewall drops packets based on their source or destination address or ports. For example, it blocks all packets from a site that we do not trust, or blocks all packets to an internal machine that should be inaccessible from an external network. Linux's *ipfwadm* and *ipchains* are examples of this type of firewall. A stateful firewall works at the session layer of the OSI model, or the TCP layer

Figure 1. Relation between the modules

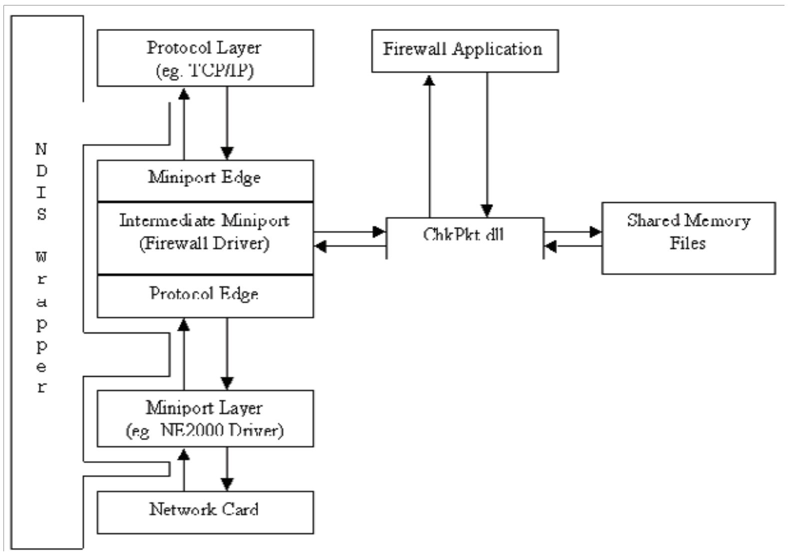

Figure 2. Screen captures of Personal Firewall for Pocket PC 2003 devices

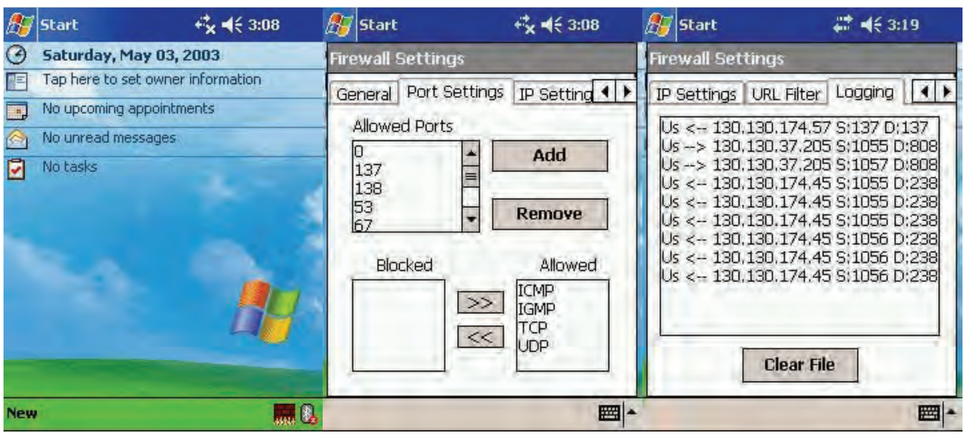

of TCP/IP. It monitors TCP handshaking between packets to determine whether a requested session is allowed. It creates a circuit then relays data between external and internal network. Stateful firewalls keep track of sessions and connections in internal state tables. It can protect against certain types of denial of service attacks. An example of this type of firewall is Checkpoint FW-1. In addition to lower levels, application-level firewalls inspect packets at the application level. A packet reaches the firewall and is passed to an application-specific proxy, which inspects the validity of the packet.

Newer types of firewalls include distributed firewalls and personal firewalls. In distributed firewalls, security policy is centrally defined but is enforced at individual network end points, such as routers, gateways, servers or user PCs. Policy can be distributed to end points in various forms. For example, policy can be pushed to end points where such policy should be enforced. Policy may also be provided to the users as credentials that will be presented when needed.

Unlike traditional firewall sitting between the external and internal networks, a personal firewall runs on a user's computers. Personal firewalls do not have problems such as end-to-end network encryption, malicious insider attacks, single point of failure, etc.

Personal Firewall for Pocket PC 2003 Handheld devices

We have designed and implemented a personal firewall for Pocket PC 2003, which filters TCP/IP traffic passing to and from the device via an Ethernet card. The concept can be extended to allow other protocols such as 802.11b to be covered. Although personal firewalls exist in the market (e.g., Norton Personal Firewall, etc.), their design and implementation are not widely available. In this chapter, we present the first open source firewall for Pocket PC 2003 operating system devices. The personal firewall is a packet-filtering type firewall, which analyzes the contents of network packets. The firewall examines, if applicable:

1. Source and destination IP address
2. Source and destination port
3. Protocol
4. HTTP domain and URL

It establishes the validity of network packets, based upon a strict set of rules. Depending on the packet validity, the firewall either accepts or rejects the network packet. If the firewall encounters a packet that is suspicious or unknown, the user will be notified, depending on the security level, and asked to respond with the appropriate action to be taken.

The design of our firewall consists of three separate modules:

1. `IMDrv.dll` — network device driver
2. `ChkPkt.dll` — dynamic link library
3. `FWApp.exe` — application

The relation between these three modules are illustrated in Figure 1.

We have successfully developed and implemented our personal firewall on Pocket PC 2003 handheld devices. Some of the screen captures of our implementation are shown in Figure 2.

THE NEED FOR MOBILE DEVICES IN HEALTHCARE

In healthcare, mobile healthcare involves conducting healthcare related activities through using mobile devices such as a wireless phone, personal digital assistant (PDA), wireless enabled computer, iPod and so on. Portability and accessibility of these devices enhance their use of them in healthcare environment. Moreover, ease of use, affordability, and ability to read handwriting attracted use of these devices (Al-Ubaydli, 2004). The devices would be suitable for conducting patient's healthcare activities in emergencies, ward rounds, homecare, chronic disease management, conducting clinical trials, and so on.

Mobile computing is suitable for healthcare as healthcare providers are mobile. Healthcare providers would like to enter information in the patient record and process information during the ward round and at the point of care (Reuss, Menozzi, Buchi, Koller, & Krueger, 2004). Health information system located at the fixed terminal is inefficient because the necessary information will not be available at the time of query and that will interrupt the workflow (Eisenstadt et al., 1998).

USAGE OF THESE DEVICES

Mobile and wireless devices can assist in ensuring patient's safety by providing easy availability of the data at the point of care. Computerised physician order entry systems are being developed in most healthcare institutions to reduce medical errors (Ash, Stavri, & Kuperman, 2003). Mobility of mobile devices embrace usage of computerised physician order entry systems (Schuerenberg, 2005) and enhance patient safety. There are various projects using mobile devices to enhance patient's care. With the advancement of medical informatics, telemedicine, and information technology, mobile data devices play an enormous role in healthcare systems. Nursing staffs at St. Clair Hospital in Pittsburgh use PDAs equipped with peripheral scanning technology. This led to identification and prevention of 5000 errors (Anonymous, 2005). A survey and interview conducted on the usage of Personal Digital Assistants by medical residents noted that the current usage is as a single information source for personal organisation and general reference materials (Barrett, Strayer, & Schubart, 2004). However, a study conducted by Fischer, Stewart, Mehta, Wax, and Lapinsky (2003) indicated that these devices have been used for accessing medical literature, as drug information databases (pharmacopoeias), patient tracking, medical education, research data collection, business management, prescribing, speciality-specific applications such as family medicine, paediatrics, pain management, critical care, and cardiology (Fischer et al., 2003).

Two types of use of these devices can be seen in healthcare, which are download on demand (DoD) and downloading data periodically via the synchronization process (Afrin & Daniels, 2001). DoD allows the real time access of data and it is suitable for medical literature, patient tracking and various speciality specific applications. Downloading data periodically is applicable to medical educational application such as iPathology application on the iPod. A study conducted on all the American Academy of Family Physicians and American College of Osteopathic Family Practice in 2000 indicated that most commonly used operating system is the Palm on handheld computer (Criswell & Parchman, 2002). Currently, most healthcare providers use handheld devices and usage increases with emergence of smart phones and blackberry. However, only a few clinical applications are available at this stage for these devices (Al-Ubaydi, 2004).

Data integrity and confidentiality of information in these devices need to be ensured to provide safe, effective and efficient healthcare. Protecting patient confidentiality and privacy during the use of handheld device is a concern in the healthcare industry (Fischer et al. 2003). Implementing personal firewall for these devices enhances security and maintains the data integrity of health information.

CONCLUSION AND FURTHER WORK

In this chapter, we identified handheld devices as important tools for the future. We briefly reviewed the two well-known handheld devices, namely Palm OS-based and Windows CE-based handheld devices. We also illustrated our work to secure these devices. Finally, we concluded with the use of these devices in the area of healthcare. In the future, we will be developing applications that will use handheld devices for specific purpose required in the healthcare area.

KEY TERMS

Bluetooth: Bluetooth is an industrial specification for wireless personal area network (PANs). Bluetooth provides a way to connect and exchange information between devices like personal digital assistants (PDAs), mobile phones, laptops, PCs, printers and digital cameras via a secure, low-cost, globally available short range radio frequency (Wikpedia, http://en.wikipedia.org/wiki/).

General Packet Radio Service (GPRS): GPRS is a mobile data service available to users of GSM mobile phones. It is often described as '2.5 G', that is, a technology between the second (2G) and third (3G) generations of mobile telephony (Wikpedia, http://en.wikipedia.org/wiki/).

Global System for Mobile Communications (GSM): GSM is the most popular standard for mobile phones in the world. GSM phones are used by over a billion people across more than 200 countries. The ubiquity of the GSM standard makes international roaming very common with "roaming agreements" between mobile phone operators. GSM differs significantly from its predecessors in that both signalling and speech channels are digital, which means that it is seen as a second generation mobile phone system. This fact has also meant that data communication was built into the system from very early on (Wikpedia, http://en.wikipedia.org/wiki/).

IrDA: IrDA refers to Infrared data association, a standard for communication between devices (such as computers, PDAs and mobile phones) over short distances using infrared signals (Wikpedia, http://en.wikipedia.org/wiki/).

Wireless LAN or WLAN: WLAN is a wireless local area network that uses radiowaves as its carrier: the last link with the users is wireless, to give a network connection to all users in the surrounding area. Areas may range from a single room to an entire campus. The backbone network usually uses cables, with one or more wireless access points connecting the wireless users to the wired network (Wikpedia, http://en.wikipedia.org/wiki/).

Chapter 7.6
E-Health Security and Privacy

Yingge Wang

INTRODUCTION

The widespread and fast-developing information technologies, especially wireless communications and the Internet, have allowed for the realization of greater automation systems than ever in health-care industries: E-health has become an apparent trend, and having a clinic at home or even anywhere at anytime is no longer a dream.

E-health, including telemedicine featured by conducting health-care transactions over the Internet, has been revolutionizing the well-being of human society. Traditionally, common practices in the health-care industry place tremendous burdens on both patients and health-care providers, with heavy loads of paper-based documents and inefficient communications through mail or phone calls. The transmission of medical data is even messy for cases in which patients have to transfer between different health providers. In addition, the medical documents prepared manually are prone to errors and delays, which may lead to serious consequences. The time, energy, and resources wasted in such processes are intolerable and unimaginable in any fast-paced society. For these problems, e-health provides powerful solutions to share and exchange information over the Internet in a timely, easy, and safe manner (Balas et al., 1997).

Incorporating fast and cost-efficient Internet and wireless communication techniques has enabled the substantial development of e-health. The use of the Internet to transmit sensitive medical data, however, leaves the door open to the threats of information misuse either accidentally or maliciously. Health-care industries need be extremely cautious in handling and delivering electronic patient records using computer networks due to the high vulnerabilities of such information. To this extent, security and privacy issues become two of the biggest concerns in developing e-health infrastructures.

BACKGROUND

As early as 1987, Dr. Thomas Ferguson proposed online health care for consumers. In 1993, Dr. Ferguson, together with several other pioneers, initiated the first national conference on e-health (Nelson & Ball, 2004). The efforts laid the very foundation for the early development of e-health. However, e-health did not make a big step until the late 1990s, mainly due to the technical difficulties and high infrastructure cost. The striking development of information technology, particularly that of the computer, Internet, and wireless communications, dramatizes the reemergence of e-business and e-health (Collen, 1999). Thus, significant improvements to a new health-care infrastructure are anticipated so that health care can take place in a ubiquitous and security-assured manner.

The Internet as a fast, open, and cost-efficient way of exchanging information still faces the big challenge of protecting medical information security and privacy. The information transmitted through the Internet could be accessed, altered, deleted, or copied illegally, jeopardizing the patients' security and privacy. The security issues of e-health, in general, represented by all the precautions taken when safely accessing, collecting, and transferring the health information, must be addressed. In fact, the exchange of health information can be made more secure than in a paper-based system when carefully designed with proper security technologies. Information privacy is controlling whether and how personal data can be gathered, stored, processed, or selectively disseminated (Fischer-Hubner, 2001). Medical information may contain some of the most sensitive information about topics such as one's HIV (human immunodeficiency virus) status, emotional and psychiatric care, and abortions. Thus, the privacy of medical information needs to be especially safeguarded.

Ensuring security and privacy in e-health while preserving the fast transaction of medical data is, however, not an easy task. Security by itself is a complicated and tough task to accomplish in every sense, and there seems to be always a balance between the optimum efficiency and cost vs. maximized security (Fischer-Hubner, 2001). Security in e-business has being studied extensively, yet not a single system has been found to meet the requirements of all levels of protection. Healthcare systems need a higher level of protection because medical data are more sensitive and vulnerable to various misuses or attacks (Mac McMillan, 2002). When accessing medical data, possible errors and attacks could occur during the identification, authentication, and authorization processes. Potential threats and dangers incurred by the transmission of e-health data may come from computer viruses such as Trojan horses and droppers, and from intercepting threats such as masquerading, IP (Internet protocol) spoofing, misrouting, information modifying, and packet sniffing. General security mechanisms, which have been widely used at present, consist of the protection of individual servers and applications, firewalls, and secure data channels during transmission.

An early work conducted by the University of California, San Diego, and others in 1996, titled Patient Centered Access to Secure Systems Online (PCASSO), successfully developed a robust security architecture for Internet access (Baker & Masys, 1999). Since then, more efforts have been directed toward developing e-health security measures for virus protection, firewalls, authentication and access control, encryption, and so forth. Many businesses and research organizations have been developing and marketing their techniques and products, for example, ActiveCard Inc., MediTrust, National Health Key Corroborative, and so forth. Current technologies exploit smart cards, digital signatures, biometric devices, digital watermarking, public-key repository infrastructures, privacy-enhancing techniques, and so on (Ball, Chadwick, & Mundy, 2003; Cheng, Wang, & Tan, 2004). We believe that effective solutions to security and privacy in e-health must rely on a unified framework, with the deployment of wide-range security and privacy technologies from various vendors.

E-health security and privacy are challenging not only due to the difficulties of developing an error-free, complex framework, but also because of the complications of various moral and legal issues among all the stakeholders in the e-health industry such as the consumers, vendors, and health providers. To protect security and privacy in health care, governments around the world need to establish necessary regulatory standards. The Health Insurance Portability and Accountability Act (HIPPA) created in 1996 is a standard made by the U.S. federal government to provide the guidelines and policies that protect medical records. HIPAA presents both challenges and opportunities to improve the way in which medical data are acquired, exchanged, and distributed (Hippaadvisory, 2004). Meeting the challenges of HIPAA legislation requires a careful study of the legal infrastructure and a thorough understanding of the HIPAA evaluation process.

CONCEPTS AND REQUIREMENTS

Security in e-health is an integrated concept requiring the confidentiality, accountability, integrity, and availability of medical data. Confidentiality is ensuring that the data are inaccessible to unauthorized users. Accountability is the ability to trace back all the actions and changes made to the data, for example, through security logs used for recording log-ins, dates, accessed content, and changes. Integrity is preventing information from being modified by unauthorized users. Availability is ensuring the readiness of the information when needed. These four features are equally important and need to be satisfied simultaneously, and by working all together, they encompass the concept of security (Schneier, 2000; Stajano, 2002).

Security issues, in general, cover strategies in four different areas: (a) access security including user-authorization identification and management, (b) communication security related to the secure communication of messages, (c) content security including the protection of content such as data confidentiality, integrity, and availability, and (d) security management including security and vulnerability assessments, the implementation of policies, and guidance (Stajano, 2002; Van de Velde & Degoulet, 2003). To address the above issues, a solution to protecting the privacy and security of e-health needs to accomplish at least the following functions.

- Authentication, the process to validate the identity of the user
- Access control, the process to ensure that only authorized users see the authorized content or information
- Encryption, the process to prevent illegal access or use during data communication
- Intrusion detection and theft termination, the process to automatically detect and disable the devices if they are being accessed or attacked illegally

Privacy is the right of an individual to determine the disclosure and use of this personal data on principle at his or her discretion (Fischer-Hubner, 2001). In e-health applications over the open Internet, privacy may be seriously endangered without sufficient protection by privacy legislation and privacy-enhancing technologies (PETs; Goldberg, Wagner, & Brewer, 1997). Besides the confidentiality and integrity of personal data considered by data security techniques, PETs need to protect user identities in terms of anonymity, pseudonymity, unlinkability, and unobservability, and also user identities in terms of the anonymity and pseudonymity of data subjects (Fischer-Hubner, 2001). PETs usually exploit encryption tools and access control, and can be enforced with security policies.

TECHNOLOGIES AND CHALLENGES

Security and privacy issues arise when accessing and communicating the health data. Basically, there are three steps for security after logging into the computerized healthcare system (Van de Velde & Degoulet, 2003).

- Identification to check who the end user is
- Authentication to check whether the information provided during the identification step is correct or not
- Authorization to check whether the user is authorized to perform certain tasks

Authentication and access control are required for security when accessing medical data through an e-health infrastructure. Many techniques have been applied for such proposes, for example, smart cards, firewalls, digital certification, biometric devices, password and PIN (personal identification number) generators, and others (Ferrara, 1998). Encryption can be incorporated into different protocols such as NCSA's Secure HTTP (hypertext transfer protocol; SHTTP) and Microsoft's Private Communications Technology (PCT; Goldman & Rawles, 2004). Theft termination is an effective and active protection strategy (Goldberg et al., 1997), and more studies are needed in developing such functionalities in e-health. In the following, we shall briefly discuss several technologies for e-health security and privacy.

Firewalls

Firewalls are a common practice set on the Internet for a business' Web site to prevent unauthorized access to confidential data. A firewall can act as an isolating layer between the inside and outside networks: All information entering the firewall is filtered or examined to determine whether the users have the rights to access the network, and whether the information entered meets the requirements of the inside network for further dissemination over the network (Gollmann, 1999).

The architecture of the firewall consists of packet filters, proxies, and internal firewalls. Packet filters are programs designed at the port level that determine access by checking the source and destination addresses of the incoming data. Proxies, also known as application-level filters or application gateways, take a step further to exam the validity of the request for the entire set of data. Proxies are also entitled the right of refusing connections based on traffic directions; for example, certain files can be uploaded but not downloaded. To prevent internal attacks from insiders, internal firewalls emerged as an access control mechanism inside the network (Stajano, 2002).

Firewalls have found widespread applications in e-health (and other industries). Some popular products include the Firewall-1 from Checkpoint, Alta Vista Firewall from Compaq, and Gauntlet from Network Associates. However, there are certain limitations to this technique. First, designing firewalls often assumes the threats or attacks are from the outside network, which is not always true in reality. Second, the firewalls cannot resist outside threats at all if we are not able to control or monitor the outside connections. Third, the packet filters cannot prevent hackers from IP spoofing, and the proxies are unable to detect many computer viruses such as Trojan horses or macro viruses. Last but not the least, there is no standard established for firewall architectures, functionalities, or interoperability (Schneier, 2000, Stajano, 2002).

Smart Card

Smart cards are actually one form of token-authentication technology, and they generate the session password that can be authenticated by the server. The whole authentication process involves one or more of the following.

1. The client software, to enter the password and communicate with the server software
2. The server software, to verify the password and record the card history
3. The application software, to integrate the token-authentication technology with other technologies (Fischer-Hubner, 2001)

In general, there are two approaches in token-authentication technology: challenge-response and time-synchronous token authentication. The former works in the following way.

- The server software generates a challenge based on the ID and password that a user entered.
- The smart card generates a response number based on the challenge number and user ID.
- The server checks the response from the smart card. The log-in session is enabled if it matches the correct one.

Time-synchronous token authentication simplifies the challenge-response authentication in that there is no server-to-client step. The user can directly enter the access code from the display of the smart card, which can be matched by the server software since every 60 seconds the smart card and the server software will generate a new access code (Goldman & Rawles, 2004). ActiveCard is an example of using smart cards in e-health services. Its one-time password method is similar to the time-synchronous token-authentication approach, while its device-PIN method incorporates digital certificates or biometric information stored on the card. Graded authentication controls different levels of access rights and needs of the confidential medical data. For example, the users are entitled different levels of rights based on their roles as physicians, clinicians, nurses, technicians, administrators, insurers, and patients. The shortcomings for using smart cards include the fact that the authentication may fail when the physical device degenerates over time, and they are easy to get lost or stolen.

Biometrics

Biometric authentication is the authentication process using the unique physiological and behavioral characteristics of a user such as fingerprints, palm prints, retinal patterns, hand geometry, facial images, voice, or others. This process requires establishing a large database for the user's biometric features as the reference during validation (Jain, Bolle, & Pankanti, 1999). Accuracy and sensitivity are important issues. Usually, a good trade-off between them needs to be achieved because accuracy depends on the ability of the equipment to detect despite small variations between biometric characteristics. Though perfect biometric devices have not yet been developed, adding biometric features to smart cards provides an improved way to achieve security and key management. Such commercial products are gradually replacing the old smart cards in e-health applications. Biometric techniques for security are an active research area, and their applications to e-health industries appear rosy.

An important challenge is how to protect privacy while exploiting biometrics. It is often possible to obtain someone's biometric sample without that person's knowledge, thus, those who desire to remain anonymous in any particular situation can be denied their privacy by biometric recognition. This covert recognition of previously enrolled people may raise privacy concerns over unintended application scopes. Besides this, unintended functional scopes also pose a privacy concern. For example, collectors may obtain or infer additional personal information from biological measurements. Such derived information could lead to discrimination against segments of the population perceived as risky. An effective way to enhance privacy while permitting all the advantages of biometric-based recognition is to decentralize the biometric system. The biometric information is stored in decentralized, encrypted databases over which the individual has complete control. To enhance privacy in using biometric information, legislation by government is necessary. The European Union has legislated against sharing biometric identifiers and personal information. Another solution to the privacy problem includes building autonomous enforcement by independent regulatory organizations like a central biometric authority.

Data Encryption of Health Data

During transmission over the Web, medical data could be intercepted and manipulated maliciously with the information confidentiality and integrity compromised. A common data-protection technique uses data encryption with either symmetric or asymmetric algorithms (Stinson, 2000). The conventional encryption algorithms include Blowfish, CAST-128, IDEA (International Data Encryption Algorithm), Data Encryption Standard (DES), and so forth. Concurrent algorithms include AES (Rijndael), Serpent, RC6, Twofish, and so on (Stinson). For symmetric encryption, the same key is used during both encryption and decryption such as DES developed by IBM. The problem for symmetric encryption lies in the difficulty of key management, where the security process will fail if the third party obtains the key.

For asymmetric encryption, a pair of keys is used including the private key that is only known to the owners, and the public key that others can process. The private key has the highest security level, which cannot be inferred from the public key though they are mathematically related. When the public key decrypts the messages encrypted with the private key, the identity of the sender can be authenticated. This technique is also known as digital signature. When the private key decrypts the messages enciphered with the corresponding public key, the identity of the receiver can be authenticated. Commonly used asymmetric algorithms include RSA (Rivest, Shamir, & Adleman, 1978), elliptic curve cryptosystems (Koblitz, 1997), and so forth. Digital signature is a common technology using asymmetric cryptography to authenticate the author of electronic transmitted documents. The biggest problem with asymmetric encryption is its high computing cost and slow process (Van de Velde & Degoulet, 2003). Thus, asymmetric cryptosystems are usually used for transmitting symmetric keys as it is inefficient for large amounts of data such as medial images.

COMPLIANCE WITH HIPPA

HIPPA has been the standard in the United States for health-care industries, with the guidelines and policies to protect the privacy and security of medical records since it was created in 1996. It includes more than 68 information security conditions in three areas that must be satisfied to ensure compliance with HIPAA. These areas include the following:

1. technical security services such as user authorization and authentication, access control, and encryption;
2. administrative procedures such as formal security planning, record maintenance, and audits; and
3. physical safeguards such as the security of buildings, and the privacy of offices and workstations that handle patient information.

The standard provides a uniform level of protection for all health information, and safeguards physical storage and maintenance, transmission, and access to individual health information. It does not require specific technologies to be used, and solutions will vary from business to business depending on the needs and technologies in place. However, all stakeholders in health-care systems including health plans, healthcare providers, and clearinghouses are required to comply with HIPPA. Such compliance ensures the protection of patient privacy and data security through e-health, and will ultimately increase public confidence in using e-health as their preferred means for healthcare. How can the e-health strategies, technologies, services, and management be deployed to ensure HIPPA compliance? Such questions are faced by the health-care industries in promoting e-health. In sum, HIPAA has a far-reaching effect on the health-care industry, presenting health-care organizations with numerous planning, operational, technical, and financial challenges.

TRENDS

Security mechanisms are usually regarded as technical means to protect privacy. However, they can also contradict privacy. Oftentimes required is the collection of sensitive personal information from the users to better protect security. The user must trust the security system and provide such private information. The government needs to enforce the laws and keep the e-health system running healthily. Technically, one global trend in e-health is the development of privacy-protection mechanisms in e-prescription systems, patient record databases, and medical information systems. The development of security business management also represents an important trend. A healthy security system requires not only the measures to prevent current threats, risks, and attacks, but also reasonable protections against future generations of attacks and misuses. With the rapid evolvement of cyberattacks, excellent security business management skills and strategies are necessary in providing visionary preparation for future threats beforehand, and in designing and managing smart security systems. Because each security technique has its own strengths and weaknesses, an important development is to build a holistic framework, taking advantage of various techniques while compensating for their drawbacks. An industrial standard is lacking but urgently needs to integrate various security techniques so that maximum efficiency can be achieved.

CONCLUSION

E-health, a fast-developing area in healthcare industries, faces the challenges of privacy and security issues. Only with high confidence in security and privacy can both patients and health providers greatly benefit from the high efficiency and quality of service of e-health systems. We discuss relevant concepts, technologies, limitations, challenges, and trends in e-health security and privacy. Also discussed are strategies and standards such as HIPAA. We conclude our article by emphasizing that only through the collective efforts of technologies, businesses, management, and legislative regulation can the security and privacy of e-health be safeguarded.

KEY TERMS

Cryptography: The conversion of data into secret codes for transmission over a public network to prevent unauthorized use.

Data Accountability: The ability to trace back all the actions and changes made to the information.

Data Availability: The ability to ensure the readiness of the information when needed.

Data Confidentiality: The ability to ensure the data is inaccessible to unauthorized users.

Data Encryption: The process of "scrambling" the data for transmission to ensure that it is not intercepted along the way.

Data Integrity: The ability to prevent the information from being modified by unauthorized users.

E-Health: Refers to the market, companies, and initiatives for conducting healthcare-related transactions electronically using the Internet and/or wireless communications.

Firewall: Special software used to prevent unauthorized access to a company's confidential data from the Internet through filtering all network packets entering the firewall at one or more levels of network protocols.

HIPAA (Health Insurance Portability and Accountability Act): Standard guidelines and policies enforced by the U.S. federal government to protect confidential medical records.

Privacy: The right of individuals to control or influence what information related to them can be disclosed, by whom it can be disclosed, and to whom it can be disclosed.

Security: Defined as the combination of processes, procedures, and systems used to attain the confidentiality, accountability, integrity, and availability of the needed information.

Smart Cards: Used in token-authentication systems. It can be either a hardware-based card or smart IDs the size of about a credit card with or without a numeric keypad.

Telemedicine: Refers to the delivery of health care at a distance using telecommunications or the Internet.

Chapter 7.7
Security in E-Health Applications

Snezana Sucurovic
Institute Mihailo Pupin, Serbia

ABSTRACT

This chapter presents security solutions in integrated patient-centric Web-based health-care information systems, also known as electronic healthcare record (EHCR). Security solutions in several projects have been presented and in particular a solution for EHCR integration from scratch. Implementations of Public key infrastructure, privilege management infrastructure, role based access control and rule based access control in EHCR have been presented. Regarding EHCR integration from scratch architecture and security have been proposed and discussed. This integration is particularly suitable for developing countries with wide spread Internet while at the same time the integration of heterogeneous systems is not needed. The chapter aims at contributing to initiatives for implementation of national and transnational EHCR in security aspect.

INTRODUCTION

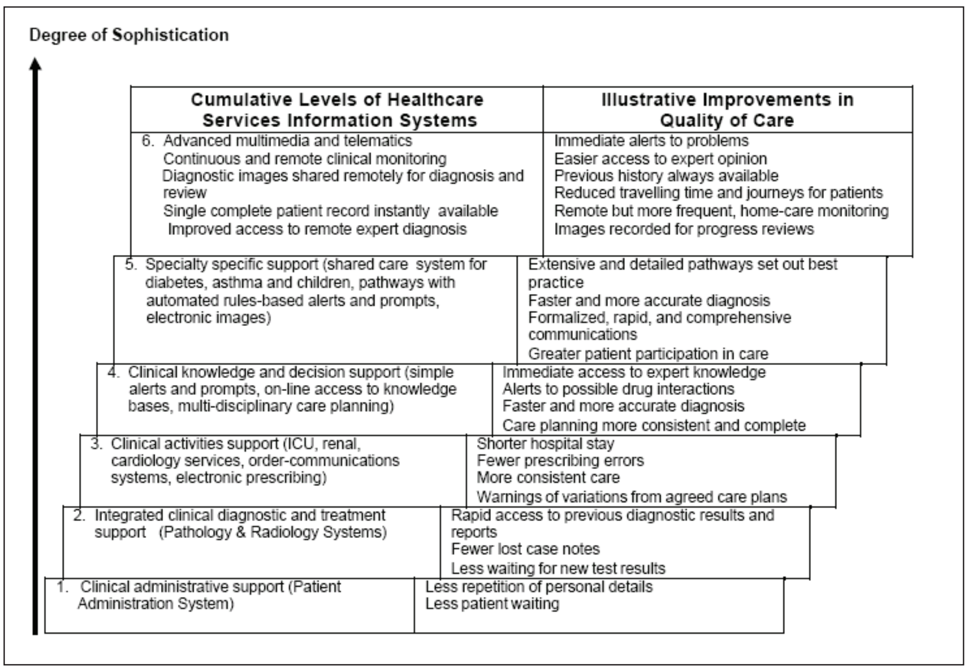
E-health has become the preferred term for healthcare services available through the Internet. While the first generation of e-health applications comprises educational and informational Web sites, at present e-health has grown into national and transnational patient centric healthcare record processing. A patient centric healthcare record, also called electronic healthcare record (EHCR) and electronic patient record (EPR), enables a physician to access a patient record from any place with Internet connection and give a new face to integration of patient data. Such integration can improve healthcare treatment and reduce the cost of services to a large extent. Benefits are based on extended possibilities for collaboration through sharing data between a physician and a patient and between physicians. In such large scale information systems, which spread over different domains, standardization is highly required. The second paragraph describes the main issues in e-health security as well as the results of EU projects EUROMED and TRUSTHEALTH, while the third paragraph presents MEDIS prototype of national healthcare electronic record suitable especially for developing countries where the Internet is widespread and healthcare information systems are not developed to large extent and therefore integration from scratch is proposed.

EXISTING SOLUTIONS

In general, the following lines of development for healthcare information system were considered as important (Reichertz, 2006): (1) the shift from paper-based to computer-based processing and storage, as well as the increase of data in health care settings; (2) the shift from institution-centered departmental and, later, hospital information systems towards regional and global HIS; (3) the inclusion of patients and health consumers as HIS users, besides health care professionals and administrators; (4) the use of HIS data not only for patient care and administrative purposes, but also for health care planning as well as clinical and epidemiological research; (5) the shift from focusing mainly on technical HIS problems to those of change management as well as of strategic information management; (6) the shift from mainly alpha-numeric data in HIS to images and now also to data on the molecular level; (7) the steady increase of new technologies to be included, now starting to include ubiquitous computing environments and sensor-based technologies for health monitoring.

As consequences for HIS in the future, the need for institutional, national, and international HIS-strategies is first seen; second, the need to explore new (transinstitutional) HIS architectural styles is needed; third, the need for education in

Figure 1. Degree of sophistication in healthcare information systems. Note. From Information Systems, Sao Paolo University Technical Report, 2006)



health informatics and/or biomedical informatics, including appropriate knowledge and skills on HIS are needed. As these new HIS are urgently needed for reorganizing health care in an aging society, as last consequence the need for research around HIS is seen. Research should include the development and investigation of appropriate transinstitutional information system architectures, of adequate methods for strategic information management, of methods for modeling and evaluating HIS, the development and investigation of comprehensive electronic patient records, providing appropriate access for health-care professionals as well as for patients (e.g., including home care and health monitoring facilities). All these requirements have implications on security issues. See Figure 1 for an example of the degree of sophistication in healthcare information systems.

Security is a very complex issue related to legal, ethical, physical, organizational, and technological dimensions defined as security policy. In that context, security addresses human, physical, system, network, data, or other aspects.

Legal Issues

Hipocrate's oath contains the obligation of keeping health data secret as a part of professional ethics «What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things shameful to be spoken about". As far as today's practice is concerned, several countries have adopted acts on medical data privacy protection, and especially on privacy protection of the electronic form of medical data. One among such documents is European Directive on the Protection of Individuals with Regard to the Processing of Personal Data and on the Free Movement of such Data of September 25, 1995, intended for privacy protection in data processing systems. Medical data privacy protection is presented in Section 3 of paragraph 2 «Special Processing Categories», whose article 1 states that member countries should forbid the processing of personal data on political attitudes, religious and philosophic beliefs, racial and ethnic origin as well as medical data unless they satisfy particular, precisely specified conditions. For medical data, these conditions are as follows:

- When data processing is performed for purposes of preventive medicine, medical diagnostics, the provision of medical treatment and management of medical protection services where these data are processed by health professionals who are bound to keep professional secrecy by national laws or rules established by competent bodies or by some other persons subject to an equivalent obligation.
- Persons to which these data refer have given an explicit consent to the processing of such data.
- Processing is required for protecting the vital data of the person to which these data pertain or of some other persons, when the person in question is physically or legally incapable of giving a consent.
- Processing of data relating to persons which have committed a criminal act or to persons which may violate safety is performed under the supervision of authorized officials.

Section 4 of paragraph 2 «Information to be submitted to a person» states the conditions under which a person has to be given the information on the processing of that person's private data, and especially the informataion about forwarding these data to a third party.

Section 5 of paragraph 2 of this Document «A subject's right to access his own data» states a person's rights to access his personal data in data processing systems.

Paragraph 3 of this document says that member countries should ensure for each person, which considers that he/she has suffered a loss because of illegal processing of his/her data, to be entitled to a compensation.

Results of EUROMED Project

All European Commision funded e-health projects are in compilance with EU directive. One of first implemented was EUROMED (Katsikas,1998). This projects (started in 1997) examines use of trusted third party (TTP) services in distributed healthcare information systems. A trusted third party (TTP) is an entity which facilitates interactions between two parties who both trust the third party; they use this trust to secure their own interactions. One of TTPs is a certificate authority (CA). CAs are defined in X. 509 standard (ITU-T Standard, 1997).

X.509 standard defines a framework for the authentication service which a directory provides to all interested users. A directory is taken to mean that part of the system which possesses authentic information on system users. A dirctory is implemented as a certificate authority (CA) which issues certificates to users. X.509 defines two authentication levels:

- Simple authentication, which uses a password for identity verification
- Strong authentication, which involves credentials—additional means of identification obtained by cryptographic

Strong authentication is based on an asymmetric cryptosystem involving a pair of keys: a public and a private key. The standard does not prescribe mandatory usage of a particular crypto system (DSA, RSA, etc.) and thus supports modifications in methods to be brought about by the development of cryptography.

Each user should have a unique distinguished name. A naming authority is responsible for assigning a name.

A user is identified by proving that he/she possesses a private key. To be able to verify a private key, a user–partner in the communication process must possess a public key. The public key is available on the directory.

A user should be given a public key from a trusted source. Such a source is a CA which uses its own public key to certify a user's public key and produces a certificate in this way. A certificate has the following properties:

- Each user having the access to a CA's public key can disclose the public key on which a certificate has been created.
- No party, except for the CA, can make a modification to a certificate without such a modification being detected. Owing to this property certificates may be stored on a directory with no need for additional protection efforts.

A certificate is obtained by creating a digital signature on a set of information about a user, such as a unique name, a user's public key and additional information about a user. This set of information also contains a certificate's validity period. This period includes the interval during which the CA has to keep the information about certificate status, i.e., publish an eventual certificate revocation. A certificate is presented in the ASN.1 notation as Shown in Box 1.

Three types of strong authentication are described in the standard:

a. **One-way authentication:** Includes only one transfer from a user A to an intended user B
b. **Two-way authentication:** Includes a reply from B to A as well
c. **Three-way authentication:** Includes an additional transfer from A to B

An example of using two-way authentication is given in CEN ENV 13729 standard which prescribes the use of strong authentication in health information systems.

Box 1.

```
Certificate                    ::= SIGNED {SEQUENCE{
        version                [0]          Version DEFAULT v1,
        serialNumber                        CertificateSerial Number,
        signature                           AlgorithmIdentifier,
        issuer                              Name,
        validity                            Validity,
        subject                             name,
        subjectPublicKeyInfo                SubjectPublicKeyInfo,
        issuerUniqueIdentifier [1]          IMPLICIT UniqueIdentifier OPTIONAL,
        subjectUniqueIdentifier [2]         IMPLICIT UniqueIdentifier OPTIONAL
        extensions             [3]          Extensions OPTIONAL   }}

Validity                       ::=          SEQUENCE {
        notBefore                           Time,
        notAfter                            Time
}

SubjectPublicKeyInfo           ::=          SEQUENCE {
        algorithm                           AlgorithmIdentifier,
        subjectPublicKey                    BIT STRING
}
Extensions                     ::=          SEQUENCE OF Extension
```

CEN ENV 13729 has defined local and remote two way strong authentication using X509 standard.

EUROMED-ETS provides integrity, authentication and confidentiality services using measures such as:

- Digital signatures to ensure data integrity
- Encryption to provide confidentiality

TTP sites were established in four different locations in Europe: Institute of Computer and Communication Systems - ICCS (Athens-Greece), University Hospital Magdeburg - UHM (Magdeburg-Germany), University of the Aegean - UoA (Samos-Greece), and University of Calabria - UniCAL (Calabria-Italy).

Among the functions performed by the Certification Authority are: initialisation, electronic registration, authentication, key generation and distribution, key personalisation, certificate generation, certificate directory management,

Figure 2. Challenge-response authentication protocol using X.509 public key certificates

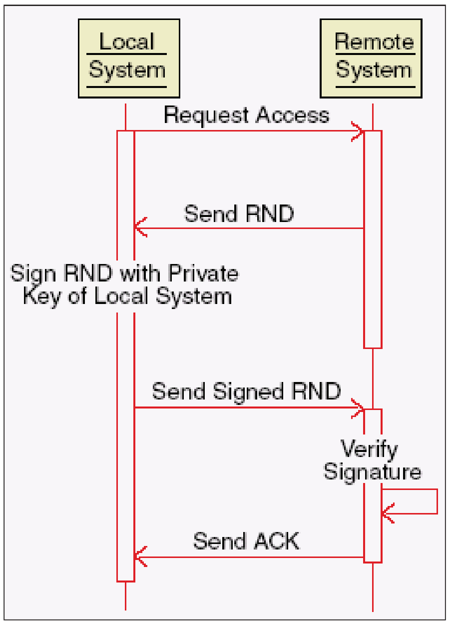


Figure 3. Remote strong authentication according to CEN ENV 13729

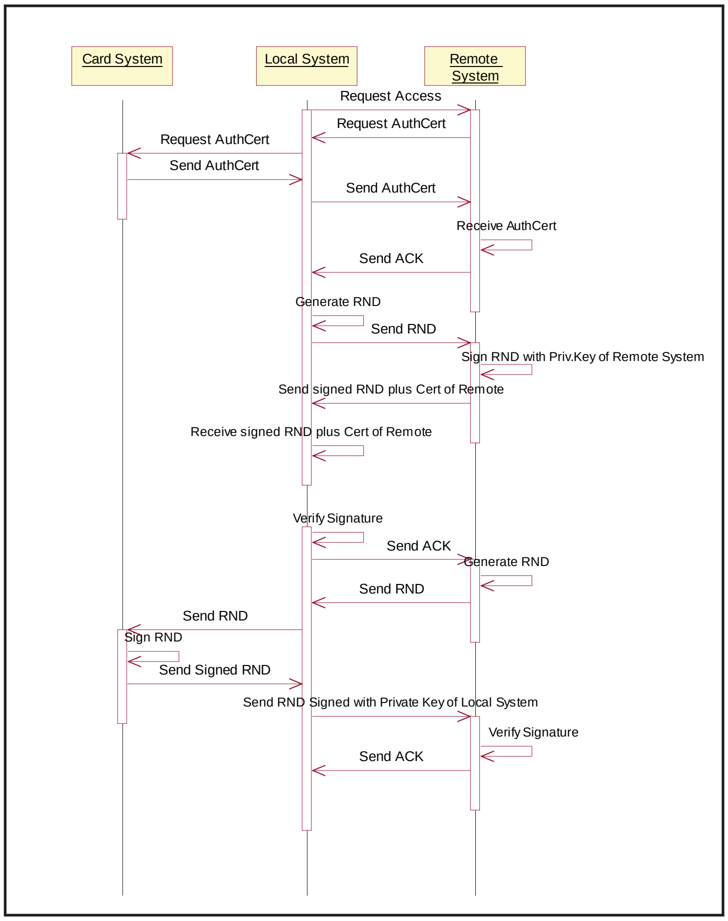

certificate revocation, CRL generation, maintenance, distribution storage and retrieval.

The Directories have served in that way as a repository for identification and authentication information; this information was utilised automatically by the EUROMED-ETS pilot Secure Web Servers to identify potential users and grant or deny to them rights; this identification information was also accessible anonymously through the Internet by the use of LDAP search tools.

Results of Trusthealth Project

«Trustworth Health Telematics 2» (Blobel, 2001) project was started in June 1998 under the auspices of the European Commission. The aim of the project is to create a national infrastructure that would provide the security on the communication and application level of health information systems in: Belgium, France, Germany, Norway, Sweden and Great Britain and the focus is on interstate interoperability. The implementation of Trusthealth I Project, which took part from 1996 to 1997 involved the introduction of:

- The use of Health Professional Cards (HPC), microprocessor cards used in the authentication process
- Card reader services
- Services of Trusted Third Party which manages certificates

Within TH-1 the following services have been provided:

- Sending of a physician's report with all relevant data to a central register.
- Execution of prespecified and freely formed SQL queries relating to a patient's EHCR.
- Statistical analyses by various criteria, also by making a SQL query
- Exchange of any information, including HL7 messages, images, etc.

A TTP involves several independent organizations responsible for defining TTP services. TTP components may be:

- Key generation instance
- Naming authority
- Registration authority
- Directory service authority

In the TrustHealth Project the public key registration authority (PKRA) is an entity that identifies, in a unique way, a user requiring the provision of a digital signature service. The professional registration authority (PRA) is an entity registering an individual as a physician, i.e. as a medical care professional. The naming authority (NA) is an entity assigning to users a unique name to be used in certificates. The NA may be involved in assigning unique names to classes within the medical profession (e.g., internal medicine) and subclasses (e.g. nephrology). The public key certification authority (PKCA) is an entity certifying the relation between a user's unique name and public key by issuing a public key certificate with a PKCA digital signature. The PKCA is also responsible for revoking and repeated issuance of a certificate with a public key, whereas the professional certification authority (PCA) certifies the relation between a user's unique name and professional status, after having created a digital signature on these data. The PCA is also reponsible for revoking and repeated issuance of professional certificates. The card issuing system (CIS) is an entity issuing microprocessor cards that must contain a private key and may contain certificates as well. The generation of a private-public key pair may be performed using a local or a central key generator (LKG), an entity that may be located locally (with a user or PKRA) or centrally (with the PKC or CIS). Certificates have to be stored on the certificate directory (DIR). The DIR is an entity that isues, on a request, certificates with a public key, professional certificates, revoked certificate lists as well as other information about users. In the TrustHealth Project the TTP services (NA, PRA, PCA, LKG, PKRA i DIR) are proposed to be implemented in institutions such as the chamber of physicians.

In this project the NA is implemented so as to assign a unique name to a user by using the name of a state, a unique number assigned to each physician on a state level and a physician's name. The RA is implemented so as to certify a user's identity and attributes such as profession or qualification. On a user's request, relevant information is verified, associated to a distinguish name –DN and sent online to a certification entity. The RA uses the information provided by the qualification authentication authority (QAA) or by the profession authentication authority (PAA). The former instance may be a university, for example, while the latter may be a chamber of physicians. In the part of TrustHealth Project implemented in Magdeburg, the chamber of physicians of the state of Saxony-Anhalt has implemented a majority of TTP services. The chamber of physicians has also included QAA services such as qualification, specialization, etc. All these pieces of information have been transmitted online to a certification body.

Based on data obtained from the RA, the Certification Authority creates certificates. Certificates that associate a user's distinguish name and the remaining relevant information to a user's public key are referred to as public-key certificates. Certificates that associate information about profession, qualification are attribute certificates. The first service is provided by the CA and the second by the PCA. CA Management Toolkit from the SECUDE package is used for X509v3 certificate creation and management in the TrustHealth Project.

The DIR directory service includes the publication and revocation of certificates using public directories. An X.500 compatible solution implemented in the SECUDE package is used in the TrustHealth Project. In this Project DIR maintains both public-key and attribute certificates. It is planned to use the Lightweight directory access protocol (LDAP) server later.

Results of PCASSO Project

The Patient Centered Access to Secure Systems Online (http://medicine.ucsd.edu/pcasso/index.html) was developed in 1997-2000 at the University of California San Diego School of Medicine. It is intended primarily to permit patients and health care providers to access health information, including sensitive health data. Access control is achieved by combining role-based access control (RBAC), mandatory access control (MAC) and discretionary access control (DAC). PCASSO is patient-centered and all data are stored on a single server in the current project stage.

According to DAC, when a user requests accessing an object, it is checked whether there is a rule allowing that user to access that object in a given mode. If there is, access is allowed, otherwise it is forbidden. Such an approach is viewed as very flexible and has found a wide usage, especially in commercial and industrial environments. Its shortcoming is the lack of information flow control. It is thought that it is easy to avoid access restrictions imposed by authorization (a set of rules stating which subject is allowed to access a particular object and in which mode). For example, when a user has read some data once, he/she may forward them to an unauthorized user without data owner's knowledge. In contrast to this, information flow from a higher-level object to a lower-level one is prevented in the MAC approach.

In MAC access rights are based on the classification of subjects and objects in the system. A particular protection level is assigned to each subject and each object. The protection level assigned to an object reflects data sensitivity level. The protection level assigned to a subject reflects the level of confidence in that subject that it will not forward accessed information to persons that do not have such rights. These levels are arranged in a hierarchy where each protection level dominates lower levels. A subject has the right of access to an object only if there is a particular relation between the protection level belonging to that subject and the protetcion level belonging to that object. One among such relations is the following: the protection level belonging to the subject has to dominate the protection level belonging to the object. MAC is used in defense and governmental departments.

Some researchers have expressed a view that DAC and MAC approaches cannot satisfy many practical requirements. The MAC approach is suitable for a military environment, whereas DAC is suitable for communities where cooperative work predominates, such as academic institutions. This is why a number of alternatives have been offered. Role based access control (RBAC) is the most widely used among them. RBAC controls a user's access right on the basis of user's activities performed in the system. A role may be defined as a set of activities and responsibilities relating to a particular activity. The advantages of RBAC approach include:

- Simpler authorization control. Authorization specification is divided into two stages: assigning roles to users and assigning object access rights to roles.
- Role hierarchy is easy to create, which is suitable for many systems

- Roles permit a user to work with a minimal-privilege role and use only exceptionally a role having maximal privileges. Error occurrence possibilities are reduced in this way.
- Separation of duties. It is possible to provide that not a single person can autonomously abuse the system. An example is the introduction of ... : each person performs only a portion of an operation instead of the entire operation.

In PCASSO users may have one of the following roles: patient, primary care provider (PCP), secondary care provider (SCP) or Emergency Caregiver. Information and functionalities available to a user depend on the role belonging to her/him. PCASSO employs the following security policy:

- The system controls all accesses to data for each single user.
- Primary care providers are allowed to access all parts of a patient's EHCR.
- PCP is privileged to mark some data in an EHCR as accessible to or forbidden for a patient or other care providers.
- A patient is allowed to access all parts of an EHCR except for those marked as "patient deniable"
- Care providers marked as PCP may change protection attributes in a patient's record. PCPs may authorize and give rights to consultants referred to as Secondary care providers. A patient's PCP may declare a SCP to be a PCP for a particular time period, after the expiration of which a previous role is resumed.
- A possibility is given to care providers to deny access to a part of a child's EHCR to parents.
- In emergency cases care providers may have an unlimited access (reading only) to a patient's EHCR.

PCASSO distinguishes 5 patient data protection levels: Patient-deniable, Parent/Guardian-deniable, Public-deniable, Standard and Low. A user will be allowed to access data having the same or a lower label (protection level) compared with the user's label (MAC approach) and belong, at the same time, to the group having the right of access to that piece of data (DAC approach).

EHCR ARCHITECTURE - CEN ENV 13 606 STANDARD

All EU transnational projects are in compliance with CEN ENV 13 606 standard.

The Comité Européen de Normalisation European Standard (CEN ENV 13606, 2002) "EHCR Communication" is a high level template which provides a set of design decisions which can be used by system vendors to develop specific implementations for their customers.

It contains several parts:

- **Part 1. Extended Architecture:** Defines component-based EHCR reference architecture.
- **Part 2. Domain Term List:** Defines terms which are used in extended architecture.
- **Part 3. Distribution Rules:** Defines data structures which are used in distribution and shared access to EHCR.

Communication as an act of imparting or exchanging information is the primary concern of this standard. In its Part 1 the standard defines an EHCR Communication View as the reuse of stored clinical data in a different context. There can be many such Communication Views and they provide presentation of information in a chronological order , "problem-oriented" manner or some other convention. This is provided by use of architectural components which are rich enough to be able to communicate data by a combination of components. There are a root component, which contains basic information about a patient, on one hand, and, on the other hand, a record component established by original component complexes (OCCs), selected component complexes (SCC), data items (DI) and link items (LI). An OCC comprises (according to data homogeneity) four basic components: folders, compositions, headed sections and clusters. A SCC contains a collection of data representing an aggregation of other record components that is not determined by the time or situation in which they were originally added to the EHCR. It may contain a reference to a set of search criteria, a procedure or some other query device whereby its members are generated dynamically (for example "current medication"). A Link Item is a component that provides a means of associating two other instances of architectural component and specifying the relationship between them ("caused by", for example). A data item is a record component that represents the smallest structural unit into which the content of the EHCR can be broken down without losing its meaning.

As a result of cooperation of CEN Technical Committee 251 and Australian Good Electronic Health Record (GEHR) project, CEN ENV 13606 Part 1 was revised in 2002. The revised standard adopted the GEHR concept in which object-oriented EHCR architecture is distinguished from a knowledge model. A knowledge model contains specifications of clinical structures named archetypes. There are many benefits of that two-layer model and one is that archetypes can be developed by clinicians at the same time when IT specialists develop EHCR object oriented architecture. In the revised CEN standard architectural components contain an identifier of archetype (for example "vitals", "blood pressure" etc.).

In part 2 CEN ENV 13 606 standard defines a list of terms, such as category names for Compositions ("Notes on Consultations", "Clinical Care Referrals" etc.) and Headed Sections ("Former Patient History", "Ongoing Problems & Lifestyle" etc.).

According to part 3 of CEN ENV 13606 standard, each Architectural Component has a reference to a Distribution Rule. A Distribution Rule comprises When, Where, Why, Who and How classes. Class Why is mandatory, i.e. one of its attributes has to be "not null". Instances of these classes define When, Where, Why, Who and How is allowed to access that component (see Figure 4).

IMPLEMENTING SECURE DISTRIBUTED EHCR: MEDIS EXAMPLE

The MEDIS project aims at developing a prototype secure national healthcare information system. Since clinical information systems in Serbia

Figure 4. Distribution rule (CEN ENV 13606 Part 3)

and Montenegro have not been implemented to a large extent, we have focused our efforts on integration itself from the very beginning, instead of on studying how to integrate various systems. In recent years Internet has become widespread in our country and using Internet to implement a shared care paradigm is becoming a reality. MEDIS is based on CEN ENV 13606 standard and follows a component-based software paradigm in both EHCR architecture and software implementation. MEDIS has been implemented as a federated system where the central server hosts basic EHCR information and clinical servers contain their own part of patients' EHCR. CEN ENV 13 606 requirements have been strictly fulfilled in clinical servers as well as in the central server. In our opinion the user interface has to be standardised and we give our proposal for standardisation. As for the security aspect, MEDIS implements achievements from recent years, such as Public Key Infrastructure and privilege management infrastructure, SSL and Web Service security as well as pluggable, XML based access control policies. Table 1. presents characteristics of EUROMED, TRUSTHEALTH and MEDIS projects.

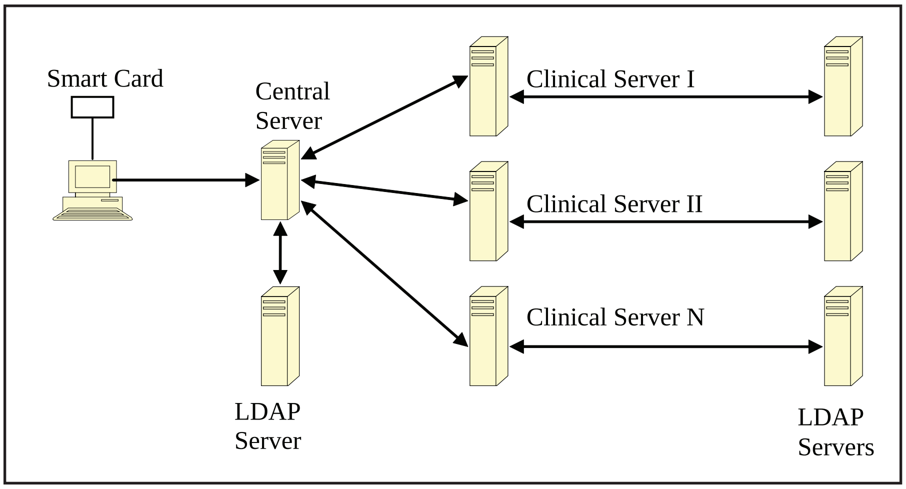
MEDIS Architecture

Since the MEDIS project refers to integration from the very beginning, EHCR reference architecture has been followed in defining the database model. Data have been stored in a hierarchical manner, where architectural components contain pointers to a supercomponent, linked components and also a selected component complex.

MEDIS has been implemented as a federated system. Architectural components are created in compliance with CEN ENV 13606 and stored there where they are created – at hospitals and clinics and are accessed via a central server which contains a root component and the addresses of the clinical and hospital servers. Architectural components that are hosted on the clinical and hospital servers have pointers to supercomponents and linked components (see Figure 5). User interface has been standardised in the following way. HTML pages are created on the central server and contain five frames: the required architectural component (AC) in the right frame, links to subcomponents and linked components in the upper left frame, links to selected component complex (actually distributed queries) in the lower left frame, the AC position in the hierarchical structure of EHCR in the upper frame and information about a user in the lower frame (see Figure 6). A physician can define the position in EHCR (and therefore HTML page) which will appear when he requests EHCR for a patient.

Currently, in the MEDIS architecture there are two types of selected component complex. Firstly, there are SCCs given as a union of queries

Figure 5. System architecture



on all clinical servers such as «current medication» or «current diagnosis». Search criteria are made according to the identifier of archetype. Secondly, there are SCCs related to architectural components on clinical servers and they contain search criteria for architectural components on that clinical server.

In MEDIS there is an authentication applet (Sucurovic, 2005) which is processed in a browser and, after successful authentication, a HTML page has been generated using JSPs on the central server. The clinical servers tier has been implemented in Java Web Services technology using Apache

Figure 6. CEN ENV 13 606 Composition Component example

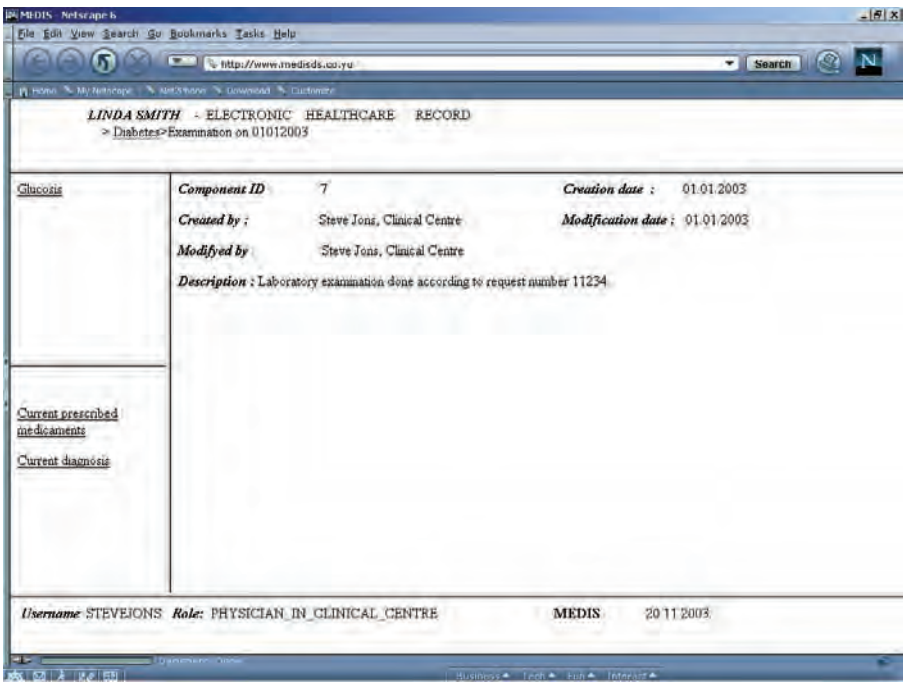


Figure 7. MEDIS access control components

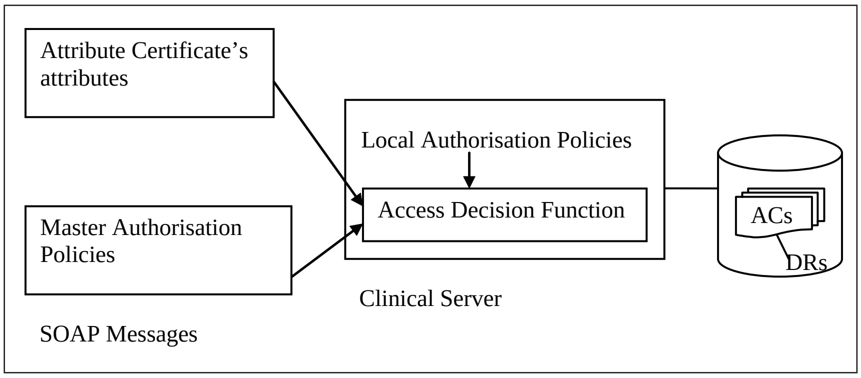

Axis Web Service server and Tomcat Web Server. Business logic has been implemented in reusable components–Java Beans. Authorisation policy is decomposed into components which can be plugged in Beznosov (2004) (see Figure 7).

Implementing Security

Using a password as a means of verification of claimed identity has many disadvantages in distributed systems. Therefore, MEDIS implements CEN ENV 13 729 (CEN ENV, 2000) which defines authentication as a challenge-response procedure using X.509 public key certificates. Solutions related to attribute certificates management have also been implemented (Sucurovic, 2006). Originally, X.509 certificates were meant to provide nonforgeable evidence of a person's identity. Consequently, X.509 certificates contain information about certificate owners, such as their name and public key, signed by a certificate authority (CA). However, it quickly became evident that in many situations, information about a person's privileges or attributes can be much more important than that of their identity. Therefore, in the fourth edition of the X.509 Standard (2000), the definition of an attribute certificate was introduced to distinguish it from public-key certificates from previous versions of the X.509 Standard (ITU-T, 2000).

In the MEDIS project X.509 PKCs are supposed to be generated by the public certificate authority, while ACs are supposed to be generated by the MEDIS attribute authority. The public key certificates are transferred to users and stored in a browser (Sucurovic, 2005). The attribute certificates are stored on LDAP server (Sucurovic, 2006), because they are supposed to be under control of the MEDIS access control administrator. In the MEDIS approach, attribute certificates contain user's attributes as XML text. There are two types of public key and attribute certificates: the Clinicians' and a Patients' as distribution rules contain a flag which denotes if the architectural component is allowed to be read by a patient. Patients will be granted reading the architectural component if physicians set a corresponding flag.

Access Control

In a complex distributed system, such as MEDIS, access control is consequently very complex and has to satisfy both a fine grained access control and administrative simplicity. This can be realised using plugable, component based authorisation policies (Beznosov, 2004). An authorisation policy is the complex of legal, ethical, social, organisational, psychological, functional and technical implications for trustworthiness of health information system. One common way to express policy definition is an XML shema-data. These schemas should be standardised for interoperatibility purposes (Blobel, 2004). The MEDIS project aims at developing the authorisation policy definitions, using XML schemadata (MEDIS Tech. Report, 2005), which are based on CEN ENV 13 606 Distribution rules attributes (CEN ENV, 2002).

Distribution rules define the attributes of architectural components related to access control (CEN ENV, 2002). A distribution rule comprises Who, When Where, Why and How objects (see Table 2). The object Why is mandatory, i.e. one of its attributes has to be "not null". The attributes and entities contained within the objects Who, When, Where, Why and How shall be processed as ANDs. If, however there is more than one Who, How, Where, When or Why object present in a distribution rule, the occurrences of each of those object types shall be processed as ORs.

The MEDIS project has adopted XML as the language for developing constrained hierarchical role based access control and, at the same time, has its focus on decomposing policy engines into components (Beznosov, 2004; Blobel, 2004; Chadwick et al., 2003; Joshi et al., 2004; Zhou, 2004).

The MEDIS project authorisation policy has several components (MEDIS Technical Report, 2005). First, there is an XML schema of user attributes that corresponds to the attribute certificate attributes. Second, there are distribution rules attached to each architectural component (see Figure 4). Third, there are local authorisation policies on local LDAP servers. Fourth, there are Master Authorisation Policies on central LDAP server. There are several types of policies:

- Authorisation policy for hierarchy. It defines hierarchies of How, When, Where, Why and Who attributes (hierarchy of roles, professions, regions etc). In that way, a hierarchical RBAC can be implemented, with constraints defined by security attributes (software security, physical security rating etc.) and nonsecurity attributes (profession, specialisation etc.).

Table 2. Distribution Rule objects [1]

Classes	Attributes	Type
Who	Profession Specialization Engaged in care Healthcare agent	String String Boolean Class
Where	Country Legal requirement	String Boolean
When	Episode of care Episode reference	Boolean String
Why	Healthcare process code Healthcare process text Sensitivity class Purpose of use Healthcare party role	String String String Class Class
How	Access method (read, modify) Consent required Signed Encrypted Operating system security rating Physical security rating Software security rating	String Class Boolean Boolean String String String

- Authorisation policy for hierarchy combinations. It defines which combination of, for example, role hierarchy and profession hierarchy is valid.
- Authorisation policy for DRs. It defines which combinations of attributes in a Distribution Rule are allowed.

There is an enable/disable flag, which defines whether the policy is enabling or disabling. There are in fact, two administrators: one on the clinical server and another on the central LDAP server. In that way, this approach provides flexibility and administrative simplicity. Our future work is to explore the best allocation of these policies between the central server and local servers.

Encryption

The MEDIS project implements Web Service security between the clinical and central server and SSL between the central server and a client (Microsoft, IBM, 2004). We use Apache's implementation of the OASIS Web Services Security (WS-Security) specification–Web Service Security for Java (WSS4J) (W3C Recommendation, 2002). WSS4J can secure Web services deployed in most Java Web services environments; however, it has specific support for the Axis Web services framework. WSS4J provides the encryption and digital signing of SOAP messages. The RSA algorithm has been chosen for signing and the TripleDES for encryption. Communication between the browser and Web Server has been encrypted using SSL. Currently, Netscape 6 browser and Tomcat 5.0 Web Server are used and the agreed chiper suite between them is SSL_RSA_WITH_RC4_128_MD5.

FUTURE WORK

If an application has a large number of users and requires a large number of roles and fine-grained access control at the same time, a formal verification of security policy properties is needed. Secondly, MEDIS project is going to develop a powerful search engine based on intensive use of distributed queries with corresponding security questions solved. MEDIS is a medical record and we are planning to make it a multidisciplinary and multiprofessional record. Nowadays, integration in electronic record comprises the integration of previously introduced HIS using a communication protocol, such as HL7, and Web Services. Hospitals and clinics are connected in grids with protocols similar to Web Services SOAP protocol.

CONCLUSION

Regarding the basic requirements of secure communication and secure cooperation in distributed systems based on networks, basic security services are required. These services have to provide identification and authentication, integrity, confidentiality, availability, audit, accountability (including nonrepudiation), and access control. Additionally, infrastructural services such as registration, naming, directory services, certificate handling, or key management are needed. Especially, but not only in health care, value added services protecting human privacy rights are indisputable. This paper presents existing solutions in transnational electronic healthcare records and also gives a proposal for EHCR architecture and EHCR security solutions in developing countries with widespread Internet.

ACKNOWLEDGMENT

The author would like to thank Mrs. Vesna Zivkovic, PhD, Director of Institute Mihailo Pupin, Computer Systems, for her overall support.

Chapter 7.8
E-Health and Ensuring Quality

INTRODUCTION

The Internet is one of the most utilized resources for obtaining information, learning, communication, and as a source of advice. The most sought after advice and information are related with health matters. In the United States, for example, over 16 million people per year visit WebMD (http://my.webmd.com/webmd_today/home/default), an online portal dedicated to providing health information and services (Sass, 2003). Health information on the Internet has grown exponentially, with up to 88 million adults predicted to access medical information online in 2005 (Ansani et al., 2005). This merging of medical knowledge and information knowledge has given birth to e-health.

Despite the growth and application of information and communications technology (ICT) in health care over the last 15 years, e-health is a relatively new concept, with the term being introduced in the year 2000 (Pagliari et al., 2005). Its use has grown exponentially, and as Pagliari et al. (2005) reported, there are over 320,000 publications addressing e-health listed in MEDLINE alone. However, there is still no clear definition of e-health. There have been two international calls, in 2001 and 2004, for a clear and concise definition of e-health, but both failed to produce an internationally acceptable definition. In the same paper, Pagliari et al. (2005) found 24 different definitions, highlighting the fact that this is a gray area. Hence, without a clear and standardized definition, the opportunities to conduct unethical behavior are made easier.

In this article Eysenbach's (2001) definition will be used, as it provides a comprehensive overview of the term e-health. It has also been used, as Eysenbach is regarded as an expert in the area of e-health and consumer informatics. He has defined e-health as:

An emerging field in the intersection of medical informatics, public health and business, referring *to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology.* (Eysenbach, 2001, p. 1)

This phenomenon has led to consumers becoming more educated and aware of their health condition. This advice is not only accessed by people who may be suffering from a health condition, but also those who are healthy and want to remain so. E-health is being used as a tool for preventive and predictive treatment, as well as a means of locating others in a similar situation and sharing various experiences. In most developed countries e-health is seen to be the first step that one will take towards healing themselves, and if not avoiding the doctor, it is a useful second opinion.
