Model building is critical in decision-making as it clarifies thinking and improves the decision-making quality (Georgantzas & Acar, 1995). Spatial modelling techniques are used for finding relationships among geographic features and helps decision-makers to address the spatial problem clearly and logically. Spatial aspects and non-spatial aspects can be coexistent in a spatial problem, so that we need to consider both aspects at the same time. It is difficult to model a complex spatial problem in a single step, but it is possible to model one aspect of a complex problem at a time. For example, create a spatial model to deal with spatial aspects and a non-spatial model that caters to the non-spatial aspects of the problem, and then integrate them.

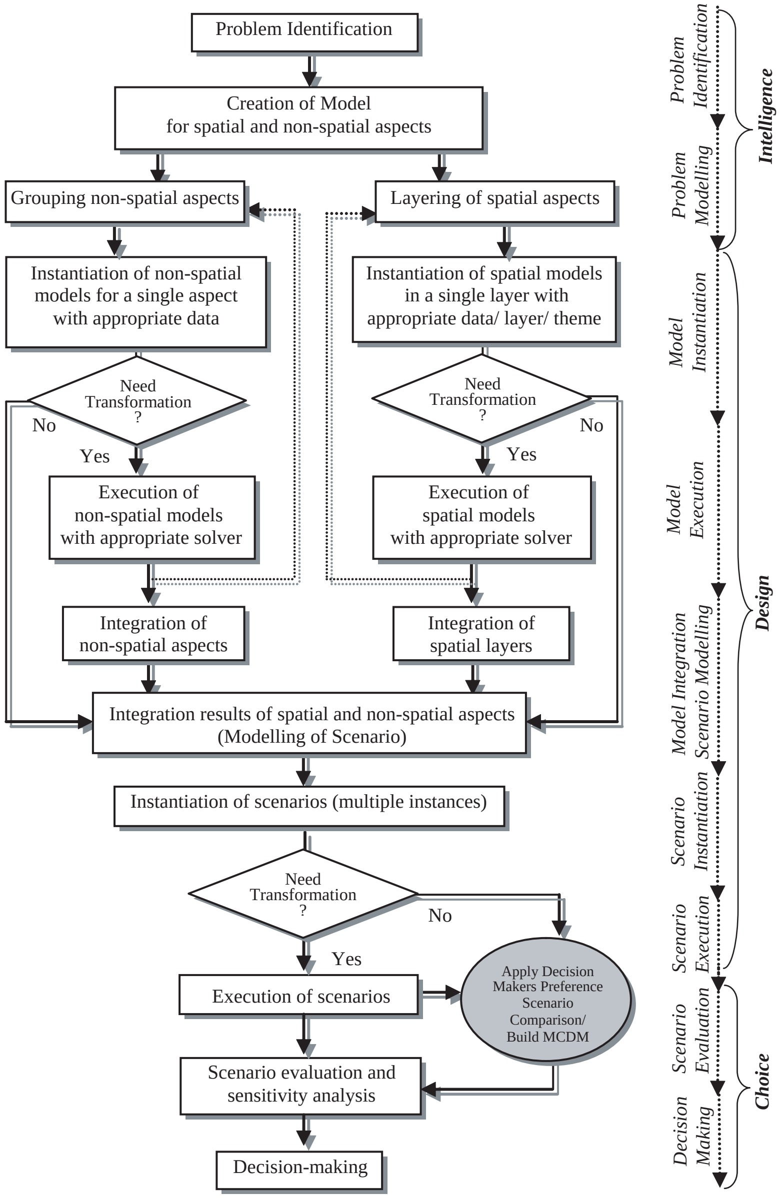
A spatial model contains spatial parameters that refer to the geographical features of a spatial problem. Vector-based spatial data can be categorised into three major groups, that is, spatial objects, spatial layers, and spatial themes. A spatial object represents a single spatial item, for example, a point, a line, or a polygon. A spatial layer contains a collection of spatial objects similar in nature, and every spatial object belongs to a certain layer. A spatial theme comprises a number of spatial objects and/or spatial layers that represent a particular meaning to a particular spatial problem. Vector data is linked to non-spatial domain data through a spatial reference system; a point could be associated with a residential location, and a line may represent a running path. Each aspect of a spatial problem can be modelled in one layer. These layers are then integrated into a complex model that represents the many facets of the problem.

We propose a spatial decision-making process (Figure 1) by synthesising ideas of decision-making processes (Simon, 1960) and the multi-criteria decision-making process (Malczewski, 1999). It also integrates concepts from spatial modelling, model, scenario, and knowledge management. The process contains nine specific steps, namely, problem identification, problem modelling, model instantiation, model execution, model integration, scenario instantiation, scenario execution, scenario evaluation, and final decision-making.

The decision-making process begins with the recognition of a real-world problem that involves searching the decision environment and identifying comprehensive objectives that reflect all concerns relevant to a decision problem. The problem is then put into a model by specifying the relevant attributes and behaviours. The parameters in a model structure are instantiated with appropriate data. Decision-makers select a solver for execution of a model instance and generate a result, that is, the scenario. A scenario improves cognition by organising many different bits of information (De Gues, 1997). Multiple scenarios are needed to explore different ways of seeing problems and enhancing the decision-making quality (Forrester, 1992). The scenario evaluation process evaluates many competitive alternatives simultaneously and helps to identify the best solution.

The process is iterative in nature so that multiple scenarios instances can be generated using the same scenario structures. The scenario integration process enables the decision-maker to combine both spatial and non-spatial scenarios to create a complex multi-criteria spatial scenario that addresses all the requirements of a complex spatial problem. When required, the instantiated scenarios are called for execution using different solvers. The execution of the scenario allows the decision-maker to further develop a more desirable solution to a particular problem. Scenario evaluation ranks the many alternative scenarios based on decision-makers' preferences. Sensitivity analysis is employed as a means for achieving a deeper understanding of the structure of the problem by changing the inputs, for example, data, solver, or evaluation model. This helps decision-makers learn how the various decision elements interact and allows them to determine the best solution. In completing the above processes, the best-evaluated scenario is selected. As there is no restriction on how the user chooses to solve a problem, decision-makers can select the phases to follow based on the nature of the specific problem and their specific purposes.

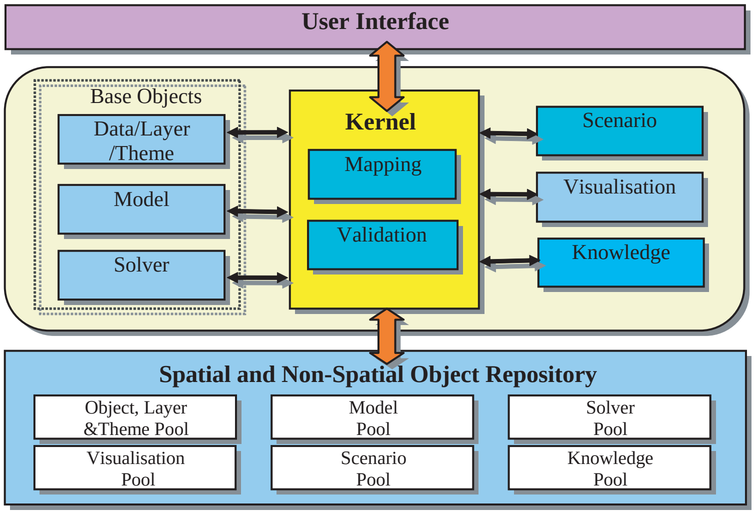
Figure 1. Spatial decision-making process



THE FSDSS FRAMEWORK

We propose a flexible spatial decision support system (FSDSS) framework (Figure 2) to support the decision-making process and overcome the problems identified earlier. The FSDSS framework is comprised of six major DSS objects or components namely, data, models, solvers, visualisations, scenario, and knowledge. These objects are stored in the object repository independently, and they communicate through the kernel, the programmatic engine that makes the system run. The framework accommodates spatial data (spatial objects, layers, and themes) and non-spatial data. It contains both spatial and non-spatial models, solvers, scenarios, and visualisations. The knowledge is the output of the decision-making process and can be stored in the system for future reference.

Figure 2. The FSDSS framework



The decision-maker interacts with the system through the user interface. Different data, model, and solver can be selected from the object repository and mapped together to generate a scenario, or a specific decision support system that is tailored for a particular problem domain.

This framework allows generating multiple scenarios at one time and stores them in the scenario pool. The framework supports the integration of several simple scenarios into a complex multi-attribute scenario that contains both spatial and non-spatial aspects through the scenario integration process. The multiple scenarios and the evaluated scenarios can be presented using the appropriate visualisation component. The output of the decision-making process can be saved in the object repository as knowledge.

The FSDSS Architecture

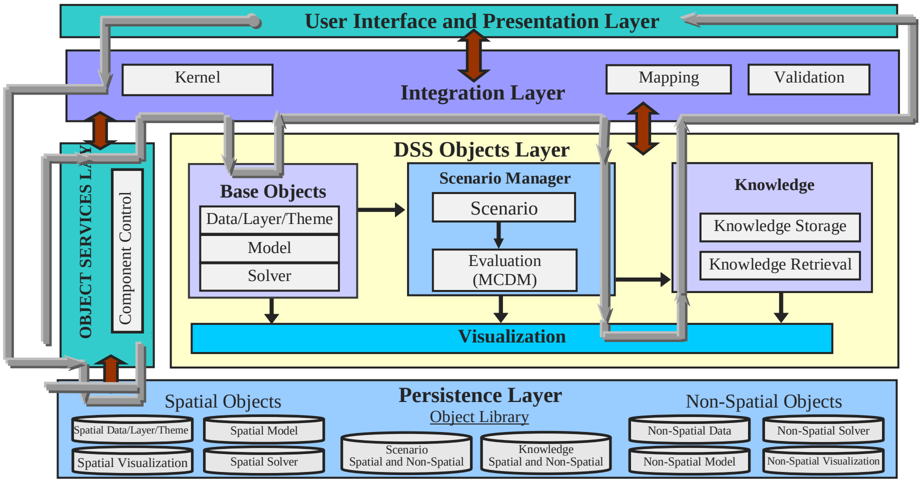
We propose an architecture that implements the FSDSS framework and supports the proposed decision-making process, as shown in Figure 3. The FSDSS architectural components are organised into five distinct layers; these are persistence layer, object services layer, DSS objects layer, integration layer, and presentation layer. These layers and their components are briefly described as follows.

The *persistence layer* contains the object library used to store the system objects. This includes the storage of non-spatial data and a variety of spatial data (objects, layers, themes, and map). It is also responsible for the storage of models, solvers, visualisations, scenarios, and knowledge, either spatial or non-spatial in nature, using the object-oriented database management system.

The *object services layer* manages the system objects through the component control that contains several parameters and methods to coordinate the component pool and the application. It exports objects from the object library to the DSS objects layer, as well as importing the resulting scenarios and knowledge from the DSS objects layer back to the object library. It also facilitates dynamic creation, updating, and deletion of the objects.

The *DSS objects layer* supports independent development and use of the decision-support components including spatial and non-spatial data, models, solvers, and visualisations, for generating basic spatial and non-spatial scenarios. It is responsible for integrating scenarios to develop complex spatial scenarios. It supports the evaluation and

Figure 3. The FSDSS architecture



ranking of multiple scenario instances using the evaluation model. This layer also facilitates the storage and reuse of the result from the decision-making process. It also provides graphical and map-based presentation of data, scenarios, and knowledge. The data component includes non-spatial and spatial data, that is, spatial objects, layers, themes, and maps. The model can be of the primitive type or the compound type (Geoffrion, 1987). Primitive type model parameters are directly derived using base data type variables or executed model values of the base models. The compound type parameters inherit and/or aggregate the base models as well as adding some other user-defined parameters. The non-spatial model handles non-spatial problems or non-spatial aspects of a spatial problem. Spatial models cater to spatial problems. The evaluation model is made of different parameters as well as the weights for each of these model parameters. The FSDSS architecture has a number of spatial-oriented solvers and generalised solvers that can be used to solve/execute both spatial and non-spatial models. The scenario combines data, model, solver, and other relevant information. The scenario structure and its multiple instances can be stored in the database. The FSDSS supports three types of visualisation: spatial, non-spatial, and map-based. Spatial visualisation is used to represent spatial data, scenarios, and knowledge. Non-spatial visualisation, for example, 3D graphs, are used to present the output of analytical results. In addition to the general graphical report functions, the FSDSS visualisation is particularly important when used with maps. Different spatial objects, layers, or themes are overlaid to generate a new map. The knowledge component contains the final results of the decision-making process, including information about the decision-maker, the rules that were applied, alternative scenarios, the final decision, as well as the system components used in reaching a particular decision.

The *integration layer* contains the communication components, that is, kernel, mapping, and validation components. In addition to activating and using the component functions, the kernel works as a user interface and is responsible for the communication and integration of system components. Mapping enables the model component to communicate with data and solver components properly through model-data and model-solver mapping processes. The model parameter or attributes are fixed; the user selects the data attributes for model-data mapping and selects the solver name and solver attributes for model-solver mapping. Validation enables proper communication between system components. The validation module is responsible for checking the input data type to the model and to the solver during the mapping process. The model-data validation tests whether the data type of the model attributes is similar or convertible to the data attributes, while model-solver validation checks whether the data types of the attributes of the model instance are similar or convertible to the data type of the solver attributes.

The *presentation layer* or user interface supports all the interactions between users and the system. It provides a flexible environment where spatial and non-spatial components are used together to solve complex spatial problems. The architecture as a whole is technology independent so that it can be implemented using commonly-available platforms.

A simple decision-making flow in Figure 3 illustrates how the FSDSS architecture supports the decision-making process. The decision-maker initiates the decision-making process at the interface layer and interacts with the system through the kernel. The component control picks up the relevant components from the persistence layer. The selected data, models, and solvers are combined in the integration layer to develop scenarios using the mapping component. The scenario manager manages these scenarios, and the evaluated scenarios can be presented using the appropriate visualisation component. The interaction between the DSS objects layer and the persistence layer are bi-directional. On the one hand, the architecture allows flexible selection of objects from the object library. On the other hand, the executed results (e.g., scenarios generated) can be stored back to the object library.

The FSDSS Implementation

A prototypical FSDSS was implemented to prove the validity of the proposed spatial decision-making process as well as the FSDSS framework and architecture. Object-oriented concepts, object-oriented database management system, and the object-oriented programming language were the tools and technologies used to develop the FSDSS prototype. *Jade* (www.jadeworld.com), a fully integrated development environment (Post, 2000) with its own object-oriented database and programming language, was selected as the implementation platform. The complete prototype was developed within Jade without recourse to any other tool. The proposed spatial decision-making process and the implemented FSDSS were evaluated through five scenarios across different spatial decision problem domains including location, allocation, routing, and/or layout. Table 1 details of the type of spatial problems and the specific domains where we tested the prototype. The same environment was used in the testing, but with different data, model, and solver sets.

Table 1. Spatial problems and implementation domains

Spatial Problem	**Application Domain**	**Example Spatial Problems**
Allocation	Geo-Marketing	Find geographical distributions
Layout	Running	Design and select best running path
Routing	Delivery	Identify the fastest route
Location	Housing	Search the most suitable house
Spatio-Temporal	Health	Trace the spread of a disease over space and time

Sample Sessions with the FSDSS

In the following sections, we explore the interaction with the FSDSS to solve three of the spatial problems mentioned above. We first use the problem of the design of a running track to introduce some of the core spatial modelling concepts such as objects, layers, and themes. The second example explores in detail the use of the FSDSS, following the proposed spatial decision-making process, in the context of the purchase of a house. To highlight the generic applicability of the system we show its use in the context of solving a spatio-temporal problem in health care.

Design of a Running Track

The first scenario we explore is the design of a path for a particular running event that takes into consideration the required amenities like drink points and toilets, as well as the distance. This example introduces some of the basic spatial concepts and functionality of the system. The decision-makers can plot a number of paths by clicking points on the map. These paths are then saved in the database as *running path 1* and *running path 2* (see Figure 4).

In addition to these two paths, the decision-makers need to consider other facilities that might be useful to this event, for example, drink points and toilets. These objects are stored in the database as individual objects or as a layer. The spatial layer manager manages these layers. As we can see from Figure 5, there are four drink points in the *drink point* layer.

Figure 6 presents the map layout of the two paths (running path 1, running path 2) and the relevant layers, that is, the four toilets in the toilet layer and four drink points in the drink point layer.

It also shows that some of the facilities are not useful for the event, for example, *toilet 4*, as it is far away from these paths. Further observation indicates that *toilet 1, toilet 2, drink point 1,* and *drink point 2* are particularly useful for running *path 1*, while *toilet 3, drink point 3,* and *drink point 4* are useful to *running path 2*. Based on these observations, the system enables the decision-maker to further group these objects or layers into spatial themes.

A spatial theme contains a group of spatial objects and/or spatial layers and presents a particular meaning to the decision-maker. In this illustration, *running path 1, toilet 1, toilet 2, drink point 1,* and *drink point 2* are grouped together to form a theme, that is, *running theme 1*. Similarly, *running path 2* along with *toilet 3, drink point 3,* and *drink point 4* forms *running theme 2*. The spatial

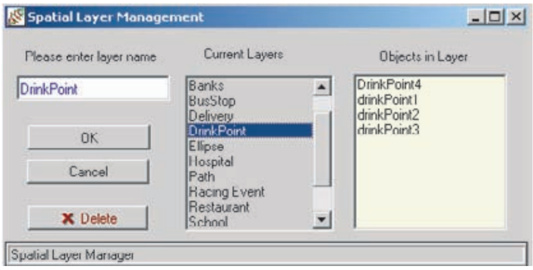
Figure 5. Spatial layer manager

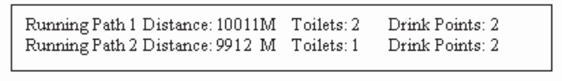


objects and layers used for creation of *running theme 1* are presented in Figure 7. Integration of these spatial items from different layers through map overlay allows viewing the whole picture of a spatial problem from different perspectives.

The spatial theme manager provided by the FSDSS manages the spatial themes. It allows the decision-makers to save themes to the database and retrieve themes from the database. The interface for the spatial theme manager is given in Figure 8.

The spatial theme manager facilitates the creation and deletion of themes as required. In addition, it facilitates the updating of themes, for example, add new objects or layers to the theme, or delete spatial objects or spatial layers from the theme. Figure 9 shows the map presentation of *running theme 1* and *running theme 2*.

Decision makers can also perform other tasks using appropriate models and solvers to further investigate the problem, for example, calculate the distance of each of these running paths using the *path* model and *distance* solver. The following illustration shows two different scenarios for the above-mentioned themes. These scenarios are compared with each other to decide the best path for this running event.



```
Running Path 1 Distance: 10011M   Toilets: 2    Drink Points: 2
Running Path 2 Distance: 9912 M   Toilets: 1    Drink Points: 2
```

In this case, *running path 1* is better than *running path 2* for two reasons. Firstly, *running path 1* has additional facilities (one more toilet) along its path compared with *running path 2*. Secondly and most importantly, the geographical layout of *running path 1* is better than *running path 2* since all available facilities are more evenly distributed along the track.

Purchase of a House

This section illustrates the implemented FSDSS to solve a location problem using the proposed spatial decision-making process. The application

of each step of the process shown in Figure 1 is described in detail.

Step 1: Problem Identification

The problem presented in this session is to identify the optimal location of a property that maximises "return," that is, the satisfaction level that is measured on the basis of the following three criteria. The value tree of after-analysis of the problem is presented in Figure 10.

- **Quality criteria:** for example, construction material, year built, size, function, and number of rooms
- **Economic criteria:** such as market price or rental cost
- **Location:** for example, property accessibility, vicinity, and environmental conditions

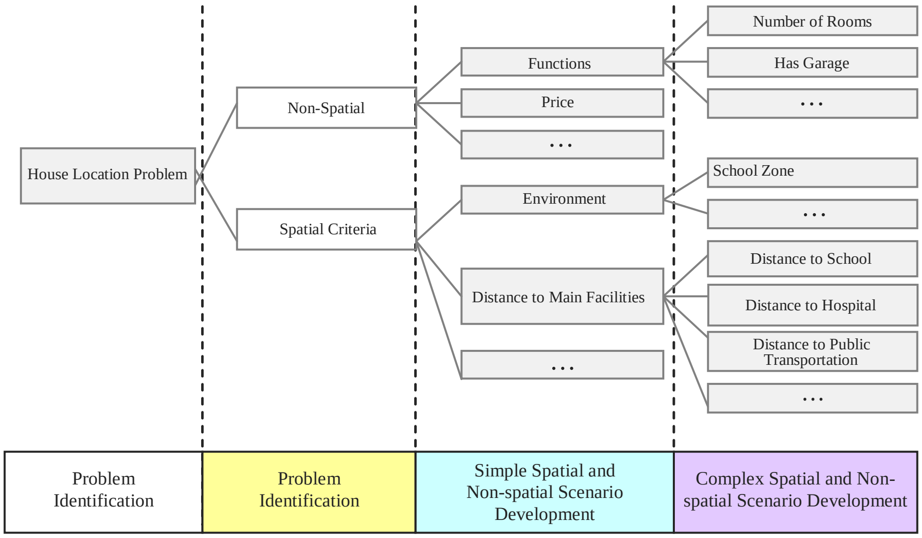
Some of these factors are difficult to evaluate or predict, as relative impacts for some of these factors on return remain unknown. It is hard to structure the problem in its entirety at one time, that is, precisely define and measure the objective for every possible solution. In the next step, the decision-maker models this problem using the proposed modelling approach by separating the spatial and non-spatial aspects of a complex spatial problem.

Step 2: Problem Modelling

The problem modelling involves both spatial and non-spatial aspects. Quality and economic factors are non-spatial in nature whereas accessibility criteria are of a spatial nature. On the non-spatial side, cost and quality of the property can be analysed using non-spatial models and solvers. The spatial aspect of the problem focuses on the location of the property, as it is an important criterion when people rent or buy a house. Location is a complex criterion that has multiple spatial dimensions, for example, environment and distance to important facilities. These spatial dimensions need to be analysed one by one in order to find a best location.

In this illustration, the decision-maker broadly selects a target area and then carries out accessibility analysis. The analysis involves both the non-spatial and spatial models, and it uses both non-spatial and spatial solvers. The problem is

Figure 10. Value tree of location problem



solved iteratively by first, considering spatial and non-spatial data, models, solvers, and scenarios; second, applying spatial and non-spatial criteria; and last, using goal-seeking and sensitivity analysis.

Step 3 and 4: Scenario Development

The decision-maker now needs to load relevant decision-making components. These include the property table and relevant map in which the properties are located, the various models, solvers, and visualisations to be used for building the different scenarios. A simple non-spatial scenario and a simple spatial scenario are developed separately at first; they are then integrated into a combined scenario. These scenarios are then transformed into a complex multi-criteria scenario through a structural integration process. The scenario development process is illustrated as follows:

Simple Non-Spatial Scenario

The non-spatial scenario is created using the non-spatial *filtering* model and the *range* solver. In this example, we have specified that we need a 3-bedroom flat with a price range between $300,000 and $400,000. Several properties are identified through this filtering process (see Figure 11). These are then stored in the database as *scenario 1* (4 instances).

Simple Spatial Scenario

The decision-maker has selected a buffer zone (a 500-meter radius circle) around a particular location (e.g., x, y coordinates: 200,200). The *filtering* model is instantiated with the *property* data and executed using the *distance* solver to find the properties within the defined circle. This process develops many scenario instances as shown in Figure 12. These scenario instances are then stored in the database as *scenario 2* (14 instances).

Combined Scenario (Pipelining Integration)

Pipelining integration of spatial and non-spatial scenarios can be done in two ways. The first way is to create non-spatial *scenario 1* and then execute the geographical filtering model using

Figure 11. Simple non-spatial scenario creation

spatial solvers, for example, d*istance* or *point-in-polygon* solver (Figure 13).

During this integration process, the four non-spatial filtered scenario instances of *scenario1* as described earlier are supplied as input to the spatial filtering model. The resulting scenario instances are stored as *scenario 3* (3 instances).

The second way for integration of *scenario 1* and *scenario 2* is to supply the spatial *scenario 2* as input into the non-spatial filtering model and then apply the non-spatial Range solver for execution, as illustrated in Figure 14. The process develops three instances that are stored in the database as Scenario 3.

The scenario pipelining integration process can take place in many ways, either from non-spatial to spatial or from spatial to non-spatial or from spatial to spatial or from non-spatial to non-spatial. The flexible use and integration of spatial and non-spatial models, solvers, and scenarios is one of the most important features of the FSDSS. The above process helps the decision-maker to

choose the properties that satisfy the non-spatial criteria, for example, quality, cost, and the basic location requirements such as area. The following section illustrates another aspect of the location problem, namely, accessibility analysis.

Complex Spatial Scenario (Structural Integration)

The complex spatial scenario is generated using the *property* data, *distance* model, and *distance* solver as shown in Figure 15. The previously created s*cenario 3* and its three instances are loaded from the scenario pool. Now, the decision-maker focuses on distance to major facilities for accessibility analysis.

Distance has multiple dimensions. It includes the distance from a particular spatial object (e.g., *property 0014*) to another object (e.g., *hospital 2*). The distance from one object to a spatial layer (e.g., *school layer*) returns multiple values, in this case the system returns the shortest distance from the target object to a single object (e.g., *school 1*) in that layer.

Step 5 and 6: Scenario Integration and Instantiation

The decision-maker integrates the simple combined scenario (*scenario 3*) structure with these newly- developed distance parameters to develop a more complex scenario that contains all the criteria for the problem.

The structural or permanent scenario integration takes place in two steps. First, a bare scenario template is created as shown in Figure 16. Then multiple scenario instances are created (Figure 17).

The scenario integration process is iterative in nature until all scenario instances have been

generated. The scenario template and its multiple instances are stored in the database as a complex scenario, and they can be retrieved for further analysis or evaluation. The distance to the schools and shops are calculated on a spatial layer, rather than a single spatial object. The system picks up the distance to the closest object in the layer for instantiation of the scenario parameter. The decision-maker can select any spatial object, layer, or theme for integration of scenarios using the spatial manager as shown in Figure 18.

Step 7: Scenario Execution

Scenarios can be instantiated with the relevant data, model, and a number of solvers can be applied for execution of the scenarios. The scenario can be executed in a simple process or using multiple steps. The integration of executed models (scenarios) is also the process of modelling the scenario. During the scenario execution process, one scenario is instantiated and executed using different solvers.

Step 8: Scenario Evaluation

The FSDSS supports the MCDM scenario evaluation process. The decision-maker needs to build a MCDM evaluation model by specifying parameters and assigning weights to each of these parameters. The evaluation model is instantiated with alternative scenario instances. These scenarios are executed using the solver that is tightly coupled within the evaluation model. The results are then ranked for selection. The sequence of the steps taken in this process is shown in Figure 19. The decision-maker selects the scenarios for evaluation to the scenario table as indicated in step 1. Then, an evaluation model is built by selecting the appropriate criteria from the input scenario. In step 3, the decision-maker assigns a weight to each of the criteria. Step 4 evaluates the scenarios using the model template created in step 2 and step 3. The built-in solver not only calculates values according to the formula but also ranks these values. The highest value is given as 100%, and other scenarios are calculated on a ratio basis by comparing the highest value.

Step 9: Decision-Making

As we can see from the results, *property 0014* (Figure 19) is ranked highest. Furthermore, the decision-maker can apply different evaluation models to explore alternative scenarios by considering the uncertainty involved in the decision-making process. Uncertainty may be caused by the error in available information to the decision-maker, or improper judgment regarding the relative importance of evaluation criteria.

Sensitivity analysis is employed as a means for achieving a deeper understanding of the structure of the problem. Sensitivity analysis is done through changing data, model, solver, scenario, and evaluation models. The decision-maker can change any one of these aspects and then re-evaluate these scenarios. This process can be repeated until all the scenarios relevant to the decision-maker are explored.

TRACE THE SPREAD OF A DISEASE

The problem presented in this section is to identify the spread of the SARS epidemic in Hong Kong. We try to understand, analyse, and manage geographically distributed data using spatial functions. Overlaying quantitative graphics on a map enables the viewer to realise potential information in an extremely clear manner so that spatial patterns can be discovered.

We have aggregated a case database that includes the date, the number of cases confirmed,

and the places they were found. Through the geo-coding process, each case was mapped to a geographical object, for example, a building or a hospital. These spatial objects can then be referenced by the geo-coding locations on the map. Figure 20 presents an overall picture of the geographical distribution of SARS cases and the population density; this gives us information about the number of SARS cases among different population groups at any given time. The visual representation would be useful for developing hypotheses about relationship between the distribution of SARS and population density or groups (Chu, Gao, & Sundaram, 2005). It could provide useful pointers for further analysis and investigations.

We explore the above scenario one step further by applying a time frame, to give pictorial views of the rate of case increases in various hospitals over time. As we can see from Figure 21, on the 13th of March, 2003, 33 SARS patients were admitted by the Prince of Wales Hospital (PWH); among them, 18 were confirmed. There were also two confirmed patients in Pamela Youde Easter Hospital (PYEH). The total number of patients admitted in Hong Kong hospital was 35 (20 confirmed).

On the 20th of March, the total number of admissions increased to 99 (58 were confirmed). The number of suspected patients in PWH jumped to 77, and PYEH cases increased to ten. New suspected patients were also found in Princess Margaret Hospital and Queen Elizabeth Hospital (Figure 22).

Using the time series mapping, we were able to map the number of patients admitted with sus-

pected SARS symptoms and compare the number of these cases being confirmed as SARS patients subsequently at later times. Similarly, we can use the FSDSS to map the spread of SARS infections in the community. The system modules are interconnected, and new entry of data dynamically changes other modules. An example of this is the dynamic refresh of collection of spatial objects where there is an infection (as seen in the drop-down combo box that appeared in the left-hand side in Figure 23). These spatial objects could include residential buildings, schools, shops, and any other objects that have a spatial reference.

Visual overlay of spatial objects over time allows us to ask a question such as "why has one block (in Lower Ngau Tau Kok Estate, quite far away from the Amoy Gardens) a much higher rate of infection than any other building?" Demographic analysis later reviewed that residents in this block comprised mostly senior citizens and that they passed through the Amoy Garden shopping mall each day to do their shopping.

FUTURE TRENDS

Advances in MCDM, GIS, other relevant technologies, and their integration will have major impacts on the future development of SDSS. Multi-criteria spatial decision support is clearly the appropriate paradigm because it is such an adaptable and comprehensive concept. Multi-criteria spatial analysis is moving to a more exploratory, interactive emphasis with new decision analysis tools. There is also an increasing emphasis on the study of complex systems through simulation (Ascough II et al., 2002).

GIS itself is moving to a greater level of integration with other types of software. Spatial data and tools will be ubiquitous, embedded in business systems, and transparent to most users as shown in Figure 24. GIS can be an interoperable part of most critical business information systems including ERP/enterprise systems (such as SAP and PeopleSoft), environmental, asset, financial, human resource, emergency, and customer relationship management systems, thus bringing the power of spatial analysis and data mining to bear to measure results (business intelligence) and future impacts (analytic intelligence). A major focus is the design and implementation of true strategic intelligence frameworks that integrates spatial and non-spatial data across different information systems and business units to create broader knowledge and understanding within organisations at all levels of decision-making (Holland, 2005).

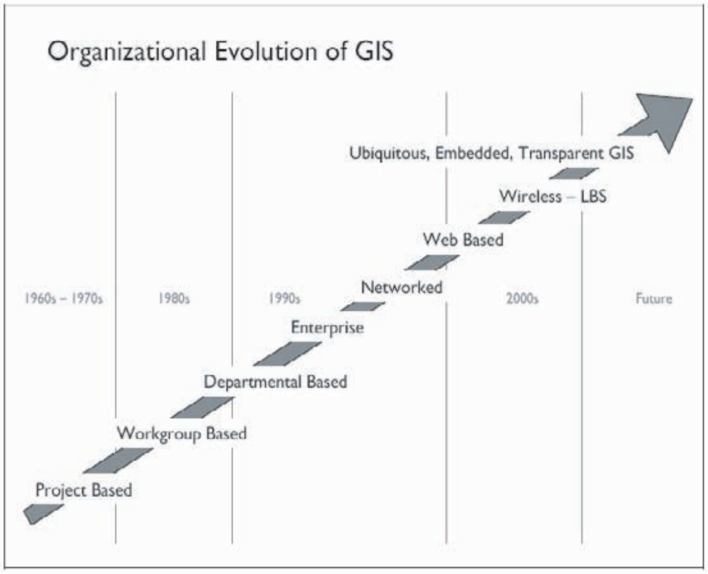
The design of an intelligent SDSS by coupling a GIS with an expert system is discussed by Zhu and Healey (1992). Spatial decision-making is based on two streams: the quantitative, which includes data analysis and modelling, and qualitative, which includes experience, intuition, judgment, and expertise. Current GIS systems focus on quantitative information and largely ignore the qualitative aspects of the process. The inclusion of expert systems, which perform decision-making tasks by reasoning, using rules defined by experts in the relevant domain, would greatly aid qualitative spatial decision-making within GIS, and thus SDSS.

CONCLUSION

Decision-makers perceive the decision-making processes for solving complex spatial problems as unsatisfactory and lacking in generality. Current SDSS fulfil their specific objectives, but fail to address many of the requirements for effective spatial problem-solving, as they are inflexible, complex to use, and often domain-specific. This research blends together several relevant disciplines in a unique way and attempts to overcome the problems identified in the fields of spatial decision-making and SDSS.

We proposed a spatial decision-making process. Within the context of the spatial decision-making process, we have proposed a modelling approach by addressing the need of differentiating the spatial and non-spatial elements for multi-dimensional complex problem modelling. We then developed a flexible spatial decision support system framework and architecture to support this process. We also implemented a prototypi-

Figure 24. Historical and future trends of GIS (Source: Holland, 2005)



cal FSDSS that acts as a proof-of-concept for the spatial decision-making process, FSDSS framework, and architecture. The proposed spatial decision-making process and the implementation of FSDSS have been evaluated through a number of scenarios across diverse domains. The evaluation results indicate that the proposed spatial decision-making process is generic, and it is effective in solving complex spatial problems in different domains. Furthermore, the flexible use across domains and different types of problems was due to the generic nature of the architecture and design that leveraged spatial modelling and object-oriented concepts.

ABSTRACT

A SDSS combines database storage technologies, geographic information systems (GIS), and decision modeling into tools which can be used to address a wide variety of decision support areas (Eklund, Kirkby, & Pollitt, 1996). Recently, various emerging technologies in computer hardware and software such as speedy microprocessors, gigabit network connections, fast Internet mapping servers along with Web-based technologies like eXtensible Markup Language (XML), Web services, and so forth, provide promising opportunities to take the traditional spatial decision support systems one step further to provide easy-to-use, round-the-clock access to spatial data and decision support over the Web. Traditional DSS and Web-based spatial DSS can be further improved by integrating expert knowledge and utilizing intelligent software components (such as expert systems and intelligent agents) to emulate the human intelligence and decision-making. These kinds of decision support systems are classified as intelligent decision support systems. The objective of this chapter is to discuss the development of an intelligent Web-based spatial decision support system and demonstrate it with a case study for planning snow removal operations.

INTRODUCTION

Spatial Decision Support Systems

The past decade witnessed an explosive growth of spatial data and various applications that utilize spatial data. Geographic information systems (GIS) have been developed to facilitate storing, retrieving, editing, analyzing, and displaying spatial information. The increasing complexity of spatial data and a need for better modeling requires decision support systems that can handle spatial data. This led to the idea of spatial decision support systems (SDSS). Since the early 1980s, SDSS have been used in several applications that provide spatial functionalities such as routing, allocation modeling, and so forth.

Most of the existing SDSS do not employ any intelligent software components to enhance decision support. Only a very few researchers have explored the possibility of integrating intelligent software components with an SDSS for applications like multi-criteria decision analysis, routing, and weather-based decision-making. Most of the literature reviewed for Intelligent GIS systems deals with architectural as well as implementation issues of GIS-based decision support systems and integrating them with agents. The use of software agents for GIS-based systems is well documented (Odell, Parunak, Fleischer, & Brueckner, 2003; Sengupta, Bennett, & Armstrong, 2000; Shahriari & Tao, 2002; Tsou, 2002). Most of these systems are not Web-based, and they lack the advantages of Web-based systems like ease-of-use, cross platform functionality, low maintenance costs, centralized data storage, and so forth.

Also, recent advances in Web technologies like rich site summary (RSS), XML feeds, and asynchronous JavaScript and XML (AJAX) can help us device a seamless interface by providing real-time access to data over the World Wide Web. Therefore, integrating the process of decision-making with an intelligent component and Web-based technologies proves to be very beneficial. When integrated with encoded human intelligence, the spatial decision support systems can rival a human expert in a particular domain (e.g., snow removal, traffic management, logistics, etc.).

This chapter explores and discusses the development of a Web-based intelligent spatial decision support system for planning snow removal operations. Specifically, this chapter addresses the existing problems with snow removal decision-making in the USA. The SDSS discussed here integrates knowledge from snow removal experts and real-time weather information into a Web-based interface. The system is intended to provide advised decision support for officials at various departments of transportation across the country, and to serve as a guideline for development of a snow removal DSS for the decision-makers and stake-holders around the world.

Background on Snow Removal Operations

Snow removal operations during the winter are of prime importance in avoiding traffic accidents and providing safe travel conditions on the nation's highways and city streets. Quality snow and ice control service is critical for preserving traffic safety, maintaining city commerce, and allowing residents access to schools and medical facilities (Hintz, Kettlewell, Shambarger, & Sweeney, 2001). Department of Transportation (DOT) of each state is responsible for snow removal on all interstates, and primary highways like the U.S. Federal highways and state highways. The city streets are snowplowed by the Street Department of that city, or sometimes by the DOT itself (Iowa Department of Transportation (IDOT), 2005). Snowplowing is done according to a set priority assigned to each road depending upon the annual average daily traffic (AADT). Higher priority roads like the interstates are cleared before the lower priority routes like city streets.

Managing snow removal operations necessitates activities ranging from the preparation of roads before the snowfall by pre-wetting by salt (e.g., most roads and bridge decks are pre-wetted with salt before the snow to avoid bonding of ice to the pavement in order to prevent slippery road conditions) to the timely clearing of the snow off the roads after the snowfall. The personnel in charge of snow removal operations keep tabs on weather forecasts to verify conditions that require snowplowing. These conditions include snow, flurries, freezing rain, and sleet. Once the weather forecast predicts these conditions, routes that need snow removal or salt-treatment are determined, and the snowplowing vehicles are loaded with material. These vehicles are then sent out to the roads, both before and after the snowfall. Considering the number of managerial aspects like monitoring weather information, allocating resources like vehicles, drivers, and material, it is an overwhelming task for the personnel in charge of snow removal operations to administer timely deployment of snowplows and manage efficient resource allocation. Therefore, maintaining snow removal operations efficiently and optimally during the winter is a major challenge for many governmental as well as non-governmental agencies and prove to be a big budgetary burden (Hintz, Kettlewell, Shambarger, & Sweeney, 2001; Salim, Timmerman, Strauss, & Emch, 2002).

Existing Methods for Snow Removal Operations and Their Disadvantages

Most of the existing methods for snowplowing management such as resource allocation, inventory management, and routing are performed manually by a person or persons in charge of snow removal operations. These methods, in most cases, are based on a pre-determined set of static rules that are inefficient for snow plowing and resource allocation under constantly-changing weather conditions. They often result in inefficient and non-optimal results and tend to increase the cost of snow removal. Moreover, the reaction time and the margin of error during heavy storm conditions can prove deadly, and human-based methods are always prone to such errors.

In addition, our observations with various snowplowing stations showed that there is no substantial use of analytical methods before planning snowplowing operations to reduce cost and maximize overall effectiveness. For example, the methods used for most local government agencies (e.g., the DOT) do not use any special measures for efficient routing and resource allocation. Many of the existing methods do not choose the shortest or the quickest path from the snowplow station to reach the snowplow route. Neither do they optimize resource allocation by taking into consideration various important factors like the cost of operation of a vehicle, availability of drivers or vehicles, and so forth. Such methods have a severe limitation of being inefficient; even a very slight change in weather conditions would almost demand double the amount of resources and unplanned travel for a different, non-predetermined route, and thus result in waste of time and money. Moreover, the existing manual methods cannot deal efficiently with resource allocation for newly-added routes and changing weather conditions .

Also, existing methods do not use automated inventory management and control. Inventory management is very important, and analytical tools must be used to keep up with the demand of snow removal. Various factors like the lead time for order, reorder point, stock levels, and so forth, must always be monitored to keep the necessary materials (e.g., salt) in stock. Keeping in mind the importance of providing speedy response after a snowstorm, inventory management tools are indispensable for planning snow removal operations. In addition, the existing methods do not provide any visual feedback when it comes to routing and resource allocation. Visual feedback not only improves the perception of the current assignments, but also helps review the allocations for better planning in future allocations. Also, there is no integrated use of weather information that could alert the snow removal crews and provide a scenario-based decision support. Thus, snowplowing operations must be carefully planned to provide optimum resource allocation and efficient routing.

Further, a literature review reveals that there is lack of extensive research in the field of GIS-based winter maintenance decision support systems. One of the existing SDSS for snow removal planning is the "snow removal asset management system," SRAMS for short. Salim, Timmerman, Strauss, and Emch (2002) developed a SDSS called "snow removal asset management system"(SRAMS). SRAMS is a stand-alone, personal computer-based program that utilizes a rule-based expert system for decision support. The test runs of SRAMS concluded that snow removal can be planned efficiently, by reducing the deadhead times and optimizing resources for snow removal. While this system is useful to a certain extent, it ignores many aspects of resource allocation like the availability of drivers for a certain shift, the ability of a driver to drive a specific category of a vehicle, inability to read live weather data, providing scenario-based solutions, and so forth. Being a stand-alone program, SRAMS cannot be accessed from any other computer. Also, SRAMS was developed bearing a non-technical user in mind and therefore, there is a significant need to develop strong winter operations maintenance system that offers expert advice and decision support, while being easy-to-use for even a non-GIS professional.

Another decision support system for snow removal is the winter road maintenance decision support system (Mahoney & Myers, 2003). The maintenance decision support system (MDSS) focuses mainly on using weather data to design a decision support system for maintaining roads during winters. While MDSS uses advanced weather data, it lacks the ability to calculate the amounts of snow removal material which are needed. Also, MDSS lacks an asset management module that would have made the system much more efficient.

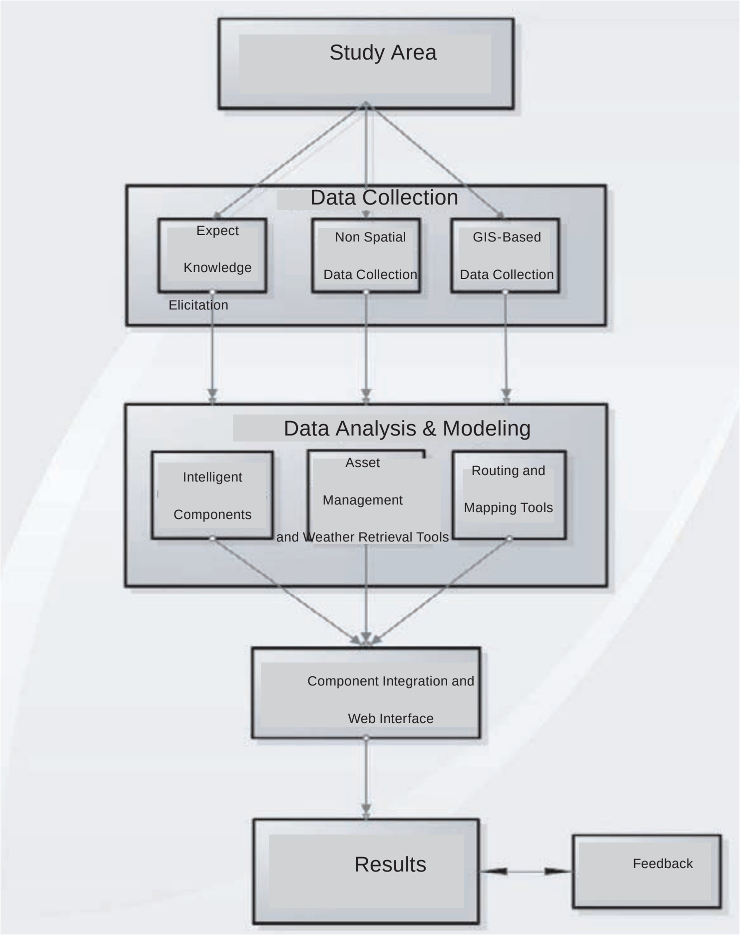
Similarly, a winter maintenance decision support system developed by the U.S. Department of Transportation (USDOT) allows viewing road-wise weather data, and various weather parameters like Visibility, Air Temperature, Snow Rate, Snow Accumulation, and so forth (U.S. Department of Transportation, 2004). Also, another system called "weather support to de-icing decision-making" (WSDDM) uses commercial weather data in the form of Next Generation Radar WSR-88D and METAR surface weather reports from automated surface observing system stations and observers. The system also uses snow gauges on the ground to measure the precipitation to provide decision support. The WSDDM essentially provides decision support for de-icing operations that take place at airports. The drawbacks of this system are the usage of commercial data and the lack of an intelligent component (e.g., expert system) for making crucial decisions.

In summary, there are no well established intelligent SDSS available for snow removal operations that integrate automatic routing, asset management, and real-time weather data. Further, the systems discussed in the literature do not leverage the potential of GIS using Web-based architectures and integrate expert system components for intelligent decision support. Therefore, there is a significant need for an intelligent system that provides analytical tools and decision support through visual feedback for managing snowplowing operations with optimal resource allocation and efficient routing.

METHODOLOGY

The methodology for developing WebISDSS encompassed the following four steps (shown in Figure 1): (a) data collection, (b) data analysis and modeling, (c) GIS and intelligent software component integration, and (d) providing results and obtaining feedback. Each of these steps is briefly described below.

Figure 1. Overall methodology adapted for developing WebISDSS (Source: Ilavajhala, 2005)



The first step in developing WebISDSS is data collection. During data collection, three categories of data were collected. These categories are expert knowledge, spatial data, and non-spatial data. The aim of expert knowledge elicitation is to gather knowledge of various snow removal operations like resource allocation, routing, and so forth, from the officials responsible for handling snowplowing operations. Officials from the Street Departments of Cedar Falls and Waterloo, IA, along with the county and Iowa DOT's highway maintenance supervisor in Waterloo were consulted to obtain the knowledge about snow removal in the study area of Black Hawk County. Through a series of direct interviews, a variety of information regarding the existing snow removal procedures was gathered.

The spatial data gathered is the county-wide roads and street dataset of Black Hawk County, IA. This data is available from the Iowa DOT's maps Web site (IDOT, 2005). The dataset essentially contains the centerlines for public roads including interstates, U.S. and state Highways, county roads, city streets, park roads, and institutional roads. For providing effective routing solutions like providing shortest or quickest path from the snowplow station to the snowplow route, the optimized road data set from GDT Inc., was purchased. This data set is commercially available in a format called spatial data engine (SDE). SDE is a format optimized to provide quick routing solutions. ArcIMS utilizes the SDE data through its RouteServer extension. The SDE data, in combination with ArcIMS, can be used to provide various kinds of routing and logistics options such as vehicle routing with multiple stops, interstate preference, and so forth.

The non-spatial data contains complementary data that could be used in combination with spatial data. There are two kinds of non-spatial information: (1) roads-related asset data, and (2) weather data. The road-based non-spatial data comes as a set of database files (DBF) that contain pertinent information like traffic volumes, number of lanes, lane length, and so forth. All the non-spatial data is available along with spatial road data from Iowa DOT's maps Web site in the form of DBF. These DBF are linked to the shapefile by the unique segment ID of each road.

The weather data is obtained from the Internet using the rich simple syndication or RSS feeds and XML technologies. RSS is an XML-based document format for syndicating news and other timely news-like information (NOAA, 2003). The reason for choosing weather feeds is that they provide a dynamic, seamless interface for obtaining live weather data without page reloads. Also, the weather feeds from most sources, including the ones from NOAA, are free of cost.

The data gathered through the various data collection procedures is analyzed and modeled in order to design the core components for WebISDSS, namely, the intelligence component (expert system) and the analytical tools (spatial and non-spatial tools). A major emphasis of this chapter is the use of an intelligent software component for decision support and integrating it with a Web-based GIS. The expert system component of WebISDSS provides decision support using the knowledge gathered from snow removal experts and real-time weather data. The functionality provided by the expert system includes providing advised decision-making for generating shortest paths and prioritized routes, allocating resources optimally for snow plowing, and generating suggestions based on real-time weather data.

The analytical tools available in WebISDSS provide functionality such as basic navigation, routing, resource management, and so forth. These tools utilize spatial and non-spatial data. The intelligent component and the analytical tools are integrated into a single interface that could be accessed through the World Wide Web. Therefore, a Web site is designed for publishing the road (street) map of Black Hawk County, IA. The Web site, in effect, will serve both as a user interface and a way to publish the resultant maps and show the results. Various routes are color coded for effectively presenting the route information visually for better understanding.

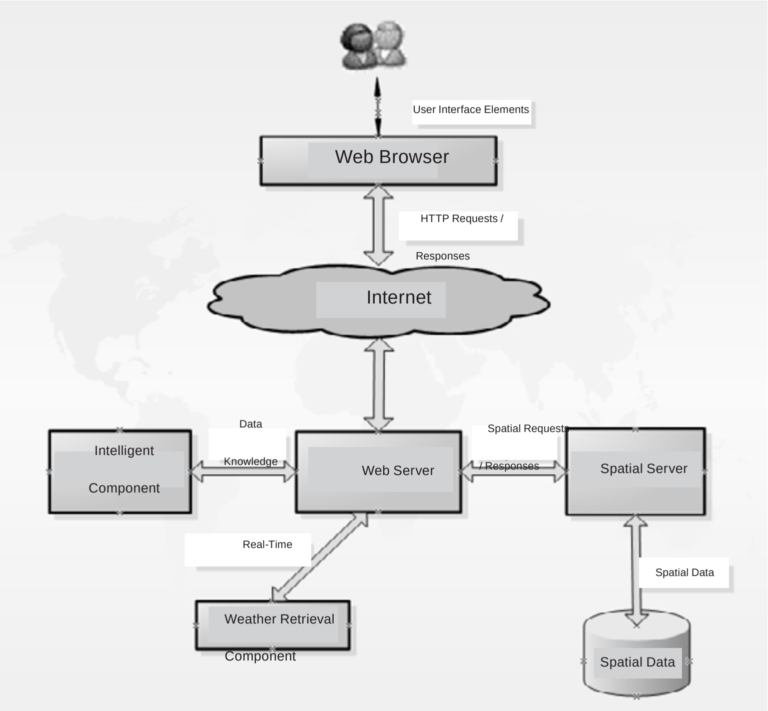
Architecture and Implementation

WebISDSS is designed using Web-based client/server architecture and rule-based artificial intelligence techniques. The implementation combines GIS and Web-based programming components from two leading technologies, Environmental Systems Research Institute (ESRI) and Microsoft. For developing the current prototype, ESRI ArcIMS ActiveX Connector is used in combination with Microsoft Internet information server and active server pages technology. The overall architecture of WebISDSS is shown in Figure 2. It contains the following two main components: (a) Web-based client interface, and (b) the server. These two components are briefly described as follows.

The Web-Based Client Interface

The primary functions of the Web-based client are providing the user interface and facilitating communication between the user and the server components. WebISDSS offers user interface by the means of a Web browser. The client corresponds with the server through requests; the server processes clients' requests and sends back a response.

Figure 2. The overall architecture of WebISDSS (Source: Ilavajhala, 2005)



The Server

The server is the "backbone" of the entire system and is composed of a set of components that work in tandem to process the user requests and provide a response. The server has the following components: (a) Web server, (b) spatial server, (c) non-spatial databases, (d) intelligent component, and (e) real-time weather retrieval component. A brief description of these components is given as follows.

The primary component on the server-side is the Web Server. It is the "central location" from where the user requests are received and processed or delegated further to other components like the spatial server or analytical tools, and so forth. The Web server for WebISDSS is the Microsoft Internet information server (IIS). The server is hosted on a Microsoft Windows XP Professional machine. All server side programming to create the analytical tools is accomplished using Microsoft active server pages (ASP) technology. The primary reason for choosing Microsoft technologies is their tight integration and ease-of-use.

The Spatial server is responsible for processing client requests that involve rendering and presenting maps and map-related information to the user. The spatial server is implemented using ESRI ArcIMS, the most popular Internet mapping software. The communication between the map display (client) and the spatial server components is performed via a standardized and proprietary XML format called ArcXML. WebISDSS utilizes ArcIMS ActiveX Object Connector v. 4.1. The ActiveX connector acts as an intermediary between the Web server and the spatial server by converting the user requests over HTTP into ArcXML statements, the language that the spatial server understands.

For providing routing solutions, the ArcIMS RouteServer extension is used. ArcIMS RouteServer comes as an additional component with ArcIMS and provides routing by using commercial data from TeleAtlas, Inc. This data is available in an optimized format called Spatial Data Engine (SDE) format. Advantages of using RouteServer are quick and efficient routing, complete integration with ArcIMS for use over the Web, and provision for obtaining fully-customized routes (e.g., percentage of interstates of travel, addition of multiple stops, etc.). All the routes are color-coded, according to a pre-determined priority, to take advantage of the visualization that GIS-based systems provide.

ESRI software was chosen over other vendors' products because we found ESRI products to be stable, scalable, and reliable. A detailed comparison of various Internet mapping software products from different vendors is beyond the scope of this chapter. Also, ESRI ArcIMS provides a programming model (object model) that is compatible with our server-side scripting language (ASP) and Web server (IIS), respectively.

The intelligent component developed for WebISDSS is a rule-based expert system. The knowledge gathered from the snow removal experts was carefully sifted and categorized into three knowledge categories, routing, resource allocation, and weather data. Categorizing the knowledge provided modularity and structure for storing the knowledge. The knowledge gathered was entirely conditions-based, in the form of a set of "actions" resulting from a set of "conditions." This sort of knowledge can be best represented as "if-then" structures. The intelligent component thus incorporates the expert knowledge and an inference engine. The expert knowledge is stored in a repository called the "knowledge base" and fed into the inference engine that provides a set of results or suggestions.

Rule Machine Corporation's Visual Rule Studio offers an easy and efficient way to code knowledge as "business rules", providing for encoding expert knowledge in the form of "if-then" rules. Each rule has a left-hand side (LHS) or conditions, and right-hand side (RHS) or results. The RHS is evaluated only when the LHS is true. These rules can be "fired" depending upon various data that is supplied and can help make a decision, rivaling a human expert. The knowledge-base is coded using Procedural Rule Language (PRL), a proprietary language of Rules Machines Corporation.

The asset databases contain information about various transportation assets that are utilized in snow removal activities such as characteristics of snowplows, capacity, mileage for equipment maintenance, odometer reading prior to assignment of the machine, details of the materials available at the central storage for snow removal, available quantity, unit cost of the material, reorder point, assignment of the operator to preferred machines, and so forth. All the asset databases are implemented in DBASE IV database file (DBF) format and are managed through the Web-based client.

As mentioned previously, the weather data for WebISDSS is obtained using the RSS and XML feeds technology. The weather data is embedded into the system by reading the free RSS and XML Weather feeds provided by www.weatherroom.com and NOAA's National Weather Service (http://www.nws.noaa.gov). These XML feeds essentially provide an XML document that encodes various weather parameters including the air temperature, wind speeds, wind direction, wind-chill, and visibility. Live as well as the forecast weather data can be obtained and presented to the user in this fashion by reading a particular weather feed from the Internet , and loading the information contained in the weather feed document. The current weather conditions help generate suggestions for material assignment and help determine the allocation of resources. The forecast data is used to generate alerts. The weather information can also be used for generating scenario-based solutions. Further, the live weather data, in combination with the encoded rules, help make intelligent decisions for snow removal and resource management and allocation.

RESULTS

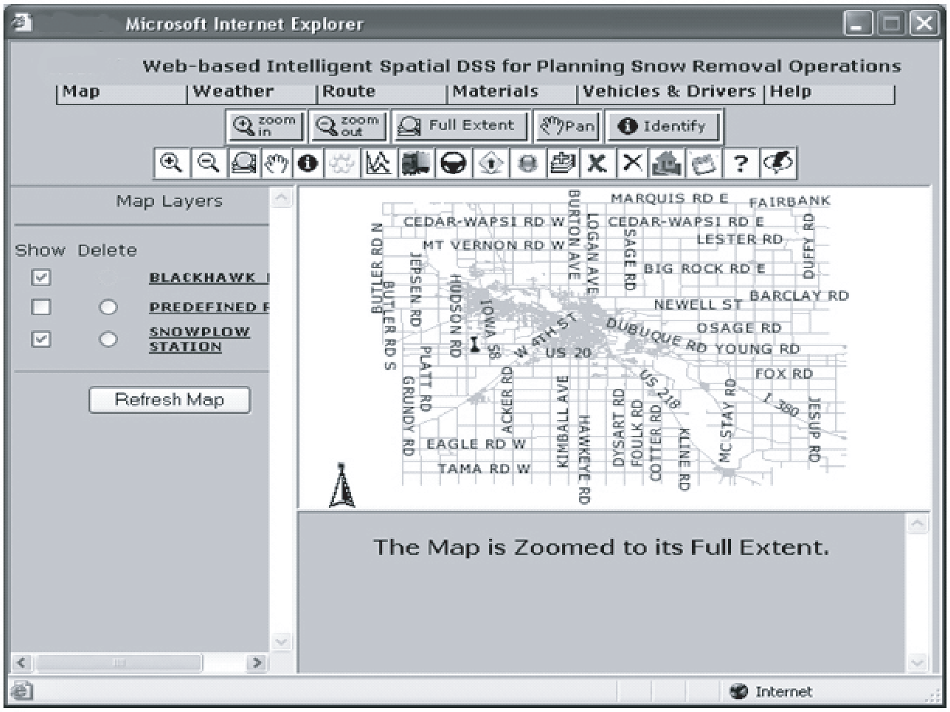
Application Example: Planning Snow Removal Using WebISDSS

One of the main objectives of WebISDSS is to provide easy-to-use Web-based interface and intelligent decision support for planning snow removal operations. To achieve this goal, the system uses the knowledge gathered from snow removal experts as well as real-time weather data. It provides an uncluttered interface, divided neatly into various "areas." For example, the menu and the tool bar appear on top, and the map and map layers area are beneath the menu, and a "message area" displays detailed messages to the users. The interface is mainly menu-driven, making it very easy to use. All the menu options are given appropriate, non-technical names so that a naïve computer user can also utilize the system. Figure 3 shows the main interface of WebISDSS and its organization into various "areas."

The system generates verbose and detailed alerts, warnings, tips, and other messages that help a non-technical user better understand the system. Most of the commonly-used menu options are provided as tools on a separate tool bar and can be used by clicking on the appropriate icon. When the user clicks on a particular tool, a message is displayed in the message area of the window. A detailed help system is available, which avoids technical jargon and provides the user with an easy guide to use the system. The salient features and functionalities of the menu interface of WebISDSS are briefly described as follows.

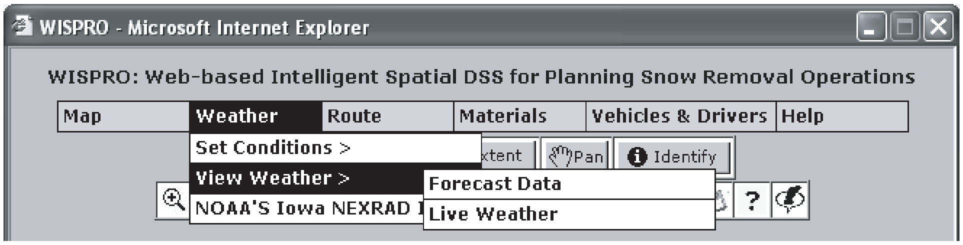
- **Weather menu:**The Weather menu lets the user set and view real-time weather information. The weather menu is shown in Figure 4. The user can choose to view live or forecast weather information and also store it. Weather conditions can be set either manually by entering a set of parameters or

Figure 3. The main interface of WebISDSS (Source: Ilavajhala, 2005)



The Map is Zoomed to its Full Extent.

Figure 4. The "Weather" menu interface of WebISDSS



by automatically obtaining them from the Web. The weather menu also provides an option to view live weather through NOAA NEXRAD radar image for the state of Iowa (Figure 5) or Forecast data. Figure 6 shows a screenshot of forecast weather retrieved by WebISDSS.

- **Route menu:** Route menu provides options for creating, deleting, and loading route information. The user can choose to create a route by clicking on the "start route" option, and then clicking on the road segments to snowplow. Clicking "end route" menu item will save the route, and generate driving directions from the station to the route by creating the shortest or quickest route, as chosen by the user. The user can also delete a route or a route segment. Deletion of route can either be temporary (deletion from the map) or permanent (deletion from the disk).
- **Vehicles and Drivers menu:** The Vehicles and Drivers menu provides options to assign drivers and vehicles. Also available from this menu is an option to manage drivers and vehicles by adding, deleting, or editing driver or vehicle information.
- **Materials menu:** Materials menu gives options related to materials management and control. Options include inventory analysis,

Forecast for Thursday

Chance of light rain showers in the morning. Then light rain likely in the afternoon. High in the mid 40s. Southeast wind 5 to 15 mph. Chance of showers 60 percent.

Forecast for Thursday Night

Light rain or light snow likely. Snow accumulation of 1 to 2 inches. Low in the lower 30s. Northeast wind 10 to 15 mph. Chance of precipitation 70 percent.

Forecast for Friday

Cloudy. Chance of light snow in the morning. Then chance of light rain and light snow in the afternoon. High around 40. Northeast wind 10 to 15 mph. Chance of precipitation 50 percent.

material assignment, addition/deletion/editing snowplowing materials such as salt, sand, and so forth.

- **Help menu:** The Help menu lets the user obtain information about how to use the system. The "Using WebISDSS" option shows the user the "Help central" screen with various options for getting help. Also, the help menu shows the product and copyright information.

SYSTEM WALKTHROUGH

The expert system provides suggestions based on user input. These suggestions include initiation of snow plowing operations, material to utilize for snowplowing, amount of material that must be used, number of lines to snowplow, and material assignment. To begin with, the user sets the weather conditions either by entering weather parameters like current conditions, temperature, dew point, wind speed, and so forth, or by using the system to read weather conditions from the Internet. The real-time weather retrieval component reads the encoded current and forecast weather data through the Web and provides a readable output to the user. Further, these suggestions are used for assisting and planning resource allocation, initiating snowplowing operations, and so forth. Thus, the real-time weather retrieval component works with the Web server and the intelligent component to provide suggested actions depending upon real-time weather information retrieved from the Web. These weather conditions are stored in a database file (DBF).

The expert system's inference engine examines the weather conditions stored in the database. The inference engine then produces a set of suggestions and stores these suggestions on the server's hard drive. These suggestions advise the user whether to initiate a snowplowing operation, which materials to use for snowplowing, and how much of each material should be used. Depending on the precipitation, the expert system also produces suggestions to either initiate anti-icing or de-icing operations. Other parameters that are used in producing suggestions are visibility and dew point. The system advises the exercise of caution if the visibility is less than a mile. The dew points are used to forecast precipitation and to caution the users to wet the bride decks to prevent icing.

Once the weather conditions are accessed and stored in the database, routes can be created. The WebISDSS calculates route parameters needed for snowplowing such as the number of lane miles, total route length, and so forth. These parameters are stored in a database along with other route parameters like route identification number, and so forth. These parameters are further used for making suggestions for material allocation.

After the routes are created, material can be assigned to these routes. Based on the weather conditions stored in the database, and various route parameters such as the route length, and so forth, the expert system provides suggestions on how much material should be used for snowplowing. Figure 7 shows part of the "rules" that the expert system uses to provide suggestions on material allocation and Figure 8 shows the material allocation interface of WebISDSS. Also, the expert system calculates the amount of material needed per route depending upon the precipitation levels. These calculations are based on a set of guidelines that the Iowa DOT uses to calculate material allocation.

WebISDSS also provides a quick way to view all current assignments in one screen. The menu option "Map > Show Current Assignments" provides a screen with current vehicle assignments, driver assignments, weather conditions, and material estimations. Figure 9 shows one such screenshot.

SUMMARY AND FUTURE WORK

We have presented a Web-based intelligent spatial decision support system (WebISDSS) in this chapter that overcomes the disadvantages of existing systems by providing intelligent decision support for effectively planning snow removal operations. The system has been designed using ArcIMS ActiveX Connector with ArcIMS RouteServer extension and Web technologies such as ASP, XML, and RSS. The system also integrates an intelligent software component with geo-spatial and analytical techniques for providing real-time decision support.

There is ample scope for further refining the WebISDSS system described in this chapter. Our future work is aimed at making WebISDSS more efficient and effective. For extending WebISDSS, ArcGIS Server 9.x can be used in conjunction with ArcObjects to provide advanced functionality like adding new features (e.g., new roads) and advanced geo-analytical tools. Additional solutions based on "intelligent technologies" such as intelligent software agents can be explored to extend the fundamental rule-based system to a full-scale "intelligent agent" based system. Also, the use of commercial weather data service that provides frequent updates and segment-wise conditions can improve the efficiency of the current prototype by generating very accurate snowplow routes and

by cutting costs further. The weather conditions can also be shown on the map to provide a visual display of various road weather conditions around the county. Furthermore, advanced algorithms can be implemented for sophisticated inventory analysis for better management of materials. Similarly, improved algorithms can be employed for driver and vehicle assignment purposes. Currently, the prototype is optimized to work with the Microsoft Internet Explorer browser. It can be expanded to work with other browsers such as Netscape, Mozilla, and Firefox by carefully considering the cross-browser functionality issues.

There is plenty of research and development yet to be done in the field of Web-based intelligent decision support systems. The prospect of employing intelligent autonomous agents for decision support is very promising. Advances in the fields of artificial intelligence and human computer interaction will have a big impact on how spatial decision support systems behave. Another emerging trend is the availability of decision support systems though a Web-based interface. This ensures cross-platform compatibility and ease-of-use. Further, these interfaces can be extended to work from portable devices like palmtops, cell phones, and so forth. In the coming years, the Web will change dramatically, reaching a wide population via a variety of handheld, smart devices. The future will also usher us into new ways of interaction with computing devices in a radically different way from today's interfaces.

The future for spatial decision support systems is promising considering the explosion of spatial data that we are experiencing. These spatial decision support systems provide many types of scenario-based decision support for governmental and non-governmental organizations (e.g., utility installation planning, right-of-way management, demographic research, etc.) and will be capable of providing advanced spatial analysis to further assist in decision-making. For example, the future spatial decision support systems will include active raster and vector data processing to provide instant results. This is a huge improvement from the various online mapping systems that use only raster data for providing driving directions, locations, and aerial photography.

ACKNOWLEDGMENTS

The authors would like to thank Midwest Transportation Consortium (MTC), Iowa DOT, and the University of Northern Iowa for sponsoring this research. We further extend our thanks to Mr. Russ Frisch, Highway Maintenance Supervisor 3 of Iowa DOT, Mr. Steve Decker of Waterloo Street Department, and Mr. Darrell Fanning and Mr. Steve Ravn of Cedar Falls Streets Department for their time and input.

Chapter 2.15

Designing Clinical Decision Support Systems in Health Care:

A Systemic View

Wullianallur Raghupathi
Fordham University, USA

ABSTRACT

Clinical decision support systems have historically focused on formal clinical reasoning. Most of the systems are rule-based and very few have become fully functional prototypes or commercially viable systems that can be deployed in real situations. The attempts to build large-scale systems without examining the intrinsic systemic nature of the clinical process have resulted in limited operational success and acceptance. The clinical function, another area of medical activity, has emerged rapidly offering potential for clinical decision support systems. This article discusses the systemic differences between clinical reasoning and clinical function and suggests that different design methodologies be used in the two domains. Clinical reasoning requires a holistic approach, such as an intelligent multiagent, incorporating the properties of softness, openness, complexity, flexibility, and generality of clinical decision support systems, while traditional rule-based approaches are sufficient for clinical function applications.

INTRODUCTION

Clinical decision support applications development in the field of medicine historically has been constrained by two factors. First, the design concept was limited to formal clinical reasoning based on expert physicians' rules of thumb. Second, design appears to have been technology driven, for nearly all of the current systems are rule-based, wherein rules in clinical reasoning (e.g., in diagnosis and treatment) are represented as rules in the clinical system. None of the clinical reasoning applications have yet to become fully functional prototypes or commercially viable (Bates, Kuperman, Wang, Gandhi, Kittler, Volk, & et al., 2003; Kaushal, Shojania, & Bates, 2003; Sim, Gorman, Greens, Haynes, Kaplan, Lehmann, & et al., 2001). The limited operational success of these large-scale systems (Kaplan, 2001) is due in large part to the failure to reflect more fully in the design the diverse systemic features of the clinical process. Newer sociotechnical approaches to design, for example, a multiagent approach, and more flexible representational methods are needed to produce viable clinical decision support systems (CDSSs).

A second area of medical activity, which we term here the clinical function, has emerged rapidly as health care participants (e.g., physicians, nurses, HMOs, hospitals, diagnostic labs) increasingly perform their clinical applications work using advanced information technology (IT), such as artificial intelligence-based (AI) systems (Wyatt & Spiegelhalter, 1991) and in-house medical staff. These new AI-based clinical function systems present design issues that differ from those of clinical reasoning systems. For example, these systems typically concern much smaller domains (e.g., alerting to drug interaction, monitoring patient vital signs, reminding to medicate patient) involving structured applications in medicine (Bates et al., 2003; Delaney, Fitzmaurice, Riaz, & Hobbs, 1999; Kaplan, 2001; Kawamoto, Houlihan, Balas, & Lobach, 2005; Ramnarayan & Britto, 2002).

The application of AI (e.g., expert systems) and other computational intelligence techniques (e.g., neural networks) to the field of medicine (Catley, Petriu, & Frize, 2004) has resulted in the attempts to develop CDSSs. Wyatt and Spiegelhalter (1991) have defined medical aids as “active knowledge systems which use two or more items of patient data to generate case-specific advice.” CDSSs have the potential to analyze, synthesize and integrate patient-related information to perform complex evaluations and provide that information to clinicians in real time. Over time, as they evolve in sophistication, they offer the prospect of improving the effectiveness and efficiency of patient care by preventing medical errors and enhancing quality (Johnston, Langton, Haynes, & Mathieu, 1994).

Further, the systems can improve preventive care services and help in adhering to recommended care standards (Kawamoto et al., 2005). The overall goal is to improve clinical decision making by focusing on individual patient characteristics and mapping them to a computerized knowledge base of characteristics of similar patients (Garg et al., 2005). They provide a range of levels of decision support, from simple alerts to complex diagnosis. For example, a CDSS can aid a physician in processing complex information to improve prescription writing practices in electronically delivered recommendations (Durieux, Nizard, Ravaud, Mounier, & Lepage, 2000). These types of systems are differentiated from operational decision support systems (DSSs), which are defined as enterprise repositories of clinical and financial information for utilization review, cost evaluation, and performance evaluation (Classen, 1998). In contrast, CDSSs focus on medical decisions (both on making decisions and assisting in making decisions). The key is to use patient specific information that transforms protocols into customized, real-time clinical advice (Kawamoto et al., 2005; Teich, Osheroff, Pifer, Sittig, & Jenders, 2005).

This paper discusses the clinical decision support applications design issues arising from the systemic differences (Churchman, 1971; Van Gigch, 1978, 1991) between clinical reasoning and clinical function systems, and it proposes that different design methodologies be used in the two domains. The paper is organized as follows. First, design issues in clinical reasoning and clinical function are discussed. Second, knowledge representation issues are highlighted. Third, the systemic properties of softness, openness, complexity, generality and purpose are discussed in the context of the two domains. Fourth, domain issues are identified. Next, operational examples of clinical reasoning and clinical function applications are described. Finally, conclusions are offered.

DESIGN ISSUES IN CLINICAL REASONING AND CLINICAL FUNCTION

Clinical reasoning is concerned with the decision processes of medical experts, such as physicians and surgeons, the interpretation of clinical information, and medical diagnostic rules. The outcome of clinical reasoning is some kind of clinical decision (diagnosis). On the other hand, the clinical function has emerged as a differentiated organizational entity. It is defined here as the set of activities that involves the routine and procedural application of medical rules and protocols to the operational needs of the medical care delivery organization. Differences between clinical reasoning and the clinical function are distinguished in terms of several system concepts. First, we discuss clinical knowledge representation and system design.

Clinical Knowledge Representation and System Design

Despite the domain complexity, most expert systems in clinical reasoning have involved the one-to-one mapping of rules of medicine onto rules in the system. This type of representational approach does not provide the flexible basis necessary to develop a sociotechnical clinical reasoning system that affords the openness, softness, complexity, and generality to deal with the dynamics of sociomedical aspects of clinical reasoning. Purely rule-based representation and problem solving are suitable for many clinical function applications that often involve narrow, structured well-designed domains. Knowledge representation for clinical reasoning, however, must include objects, frames, semantic nets, rules, and combinations of these to adequately represent different levels of knowledge, in combination with abstract medical concepts at higher levels and clinical rules at lower primitive levels. Combined with a multiagent systems model for complex problem solving, these representational modes enable interaction between multiple sources and levels of medical knowledge and different types of clinical reasoning, which comprise the problem-solving methodologies. The use of multiagent models will be a major departure from the current limited, rule-based approaches for implementation of AI clinical decision support systems.

Softness and Openness

Natural systems have been characterized as being somewhat hard, mechanistic, and rigid (Van Gigch, 1978). While clinical reasoning does involve some rigidity in terms of medical rules/procedures, the application of clinical reasoning reflects the relatively soft nature of the sociomedical aspects of medicine (e.g., consideration of gender, ethnicity, culture, religion, individual patient customized protocol). Softness considers subjectivity and value as important considerations in the design of clinical reasoning applications. Applications in the clinical function, on the other hand, usually involve specific routine procedures or repetitive tasks. Design models for the clinical function, therefore, should be more rigid and mechanistic in view of the procedural nature of this applied medical work.

Clinical reasoning involves open system properties (Hewitt, 1985), for, as an integral part of society and health care organizations, the medical system continually processes inputs and feedback from the environment, including changes in medical practice, new/modified protocols, new drugs, effect of clinical trials, societal values, replacement of medical experts, organizational perspectives (e.g., hospital mission), and others. The medical systems, as a model at the cusp of hard (pure science) and soft (social science) sciences, exhibits its negentropic nature as clinical reasoning adapts to changing goals (e.g., prevention vs. treatment), new research findings and advances in medicine, different sources of knowledge, and learning from experience. The clinical reasoning system must be capable of arriving at similar decisions equifinally by accepting inputs from multiple experts and applying alternate reasoning paths and different approaches to problem solving (Hewitt, 1985).

While the medical literature emphasizes the open-textured nature of medicine, openness is a feature of the entire medical system. Openness in the design of clinical reasoning systems provides for the flexibility to include several interacting domains in clinical reasoning, accepting inputs from multiple external sources of information and expertise, and accommodating the various reasoning mechanisms that are part of clinical decision processes.

In contrast, applications in the clinical function are essentially closed-system models requiring minimum feedback. Dynamic interaction and flexibility are limited because of the structured nature of clinical function tasks.

Complexity in DSSs

Complexity in CDSSs results from interaction internally between subsystems and externally with various systems in the environment, such as the economic (insurance) and primary care systems, as well as government entities, such as Medicare and Medicaid. Within an organizational health care delivery system (e.g., a hospital), there is also interaction and interdependence with the legislative bodies, the judiciary, the National Institutes of Health, the American Medical Association, medical experts, ethicists, managers, and the general public. The design of expert clinical reasoning systems must include provisions for the various modes of inquiry (Churchman, 1971) and complex interactions among various sources of clinical knowledge, such as medical facts, protocols, judgmental experience of medical experts and health care managers (e.g., nurse managers, discharge planners), customs, and medical precedents. Since societal values also impinge on outcomes, holism in design is essential to deal with the sociomedical complexity.

In the design of CDSSs for clinical reasoning, the trade off has historically been in formulating a computer model that is well structured and rigid in specification as opposed to one that provides for flexibility and adaptability. Strictly reductionaistic, rationalistic approaches to the design of clinical decision-making applications effectively eliminate these essential features. Mutiagent models hold considerable promise for assimilating the variety of inputs for complex clinical reasoning. The clinical function has emerged in health organizations because of increased organizational complexity and environmental uncertainty (e.g., hospitals). The growth of the clinical function was part of a general pattern of organizational elaboration and differentiation of specialized functions. While clinical reasoning is complex by nature, the clinical function is relatively simplistic, and interaction with the environment is minimal. Because of the procedural nature of most clinical function activities, rule-based (procedural) system approaches to application design are adequate and most often used.

Generality and Purpose in CDSSs

Research in AI frequently has emphasized the need for generality in the problem-solving methods. This is an important issue, for clinical reasoning applications should be capable of handling a wide range of medical problems.

Current design efforts for AI-based systems in clinical reasoning, however, tend to be limited to a single domain of medicine or reasoning. Generality in clinical reasoning suggests that the system cannot be limited to a single domain or a particular type of reasoning mechanism. For purposes of design, more general problem-solving models for the clinical reasoning domain have to be investigated. Again the multiagent model (e.g., the blackboard approach) possesses the characteristic of generality, and being conceptual, also can accommodate features that are unique to particular domains. In contrast, clinical function tasks are situation specific and do not require the generality needed by clinical reasoning systems.

Clinical reasoning applications are typically designed to arrive at a clinical decision. Examples of such systems include diagnosis of the cause of patient's chest pain (Hunt, Haynes, Hanna, & Smith, 1998); treatment of infertility (Garg et al., 2005); implementation of clinical guidelines on venous thromboembolism prophylaxis in an orthopedic surgery department (Durieux et al., 2000); analysis of outcome of patient cardiovascular risk (Montgomery, Hahey, Peters, MacIntosh, & Sharp, 2000); interpretation of blood work results (Classen, 1998); and others. Clinical reasoning culminates in decisions (e.g., outcomes—diagnosis of a disease, treatment selection) as the result of the interaction among various sources of knowledge and types of reasoning. The goals for clinical reasoning applications are relatively vague and ill defined. Clearly, a holistic and integrative view of design is needed, rather than the current focus on segmentized, disparate approaches that compartmentalize types of clinical reasoning, including analysis, critiquing, diagnosis, pattern recognition, and treatment recommendation, to name a few (Ramnarayan & Britto, 2002).

Clinical function applications are designed to execute programmed decisions involving narrowly defined medical tasks to achieve specific goals in the health care delivery organization. Some generic examples of such clinical function applications include detection of drug overdose (Hunt et al., 1998); selection of appropriate drug dosage, providing immunization reminders (Garg et al., 2005); alerting to drug interaction and monitoring patient vital signs (Classen, 1998); and others. Typically, the clinical function activities include alerting, recognition, alerting, and monitoring (Kawamoto et al., 2005; Ramnarayan & Britto, 2002).

Domain Issues

The variety of issues faced by clinical decision processes poses significant problems for domain definition in design. Historically, the boundary identification problem in design has been addressed by limiting the system domain to a particular specialty of medicine (e.g., disease), type of reasoning (e.g., rule-based, case-based), or problem-solving approach. Such design limitations have led to the problems with clinical reasoning systems discussed previously. The design of clinical function applications, while not trivial, is less challenging, for the boundaries of individual systems are limited to specific tasks. It is becoming more common for these tasks to be performed by nurse practitioners, nurses, and clinical technicians, who have gained expertise in routine and repetitious tasks in narrow medical domains and who are being increasingly supported by clinical function systems. Examples of clinical function applications include nurse practitioner functions. By and large these are the most readily developed for rule-based applications. Nurse practitioners carry out routine repetitive tasks and develop expertise in such domains as alerting, monitoring, and reminding and, therefore, provide input for clinical decision processes at higher levels. A number of generic applications are currently available to support nurse practitioner tasks. Most of the applications are fairly simple and implemented as rule-based systems. However, they lack the sophistication necessary to support clinical reasoning tasks.

Examples of clinical reasoning tasks include diagnosis, interpretation, and planning. All these high-level clinical decisions are characterized by complexity, ill-structuredness, and uncertainty. Typically, such decisions are collectively made by a group of medical experts. Table 1 summarizes the example of clinical reasoning and clinical function tasks in health organizations. As seen in Table 1, most programmed tasks are performed at lower and middle levels. Rule-based approaches are suitable for (expert system) applications development for these tasks. The higher-level tasks are typically nonprogrammed, ill-structured, and complex. Multiagent models are more appropriate for applications supporting these activities.

Table 1. CDSSs

Health Organization Level	Problem Type	Tasks
Top		
Physicians Surgeons Medical directors Residents Specialists	**Ill-structured, complex Nonprogrammed (multiagent model)**	**Diagnosis Causal analysis Clinical reasoning Recommendation Interpretation Prediction**
Middle		
Physician assistants Nurse practitioners Nurses	**Semistructured, somewhat Comples, nonprogrammed (single to multiagent)**	**Alerting Monitoring Clinical reasoning Clinical function Reminding**
Lower		
Nurses Clinical assistants Discharge planners	**Structured, routine, Programmed (single angent)**	**Alerting Reminder**

Other Issues

The identification of users and experts in the clinical function is straightforward, while deciding whether the physician is the only user or the expert in clinical reasoning is not always so clear. Clinical reasoning involves deeper epistemological and ontological considerations; the development time for a clinical reasoning application is lengthy; the cost is very high; the design and implementation effort is extensive; risks are considerable (e.g., misdiagnosis); and the payoffs are uncertain. In contrast, clinical function applications involve shorter development time, low costs, and considerably less effort. A clinical function application can be built using available technology, such as shells (rule-based expert system). Unlike clinical reasoning applications, these systems do not require extensive medical knowledge on the part of the knowledge engineer. Knowledge acquisition is easier and application validation is more readily achieved. User acceptance of clinical function applications is higher, especially for systems that act as “intelligent clinical assistants” for medical task performance (e.g., drug dosage tracking, monitoring patient vital signs), leading to increased potential for use and commercial viability. Table 2 summarizes the systemic differences between clinical function and clinical reasoning.

Operational Examples of Clinical Reasoning and Clinical Function Systems

With regard to clinical reasoning systems, St. Mary’s Medical Center in West Palm Beach, FL, maintains statistics about infants (e.g., vital signs) in an electronic documentation system. This data is analyzed and mined, for example, to identify potential risks and side effects from commonly used medications (Landro, 2006). At Partners Health in Boston, expert systems provide information on medication dosing for specific types of patients, taking into account several factors. Also, iLog, a decision support software, enables the sharing of clinical best practices to gather and analyze

Table 2. Clinical reasoning versus clinical function

Concept	Clinical reasoning	Clinical function
Nature of model	Open Soft Flexible Dynamic Holistic	Closed Hard Inflexible Axiomatic Sequential
Solution	Satisficing	Optimal
Reasoning	Opportunistic Mulitagent	Rule-based
Knoweledge Representation	Accommodates rules Frames, objects, and others Modular	If-then rules Chain of rules
Control	Mostly explicit	Mostly implicit
Domain Characteristics	Ill-structured Multiple sources of knowledge Multiple reasoning mechanisms Nonprogrammed	Structured Single source Single line of reasoning (typically rule-based) Programmed
Decision tasks	Planning Diagnosis Interpretation	Alerting Monitoring Reminder
Knowledge Acquisition	Modular, Multiple	Data intensive Integrated

new or yet untapped data (Mcgee, 2006). IBM and Sloan-Kettering Cancer Center are working with systems to extract lab-result details from text intensive pathology reports to discover correlations by analyzing patterns, for example, of how specific kinds of tumors respond to various therapies (Mcgee, 2006). At West Mead Hospital, Sydney, Australia, Brain Resource in collaboration with IBM is building DSS software that can help analyze data from millions of sources of brain data (Mcgee, 2006). Mayo Clinic and IBM are applying pattern recognition and data-mining techniques to the electronic records of millions of patients to customize medical treatments to individual patients, such as selecting the best chemotherapy for a cancer patient with a particular genetic marker (Mcgee, 2004). In surgery, New York-Presbyterian Hospital is testing Penelope, a robot arm, that uses voice and visual recognition techniques to provide nursing assistance in the operating room (Santora, 2005). A system to analyze lab, pharmacy, patient, and other data, using inference engine software (infection control system), is being used at New York-Presbyterian Hospital. The purpose of this is to study data patterns to alert infectious disease nurses when a situation within the hospital could lead to an outbreak (Havenstein, 2005; Mcgee, 2005). Additionally, AI software is used to create treatment plans for patients in the cardiac intensive care units (using case-based approaches). Furthermore, the Cleveland Clinic and IBM are developing a translational medical platform and infrastructure to apply data-mining techniques to support clinical decision making. In another example, Kaiser Permanente's comprehensive medical database was used (via analysis and pattern recognition) to demonstrate that the arthritis drug Vioxx could cause heart problems (Eweek, 2006). In terms of clinical function applications, Aurora St. Luke's Medical Center, Milwaukee, uses the eICU system, which monitors patients electronically, helping a team of doctors and nurses to keep constant watch on more than 10 ICUs in four different hospitals across eastern Wisconsin (Fischman, 2005). A prototype wristwatch that monitors recovering cardiac patients' vital signs and sends them to their doctors via the cell phone network is being scheduled to be launched in 2006. The system called MDKeeper is being developed by Tadiran Spectralink of Israel (New Scientist, 2005). In Canada, the Global Public Health Intelligence Network (GPHIN) functions as a secure Internet-based early warning system assessing and cross referencing patients to track the length of time spent in a hospital or in quarantine. This type of information assists in providing a big-picture view of the operations of pandemics over large regions (Songini, 2006). Kranhold (2005) reports about a physician-alert system that alerts physicians if they are prescribing a medication that may react with another medication that the patient is taking—the system tracks patients' allergies and warns physicians if a medication might interact badly with the allergy. At University of Pittsburgh Medical Center (UPMC) in western Pennsylvania, a clinical information system delivers treatment information to doctors and nurses at the bedside, providing fast access to lab tests and X-rays, so they do not have to be repeated. The data also can be analyzed for possible outbreaks (Landro, 2005a). Also, another computer-order entry system at the UPMC Children's Hospital automatically calculates appropriate drug doses, based on a child's age and weight, and flags possible allergies or drug interactions (Landro, 2005b). Another application allows doctors to type in a patient's symptoms, and, in response, the system outputs a list of possible causes is reported in Leonhardt (2006). At St. Joseph's Hospital Health Center, Syracuse, NY, a picture archiving and communications system enables physicians and lab technicians to search and access patient information, data, and X-Rays via a Web portal (Mearian, 2005). Children's Memorial Hospital of Chicago is using a new system that confirms that the right medication is being administered at the right time to the right patient by scanning bar codes on the medication bags and sending it to a central computer that performs the matching (Pettis, 2006). The New York City is using a system for early warning of disease patterns called the Syndronic Surveillance System. It uses statistical analysis to calculate risk probabilities for possible disease outbreaks (Perez-Pena, 2003).

CONCLUSIONS

Distinguishing the systemic differences between clinical reasoning and the clinical function can enhance the design of CDSSs by assisting in the selection of the appropriate problem-solving architecture. The automation of clinical reasoning required a holistic approach that incorporates the properties of softness, openness, complexity, flexibility, and generality of medical systems.

The trend toward distributed systems, multiagent models, parallel open-system architectures, and general models of intelligence for complex problem solving indicates that these alternatives must be explored in the design of automated clinical reasoning systems. Decision support applications development in medicine is in a primitive stage compared to other domains, but the use of system constructs in design can accelerate its maturing process.

Chapter 2.16

A Framework for a Scenario Driven Decision Support Systems Generator

M. Daud Ahmed

David Sundaram
University of Auckland, New Zealand

ABSTRACT

Traditional Decision Support Systems (DSS) provide strong data management, modelling and visualisation capabilities for the decision maker but they do not explicitly support scenario management appropriately. Systems that purport to support scenario planning are complex and difficult to use and do not fully support all phases of scenario management. We introduce scenario as a core component of decision making systems and present a life cycle approach for scenario management, which helps the decision maker with idea generation, scenario planning, development, organisation, analysis, execution, evaluation, and decision support. This research designs and develops a domain independent framework and architecture for Scenario-driven Decision Support Systems Generator that aligns the DSS with the scenario management process. We then propose a generalised evaluation process that allows homogeneous and heterogeneous scenario comparisons among multiple instances of similar and dissimilar scenarios respectively. The framework and architecture is implemented and validated through a concrete prototype.

INTRODUCTION

Herman Kahn, a military strategist at Rand Corporation, first applied the term scenario to planning in the 1950s (Schoemaker, 1993). Scenario analysis was initially an extension of traditional planning for forecasting or predicting future events. Currently, scenarios are constructed for discovering possibilities, leading to a projection of the most likely alternative. Scenario has been defined as a management tool for identifying a plausible future (Alter, 1980; Porter, 1985; Schwartz, 1991; Tucker, 1999) and a process for forward-looking analysis. Scenario has also been defined in many other ways, for example. a kind of story that is a focused description of a fundamentally different future (Schoemaker, 1993); that is plausibly based on analysis of the interaction of a number of environmental variables (Kloss, 1999); that improves organization learning by putting many bits of information in order (De Geus, 1997; Desmarais, 2000; Van der Heijden, 1996; Wack, 1985); that is analogous to a "what if" story (Tucker, 1999); that is more dynamic and interactive than the what-if analysis (McGillivray & McGillivray, 1995). It is a description of the current situation and a series of events that could lead the current situation to a possible or desirable future state (Schoute, Finke, Veeneklaas, & Wolfert, 1995). Scenarios are not forecasts (Schwartz, 1991), future plans (Epstein, 1998), trend analyses or analyses of the past. It is for strategy identification rather than strategy development (Schoemaker, 1993) and to anticipate and understand risk and to discover new options for action. Ritson (1997) agrees with Schoemaker (1995) and explains that scenario planning scenarios are situations planned against known facts and trends but deliberately structured to enable a range of options and to track the key triggers which would precede a given situation within the scenario.

Scenarios explore the joint impact of various uncertainties, which stand side by side as equals. Usually sensitivity analysis examines the effect of a change in one variable, keeping all other variables constant. Moving one variable at a time makes sense for small changes. However, if the change is much larger, other variables do not stay constant. Schoemaker (1995) argues that scenario, on the other hand, changes several variables at a time, without keeping others constant. Decision makers have been using the concepts of scenarios for a long time, but due to its complexity, its use is still limited to strategic decision making tasks. Scenario planning varies widely from one decision maker to another mainly because of lack of generally accepted principles for scenario management. Albert (1983) proposes three approaches for scenario planning, namely, expert scenario approach, morphological approach and cross-impact approach. Ringland (1998) identifies three-step scenario planning—namely brainstorming, building scenarios, and decisions and action planning. Schoemaker (1995) outlines a ten-step scenario analysis process. Huss and Honton (1987) describe three categories of scenario planning. The literature still lacks a suitable approach for planning, developing, analyzing, organizing and evaluating the scenario using model-driven decision support systems. Currently, available scenario management processes are cumbersome and not properly supported by the available tools and technologies. Therefore, we introduce a life cycle approach based scenario management guideline.

Generation of multiple scenarios and sensitivity analysis exacerbate the decision maker's problem. The available scenario planning tools are not suitable for assessing the quality of the scenarios and do not support the evaluation of scenarios properly through comparison processes. We introduce an evaluation process for comparison of instances of homogeneous and heterogeneous scenarios that will enable the user to identify the most suitable and plausible scenario for the organization. Considering the significance of scenarios in the decision-making process, this research includes scenario as a decision-support component of the DSS and defines Scenario-driven DSS as an interactive computer-based system, which integrates diverse data, models, and solvers to explore decision scenarios for supporting the decision makers in solving problems.

Traditional DSS have been for the most part data-driven, model-driven and/or knowledge-driven but have not given due importance to scenario planning and analysis. Some of the DSS have partial support for sensitivity analysis and goal-seek analysis but this does not fulfill the needs of the decision maker. In most cases, the available scenario analysis tools deal with a single scenario at a time and are not suitable for development of multiple scenarios simultaneously. A scenario impacts on related scenarios but currently available tools are not suitable for developing a scenario based on another scenario.

To address the problems and issues raised above we followed an iterative process of observation/evaluation, theory building, and systems development (Nunamaker, Chen, & Purdin, 1991), wherein we proposed and implemented a flexible framework and architecture for a scenario driven decision support systems generator (SDSSG). It includes scenario as a DSS component, extends the model-driven DSS, and incorporates knowledge and document-driven DSS (Power, 2001). A prototype was developed, tested and evaluated using the evaluation criteria for quality and appropriateness of scenarios (Schoemaker, 1995) and principles of DSSG frameworks and architectures (Collier, Carey, Sautter, & Marjaniemi, 1999; Geoffrion, 1987; Ramirez, Ching, & Louis, 1990). The details of these validation criteria are mentioned in the implementation section. The conceptual framework as well as the prototype was modified on the basis of the findings and the process was continued until a satisfactory result was achieved.

In the rest of this article, we first introduce a life cycle approach for management of scenarios including a detailed discussion of handling homogeneous and heterogeneous scenarios. We then propose a scenario-driven flexible decision support framework and follow this up with a discussion on how it realizes the scenario management process. We then present an n-tiered architecture that details the SDSSG framework. Finally we discuss the implementation platform and domain within which the proposed process, framework, and architecture were validated.

SCENARIOS: A DEFINITION AND AN EXAMPLE

Definition of a Scenario

The definitions given in the previous section do not give a complete picture of scenario modeling as they do not entail the exact scenario structure. Chen (1999) provided an implementation level definition of scenario—*a combination of the instance of data, model, solver, and visualization*. This definition is very narrow and specific for a generic scenario management process. To overcome this shortcoming, an implementation level scenario definition is provided that addresses the structure of the problem situation and its dynamic behavior. A scenario is a situation that is comprised of one or more problem instances. A change in one scenario might have chain effects on any related scenarios. The basic structure and behavior of the scenario is similar to the decision support system components model and solver respectively. Hence, we define scenario as a complex situation analogous to a model that is instantiated by data and tied to solver(s). A scenario can be presented dynamically using different visualizations. A scenario may contain other scenarios. Hence, a scenario structure is an object that establishes a complex relationship among various models, solvers, visualizations, contained scenarios (if there be any), and related data for integrating them.

An Example Scenario

Before we discuss scenario management, we discuss an example that will be used during the discussion of implementation. For example, mortgage management includes a series of external environment sensitive inter-related scenarios. AMP (2001) describes a mortgage scenario wherein the median wage and the home price increase and the interest rate drops. What is the impact of this change or any other changes on the individual buyer as well as on the mortgage market? The change in interest rate, average income of the people, demand and supply of houses, and so forth, highly influence the mortgage markets.

This scenario broadly depends on several other scenarios, for example, affordability scenario, loan scenario, and payment scenario. The affordability scenario helps in understanding the borrower's eligibility to get a loan and capacity to repay the loan. The loan scenario analyses the cost of financing, loan amount, and installments. Depending on the loan type, this analysis process can differ widely. The payment scenario analyzes installments, interest payments, principal repayment, and loan balance. The payment scenario addresses the entire life cycle of the loan repayment. Affordability scenario is a constraint to the loan analysis scenario. Each of these scenarios can again be decomposed into several smaller scenarios, for example, the affordability scenario depends on the the income scenario and expense scenario while the income scenario may be sub-divided into the personal income scenario and family income scenario. All these scenarios are inter-related and the higher level scenarios are dependent on the lower level scenarios. Sensitivity analysis and goal-seek analysis of these scenarios would greatly enhance the decision making process.

SCENARIO MANAGEMENT: A LIFE CYCLE APPROACH

The scenario can be different for different problems and domains but a single management approach should support the model-driven scenario analysis process. Therefore, this research introduces a scenario management process using life cycle approach that synthesizes and extends ideas from Ringland (1998, 2002), Schoemaker (1995), Albert (1983), Huss and Honton (1987), Van der Heijden, (1996), and Wright, (2000). The proposed life cycle approach for scenario management process addresses a variety of problem scenarios. The life cycle process starts with scenario idea generation and finishes with the usage of scenario for decision support as illustrated in Figure 1. The following sections present all the phases of the life cycle approach for scenario management.

Idea Generation

The scenario planner foresees the key issues that exist within the scenario and analyses the concerns for identifying the influential driving forces and parameters for the scenarios. In addition the planner may also use the existing scenarios from the scenario pool. The leading factors, which could be either internal and/or external, could lead to various changes to the system. The decision maker as a domain expert predicts the possible changes to the indicators that would guide to the development of ideas for scenario planning.

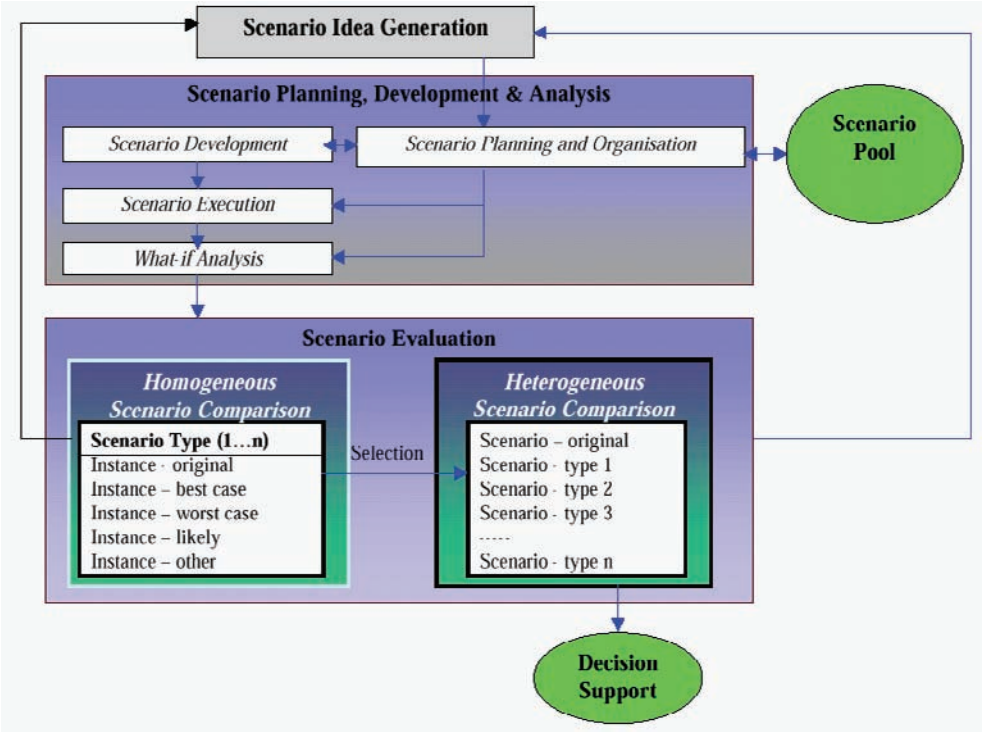
Scenario Planning, Development and Analysis

In this phase, the decision maker will carry out the tasks of scenario planning and organization, scenario development, scenario execution, and what-if analysis. Existing scenarios could also act as inputs to this phase apart from the ideas generated from the previous phase.

Scenario Planning and Organization

The scenario planning step mainly focuses on decomposing the whole big scenario into multiple inter-related scenarios that are suitable for development, execution, analysis and evaluation. It also includes scenario structuring and identification of the scenario components.

Figure 1. Scenario Management: A Life Cycle Approach



Scenario Structure

The components of the scenario can be either pre-customized or loosely coupled. For a pre-customized scenario, the relationships between data, model, and solver as well as with other dependent scenarios are inflexible. The relationships between data-model, model-solver, and data-model-solver-scenario are defined during scenario planning. For example, a scenario is a collection of data, models, solvers, and scenario(s) in which the relationships among the constituent components are fixed and the model instantiation and model evaluation processes by data and solver are distinct. So, the scenario components are tightly integrated and the relationships are not exposed for the decision maker as shown in Figure 2.

For a loosely coupled scenario, the scenario components namely, the data, model, solver, and dependent scenarios remain independent within the scenario. The relationships among these components are established at runtime using a mapping component as shown in Figure 3.

The visualization component is omitted as it can be flexible for both the pre-customized and loosely coupled scenarios.

A Mechanism for Structuring Scenarios

Scenarios are complex and dynamically related to other scenarios. In view of addressing the complexity and inter-relatedness of scenarios, we propose to divide larger scenarios into multiple simple scenarios having independent meaning and existence. In this context we identify three types of scenarios, namely:

- Simple Scenarios—The simple scenario is not dependent on other scenarios but completely meaningful and usable.

Figure 2. Pre-customised Scenario Structure

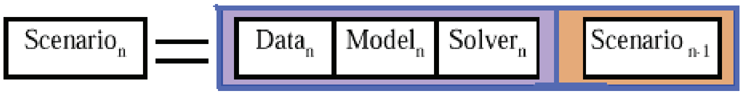


Figure 3. Loosely coupled scenario structure

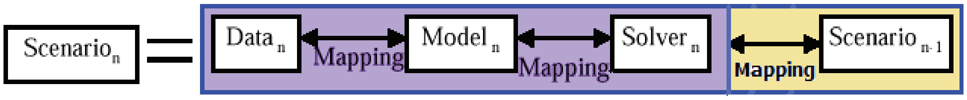


- Aggregate Scenarios—This scenario is comprised of several other scenarios. The top level scenario can be broken down to low level scenarios or several low level scenarios can be added together to develop a top level scenario. The structures of different scenarios or results from multiple scenarios are combined together to develop an aggregate scenario.
- Pipelining Scenarios—One scenario is an input to another scenario in a hierarchical scenario structure. In this type of scenario, each constituent scenario will have independent existence but the lower-level scenarios may be tightly or loosely integrated with the higher-level scenario.

The decision maker may combine simple as well as complex scenarios together using pipelining and aggregation to develop more complex scenarios.

Scenario Organization

Scenario organization activities include making available already developed scenarios, storing, retrieving, deleting, and updating scenarios to and from a scenario pool. This scenario pool should support both temporary and permanent storage systems. The temporary storage, termed as a runtime pool, is used for managing scenarios during development, analysis and evaluation. The newly developed and retrieved scenarios are cached in the runtime pool for developing aggregate and/or pipelined scenarios. The scenario pool also permanently stores scenarios for future use or reference. Both the temporary and permanent storage systems are capable of storing the scenario structure, scenario instance and executed scenarios.

Scenario Development

Scenario planning and scenario development stages are inter-dependent and iterative. Scenario development is the process of conversion and representation of planned scenarios into fully computer based scenarios. Chermack (2003) argues that scenarios have rarely been applied to develop alternative processes. The proposed life cycle approach supports development of alternative process models and scenarios. In this stage, the decision maker organizes the related data, model, solver, and dependent scenarios for constituting the relationships among them to develop scenario(s). The decision maker could potentially use pre-customized and/or loosely coupled scenarios and may skip this step if they use previously developed scenarios. The scenarios are developed in mainly two steps. In step 1, the basic scenarios of the domain are developed, and in step 2, scenarios related to what-if (goal seek and sensitivity) analysis are developed.

Scenario Execution

The proposed scenario development process ensures that the scenario can be executed and analyzed for determining quality and plausibility. In this step, the models are instantiated with the data, and then the model instance is executed using the appropriate solver(s). Model selection is completely independent while one or more solvers may be used for a model execution. A flexible mapping process bridges the state attributes of the model and solver to engage in a relationship and to participate in the execution process. For a complex scenario, the decision maker may need to apply several models and solvers to analyze various aspects of the scenario. If a scenario contains other scenario instances, execution of the containing scenario will depend on the execution of the contained scenarios. But if the containing scenario contains the structure of the contained scenarios, the execution of the containing scenario depends on a series of model instantiation and model execution. This process may be pre-customized during the scenario development step or customized during the execution step. The decision makers can skip this step if they use only the previously stored scenario instances and executed scenarios from the scenario pool.

What-if Analysis

What-if analysis can be divided into two categories, namely sensitivity analysis and goal-seek analysis. Sensitivity analysis allows changing one or more parametric value(s) at a time and analyses the outcome of the change. It reveals the impact itself as well as the impact on other related scenarios. Because one scenario contains other scenarios, each and every change dynamically propagates to all the related scenarios. Goal-seek analysis accomplishes a particular task rather than analyzing the changing future. This goal seek analysis is just a reverse or feedback evaluation where the decision maker supplies the target output and gets the required input.

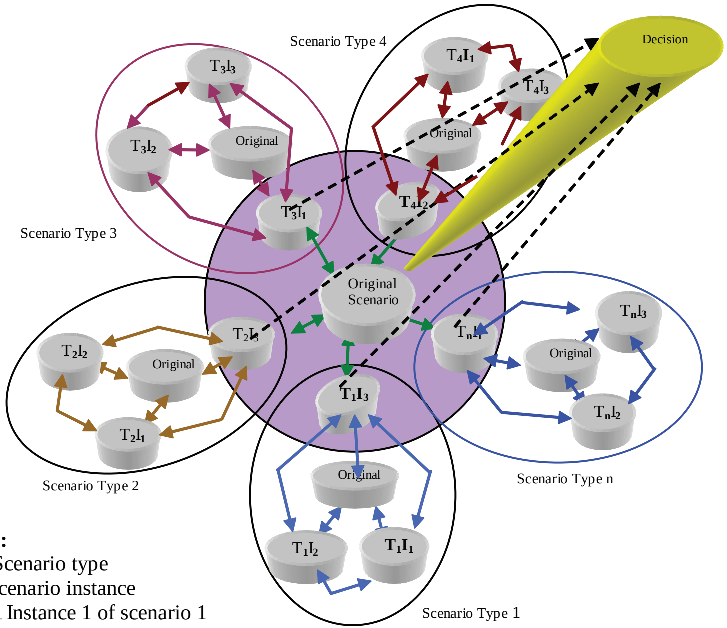
Scenario Evaluation Process

Scenario evaluation is a challenging task (Chermack, 2002) but some end-states are predetermined dependent upon the presence of an interaction of identified events (Wright, 2000), which can be used to devise an evaluation process. The decision maker could potentially develop many scenarios. The question is do all these scenarios represent a unique situation? Each scenario might appropriately draw the strategic question; represent fundamentally different issues; present a plausible future; and challenge conventional wisdom. Schwartz (1991) and Tucker (1999) discourage too many scenarios and advocate the use of best-case scenario, worst-case scenario and most-likely scenario. The evaluation is done through scenario execution and comparison of the executed results. A visualization object displays results of all the executed scenario instances either as a table or as a graph. This presentation helps comparing the computed inputs and outputs including other attributes. The comparison may take place among homogeneous scenarios or heterogeneous scenarios as shown in Figure 4. This two-phase comparison process is detailed in the following sections.

Homogeneous Comparison

Homogeneous scenarios are a similar type of scenario but the instances are quite distinct from one another. The decision maker selects a scenario instance on completion of each homogeneous scenario comparison. For example, in Figure 4, five outer ellipses represent five different scenarios while small ellipses, for example, $\mathbf{T_1I_1}$, $\mathbf{T_1I_2}$ and $\mathbf{T_1I_3}$ represent three instances of type 1 scenario

Figure 4. Scenario evaluation process



Note:
T – Scenario type
I – Scenario instance
T_1I_1 – Instance 1 of scenario 1
T_1I_2 – Instance 2 of scenario 1
T_2I_1 – Instance 1 of scenario 2
T_2I_2 – Instance 2 of scenario 2

and the ellipse containing **Original** represents the current instance of the type 1 scenario**.** The $\mathbf{T_1I_1}$, $\mathbf{T_1I_2}$, $\mathbf{T_1I_3}$ instances and the original instances are compared and the decision maker selects the most plausible scenario instance, which happens to be $\mathbf{T_1I_3}$ as shown in the Figure 4. If none of the instances are plausible, or do not have an optimal result, then the decision maker can go back to the idea generation step and repeat the whole process. From this homogeneous scenario comparison, the decision maker can select at least one scenario instance for each type of scenario. In Figure 4, the selected scenario instances are $\mathbf{T_2I_3}$, $\mathbf{T_3I_1}$, $\mathbf{T_4I_2}$, and $\mathbf{T_nI_1}$ for scenario type 2, 3, 4, and n respectively.

Heterogeneous Comparison

Heterogeneous scenarios are different types but inter-related scenarios as shown in the big middle circle in Figure 4. It is almost impractical to compare heterogeneous scenarios as the attributes of these scenarios could vary widely from one another. The decision maker can only compare them by presenting the executed scenario outputs using some common attributes. If the decision maker finds that a specific instance of the scenario is not suitable for heterogeneous comparison, then the decision maker can go back to the idea generation and repeat the whole process to identify a new instance for that scenario. This gives the decision maker an excellent picture of the entire decision problem and the probable solutions. For example, as shown in the Figure 4, instances of five scenarios i.e. T_1I_3, T_2I_3, T_3I_1, T_4I_2, and T_nI_1 have been compared with the instance of the current situation during heterogeneous comparison.

Decision Support

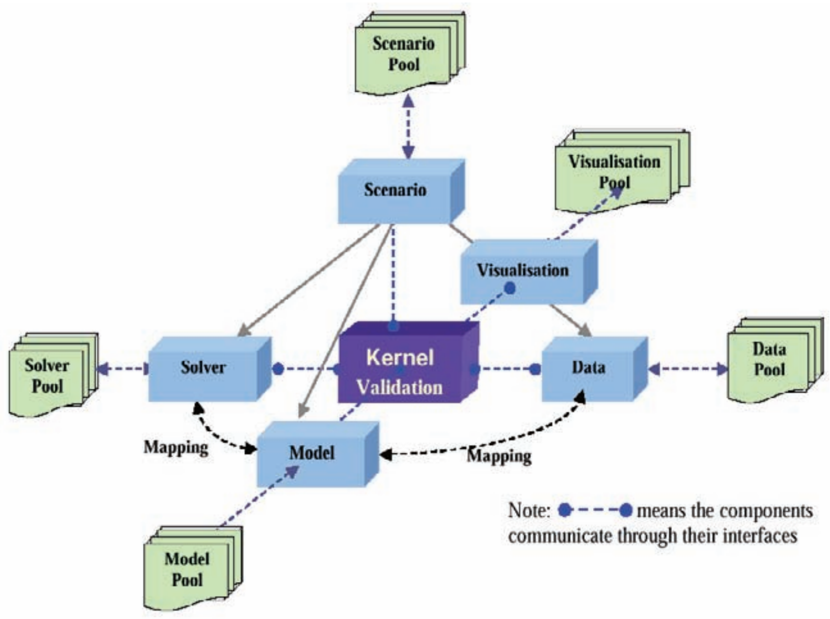
The previously described scenario planning, development, and evaluation through comparative analysis results in improved participant learning (De Geus, 1988; Godet, 2001; Shoemaker, 1995) and helps decision makers re-perceive reality from several points of view (Der Heijden et al., 2002) and thereby provides better support for decision making. The following section proposes a framework that realizes the proposed scenario management process.

SCENARIO DRIVEN FLEXIBLE DECISION SUPPORT SYSTEMS FRAMEWORK

Few of the DSS frameworks emphasize fully featured scenario planning, development, analysis, execution, evaluation and their usage for decision support. DSS components such as data, model, solver, and visualization have been extensively used in many DSS framework designs but they do not consider scenarios as a component of DSS. Scenario plays such an important role in the decision-making process that it is almost impractical to develop a good decision modeling environment while leaving out this component. While scenarios resemble model-driven DSS they are more complex than models and need to be considered as independent entities in an explicit fashion. Therefore, we propose that scenario-driven DSS should add the *scenario* as an independent component in addition to existing decision-support components. The scenario does not have a separate existence without its base components. Every scenario is built up from a unique problem (model) that can have a number of alternative unique instances (data) and each instance can be interpreted, executed or implemented using one or more alternative methods (solvers).

To overcome the problems and address the issues mentioned above we propose a scenario-driven decision support systems generator (SDSSG) framework as illustrated in Figure 5. The SDSSG components are separated into the following three categories:

Figure 5. Scenario-Driven Decision Support Systems Generator (SDSSG) Framework



Note: ●- - -● means the components communicate through their interfaces

- Decision-support components (DSC) that include the data, model, solver, scenario and visualization.
- Integration components (IC) that include kernel, component set, mapping, and validation component.
- Component pools that include data pool, model pool, solver pool, scenario pool, and visualization pool. Each component of the DSC has a direct relationship with a component pool.

In this framework, the DSCs, ICs and component pools are independent of each other. The DSCs communicate via the kernel component. The mapping component develops the correct path of communication between data and model, and model and solver, while the validation component tests the correct matching of the component interface and the proper communication between the components.

The data, model, solver, scenario, and visualization can be stored in different component pools as shown in Figure 5 and the framework allows retrieving these components from the component pools. The related model, data and solver can be combined together to develop a scenario. This scenario can be saved to the scenario pool for future use. This also allows using the scenario(s) as an input for developing a number of simple, aggregate, and pipelined scenarios. Every instance of the scenario can be termed as a specific decision support system. Therefore, the framework is a generator of scenarios as well as decision support systems.

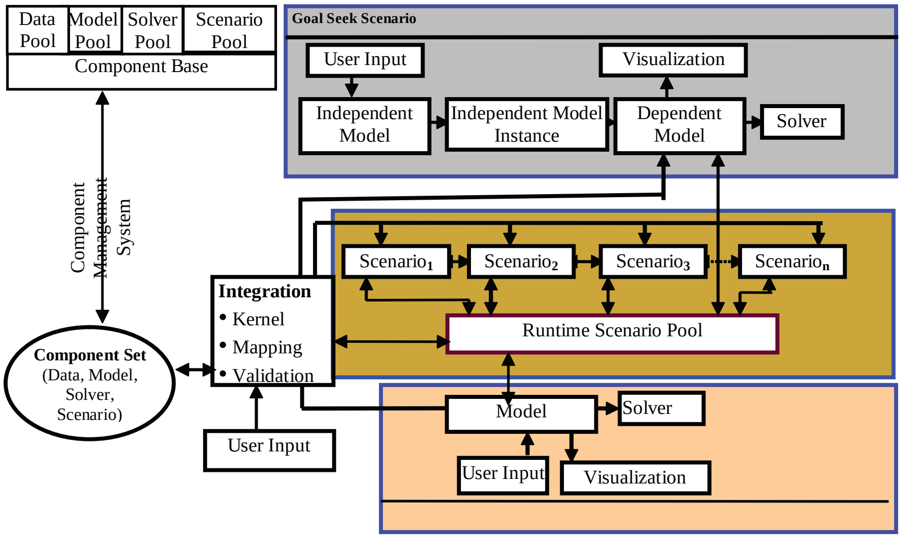
Scenario information can be saved and retrieved to and from the scenario pool and the same can again be customized using models and solvers. The scenario instances can be used as complex data for input to the next level model for further analysis. Different scenarios can be computed simultaneously and sensitivity and goal-seek analysis can be done. The framework is suitable for analyzing internally coherent scenarios or scenario bundles, and examining the joint consequences of changes in the environment for supporting the decision maker's strategy.

REALISATION OF THE SCENARIO MANAGEMENT PROCESS USING THE SDSSG FRAMEWORK

In this section we discuss and illustrate (Figure 6) the mechanisms through which the scenario management process is realized using the SDSSG framework. Specifically we discuss the means by which the framework supports all the life cycle phases of the proposed scenario management process. The key features of this framework are as follows:

- **Supporting idea generation:** Allows retrieving the required data, model, solver, and scenario from the respective pools. The decision maker develops a scenario that uniquely represents an instance of a scenario type through establishing the relationships among these retrieved scenario components. A problem can be represented by different models and various solvers may be used for their execution. Therefore it supports generation of multiple instances of a scenario through various combinations of constituent components.
- **Scenario planning*:*** Supports the planning of modeling-based scenario structure, pre-customized and loosely coupled scenarios.
- **Runtime scenario organization:** Incorporates a runtime only temporary storage system named runtime scenario pool (RSP) to store the completed scenarios. The completed scenario(s) can be pulled from the RSP to develop complex scenarios and this completed scenario can again be stored in the RSP.
- **Scenario storing and retrieving:** Allows saving, retrieving, updating or deleting the

Figure 6: Realisation of the Scenario Management Process using the SDSSG Framework



scenarios from the scenario pool using the data access component. The RSP is linked with the component set through the kernel and data components. This allows scenarios to be saved to the scenario pool.

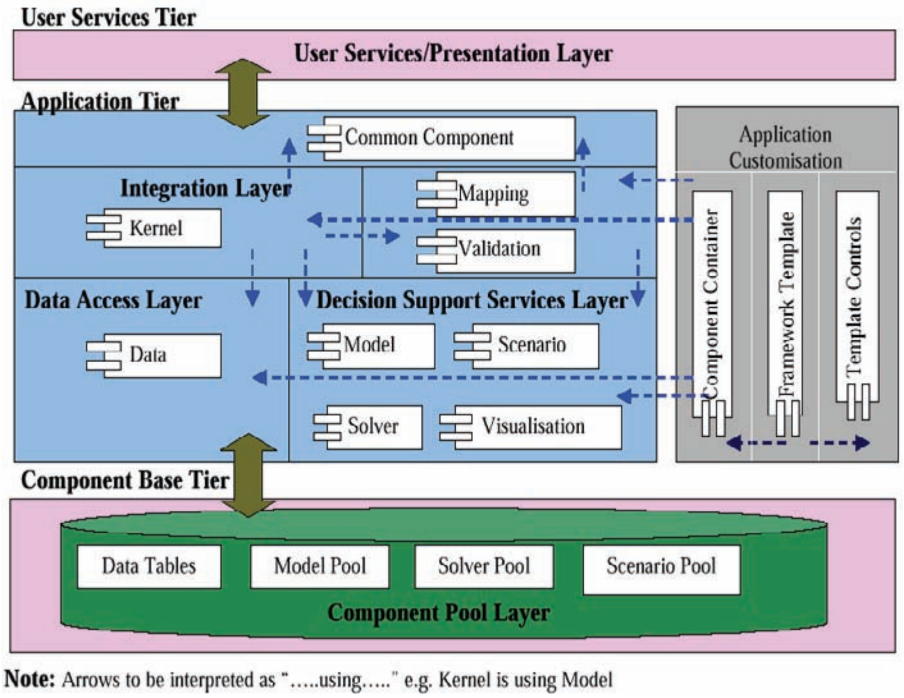
- **Scenario development:** The basic scenario is developed using building blocks such as data, model, solver, and previously executed scenarios. The sensitivity and goal-seek scenario analysis processes use original data sources, user input data regarding the changes of scenario parameter, dependent scenario values from the runtime scenario pool along with related sensitivity model(s) and solver(s) to represent and solve problems.
- **Development of aggregate and/or pipelined scenarios:** In a pre-customized pipelining system, scenarios are pre-defined as a chain from lower level to upper-level scenarios. The upper-level scenarios directly receive the executed value of the lower-level scenarios. But, in loosely coupled scenarios, a top-level scenario uses the values of the lower-level scenario from the runtime scenario pool.
- **Scenario selection:** The framework allows the user to select any scenario depending on the suitability and appropriateness of the scenario.
- **Scenario execution:** The framework facilitates instantiation of model with the data and execution of the instantiated model with appropriate solvers.
- **Scenario evaluation:** The framework supports evaluation of scenarios through visualizing the output of basic, sensitivity, and goal-seek scenarios in a comparison table or graphs.
- **Decision support:** The framework supports Simon's (1960) decision-making phases. These phases are comparable to scenario generation, analysis, comparison, and selection of plausible scenarios. Scenario analysis and evaluation using the comparison process increases the cognitive knowledge of users which in turn supports and leads them towards the final decision.

SDSSG ARCHITECTURE

In order to implement the SDSSG framework we develop a component-based layered architecture as shown in Figure 7 that is suitable for implementation as an n-tiered system. The proposed architecture is comprised of the user services tier, application tier, and component base tier; and the layers are user services, integration, data access, decision support services, application customization, and component pool. The component pool layer stores data, models, solvers, and scenarios. A relational database management system or XML documents can be used as a component layer. The data access layer provides components' management services such as addition, retrieval, update, and deletion of component information. The decision support services layer provides the services of DSS components namely, model, solver, scenario, and visualization. The integration layer provides integration, mapping and validation services through kernel, mapping, and validation components. The kernel arranges communication between data-model, model-solver and scenario-visualization using the mapping component for model instantiation, model execution, and scenario presentation respectively. It also uses the validation component to validate the proper communication and execution of the components. The common component facilitates creation of dynamic graphical user interfaces (GUI) and presentation layer depending on the decision maker's selection of data, model, solver, scenario, and visualization components at runtime. This GUI supports decision maker interactivity with the system for input, mapping, scenario development, execution, analysis, evaluation, and presentation activities.

The architecture also contains an application customization module, which contains component container, framework template, and template controls. This module facilitates customization of the SDSSG system with newer components. The Application Customization module works

Figure 7. SDSSG architecture



Note: Arrows to be interpreted as "…..using….." e.g. Kernel is using Model on top of the other architectural components for their customization. This framework template component is the medium of user interaction for customization of the system. Framework control component creates controls on the framework template for user interaction with the customization process of the system. The component container contains abstract components and interfaces of all the architectural components.

The architecture separates the decision-support components from the integration components. It supports independent development and use of the components, flexible scenario modeling, scenario manipulation and integration, flexible mapping between different DSS components, flexible integration of DSS components, and finally scenario analysis. Pre-customized and customizable modeling systems can be achieved through predefined relationships and the mapping components respectively. The mapping component facilitates dynamic communication between model-data, model-solver, and model-visualization pairs.

IMPLEMENTATION

The SDSSG framework and architecture can be implemented using any platform that supports component-based development. Since object-orientation and componentization concepts are the central focus of the SDSSG framework and architecture, C# was used for implementing the SDSSG architecture that leverages Microsoft's .NET Framework. Relational database management systems (e.g., SQL 2000 Server, Microsoft Access) and extensible markup language (XML) were also used in building the system for managing data, model, solver, and scenario components.

Ringland (2002) explains that business case should be at the centre of the scenario planning. Therefore the SDSSG framework and architecture have been implemented within the context of the mortgage domain introduced in section 2.2. We implemented base scenarios e.g. affordability scenario, lending scenario (equal installment, reducing installment, interest only lending scenarios), payment scenario, and so forth. A user interface of the system is shown in Figure 8.

We explored a number of alternative scenarios including the best-case and worst-case scenarios through sensitivity analysis and evaluated the executed instances of homogeneous and heterogeneous scenarios through comparison. Within each of these scenarios we explored sensitivity and goal-seek analyses. The system compares multiple scenarios of similar type (homogeneous comparison as shown in figure 9) or different types (heterogeneous comparison as shown in figure 10) or both homogeneous and heterogeneous at a time in a single visualization.

The system was tested and evaluated for sensitivity analysis for strategic management of the loan in future for scenarios of interest rate change (IRC), loan amount change (LAC), an on-off payment (IPC) at any time, installment change (IC), and loan period change (PPC). The loan payment scenario sensitivity for different instances of IC scenario is shown in Figure 9 for a $200,000 loan at the rate of 6 percent per annum. Figure 10 shows another example of the sensitivity analysis of the same loan for IRC, PPC, IC and IPC scenarios. Both the analyses

present the impact on the payment period, net savings/loss, and installment. PPC, IC, and IPC scenarios do not have any impact on IRC scenario as this is an external factor. Apart from this we also explored sensitivity analysis on complex interlinked scenarios which in turn were made up of sub-scenarios.

The system supports complex analyzes from very lower-level/simple scenarios to higher-level/aggregate scenarios. Scenarios analyzed bottom-up may or may not satisfy the prime objective. In this circumstance, a top-down scenario analysis (goal-seek analysis) could bring the optimum acceptable scenarios that would satisfy the objective. The prototype supports different level of users (Sprague, 1980) and various levels of customization and abstraction. In order to minimize the trade-off between versatility and usability (Matheus, Chan, & Piatesky-Shapiro, 1993), SDSSG enables the decision maker to use both customizable generic systems and pre-customized and packaged scenarios for a particular use. A DSS builder configures the SDSSG system to develop purpose-built very specific and effective DSS and stores them for use by decision makers. Due to the nature of dynamic user interface and visualization, this specific DSS is easy to use for the intended purpose.

We used eight different categories of evaluation criteria namely: scenario management, scenario analysis and development, scenario evaluation, appropriateness of scenarios, com-

putational performance, functionality, usability, and ancillary task support for evaluation of the SDSSG framework and architecture, and various processes. The principles proposed by Geoffrion (1987), Ramirez, Ching, and St. Louis (1990), and Collier et al. (1999) namely, ease of model selection, algorithmic variety, flexible visualization, management of components, data-model independence, model-solver independence, data-visualization independence, mapping, reusability, domain independence, extensibility, model abstraction levels, purpose independence, model instantiation, model termination, model execution, and model version support were applied for critical evaluation and validation of the SDSSG framework and architecture. The quality and appropriateness of the scenarios were evaluated based on the appropriateness, usability, uniqueness, variety, and quality as prescribed by Schoemaker (1995). The evaluation criteria were extended to assess various processes such as scenario management, scenario planning, scenario development, scenario analysis, scenario evaluation, and mapping between components. The scenario management process was evaluated using the life cycle stages of scenarios namely idea generation, scenario analysis and management, scenario development, scenario storage and retrieval, runtime scenario management, scenario execution, and scenario evaluation. Scenario planning, development and analysis processes were evaluated using principles of scenario structuring (simple scenario, simple pipelining scenario, complex scenario, complex pipelining scenario), provision of runtime scenario pools, ability to conduct sensitivity and goal-seek analysis, ease of scenario generation, and the tightness and flexibility of coupling of components. Scenario evaluation sub-processes were evaluated based on the ability to compare multiple instances of a scenario and instances of multiple scenarios, ease of scenario comparison and use, support for decision making, and organizational learning. In addition to the above mentioned processes, the observations of various conference review groups (e.g., Ahmed & Sundaram, 2005) have also been incorporated during finalization of the framework and architecture, and scenario life cycle processes.

The structure of many of the models and solvers that we used are domain independent and they can be used in any applicable domain. Specialized scenarios are more oriented towards the domain to represent the problem domain. These types of models and their relevant solvers are sometimes domain dependent. We have extensively explored the use of the system in the context of the mortgage domain but due to its generic nature the concept, models, and solvers explored are equally applicable to other domains where ‘what-if’ analysis, goal-seek and iterative problem solving/search is of importance. The current SDSSG system allows minor versioning of the components without any impact on the kernel; however a major change in the paradigm could necessitate a change to the public interface of the components which in turn may require modification of the kernel component.

CONCLUSION

Current scenario planning and analysis systems are very complex, not user friendly, and do not support modeling and evaluation of multiple scenarios simultaneously. To overcome these problems we propose a scenario management life cycle, and a framework and architecture that support the lifecycle. The lifecycle as well as the framework and architecture are validated through a concrete implementation of a prototype.

This research introduces the concepts of scenario structure and their development strategy. It decomposes large complex scenarios into multiple small and executable scenarios and uses the decomposition and re-composition methodology for defining the scenario structure. The research also proposes a life cycle approach for scenario management that supports a range of activities from conceptualizing and understanding the scenario to final use of the scenario for decision making. Key phases of the life cycle are idea generation, scenario planning, organization, development, execution, analysis, evaluation, and finally decision support. The process hides external factors and complexities of the scenario and allows the seamless combination of decision parameters for appropriate scenario generation. We also propose a generalized scenario evaluation process to enable the decision maker in finding appropriate and plausible scenarios through homogeneous and heterogeneous scenario comparisons among the multiple instances of similar and dissimilar scenarios respectively.

The research further realizes the scenario-driven decision-making processes through extending model-driven decision support systems. We develop a generic scenario driven flexible decision support systems generator framework and architecture that supports the above-mentioned scenario management processes as well as sensitivity and goal-seek analysis. Scenarios are introduced as a new DSS component alongside the traditional data, model, solver, and visualization components.

The proposed framework and architecture are domain independent, platform independent, component-based and modular. The architecture is comprised of multiple layers, namely component pool layer, data access layer, decision support services layer, integration layer, and user services layer. Each layer performs specific functions, which are suitable for implementation of the architecture as an n-tiered system. The implemented system supports customization for developing semi-automated, pre-customized, and specific DSS.

FURTHER RESEARCH AND IMPLEMENTATION

The generalizability of these concepts, frameworks, and architectures has been proved in other domains and other paradigms. For instance, Ahmed and Sundaram (2007) have applied these principles for developing a generic DSS framework and architecture for sustainability modeling and reporting. The concept of this framework, architecture and scenario management processes can be applied to the decision making components of existing enterprise systems such as SAP and Oracle. Future research could explore the applicability of our concepts, frameworks, and architectures to other domains and paradigms as well as their use in conjunction with existing transaction processing, analytical, and strategic information systems.

ABSTRACT

Decisions at different levels of the supply chain can no longer be considered independently, since they may influence profitability throughout the supply chain. This paper focuses on the interest of multi-agent paradigm for the collaborative coordination in global distribution supply chain. Multi-agent computational environments are suitable for a broad class of coordination and negotiation issues involving multiple autonomous or semiautonomous problem solving contexts. An agent-based distributed architecture is proposed for better management of rush unexpected orders. This paper proposes a first architecture validated by a real and industrial case. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

The Supply Chain (SC) is increasingly interest for many business enterprises and a challenge for logistics management in the 21st century. Supply chain is defined as the chain linking each entity of the manufacturing and supply process from raw materials through to the end user (New and Payne, 1995). A supply chain comprises many systems, including various manufacturing, storage, transportation, and retail systems (Han et al., 2002). Supply Chain Management (SCM) has commanded attention and support from the industrial community. It consists in the coordination of production, inventory, location, and transportation among the participants in a supply chain to achieve the best mix of responsiveness and efficiency for the market being served (Hugos, 2003). The optimal deployment of inventory is one of the principal goals of SCM. Indeed, Many collaborative processes (e.g. CPFR: Collaborative Planning, Forecasting and Replenishment (VICS Association, 2007), VMI: Vendor Managed Inventory (John Taras CPIM, 2007), CRP: Continuous Replenishment Program and ECR: Efficient Consumer Response (ECR, 2006) and software systems (e.g. APS: Advanced Planning Systems (Simchi-Levi et al., 2000), ERP: Enterprise Resource Planning (Baglin et al., 2001) are used for management and control of inventory in order to reduce the total system cost of inventory as much as possible while still maintaining the service levels that customers require. Literature shows that the common objectives of these practices is to avoid the surplus inventory, reduce the inventory shortage, minimize the safety stock, produce and deliver products in the right quantities and at the right time. However for the distributor centers, it is difficult to achieve this goal, because the rush unexpected orders placed by the wholesalers always present a challenge. This challenge will vary from one company to another and from one supply chain to another. In fact, the distributor can not predict the date and the ordered quantity of this type of orders since it is a random one whose causes are multiple and depend closely on the branch of industry. In addition, this type of orders has a very short delivery date. In this emergency case, the distributor is not able to wait for the next planned delivery of products from the supplier. Therefore, generally the order can be cancelled or can cause an inventory shortage if the ordered quantity is large. This will have a bad impact on the quality of the offered service within the satisfaction of the final customer policy.

Some suppliers allocate an additional human resources and logistics for delivering the rush unexpected orders of their distributors. The disadvantage of this solution is that the costs suggested are generally very high.

In multi-echelon networks, which is a common distribution model for many distributors and manufacturers, the distributors can deliver the rush unexpected orders. The echelon inventory includes the sum of local stock and the stock of all the forward distribution centers (Siala et al., 2006). However, multi-echelon inventory management is more coherent to the centralized decisions and it requires that all locations must be submitted to the relevant control of a single enterprise. In addition, it requires a high degree of information sharing between the various actors of the SC, but if the supply chain consists in independent enterprises, information sharing becomes a critical obstacle, since each independent actor is typically not willing to share with the other nodes its own strategic data (as inventory levels). Also, it monitors his inventory levels (by using autonomous action and policies) and places the orders to its suppliers in order to optimize its own objective (Siala et al., 2006).

This paper focuses on unexpected swings in demand and on unexpected exceptions (problem of production, problem of transportation, etc.), which are important coordination and communication issues in SC management (Giannoccaro et al., 2003) (Zhao et al., 2002). Both events can engender the presence of a rush unexpected orders in a node of supply chain; in particular, at the wholesalers and the distribution centers levels. In this context, we propose a collaborative process which presents an effective solution (to the distributors) for better management of the rush unexpected orders for which the quantity of product cannot be delivered partially or completely from the available inventory. This process includes the distributors of the same or equivalent products and their wholesalers. The participants in the process can be competitors. To implement the process, we apply an agent-based distributed architecture in order to guarantee the autonomy and the strategic data confidentiality of all participants. Agent technology provides to the distributed environment a great promise of effective communication (Swaminathan et al., 1998). An agent is a program that performs a specific task intelligently without any human supervision and can communicate with other agents cooperatively. Therefore, agent technology is suitable to solve communication concerns for a distributed environment. Recent researches also show that the multi-agent approach plays a significant role in supply chain management, for example (Kimbrough et al., 2002), (Wu, 2001) and (Swaminathan et al., 1998).

This paper is organized as follows; in Section 2, the literature on supply chain coordination and agent technology is reviewed; in Section 3, the rush unexpected order is presented. The collaborative process and system architecture are proposed in Section 4. In Section 5, a set of negotiation protocols are presented and modeled within UML sequence diagrams. A case study is presented in Section 6 to validate the proposed architecture. Section 7 concludes the paper.

BACKGROUND REVIEW

To improve the supply chain's performance under demand uncertainty and exceptions, various levels of collaboration techniques based on information sharing were set up in real supply chains. These techniques are essentially, VMI, CRP and CPFR. VMI and CRP are very similar, but are used in different industries. The idea is that retailers do not need to place orders because wholesalers use information centralization to decide when to replenish them. Although these techniques could be extended to a whole supply chain, current implementations only work between two business partners. In fact, many customers are attracted to these techniques, because they mitigate uncertainty of demand. Moreover, the frequency of replenishment is usually increased every month or every week (or even daily), and from which both partners benefit. CPFR is a standard that enhances VMI and CRP by incorporating joint forecasting. Like VMI and CRP, current implementations of CPFR include only two levels of a supply chain, i.e., retailers and their wholesalers. With CPFR, companies electronically exchange a series of written comments and supporting data, which includes past sales trends, scheduled promotions, and forecasts. This allows participants to coordinate joint forecasting by focusing on differences in forecasts. Companies try to find the cause of such differences and agree on joint in order to improve forecasts.

In the literature, various researches to compensate for the uncertainty that exists in a supply chain have been reported. Cohen and Lee (Cohen and Lee, 1988) have developed a planning model to optimize material supply, production and distribution processes. Arntzen et al. (1995) have proposed a resource allocation and planning model for global production and distribution networks. Kimbrough et al. (2002), McBurney et al. (2002), Chen et al. (2000) focused on demand forecasting. Most of these researches suppose that companies in the supply chain share the information and coordinate the orders. But if the supply chain consists of autonomous enterprises, sharing information becomes a critical obstacle, since each independent actor typically is not willing to share with the other nodes its own strategic data (as inventory levels) (Terzi and Cavalieri, 2004); An example is the case of several competitor wholesalers (located in the same or different geographical areas) which source of the same distributor.

Various projects applied the multi-agent system paradigm to solve different problems in Supply Chain (as inventory planning, demand and sales planning, distribution and transportation planning, etc). DragonChain was implemented by Kimbrough et al. (2002) at the University of Pennsylvania (Philadelphia, PA, USA) to simulate supply chain management, and more particularly to reduce bullwhip effect. For that, they base their simulation on two versions of the Beer Game, the MIT beer game (i.e. the original game) and the Columbia Beer Game, and they use agents that look for the best ordering scheme with genetic algorithms. Maturana et al. (1999) have developed a hybrid agent-based mediator-centric architecture, called MetaMorph, to integrate partners, suppliers and customers dynamically with the main enterprise through their respective mediators within a supply chain network via the Internet and Intranets. In MetaMorph, agents can be used to represent manufacturing resources (machines, tools, etc.) and parts, to encapsulate existing software systems and to function as system or subsystem coordinators/mediators. Swaminathan et al. (1998) have proposed a multi-agent approach to model supply chain dynamics. In their approach, a supply chain library of software components, such as retailers, manufacturers, inventory policy, and so on, has been developed to build customized supply chain models from the library. Sadeh et al. (2001) have developed an agent-based architecture for a dynamic supply chain called MASCOT. The MASCOT is a reconfigurable, multilevel, agent-based architecture for a coordinated supply chain. Agents in MASCOT serve as wrappers for planning and scheduling modules. Petersen et al. (2001) have proposed a multi-agent architecture, called AGORA, for modeling and supporting cooperative work among distributed entities in virtual enterprises. We have already proposed (Nfaoui et al., 2006) an agent-based distributed architecture of simulation in decision-making process within the supply chain context. Agents in this architecture use a set of negotiation protocols (such as Firm Heuristic Negotiation, Recursive Heuristic Negotiation, CPFR Negotiation Protocol) to make decisions collectively in a short time. Chehbi et al. (2003) have proposed multi-agent supply chain architecture to optimize distributed decision making.

THE RUSH UNEXPECTED ORDER AND SAFETY INVENTORY

Safety inventory is necessary to compensate for the uncertainty that exists in a supply chain. Retailers and distributors do not want to run out of inventory in the face of unexpected customer demand or unexpected delay in receiving replenishment orders so they keep safety stock on hand. As a rule, the higher the level of uncertainty is, the higher the level of safety stock is required.

Safety inventory for an item can be defined as the amount of inventory on hand for an item when the next replenishment EOQ (the Economic Order Quantity) lot arrives. This means that the safety stock is inventory that does not turn over. In effect, it becomes a fixed asset and it drives up the cost of carrying inventory. Companies need to find a balance between their desire to carry a wide range of products and offer high availability on all of them and their conflicting desire to keep the cost of inventory as low as possible. That balance is reflected quite literally in the amount of safety stock that a company carries.

In practice, the safety stock is not enough to cover all types of unexpected swings in demand and the unexpected exceptions. As an example, the case of a customer (retailer, wholesalers, etc) who contacts his supplier (distributor) and asks for a product quantity as an immediate request, and the supplier discovers that his safety stock is lower than the ordered quantity at that moment. If this happens after the item has been logged in as a confirmed order, will the supplier be able to respond within a suitable timeframe to the customer?

We propose hereafter an agent-based distributed architecture to solve this problem of rush unexpected orders. The rush unexpected order is an object which is characterized by two attributes, the ordered quantity and the short delivery time. Multiple causes of rush unexpected order exist, they closely depend on the branch of supply chain sector. For distributors, the main interest got from such rush unexpected order delivery depends on the customer's profile and other additional criteria such as:

- It allows interesting benefit;
- The distributor does not look for benefit, but he only interests to attract and retain the customer. It is the case for a wholesaler strategic customer for example.
- It helps increasing the number of customers. It is the case of a wholesaler who is a customer of another distributor or a regular customer who is in hurry, which will appreciate the offered service and may become a new customer.

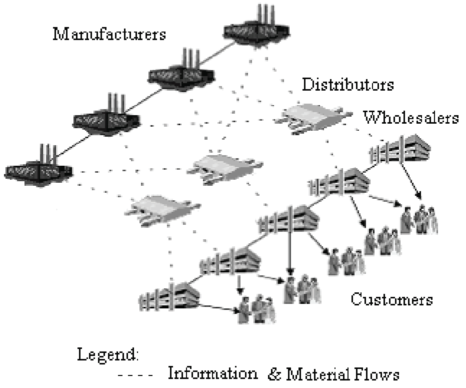
AGENT BASED APPROACH

In this section, the agent-based approach is presented, the multi-agent system architecture is described and different agents, as well as their specific roles, are defined.

Main Idea

Figure 1 shows the typical structure of a global distribution supply chain. Systems that are defined as distribution systems can be of important varying structure. Nonetheless, such systems need to contain a number of common properties. A distribution system needs to include one or more customers who are defined by having a demand on a given product. In addition, the system needs to include one or more sources, which are defined by producing or containing the product demanded by the customer(s). Finally, the system needs a connection between the source(s) and customer(s), which can accommodate a flow of the product from the source(s) to the customer(s) in order to obtain fulfilment of the demand.

Figure 1. Overview of a global distribution supply chain



Let us suppose that a wholesaler or a particular customer had placed a rush unexpected order which is characterized by two attributes:

- The ordered quantity OQ which cannot be delivered partially or completely from the distributor's available inventory;
- The delivery time DT.

Two cases are then possible:

a. The distributor does not have any part of the ordered quantity OQ;
b. It has a part of the ordered quantity and must complete the rest.

In both situations:

$$OQ = DisQ + RQ$$

Where DisQ: available quantity which can be delivered by the distributor. Two situations are possible: DisQ = 0 (a) or DisQ < OQ (b).

RQ: required quantity which must be looked for.The problem can be then summarized as follows:

Find the required quantity RQ in order to deliver the rush unexpected order while respecting the delivery time DT.

One of the practices of the distributors (see other solutions in introduction) consists of seeking the required quantity from another wholesaler or distributor. In general, the distributor will be limited to some close and faithful wholesalers or to distributors of the same company. This shows that the chosen solution (if it is found) can not be the best. Moreover, it takes enough time since the negotiation is carried out generally by phone. Within the context of SCM, we propose to extend this practice by involving (into collaboration) several wholesalers, same products distributors and equivalent products distributors. So, the distributor will be supplied from three different actors:

- 1st type (distributor and its wholesalers)
    - Wholesalers belonging to the same area as the customer;
    - Wholesalers belonging to different areas from the customer;
    - Both cases above.
- 2nd type (distributor/same products distributors)
    - The same products distributors and/or their wholesalers.
- 3rd type (distributor/equivalent products distributors)
    - The equivalent product distributors and/or their wholesalers.
- 4th type
    - Hybrid Solution: two or three types at the same time.

In practice, to implement this process in the industrial cases, and in order to satisfy the distributors' needs, three conditions must be checked:

- Quick and automatic solution. The manager contacts the collaborative participants only to confirm the solution.
- Autonomy and data confidentiality of each participant must be guaranteed since they can be independent.
- Transportation costs should be minimized, which will be added to the basic high purchase price since the products will not be delivered directly by the distributor.

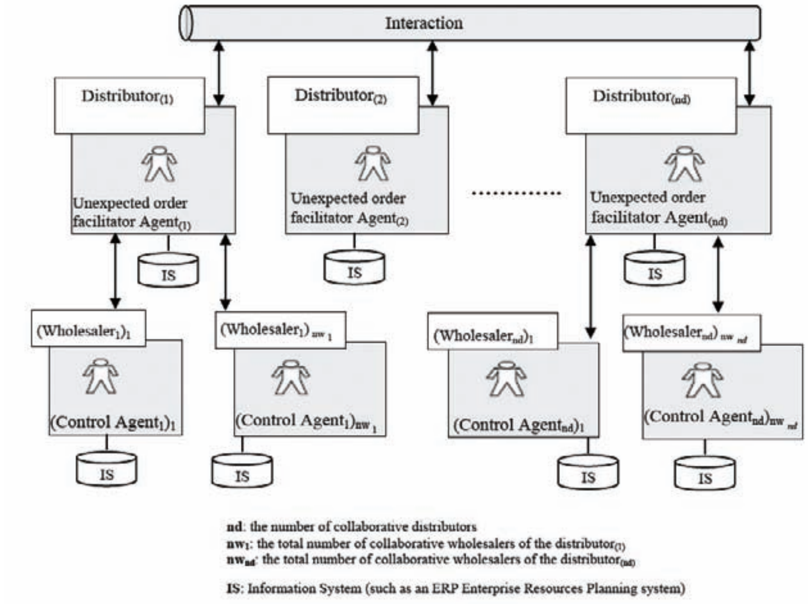
As shown in the background review (section 2), the agent technology is more suitable for this type of problem. In this respect, we propose in the section below an agent-based distributed architecture which implements this process.

Agent-Based Solution Approach

The proposed system does not substitute the existing tools and the SCM strategies and practices, but it can be used as a complement which improves them in the case of the presence of a rush unexpected order. The system architecture is shown in Figure 2.

The main purpose of this system is to coordinate all collaborative participants in order to find the OQ quantity and minimize total cost of transportation when a rush unexpected order is presented. The complete architecture includes two types of agents: control agents "*WhoAgent*" for wholesalers and the unexpected order facilitator agents "*DisAgent*" for distributors. Each distributor is modeled by a $DisAgent_i$ (where i ∈ [1, nd] and *nd* is the number of collaborative distributors) and each wholesaler is modeled by a $(WhoAgent_i)_j$ (where j ∈ [1, nw_i] and nw_i is the total number of collaborative wholesalers of the distributor$_{(i)}$). These coordinated agents have the ability to specify both static and dynamic characteristics of various supply chain entities (Lee, 1997);

Figure 2. System architecture



in particular, the level of distributors and their wholesalers.

The control agent plays a liaison role between a supply chain manager and the system. It collects strategies from managers, seeks the accurate data and aims at building a rule-base for better coordination and better decision-making process. When an unexpected order facilitator agent $DisAgent_i$ asks a control agent $(WhoAgent_i)_j$ (where $j \in [1, nw_i]$ and nw_i is the total number of collaborative wholesalers of the distributor$_{(i)}$) for possible quantity of product that it can deliver, control agent $(WhoAgent_i)_j$ sends information about possible quantity and costs, and transportation costs. The agent system is autonomous because it allows any manager to change strategies of that node. Also, it allows overcoming the hurdle which consists of need for sharing sensitive information of participants in the SC, because the agents do not exchange information about inventory levels and strategies. In real world coordination, sharing information truthfully is problematic since intra-organizational trust cannot be easily developed. Next, if the collaborative participants (wholesalers and their distributors) are independent and operate within the same sector (same or equivalent products); information sharing becomes a critical obstacle, since each independent wholesaler/distributor is typically not willing to share with the other nodes its own strategic data (as inventory level for example). On the real global distribution cases, and especially in the same distribution sector, it is easy to implement the interaction between a distributor and its wholesalers. However, it is difficult, even impossible, to implement it between a distributor and the wholesalers of another distributor. Indeed, the participants are confronted to the increasing impact of competitive pressures. Also, each distributor tries to increase the number of its customers. To represent the real global distribution cases, each agent $DisAgent_i$ can interact with other agents $\{DisAgent_k / k \in [1, nd], k \neq i\}$ and control agents $\{(WhoAgent_i)_j / j \in [1, nw_i]\}$, but a control agent can interact only with its distributor agents.

The unexpected order facilitator agent $DisAgent_i$, which communicates with control agents and other unexpected order facilitator agents, plays the same role of control agent. In addition, it provides the best solution of solving the rush unexpected order, which tries to minimize the total transportation costs. When a rush unexpected order (which characterized by: OQ and DT) is presented at the distributor$_{(i)}$, the manager asks the unexpected order facilitator agent $DisAgent_i$ to search the best solutions. At this moment, the agent carries out the algorithm "search_OQ" for solving the problem which can be summarized as follows:

- Search the RQ: it can be delivered completely by only one wholesaler or gathered from several wholesalers (1st type).
- Find and classify a series of possible paths in an ascending order depending on transportation cost (which depends closely on the distance) to transport OQ while respecting the delivery time DT.
- Propose quantity Q_j to be supplied by each participant belonging to a path.

Algorithm Search_OQ Constants'

- ($d_{k,j}$) distances (D matrix) and ($t_{k,j}$) times (T matrix) between wholesalers (where $1 \leq k,j \leq nw_i$ and nw_i is the total number of collaborative wholesalers of the distributor$_{(i)}$). (See Boxes 1 and 2.)

- (dd_j) distances (DD matrix) and (td_j) times (TD matrix) between distributor$_{(i)}$ and its wholesalers.

$$\mathrm{DD} \ = \ (\mathrm{ddj}) \ = (dd_1 \quad dd_2 \quad \ldots \quad dd_{nw_i})$$

$$TD(tdj) = td_1 \quad td_2 \quad \ldots \quad td_{nw_i}$$

- The Minimal quantities ($qm_{k,j}$) (QM matrix) of product which can be transported in the segments connecting the wholesalers (see Box 3).
- The Minimal quantities (qmd_j) (QMD matrix) of product which can be transported in the segments connecting the distributor$_{(i)}$ and its wholesalers.

Box 1.

$$\mathrm{D} \ = \ (\mathrm{dk,j}) \ = \begin{bmatrix} 0 & d_{1,2} & d_{1,3} & .... & d_{1,\mathrm{nw_i}} \\ d_{2,1} & 0 & & & \\ . & & 0 & & \\ . & & & 0 & \\ d_{\mathrm{nw_i},1} & & & & 0 \end{bmatrix}$$

Box 2.

$$\mathrm{T} \ = \ (\mathrm{tk,j}) \ = \begin{bmatrix} 0 & t_{1,2} & t_{1,3} & .... & t_{1,\mathrm{nw_i}} \\ t_{2,1} & 0 & & & \\ . & & 0 & & \\ . & & & 0 & \\ t_{\mathrm{nw_i},1} & & & & 0 \end{bmatrix}$$

Box 3.

$$QM = (qmk,j) = \begin{bmatrix} 0 & qm_{1,2} & qm_{1,3} & .... & qm_{1,nw_i} \\ qm_{2,1} & 0 & & & \\ . & & 0 & & \\ . & & & 0 & \\ qm_{nw_i,1} & & & & 0 \end{bmatrix}$$

$$QMD = (qmd_j) = (qmd_1 \text{ and } qmd_2 ... qmd_{nw_i})$$

- (ccp_j) coefficients of collaborative proximity (trust, levels of seniority,…) of each $(\text{wholesaler}_i)_j$ towards the $\text{distributor}_{(i)}$:

$$CCP = (ccp_j) = (ccp_1 \quad ccp_2 \quad ... \quad ccp_{nw_i})$$

```
Begin
// determine the customer's place
If (the customer is a collaborative wholesaler) Then
Its distances are defined (D, DD, T and TD matrices)
Else
Use the distances of the wholesaler nearest to the customer
End If
Read DT // the Delivery Time
Read OQ // the Ordered Quantity
Read DisQ // the available quantity which can be delivered by the distributor$_{(i)}$
RQ = OQ – DisQ // Deduce the Required Quantity
```

Send a message of performative *QUERY-REF* to control agents $\{(WhoAgent_i)_j \,/\, j \in [1, nw_i]\}$ (nw_i is the total number of collaborative wholesalers of the $\text{distributor}_{(i)}$) to ask them for its maximum quantities of product which they can deliver. The agents use the FIPA-ACL language (FIPA, 2002) for communication. QUERY-REF is the act of asking another agent to inform the requester of the object identified by a descriptor. Each control agent $(WhoAgent_i)_j$ replies by a message of performative *INFORM* indicating the maximum quantity $Qmax_j$ which can deliver (or a message of performative *REFUSE* in case of rejection).

```
Construct an empty list LWC // the list of wholesalers candidates
Do //loop 1
Do //loop 2
Read N // N is the maximum number of wholesalers including in a path. $N \in [1, nw_i]$.
Determine the list LWC of wholesalers candidates: $\{(WhoAgent_i)_j \,/\, j \in [1,t] \text{ and } t \le nw_i\}$.

/* If (N=1) then: $(WhoAgent_i)_j$ is candidate if it satisfies the constraint below :
    $Qmax_j \ge RQ$
If (N≥2): $(WhoAgent_i)_j$ is candidate if there exists at least N-1 $(WhoAgent_i)_{k \neq j}$ which belong to LWC and satisfy the constraints below :
-   (The sum of the quantity $Qmax_j$ and quantities $Qmax_k$) $\ge RQ$
-   $Qmax_j < RQ$
-   Each $Qmax_k$ is less than $RQ$
*/
While ((LWC is empty) AND ($N < Nu$)) // Nu is the unacceptable value of N. Nu depends on RQ.
//End loop 2
If ($N \ge Nu$) // the unacceptable value of N is reached
Then
```

```
Break and start a new research in same products
      distributors or equivalent products distributors (2nd type, 3rd type or 4th type).
End If
   Construct an empty list LPP // the list of possible paths
```

At this step, the agent must found a list *LPP* of possible paths and order it by transportation costs (in case of close solutions, the manager will use the coefficients of collaborative proximity (CCP_j)). It must also propose the quantity Q_j ($Q_j \in [Qmin_j, Qmax_j]$) for each wholesaler belonging to a path. A possible path is characterized by:

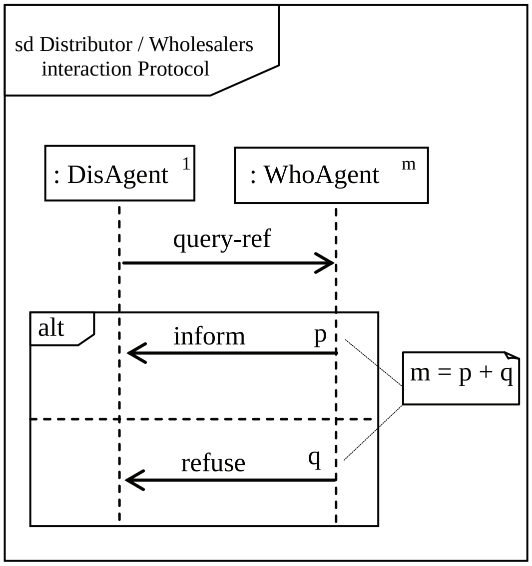
- Starting point ;
- Destination point (customer) ;
- It includes *N* wholesalers. Each wholesaler belongs to the list *LWC* and can deliver Q_j.
- It must satisfy the constraints below :

```
  If (the distributor$_{(i)}$ is included in the path)
      Then
    -   The sum of the quantity DisQ and quantities $Q_j$ must be equal to OQ.
    -   The time of path (TP) must be less or equal to the delivery time (DT).
  Else
    -   The sum of the quantities $Q_j$ must be equal to OQ.
    -   The time of path (TP) must be less or equal to the delivery time (DT).
  End If
  While ((the list LPP is empty) AND ($N < Nu$))
  // End loop 1
  If ($N \geq Nu$) // the unacceptable value of N is reached
  Then
  Break and start a new research in same products distributors or equivalent products distributors (2nd type, 3rd type or 4th type).
  End If
End //algorithm Search_OQ
```

Figure 3 shows the UML (Unified Modeling Language) sequence diagram (Bauer and Odell, 2005) that expresses the exchange of messages through the interaction protocol between the unexpected order facilitator agent $DisAgent_i$ and the control agents $\{(WhoAgent_i)_j \ / \ j \in [1, nw_i] \}$. These agents use other negotiation protocols (cf. section 5).

If no solutions are found (whenever an unacceptable value of *N* is reached) or the manager is not satisfied by the proposed solutions, the agent can interact with the unexpected order facilitator agents $\{DisAgent_k \ / \ k \in [1, nd], k \neq i\}$ of other distributors in order to find the best solution. In this case, the agent $DisAgent_i$ sends a message of performative *QUERY-REF* to all the collaborative unexpected order facilitator agents to find the *RQ*. Each agent applies his decision-making process in order to deliver the *RQ*. They can interact if necessary with the control agents to get the best solution. At the end, the unexpected order facilitator agent $DisAgent_i$ sorts all the received solutions. Figure 4

Figure 3. Distributor/wholesalers interaction protocol

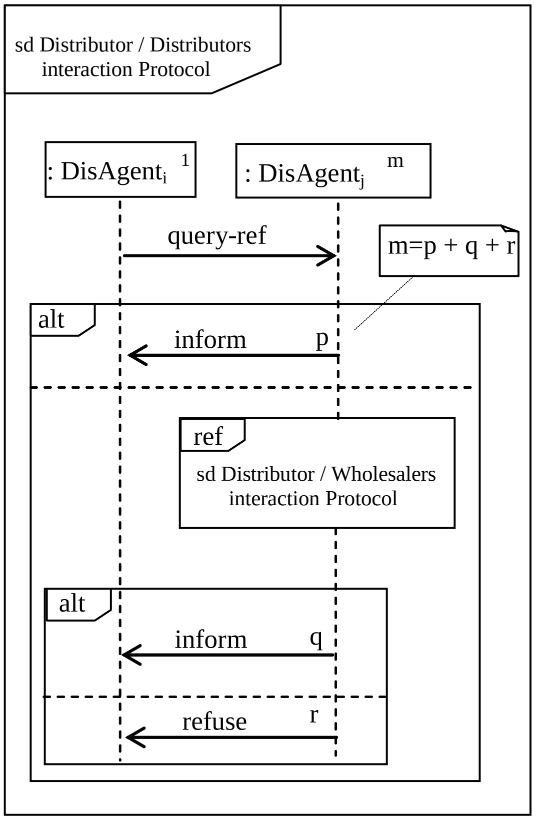


shows the UML sequence diagram that expresses the exchange of messages through the interaction protocol between the unexpected order facilitator agents of several distributors. These agents use other negotiation protocols (cf. section 5).

NEGOTIATION PROTOCOLS

In our distributed architecture, the agents use several negotiation protocols. The negotiation is the mechanism by which the agents can establish a common agreement. In the case of intelligent agents and of the MAS (Multi-Agent Systems), the negotiation is a basic component of the interaction because the agents are autonomous (Jennings, 2001); there is no solution imposed in advance and the agents must find solutions dynamically, while solving the problems.

Figure 4. Distributor/distributors interaction protocol



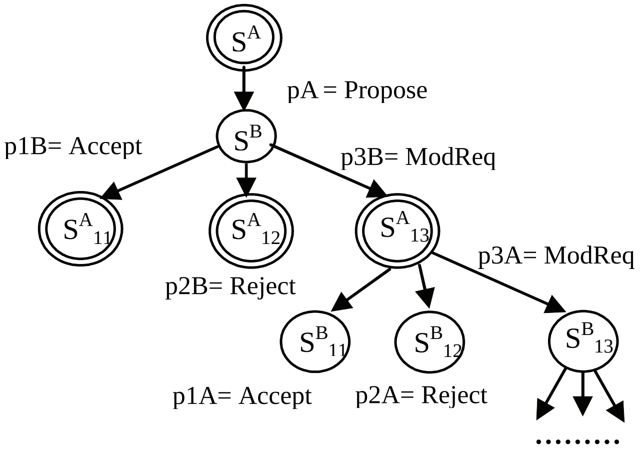
In the SCM process, the agents are co-operative, having the same goal (aggregation of the local objectives). They share and solve problems together. For this reason, the agents must provide useful reactions to the proposals that they receive. These reactions can take the form of a counterproposal (modified proposal). A counterproposal of an agent for a proposal is defined as the solution which is constructed by modifying the communicated proposal (Yoshida, 2007). From such reactions, the agent must be able to generate a proposal which is probably ready to lead to an agreement. Consequently, the agents of our system must use protocols respecting the criteria which have been stated above and that mainly depend on three parameters:

- The branch of supply chain sector (textile and clothing sector, consuming goods sector, etc.);
- SCM strategies and practices used for the companies' co-operation and coordination;
- Objects to be negotiated: rush order, ordinary order, sales forecasts, orders forecasts; modification of delivery plans in case of trouble, etc.

Heuristic Negotiation

The heuristic negotiation is shown in figure 5 (Florea, 2002). In this protocol several proposals and counterproposals can be exchanged in various steps. Agent "A", with proposal "pA", is the initiator of the negotiation, whereas the agent "B" (participant) can reply with the answers "p1B", "p2B" and "p3B" (to modify the request). The number of the counterproposals is limited. Once this limit is reached, the agents arrive to a rejection. We propose to recapitulate the heuristic negotiation protocol using an UML sequence diagram (Figure 6).

Figure 5. Heuristic negotiation



Proposal for a Firm Heuristic Negotiation

In some situations of negotiation, the collaborative agents must find an agreement. For this reason, the heuristic negotiation (cf. Figure 6) should include only ACCEPT-PROPOSAL or PROPOSE performatives (without the REFUSE performative). Thus, we propose the "firm heuristic negotiation protocol" which is a particular case of the heuristic negotiation. The word "firm" stands for this protocol since it always leads to an agreement. Figure 7 shows the sequence diagram that describes this protocol.

Proposal for a Recursive Heuristic Negotiation

The recursive negotiation protocol that we propose takes place at least between three agents, the initiator of the negotiation (sender), and the receiver who could become the initiator of a new heuristic negotiation with the third agent; hence the word "recursive" qualifying this heuristic protocol. Figure 8 shows the corresponding sequence diagram.

In our system, the recursive heuristic negotiation either belongs to a protocol corresponding to a SCM practice and strategy or corresponds to the negotiation of a rush order or scenario to be adopted in the case of disturbance (such as a disturbance of transport). In the general case, the negotiation takes place in the following way:

- The initiator of the negotiation sends messages (not necessarily identical) of type PROPOSE to all the direct agents (upstream and/or downstream) whom he thinks could be candidates in a negotiation. So, the initia-

Figure 6. Heuristic negotiation

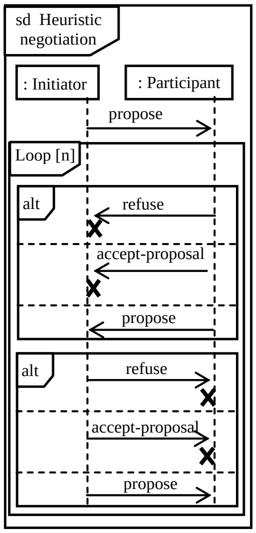


Figure 7. Firm heuristic negotiation

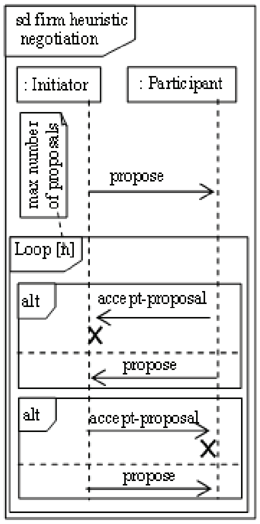

Figure 8. Recursive heuristic negotiation

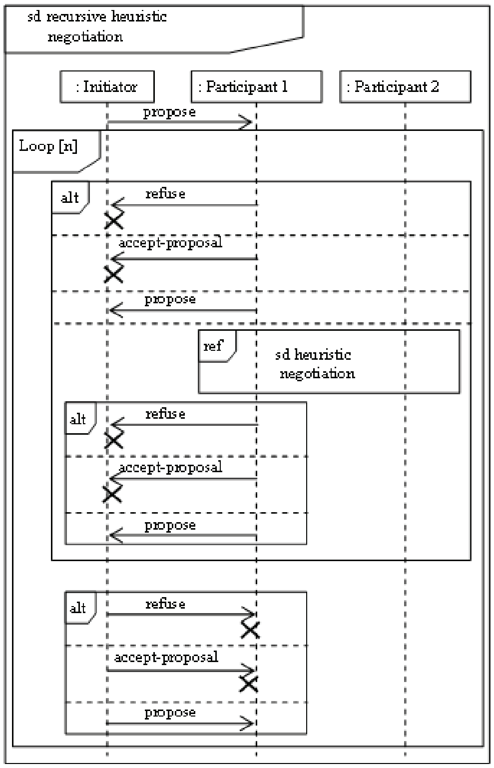

tor launches several independent negotiations. It does not wait for all the answers to make a decision. Moreover, according to the situation and the time interval, it can come up with the best solution by creating new proposals deduced from the received answers;

- Since the agents of our architecture are cooperative, each one of them - receiver of a message - can start a negotiation if necessary between other agents in order to find the best solution.

CASE STUDY: VALIDATION OF SOLUTION APPROACH

Description

A case study of the proposed agent-based distributed architecture is conducted at a leading distribution company in North Africa. The aforementioned company operates in the sectors of toilets and showers (washbasin, baths, etc.), taps, tiling, plumbing and pieces of furniture. It offers about 800 low-end and high-end items at both its wholesale and retail market locations which are geographically distributed throughout the region. The products are sourced from two national suppliers (Morocco) and two main foreign suppliers (Spain and Turkey). The distributor mainly manages three types of independent-demand inventory systems: Periodic Review system (sometimes called a fixed interval reorder system or periodic reorder system) (Baglin et al., 2001) which is used to manage the inventory of the high-end products sourced from the foreign suppliers; a new order is always placed at the end of each review; the Time Between Orders (TBO) is fixed at 6 months for high-end items of plumbing, and 1 month for high-end items of tiling. The reorder point system (or fixed ordering quantity system), which tracks the remaining inventory of an item (sourced from national suppliers) each time a withdrawal, is made to determine whether it is time to reorder. Demands are estimated from forecasts and/or customer orders. A sourcing-to-order is used for some items depending closely on taste and last fashion (like products of tiling, etc).

The distributor has noticed that, in the whole, there are 6 to 10 rush unexpected orders that could take place each month. Actually, it is a big challenge because the aforementioned orders do not concern the same product. At the average level, 60% of such orders are cancelled, 20% are made at other distributors, and the delivery time of the other 20% can be modified after a tough negotiation with the customer.

Example of an Emergency Situation

At the beginning of the month of January 2007 (the beginning of the low sales season), a real-estate operator (who already promised the delivery of the apartments to the customers at a precise time) must have closed the building site (located in Fez city) during one week in order to have the housing license agreement as soon as a high-end item required in the construction had been in shortage. This latter is due to the inventory shortage of this item at the distributor. Because of a problem in the supplying process mainly due to one of the foreign suppliers, the next planned delivery of this item has been backlogged. In addition, the required high-end item cannot be supplied from other distributor because the aforementioned distributor is the only exclusive actor of such product. This order placed during the first week of the month was regarded as an unexpected firm rush order (delivery time: 9 hours; and it can neither delayed nor cancelled).

Adopted Solution

In this emergency case, the distributor was compelled to place an order of an equivalent item (brand, color…) at another competitor distributor located in Casablanca city (289Km from Fez city). Even if the costs were high, the distributor was interested to attract and retain the real-estate operator.

Solutions Provided by the Proposed System

In order to show the effectiveness and usefulness of the suggested architecture, we have made use (as a tangible demonstration) of the aforementioned item inventory level history of 37 wholesalers distributed throughout the country (Table 1). They are identified by scm1, scm2… scm37.

Figure 9 shows three of 13 existing solutions (paths and quantities) proposed by the unexpected order facilitator agent, according to the value of the number of wholesalers involved in each path. This number is chosen by the manager (Figure 10). Figure 11 shows only the first three paths. In the Figure 9, Qmin is the minimal quantity of product which can be transported in a segment connecting a wholesaler and the next wholesaler in the same path.

Results and Discussions

We notice that even if the required quantity cannot be delivered completely by only one wholesaler, it can gathered from both wholesalers scm26 (Ourzazate) and scm23 (Marrakech). This solution is not appropriate since the distance of the path is 687km. Indeed, the costs of transportation will be high.

The distributor has 12 choices concerning the paths including 3 wholesalers. The time of the first three paths are almost equal to half of the required delivery time. The distances (323km, 343km) of the first two paths (Tetouan, Chefchaouen, Meknes, Fez; Tanger, Tetouan, Chefchaouen, Fez) are about 289km (distance between the competitor distributor and the customer). Certainly, these two solutions are better than the adopted solution, at least for two reasons:

1. The costs of transportation will be almost the same;
2. The purchase prices offered by the collaborative wholesalers (involved in the same

supply chain) are lower than the offered prices from the competitor distributor.

We deduce that the distributor had three solutions better than the adopted solution. We can conclude that more the number of actors constituting a path and the required quantity are large, more the number of choices is important.

In practice, several emergency situations exist and depend closely on the branch of supply chain sector.

Implementation

The prototype has been implemented using JADE (Java Agent DEvelopment Framework) from CSELT, Turin, Italy. JADE is a middle-ware that

Operating system	Windows XP

could be used to develop agent-based applications in compliance with the FIPA specifications for inter-operable intelligent multi-agent systems (Bellifemine et al., 1999). JADE is java-based and provides the infrastructure for agent communication in distributed environments, based on FIPA standards. Table 2 shows our implementation environments for the prototype.

CONCLUSION AND FUTURE WORK

In this paper, we presented an agent-based distributed architecture for collaborative decision-making processes within the global distribution supply chain. We proposed a process (thanks to the multi-agent properties) for a best management of the rush unexpected order. At this stage, the architecture is validated and tested on a leading distribution company. The results are very promising and show that our proposed system could be connected to the existing SC tools. In this case, enterprise application integration assumes a great importance. Enterprise Application Integration (EAI) enables an enterprise to integrate its existing applications and systems and to add new technologies and applications to the mix.

In the next stage of this work, we will take into account the size of the transported batches, i.e. to represent the price of transportation per unit of product as being lower when the transported quantity is large. In this case, it will be necessary to seek the quantities which optimize the costs of transportation (we intend to use a genetic algorithm). Then, we will extend our architecture in order to use it in the global manufacturing supply chain (including manufacturers, suppliers…).

Chapter 2.18

Effective DMSS Guidance for Financial Investing

Guisseppi A. Forgionne
University of Maryland, Baltimore County, USA

Roy Rada
University of Maryland, Baltimore County, USA

ABSTRACT

Investment decisions have a significant impact on individuals, groups, organizations, the economy, and society. As a result, many formal methodologies and information systems have been designed, developed, and implemented to assist with financial investing. While these tools can improve decision making, none offer complete and integrated support for financial investing. This article seeks to close the support gap by offering a theoretical decision making support system for financial investing and illustrating the system's use in practice. The demonstration indicates that the theoretical system can improve the process of, and outcome from, investing.

INTRODUCTION

Financial decisions are some of the most challenging and important decisions made daily by individuals, groups, organizations, and other entities. These decisions are complex and, at best, semi-structured, and the selected actions will have a substantial impact on the well-being of these entities, in particular, and the economy, in general.

A large amount of available quantitative data support financial decision making, and many rigorous models capture financial phenomenon (R C Merton, 1995). Various information systems are available to deliver the model's embedded expertise to the investor (C. Zopounidis & M. Doumpos, 2000). Vellido et al (1999) reviewed neural network applications in finance, concluded that the literature is rich with neural network applications, and suggested that future work should explore the combining of knowledge-based techniques with neural network techniques. A review of articles on the subject of finance in the journal *Expert Systems with Applications* highlighted a pattern of knowledge-based work in the 1980s and early 1990s and machine learning work from the mid-1990s till now (Roy Rada, 2008).

Yet, most of the models, and thereby the information system delivery, focus on an aspect of the financial situation and typically are tailored to specific categories of investors. Such a fragmented and incomplete approach to financial analysis may not provide the investor with the specific and precise guidance needed for effective decision making in practice (Bob Berry, 2004).

This article examines the issue of effective guidance for financial investing. First, the relevant literature is reviewed. Next, the financial investing approaches inspired by this literature and the pertinent decision support gaps in the approaches are identified. Then, the article offers a decision making support system that can close the support gaps and provide specific and precise guidance for financial investing in a complete and integrated manner. The article concludes with an examination of the implications for financial decision making, in particular, and for financial engineering, in general.

FINANCIAL ENGINEERING

Financial investing may be seen as a three step process of collecting data about assets, evaluating assets, and buying and selling assets into and from a portfolio. Usually, investors will seek professional advice to assist in the investment process. Typically, the professional's organization employs technical experts, or financial engineers, to develop tools that help financial professionals in the advisement process.

Financial engineers, broadly speaking, design new financial instruments and create solutions to financial problems. In particular, financial engineering includes these four areas (J M Mulvey *et al*., 1997):

1. Corporate Finance (new instruments to secure funds, engineering takeovers and buyouts)
2. Trading (develop dynamic trading strategies)
3. Investment Management (repackaging and collaterization)
4. Risk Management (insurance, hedging, and asset management)

Risk management may in turn be decomposed into (J M Mulvey et al., 1997):

- strategic asset management (via multi-stage stochastic optimization) and
- operational asset management (via immunization models).

Often, financial engineering is accomplished with the assistance of optimization, statistical, and econometric approaches. Sometimes, these approaches assume the problem is well-posed and has a single objective. Financial decisions, however, could involve:

- the existence of multiple criteria,
- conflicts among criteria,
- ill-structured evaluation, and
- political and social factors involved with human decision-making.

Management scientists, economists, and others have developed additional models to deal with these financial complexities.

Investors and the investment professionals typically do not have the knowledge about, or interest in, the financial models to effectively utilize these tools in practice. Consequently, financial engineers, and information systems professionals, have developed information systems designed to deliver the available financial models to the investors and investment professionals (C. Zopounidis & M. Doumpos, 2000). The most efficient and effective delivery vehicle for such a purpose is the decision making support system (DMSS).

FINANCIAL DECISION MAKING SUPPORT

Decision-making Support Systems (DMSS) are computer-based information systems that support individual, group, or organizational decision-making processes in an interactive manner. Depending on the supported decision making phases or steps supported, a DMSS may take the form of a Decision Support System (DSS), Executive Information System (EIS), Expert System (ES), or some integrated combination of the functions delivered by a DSS, EIS, and/or ES (G Forgionne *et al*., 2005)

For example, recent advances in information technology and artificial intelligence could be used to enhance DSS or EIS processing, giving rise to Intelligent-DMSS (IDMSS) (Jatinder Gupta *et al*., 2006). The support rendered in an IDMSS can occur at four levels (B Roy, 1996):

1. Determine object of the decision
2. Analyze criteria
3. Model preferences
4. Develop recommendations

This support often is achieved through the delivery of operations research methods such as:

1. multi-objective mathematical programming
2. multi-attribute utility theory
3. outranking relations, and
4. preference disaggregation analysis.

Each of these methods has been applied to a rich variety of financial problems. For instance, multi-objective mathematical programming was applied to the investment problem of fund allocation among shopping malls (R Khorramshahgol & A A Okoruwa, 1994), and multi-attribute utility theory was used to assess sovereign risk (J C S Tang & C G Espinal, 1989).

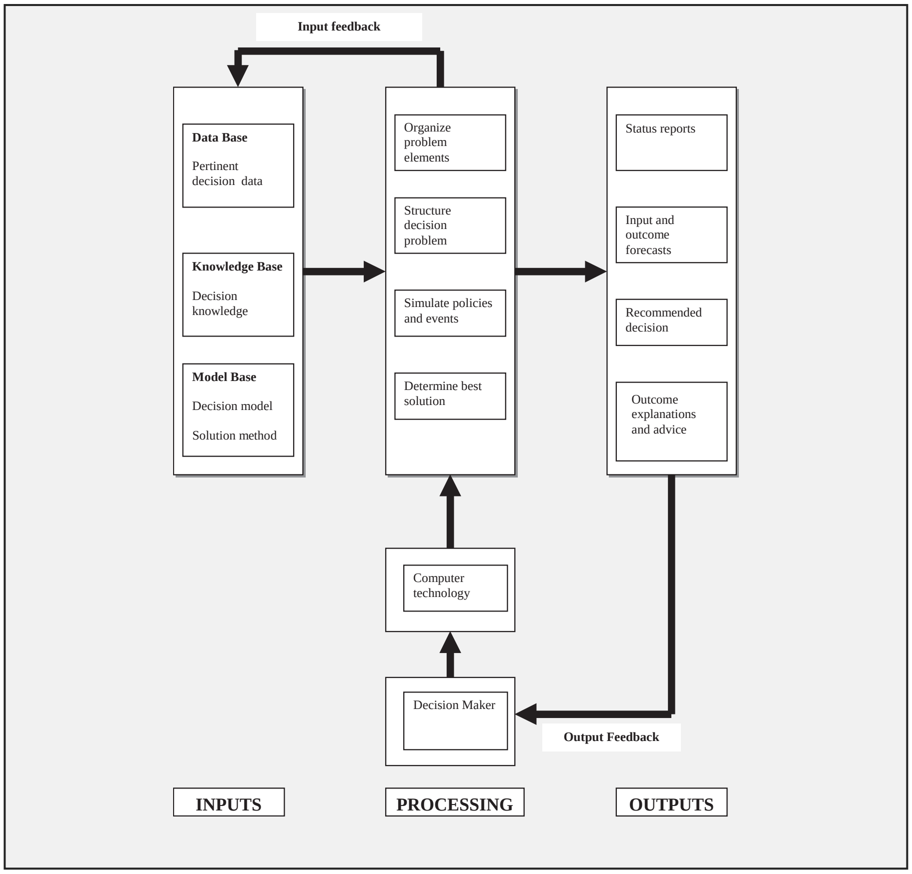
Decision Making Support System Architecture

Decision making support systems (DMSS), regardless of their specific form, generally will have the architecture shown in Figure 1. As this figure shows, DMSS inputs include a database of pertinent decision data, a knowledge base of decision knowledge, and a model base that contains a model of the problem and an appropriate solution method. Knowledge may be represented as production rules, semantic networks, frames, or in some other way.

The decision maker utilizes computer technology to access the various input bases and execute the processing tasks of organizing problem elements, structuring the problem, simulating policies and events, and finding the best problem solution. This decision maker controlled processing usually is called the dialog management system and is the mechanism that makes a DMSS interactive. Processing generates status reports on the problem elements, forecasts of inputs and outputs, recommended decision actions and strategies, and explanations for the recommendations.

Processing may be assisted through artificial intelligence methodologies. For example, expert system and case-based reasoning functionality can help decision makers access data and models, infer relationships, and interpret outputs (G I Doukidis, 1988). Machine learning can be used to generate forecasts of problem elements, and natural language and vision processing can facilitate dialog management.

Figure 1. General decision making support system architecture



Feedback loops from outputs to the decision maker and from processing to inputs indicate that DMSS processing is dynamic and continuous in nature. Outputs may suggest further decision maker processing, and processing may create new or additional data, knowledge, models, or solution methods relevant for future processing.

A specific DMSS may have all or parts of this general architecture. For example, an IDMSS would have a knowledge base, but a DSS would not. Moreover, the content of the data, knowledge, and model bases and the processing tasks may differ from one DMSS to another. For instance, an EIS model base may contain data mining and statistical models, while a DSS model base may require an economic, accounting, or management science model. Similarly, an EIS may not find a best problem solution, while optimization may be the dominant task in a DSS.

DMSS in Finance

A number of Decision Making Support Systems have been applied to finance. An example of an expert system for finance is the FINEVA system (N.F. Matsatsinis *et al*., 1997**.** FINEVA has a knowledge base about assessing companies for financial viability. It has hundreds of rules which operate on input of financial ratios from financial statements. The system also interacts with the user to collect qualitative data about the management of the companies that are being assessed. The financial ratios that are considered are those which experts have said they typically use (and correspond generally to what the textbooks say are relevant ratios), such as the Quick ratio. The rules (as the ratios) are grouped into categories of profitability, solvency, managerial performance, and qualitative criteria. The rules connect with each other in a hierarchy. For instance, some rules look at debt ratios and some other rules look at liquidity ratios. The rules for debt and liquidity ratios are combined at a higher level into rules about solvency.

If one takes the area of machine learning and looks at recent examples of applications to finance, one can find a host of integrated techniques, and model them in various ways. The following studies illustrate the mixture of machine learning techniques with representational issues and diverse approaches to financial problem solving:

- Lam and Ho (Wai Lam & Kei Shiu Ho, 2001) used knowledge about stock valuation to support natural language processing of financial news articles. Their system learned through experience and was intended to identify data for an asset valuation system.
- Chen and Chen (A.P. Chen & M.Y. Chen, 2006) semi-manually took rules from experts and other sources, and then their genetic algorithm integrated those rules to predict values of a stock market index. Dhar and Chou (V. Dhar & D. Chou, 2001) prepared rule templates for their genetic algorithm that were specific to knowledge of the domain. For instance, their system might have been initiated with a rule such as "if the ER index is greater than the Pth *percentile*, and the *N day industry trend* exceeds *S standard deviations,* then the company will deliver *an earnings surprise of type T.*" The genetic algorithm was expected to find useful values for P, N, S, and T. Lajbcygier (P. Lajbcygier, 2004) incorporated the Black-Scholes options pricing model into the representation of his hybrid neural network.
- In the buying and selling of currencies, a natural symmetry exists that Bhattacharya et al (S. Bhattacharyya *et al.*, 2002) exploited to constrain the combinations of logical and numerical operators that their genetic program generated. Tsakonas et al (A. Tsakonas *et al.*, 2006) used neural logic networks that they argued were intrinsically suited for finance, and they constrained their genetic programming method to only produce syntactically correct neural logic nets.
- Dempster and Leemans (M.A.H. Dempster & V. Leemans, 2006) added a knowledge-based financial portfolio management layer to their neural network price predictor.

Substantial work has been done on the subject of computer systems to evaluate assets. Machine learning methods have been employed to fine tune the numerical parameters of asset valuation programs. However, too little work has been done on the subject of representing financial knowledge in such a way that a machine learning program can make meaningful changes in the asset valuation program beyond the level of numeric parameters. One of the few such papers (Bhattacharyya, Pictet, & Zumbach, 2002) showed how symmetry in financial markets could be exploited by a learning program.

Incomplete and Fragmented Support

Each of the reported Decision Making Support Systems, and thereby the delivered decision technology, focuses on a specific aspect of financial investing. System inputs, processing, and outputs will be limited to this aspect. For example, a DMSS designed to support asset valuation will have a data base of the pertinent asset information, an appropriate asset evaluation model and solution methodology, and perhaps some asset valuation knowledge. Processing will structure the evaluation model, simulate asset values, and generate forecasts of the asset values.

To support the entire financial decision making process, then, it would be necessary to have a more complete DMSS than has been offered in the literature or known practice. One possibility is to have several decision making support systems for financial investing. Such a fragmented approach, however, would require linkages between disparate systems that may have different data formats, various modeling approaches, and different computer software and hardware platforms. This fragmented approach also would negate the potential synergistic effects achievable from integrated decision making support systems (G Forgionne, 2000). The fragmented approach also would involve more time and cost for design, development, and implementation than the integrated approach and be less user-friendly than one integrated and complete system, like the architecture offered in Figure 1.

There is also a practical difficulty with incomplete and fragmented DMSS for finance. Most investors and practicing financial advisors will be unaware of the available decision making support or lack proficiency in DMSS usage. When there are multiple support tools available, the practitioner's lack of awareness and knowledge will necessitate education and training across several support tools and require personnel to provide such education. These impediments could deter practitioners from seeking the desired support and/or lead to inappropriate financial decisions.

The potential technical, economic, and practical problems can be alleviated, or even eliminated, by instantiating Figure 1's architecture for financial investing. Such instantiation can provide an effective and efficient decision making support system for financial investing.

DMSS FOR FINANCIAL INVESTING

Much data are potentially useful for financial investment analysis. Such data would include:

- qualitative information, such as the quality of management and a firm's reputation,
- stock market data, such as stock price and dividend yield,
- macroeconomic data (interest rates, exchange rates, inflation rates), and
- finance statements (balance sheets, income statements).

In addition, various models could assist a financial decision maker. Existing financial models include:

- financial accounting statement frameworks,
- economically-based financial and stock market ratios,
- portfolio theory models, and
- capital asset management models.

Existing statistical methods include descriptive methodologies, such as correlation, and inferential methods, such as principal components analysis. In addition, decision analysis can provide multiple criteria methods for implementing the financial theories, both for evaluating stocks and composing a portfolio. For instance, while the financial statement models speak to the features of attractive stocks, decision analysis can be used to identify a desirable set of stocks.

In any given circumstance, however, only a small portion of the available data will be pertinent to a specific investor's needs. Moreover, some statistical, economic, or accounting analysis may be needed to synthesize the available data and focus the results for the investor's needs. Similarly, the investor's situation may not require all available financial models and supporting decision technologies. As with the data, then, model filtering and focusing may be necessary.

Warehousing and Marting

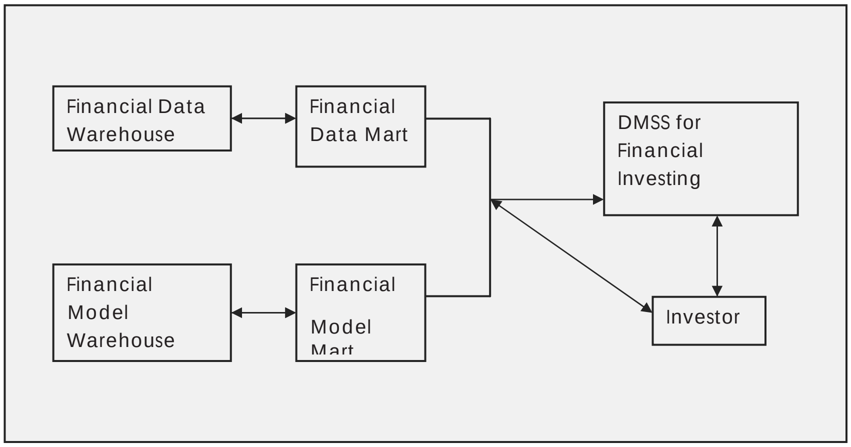
To support the range of needs likely to be encountered in financial investing, it would be useful to create warehouses of potentially relevant financial data and models. The financial data warehouse would draw from available external financial information data sets, such as those available from Standard & Poor's (www.standardandpoors.com) and Bloomberg (www.bloomberg.com), and internal sources, such as an organization's accounting ledgers, to form a repository of potentially relevant data for financial analysis. Similarly, the financial model warehouse would serve as a repository for reported theoretical financial analysis methodologies and methods and reported practice-based investment heuristics and methodologies.

Such data and model warehousing would become a primary activity in financial engineering, much as data warehousing has become common in information systems operations for modern organizations (Michael Mannino *et al*., 2008). Internal accounting transactions captured by information systems data warehouses also can, and often do, provide pertinent data for financial analyses (Arlen Khodadadi *et al*., 2006).

To meet the investment needs of a specific investor, pertinent data could be viewed in the financial data warehouse, and relevant models could be viewed in the financial model warehouse. Relevance could be defined interactively by the investor, predefined from the investor's financial profile and implemented through artificial intelligence, or be determined dynamically by artificial intelligence adjusted interactively by the investor. The views would form virtual data and model marts for the investor. Once the views are accepted by the investor, the accepted data could be extracted from the financial data warehouse to form the investing DMSS database. Similarly, accepted model views could be extracted from the financial model warehouse to form the investing DMSS model base. Captured views and extractions form the pertinent problem knowledge for the investing DMSS knowledge base.

Figure 2 illustrates the financial warehousing and marting process for the specific financial investment support. As this figure demonstrates, the investor-controlled data and model marting process ensures that the investing DMSS data, model, and knowledge bases are populated only with filtered and focused information directly relevant to the specific investor's financial inter-

Figure 2. Financial warehousing and marting relationship to DMSS for investing



ests and needs. Such filtering and focusing also means that the DMSS bases are likely to be small in volume but dynamic in nature and reflective of the investor's changing preferences as new knowledge is gained. Figure 2 also makes it clear that the investor, either directly or through a professional financial advisor, controls the financial marting process, either unassisted or with the aid of artificial intelligence.

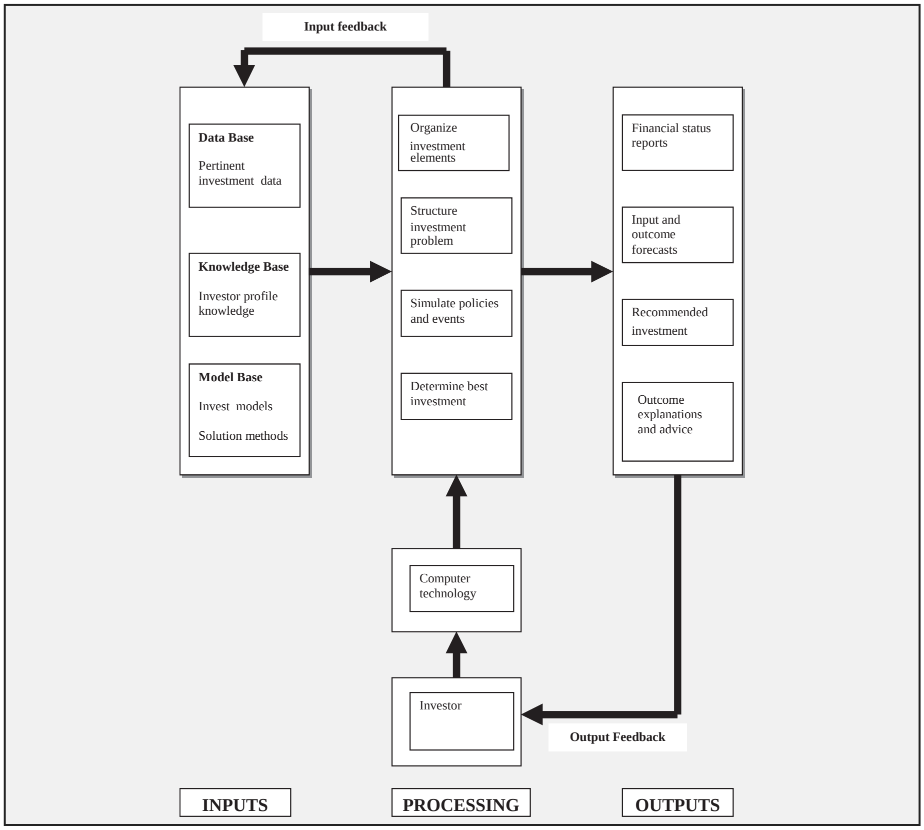
DMSS Architecture and Operations

In a typical scenario, the investor engages in a financial decision making process. Initially, the investor analyzes securities and identifies the subset of securities deemed worthy of investment. This analysis and identification corresponds to Simon's intelligence phase of decision making. Next, the investor develops a formal or informal evaluation model, consisting of financial performance measures, alternative investments, and economic and other events, and the relationships between these factors. Such modeling constitutes Simon's design phase of decision making. Then, the investor utilizes the designed investment model to determine the amount invested in the identified securities. This selection corresponds to Simon's choice phase of decision making.

While the financial decision making can be very dynamic in nature, the process is iterative. Design cannot occur without intelligence, and choice cannot precede design.

The decision making support system for investing, shown architecturally in Figure 3, can support the financial decision making process in a complete and integrated manner. As this figure shows, the DMSS for investing has a data base that consists of the financial information

Figure 3. DMSS for investing architecture



gleaned from the investor-controlled data marting illustrated in Figure 2. This marting also creates the investor profile that, along with any other previously captured investor-relevant facts and factual relationships, populates the DMSS knowledge base. Similarly, Figure 2's financial model marting generates the investor-relevant models and model solution methods captured in the DMSS model base.

The investor uses workstation-based computer technology and custom software to control the DMSS processing. Initially, the system offers a list of securities currently available for investment, and obtained from the financial data warehouse as part of the financial data marting illustrated in Figure 2. This listing supports the investor's intelligence phase of decision making. As the top feedback loop in Figure 3 demonstrates, the listing will be dynamic and recursive in nature, with the new data and knowledge captured in the system's databases and knowledgebases for further processing.

After obtaining the investor's desired list, the DMSS prompts the investor for her/his/their desired performance measures. These measures, pertinent uncontrollable inputs (such as economic indicators and organizational qualitative information), captured from the financial data marting, and investment models captured during financial model marting will be used by the DMSS to structure the investment problem. This structure will explicitly and precisely establish the relationships between the invested-specified performance measures, listed securities, and uncontrollable factors. During the structuring, pertinent parameters from the system's data base, and perhaps further estimated through statistical and other analyses, will be attached to the investor's specified model by the DMSS. The structuring, which supports the design phase of decision making, is likely to be assisted with artificial intelligence methods stored in the system's model base. As with the organizing of financial information, the structuring will be dynamic and recursive in nature with the new knowledge and models captured in the system's knowledge and model bases for further processing.

The DMSS will select from the model base, perhaps through artificial intelligence assistance, the solution methodology best suited to the investor's specified model. Depending on the model and selected methodology, the system will either simulate the outcomes from selected securities under specified financial conditions or recommend the portfolio that best meets the investor's stated performance measures. Since the results were generated from an explicit and precise model of the investment problem, the DMSS can provide a detailed explanation for the recommendations and advice by tracing the logic in the model's equations or other relationships. As indicated by the bottom feedback loop in Figure 3, the generated forecasts from the simulations or recommendations from the model optimization will be performed in a dynamic and recursive manner conducive to confidence building on the part of the investor. The simulations and/or optimizations support the choice phase of decision making.

Theoretical Methodolgy

The proposed decision and information technology and decision making support architecture have been developed and applied successfully to a closely related problem (Forgionne, 1997). In the approach, investor needs will be identified from a dialog session between the investor and the prototype system. Predefined production rules will map the selections to appropriate captured financial model components. The research also will explore the use of neural networks to refine the predefined production rules and the potential use of fuzzy logic as a knowledge representation scheme alternative to production rules for the mapping process. Intelligent agents, with encapsulated statistical, management science, accounting, and economic knowledge, will join the relevant captured model components to form a model specific to the investor's needs. Other intelligent agents search for the data pertinent to the investor's model from captured data warehouses and data marts, use appropriate statistical methods on the gleaned data to estimate the model's parameters, attach the estimated parameters to the investor's specific model, perform an appropriate model analysis, and report recommendations to the investor. The investor then can either accept the recommendations or request additional analysis through pertinent dialog with the prototype system. Further requests dynamically trigger model modifications, analyses, and new recommendations.

It should be clear that the successful operation of the theoretical DMSS for investing is based on strong supporting financial data and model warehouses. This link suggests that the methodology for developing the theoretical DMSS should follow the process outlined in Figure 4.

Professional organizations already gather much financial data, and the academic and practitioner literature reports many financial models. Moreover, there are several financial data warehouses in professional investment firms and other organizations, some of which may be available to investors (Hsin-Ginn Hwang *et al*., 2004). Still, the available warehouses may be incomplete and fragmented. Model warehouses are rare and usually not available to investors (I. Belov *et al*., 2006).

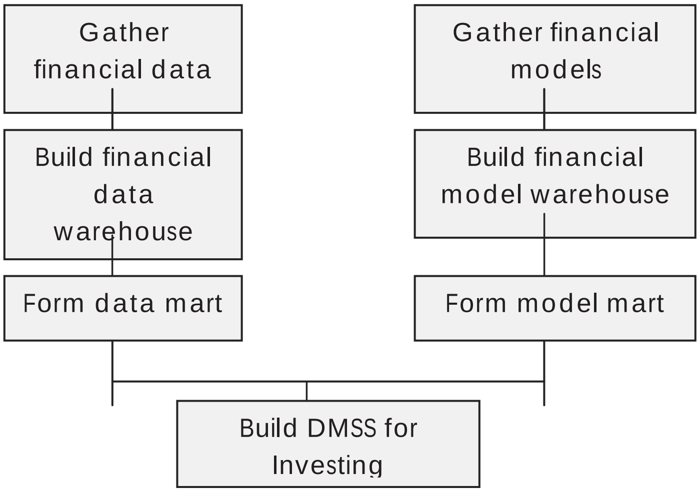
Financial data and model marting are underdeveloped areas and will be specific to the investor. The DMSS for investing, of course, is just a theoretical concept at this point. There are many information and decision technologies available and in use that could be adapted to these tasks (Shu-Heng Chen, 2006; Shu-Heng Chen & Paul P Wang, 2004).

ILLUSTRATIVE EXAMPLE

The implementation of the DMSS for investing concept will be specific to an investor with a particular financing problem. This concept, however, can be illustrated with the aid of an ongoing research project. In this research project, data, models, and knowledge (as suggested in Figure 3) have been identified and preliminary experiments are being done with a prototype iDMSS that is called the Intelligent Investing System (IIS).

IIS would ultimately include data from various asset classes, as well as macroeconomic information. Some of the asset classes would include

Figure 4. DMSS for investing development process



stocks, bonds, commodities, and real estate. The first prototype considers only stocks and relies on the licensed data set called Compustat from Standard & Poor's. Macroeconomic data sets have been identified on the US Department of Treasury site.

For the model base, the program attempts to collect, formalize, and categorize relevant financial models that look across entities and across time at one entity. For across-entity analysis, the thresholds and rules that are applied to financial ratios of (N.F. Matsatsinis et al., 1997) have been implemented. Those thresholds and rules are used to identify company financial viability based on the latest financial ratios. For modeling financial statements across time, IIS includes an implementation of the forecasting model presented in (Chandan Sengupta, 2004). The forecasts cover not only financial statement items, such as sales and long-term debt, but also stock data, such as stock price and dividends. With the dividend forecasts, the IIS can reach into the model base, grab the Dividend Discount Model, and further value a stock based on the forecast dividends.

For portfolio management, IIS includes various implementations of the optimally efficient portfolio. Particularly useful has been the method delineated initially by Merton (Robert Merton, 1972) as implemented in a spreadsheet by Holden (Craig W Holden, 2005). IIS also includes an implementation of the optimization technique presented in (William Sharpe, 2007). The single index approach to computation of the covariance matrix is also available to IIS.

The knowledge base provides guides for problem solving. For instance, when thousands of stocks are being considered, the computation of the covariance matrix is not practical because it requires the covariance to be laboriously computed for every pair of companies. The amount of computation can be reduced from being proportional to the square of the number of companies to being linear in the number of companies by using the simplifying assumption about the stock index. Accordingly, when the portfolio weights on more than one hundred stocks are to be computed, the portfolio optimization routine might use the index model.

More innovative examples of the knowledge base at work concern modifications to the forecasting based on financial statements. The knowledge base knows which aspects of the model of financial statements might be refined in which ways. The financial statement models have different types of components; for instance,

- Some relationships in the model are true by definition and entirely enclosed within the financial statement, such as "gross operating income = sales - cost of goods sold".
- However, other relationships in the model may be elaborated. For instance, interest expense approximately equals (short-term interest rate * short-term debt) + (long-term interest rate * long-term debt). Independent forecasts of interest rates can be obtained and connected to the financial statement forecasts. Furthermore, long-term debt is not strictly a single long-term interest rate times a single long-term debt quantity but is rather a complex function of the portfolio of company borrowings which also can be further investigated by IIS.
- Other relationships in the financial model may or may not apply to a particular company, depending on the company. For instance, some companies want to manipulate debt and equity to achieve certain target proportions. If the company has such a goal, then what its target proportions may be is not fixed across companies.

IIS formalizes these relationships so that the system can manipulate the model and test the impact on forecasting accuracy.

The knowledge base includes both financial-type data, such as industry classification of a company, and computational knowledge. The preceding description of the role of the index model in supporting fast computation of portfolio weights illustrates computational knowledge. However, a deeper example concerns knowledge about various functions that can be used to fit data. For instance, the financial statement forecasting will experiment with linear, polynomial, exponential, and sinusoidal functions to see which best captures certain time series in the financial statement.

The reasoning may be seen as occurring in the Processing Phase of the IIS (recall that Figure 3 shows an input phase, a processing phase, and an output phase). The user presents to IIS the user's investment constraints including the amount of money to invest, the amount of risk to take, and the types of asset classes preferred. The IIS then operates with this information and the data, models, and knowledge. In the processing phase, the IIS engages in extensive back-testing of its tentative recommendations. Compustat provides several decades of data which can be exploited to test hypotheses about assets relative to past performance.

Given that appropriate models to apply to a company's financial statements will depend among other things on the industry classification of the company, the IIS classifies a financial statement by the industry classification of the company and looks for similarities in models based on industry sector. Compustat classifies companies into the Global Industry Classification Standard (GICS), which consists of 10 sectors, 24 industry groups, 62 industries and 132 sub-industries. Reasoning is performed on the GICS structure to determine the appropriate level of generalization depending on the problem at hand.

The companies likely to produce the greatest surprise to investors are those companies which least fit any of the standard models. IIS would continually refine its modeling and backtest. A company whose data resisted being modeled would be further investigated.

The IIS also uses machine learning, particularly evolutionary computation. In IIS, the genetic algorithm has been used to experiment with the role of knowledge in financial asset evaluation, as suggested by (S. Bhattacharyya et al., 2002), and neural networks have been used to refine criteria, as suggested by (A. Tsakonas et al., 2006).

The IIS prototype has been developed in Excel 2007 with Visual Basic for Applications (VBA). The VBA code inserts commands in the worksheets which in turn invoke Compustat and download financial data. The VBA modules also enter formulas into the worksheets which indicate the relations among the data and ultimately are responsible for the asset valuation and portfolio management. Excel was chosen for the prototype for several reasons:

- many financial investors use Excel,
- existing financial models have often been implemented in Excel and thus can be imported into IIS,
- Excel has a large library of financial functions embedded within it,
- output in Excel is easily made visually appealing and the output can include simultaneously the number plus the formulas which computed the numbers (and users can select to immediately see the computation behind the number).

Future prototypes might connect other tools to Excel.

CONCLUSION

Financial investing is a very important problem that has a significant impact on individuals, groups, organizations, the economy, and society. While much wisdom and knowledge has been offered to guide investments, the support has been incomplete and fragmentary. This article proposes the DMSS for investing as a tool to improve support and suggests a methodology to develop the tool.

At this point the proposed system is conceptual and requires further system development. There is a need to: (a) establish a development plan and methodology, (b) identify software to implement the concept, (c) use the software to develop the system and implement a prototype, (d) utilize the prototype to test the efficiency and efficacy of the plan, and (e) establish an implementation plan.

The concept also establishes a theory that the DMSS for investing can improve financial decision making by offering complete and integrated support and guidance for the process. This theory suggests the following research question and hypotheses:

- **Research Question:** Can the DMSS for investing improve the process of, and outcomes from, financial investing?
- **Null Hypothesis:** The DMSS cannot improve the process of, and outcomes from, financial investing.
- **Alternative Hypothesis:** The DMSS can improve the process of, and outcomes from, financial investing.

The question can be answered by designing studies that will compare the process results and outcomes from DMSS for investing usage with the corresponding results and outcomes from existing forms of human and system guidance. There are a number of process and outcome measures from the literature that can be used in these studies (G Phillips-Wren *et al*., 2006). The studies can be executed through experimental approaches or by other means.

Chapter 2.19

Exploring a UML Profile Approach to Modeling Web Services in Healthcare

Wullianallur Raghupathi
Fordham University, USA

Wei Gao
Fordham University, USA

ABSTRACT

The Web services paradigm offers numerous potential benefits to the health care area. These include interoperability, portability, scalability, and compliance with universal standards. However, development of large-scale Web services applications in health care is relatively scarce. Multiple challenges are slowing the diffusion of information technology practices in health care, starting with the absence of modeling tools and methodologies that are the bases for building such technology. This article describes a UML profile approach to developing Web services applications in the health care area, emphasizing the use of such extensions as stereotyping and tagging to model the unique elements of health care processing. We apply these ideas to a health clinic example. From here, one can imagine building incrementally upon these ideas to develop frameworks for Web services applications in health care. The benefits would enhance the overall quality of health care delivery and lower costs.

INTRODUCTION

Web services are self-contained, Internet-enabled applications capable not only of performing healthcare-related activities independently, but also possessing the ability to engage other Web services to complete higher-order business (health) transactions (Papazoglou & Dubray, 2004). The key is modularity characterized by open standard and internet-oriented interfaces. Examples of such patient services include verifying appointment availability, producing a bill, ordering lab tests, prescribing medication, and discharge planning. The platform-neutral nature of Web services (Kreger, 2001) creates the opportunity for building composite services using existing elementary or complex services, possibly offered by different service providers (Meredith & Bjorg, 2003; Yang, 2003). On a larger scale, these services can be considered a set of interoperable technologies and standards, designed to support the integrating of several autonomous and heterogeneous systems. Web services are particularly geared toward the service-oriented computing paradigm, which can be considered a collection of services, coordinating, and communicating with each other to support a system's specific function or concept. Service-oriented computing has the potential to be the healthcare industry's new foundation for distributed systems and internet-based processing. Web services specifications, such as SOAP, WSDL and UDDI, facilitate open, XML-based methods to support application interoperability, service description, and service discovery (Estrella, McClatchey, Rogulin, Amendolia, & Solomonides, 2004).

The rapid adoption and diffusion of service-oriented architecture (SOA) and Web services in various industries indicate that the advantages and benefits (componentization, interoperability, platform-independence, modularity, reusability, etc.) therein could provide similar benefits for healthcare. Overall, there has been a major change in the way large scale software applications are designed, modeled, implemented and used (Stojanovic, Dahanayake, & Sol, 2004). Services are autonomous, platform-independent processes that can be identified and defined, published, discovered, choreographed, and programmed using universally accepted protocols for building health applications that work together seamlessly, both intra-enterprise (i.e. the healthcare delivery organization) and inter-enterprise (i.e. the consortium of healthcare delivery participants). When services are delivered via the Web we call them Web services. These have emerged as a framework for application-to-application interactions, making these applications available as Web services (Vara, De Castro, & Marcos, 2005). While Web applications via the Internet have been used in the healthcare industry for a few years now, these applications are mostly intra-enterprise, that is, services are within the specific healthcare organization using them. There is limited capability for supporting cross-functional and inter-enterprise applications. Recently, however, practitioners and researchers have started to address the distributed and inter-enterprise nature of healthcare delivery (the interaction arising out of the exchange of information among physicians, insurance companies, hospitals, labs, and pharmacies, for example). The desire to exploit the scalability of Web services within the SOA is understandable. Catley, Petriu, and Frize (2004) describe a prototype Web services architecture for physicians designed to provide clinical decision support. The objective is to integrate and access clinical decision support systems (CDSSs) and medical databases from various medical domains. Their rationale for integrating distributed databases is that different medical domains often exhibit complementary abilities in predicting medical outcomes. They give the example of the collective domains that include obstetrical, prenatal and neonatal databases. The overall goals have been multifold: the Web services are expected to integrate different types of CDSSs; provide for a way to link disparate distributed databases on multiple platforms; and making the CDSSs available locally as well as remotely (Catley et al., 2004).

Estrella et al. (2004) describe another application based on grid computing and the SOA. The MammoGrid project is expected to support collaborative medical image analysis. An important objective is to manage federated mammogram databases distributed across Europe. The framework would include regions with varying protocols, lifestyles and diagnostic procedures and would enable a range of functions including data mining, epidemiological studies, statistical analyses, and deployment of a standardized Standard Mammogram Form. The goal is to federate the distributed mammogram sources into a single virtual organization. While these applications are in very specific medical domains, they highlight the potential of SOA-enabled Web services in the health domain. The health domain is more encompassing than the medical domain because it includes business-related services such as patient billing, insurance approval, payment processing and case management. Even so, the groundwork is in place to scale up applications for more encompassing healthcare delivery systems, delivering services via the Internet. In this way, the industry may exploit the natural alignment of SOA-enabled Web services in healthcare processes. At the enterprise level, one can envision the strategic alignment of information technology with a healthcare organization's goal of delivering quality care.

But while the potential benefits are great, particularly the use of the Internet to deliver important health services, so are the challenges. A key issue is the need for robust modeling and development of Web services applications. Healthcare delivery is a highly complex process characterized by a multi-provider, multi-payer system. Modeling and representing healthcare processes—amidst the need for data integrity, privacy, security, real-time processing, interoperability (open system), portability, and scalability—is daunting. One solution is to extend existing techniques, such as the UML, which many consider the de-facto standard. A starting point is the standard UML modeling notation base defined by the W3C Web services group and OMG (Amir & Zeid, 2004). Aspects of the Web services applications across various platforms—such as the roles of service providers, requestors, and registries as well as the three operations of publish, find, and bind—need to be conceptualized in the SOA format. Further, a notation can be defined to support the actions. Moreover, the semantics of healthcare domain concepts have to be described to enable interpretation of their behavior. Additionally, the ontology of healthcare services must be developed.

These challenges in mind, we explore in this article the potential of a UML profile to model Web services in healthcare. We develop an application for a hypothetical health clinic, showing various elements that would comprise such a profile. This clinic is positioned to be an integral part of a larger, distributed healthcare delivery system that encompasses hospitals, labs, pharmacies, and insurance providers, such as HMOs. The diagrams that follow illustrate our model and visually identify its various parts. In this regard, one can use collaboration diagram notation. We propose a hierarchy of service components as the primary building blocks of the Web services architecture via concepts, meta models, and granularity types. Health service components are modeled as contract-based service providers and support the health organization's health processes through a formal orchestration. Simultaneously, they are realized as a composition of lower-level application service components (Skogan, Gronmo, & Solheim, 2004). These can be further mapped to more encompassing software artifacts. Fashioned in this way, the Web services architecture represents layers of abstraction between the healthcare processes and the operational information, minimizing inconsistencies. We introduce the concept of service component as the primary Web services building block. An important aspect of the article is the enunciation of a modeling approach that emphasizes the identification and specification of the service components of varied scope and granularity. This approach enables the evolution of a Web services healthcare solution.

The article is organized as follows. First, we discuss the potential of Web services in healthcare. Next, we explain the usefulness of the UML, particularly the profile in developing models. Then we develop the notion of a partial UML profile for a distributed health clinic example. Finally, we offer our conclusions for future applications and research

WEB SERVICES IN HEALTHCARE

Web services are defined as functional components (processes) situated in a particular domain and available over the Internet. In the healthcare area, these could include online query/response consultation with a physician, scheduling a patient visit, confirmation of a referral, and so on. The architecture would comply with a set of standards, such as those used with HTTP, XML SOAP, WSDL, or others (Vara et al., 2005). Alternatively, it is any service accessible over the Internet which takes XML as input and produces an XML result. The rationale behind a Web service composition is that many smaller tasks already identified as Web services can work together to execute a larger task. Such commands as VERIFY PATIENT DATA, CONFIRM PHYSICIAN, ROOM ASSIGNMENT, DATE/TIME AVAILABILITY, ASSIGN PATIENT TO SCHEDULE, and PROVIDE CONFIRMATION could collectively represent "PROCESS PATIENT VISIT SCHEDULE DATA." At the highest level a Web service implies delivery of high quality healthcare via the Internet. The services can be offered by multiple providers within the confines of the federation, a loosely coupled consortium of healthcare participants, and are typically published in a central repository. Finding the service is coordinated by a brokering mechanism. The Web services paradigm, then, enables the health services consortium to continue to function in a distributed fashion with localized control and use. In this way, applications extend beyond the intra-enterprise boundary to the inter-enterprise. Additionally, redundancy in services can be minimized by a repository. All participants in this "federation" can contribute to the creation of the services and use them. The benefits are numerous. Web services architecture mirrors the healthcare delivery mode and can be strategically dovetailed with the delivery organization functions. Also, middleware provides the interface so that legacy systems are not abandoned. Web services standards enforce compliance by vendors and platforms, thereby providing interoperability. This exploitation of the Internet would lead to maximal use of the health organization's capabilities and offerings, resulting quality patient care and satisfaction. That said, the application of Web services and SOA in the healthcare area is a relatively recent phenomenon. While knowledge about systems development can be transferred from other industries, the healthcare industry is more complex (fueled in part by the multiplicity of payers and providers) than most other industries. While the current trend towards universal electronic health records is a positive one, scalability and portability are important design challenges. Another hurdle is the minimal understanding of healthcare processes and workflow by application designers and vendors. Existing applications are ad hoc, incompatible system implementations. Plus, current standards are not at a level that Web services can be easily implemented. Methodologies and modeling tools are seriously lacking (Gronmo & Solheim, 2004).

But there is a bright side. UML-based approaches can be extended to the healthcare process modeling, providing a solid foundation for the implementation of Web services. For example, consensus on communication rules is important for all participants to succeed. This implies agreement on the ontology (Heuvel & Maamar, 2003). Anchoring the modeling of healthcare processes around the UML can minimize the learning curve because one can draw on the experience and knowledge currently available. The added advantage of bypassing legacy approaches and systems (especially in environments with no prior automation efforts) accrues.

Operationally, applications that are "services" must spell out their functional and non-functional (utility/procedural) requirements and capabilities in a prior agreement. Based on declarative service descriptions, automated service discovering, selection and binding provide the foundation for Web services applications. Therefore, an advantage arising from the dynamic binding is looser coupling between applications (Curbera, Khalaf, Mukhi, Tai, & Weerawarana, 2003). The componentized model emerging out of this process provides for "health services" forming the initial units for creating the application. Service composition and management become critical issues (Casati, Shan, Dayal, & Shan, 2003).

In healthcare, a service composition combines services and follows a certain pattern to achieve a healthcare goal, for example, properly discharging a patient from the hospital. An architecture that supports Web services includes the following aspects:

- The dynamic discovery of registered service, including searching for services that meet certain criteria, especially health criteria such as patient wait time, quality of care, and so forth;
- The intuitive organization of services so that one easily can understand what a service offers;
- The clear description of services, ensuring the proper use of each service.

This includes formats and protocols for invoking the Web service (Leymann, Roller, & Schmidt, 2002). A typical Web service follows this pattern: a service is created; the service is published; the service is located; the service is invoked. (Optionally, the service may be unpublished.) The complex services that a typical medical clinic provides vary widely across the patient group. An effective solution for the management of disparate medical data sources is federation of autonomous multi-center sites which transcends inter-enterprise boundaries. The resources in the federation—such as hospitals, diagnostic labs, and pharmacies—would be governed by the same sharing rules with respect to authentication, authorization, resource, and data access. These rules (protocols) create a highly controlled environment which dictates what is shared, who is allowed to share, and the conditions under which sharing occurs among the medical sites. Federation in this application implies cooperation of independent medical sites. Individually, these sites are autonomous in that they have separate and independent control of their local data. Collectively, those sites participate in a federation, and the federation is governed by the umbrella organization (let's say, a consortium of health providers) (Estrella et al., 2004). The ability of Web services to go beyond the health entity boundary (i.e. the firewall), the loose coupling between applications encouraged by Web service interfaces, and the wide support for core Web service standards by major enterprise software vendors are the key reasons why Web services have the potential to make integration of health applications both within and between health enterprises significantly more effective in terms of ease of implementation and cost savings. Loose coupling means that not only can applications be implemented on different platforms and operating systems, but also that the implementation can be changed readily without affecting the interfaces (Jiang, Xing, He, & Yang, 2005). One of the important modeling and design issues in building Web services is determining the type, scope, and granularity of service components necessary for representing the main architectural abstractions. Moreover, these different types of service components must be put in the wider context of a development process to provide that traceable business requirements are mapped to the software artifacts supporting them.

Having discussed the potential and implications of Web services in healthcare, we now turn to the examination of UML, its extensions and profile to model heath care processes in a robust fashion. How do we derive good service abstractions from high level healthcare domain requirements and health process models?

As a corollary, additional questions arise. What are good (health) services? For example, what is the right service granularity, and what does health process and information technology alignment mean from a modeling standpoint? How can the healthcare automation landscape be transformed into an integrated healthcare ecosystem? From a modeling standpoint, how can well-designed and meaningful service abstractions be characterized and constructed systematically? How are services in a Web service application identified and described? What is the process for developing Web services? How are health processes realized in terms of Web services? Which development approaches are relevant to a Web service? How can legacy systems and packaged applications be adapted as services? All of these questions emphasize the need to use an appropriate modeling approach.

UML PROFILE APPROACH TO MODELING WEB SERVICES IN HEALTHCARE

The identification and construction of a modeling language for Web services pose significant challenges. To provide rich and robust functionality there is a need to focus on the architecturally significant components particular to the Web services in a specific health system and to somehow model them with UML extensions. One way to manage the complexity of Web services is to abstract and model them. In a typical system there are multiple models, each representing a different perspective, layer of abstraction, and detail. Models help us understand systems by simplifying some of their details. But the decision as to what to model has a significant effect on the understanding of the problem (What are the health processes amenable to Web services modeling?) and solving it (How do you enable them?). UML has the potential to answer these challenges (Jiang et al., 2005). UML models and other architectural artifacts such as system context, component interaction and collaboration diagrams can play a key role during analysis and early design (Gronmo, Skogan, Skolheim, & Oldevik, 2004; Zimmermann, Schlimm, Waller, & Pestel, 2005). Also, use case, sequence, and class diagrams can help represent various modeling elements (Conallen, 2003).

A natural starting point for modeling Web services is component-based and interface-based modeling and the standard UML. But to what extent can component-based approaches and the UML fulfill requirements and provide necessary concepts and mechanisms for modeling the Web services, such as componentization, low coupling, high cohesion, interface-based design, hidden implementation, as well as flow of objects and actions? One can develop high-level models in UML, define conversion rules from UML to a target platform, and then use code generation to derive much of the implementation code for a desired platform.

Two key aspects have to be modeled: the service itself, and the workflow. Service modeling identifies which services are to be exposed with their interfaces and operation, while workflow modeling identifies the control and data flows from one service to the next. In a typical inter-enterprise application, one may first discover existing Web services, if any, from a registry. Then, service modeling identifies the interface of the composite Web service and the workflow focuses on reusability. Transformation rules from both models can be specified (Foster, Uchitel, Magee, & Kramer, 2003). The former is mapped to a WSDL document and the latter to a XML document. Finally, the XML document generates the code via a workflow engine. The WSDL document is published as a Web service registry. The UML, having evolved into a standard modeling language, is appropriate to model the service and the workflow. Given its visual format and wide use, the UML is a good candidate for diagramming comprehensible models. Diagrams are a natural part of UML and are used for workflow modeling of Web service compositions. Building composite Web services lacks sufficient support in traditional workflow modeling. Further, the UML seems suitable for expressing Web service patterns (Gronmo & Solheim, 2004). The diagrams and modeling elements can be extended to develop a high level profile of the healthcare process.

UML Profile

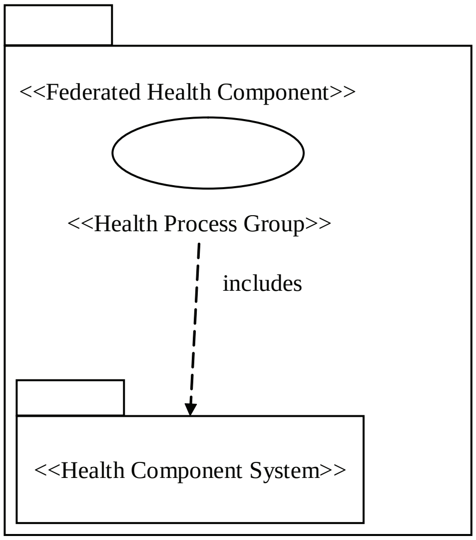
One strength of the UML is its adaptability to specific vertical markets with specific concepts and needs. In the UML standard these are called profiles (Heckel, Lohmann, & Thone, 2003). Various groups working with UML have started to address the customization of UML models for various domains by defining "profiles." The objective for the healthcare process domain is the definition of a generalized UML subset, embellished with UML-compliant extensions, which would permit the annotation of such concepts (Baresi, Garzotto, & Paolini, 2001). Thus, the resulting profile corresponds not to specific domains in healthcare (e.g. diabetes monitoring) but to healthcare processing wherein diabetes monitoring is one service component. While profiles may be standardized in the future, stable initiatives from various groups can form the basis for the definition and standardization of UML profiles (Thone & Varro, 2003). Profiles thus facilitate consideration of the key issues in healthcare processing, namely interoperability, portability, scalability, and universal standards. UML being a complex language, additional features cannot be described easily in the current version, though Version 2.0 may provide extensions. Therefore, UML provides mechanisms such as stereotypes and tagged values to enable extensions (Fontoura, Pree, & Rumpe, 2002; OMG.), and the defined extensions can be grouped into profiles. A UML profile is further defined as an extension of the UML standard language with specific elements. The profile provides new notational elements and typically facilitates specialization of the semantics of some of the elements. Usually the profile builds a hierarchy. The creators of the UML realized that there would always be situations in which, out of the box, the UML would not be sufficient to capture the relevant semantics of a particular domain or architecture. To address this issue, a formal extension mechanism was defined to allow practitioners to extend the semantic of the UML. UML provides two extension mechanisms—stereotypes and tagged values—for describing specific properties of the elements, such as classes, associations and methods (for example, role of "human" as "patient", a patient "visit", and a patient "schedule" in the context of healthcare). The roles and artifacts of the service-oriented style are represented in several diagrams that follow. The mechanism enables one to define stereotypes, tagged values and constraints that can be applied to model elements. A stereotype is an elaboration that allows one to define a new semantic meaning for a modeling element. Stereotypes indicate that the class is an abstraction of the logical behavior of a Web service on either the client or the server. Tagged values are key value pairs that can be associated with a modeling element and allow us to tag any value onto that element. Tagged values are used to define the parameters that are passed along with a link request. The <<link>> association tagged value "parameters" is a list of parameter names (and optional values) that are expected and used by the server page that processes the request. Constraints are rules that define the structure of a model (Fontoura et al., 2002).

One could say each Web service is a UML class. The server side of a Web service can be modeled with one class and the client side with another, distinguishing the two by using UML's extension mechanism to define stereotypes and icons for each <<server page>> and <<client page>>. Using stereotypes makes its easier to model a service's actions and its relationships. Class stereotypes used to model the logical behavior of Web pages means their collaboration with the server side components can be expressed in much the same way as any other server side collaboration (Conallen, 1999). While UML was not originally devised to model health processes or services, one can use the stereotyping capability to develop new extensions to UML. The UML business profile, designed to facilitate business process modeling purposes, is one example.

The Health Clinic Example

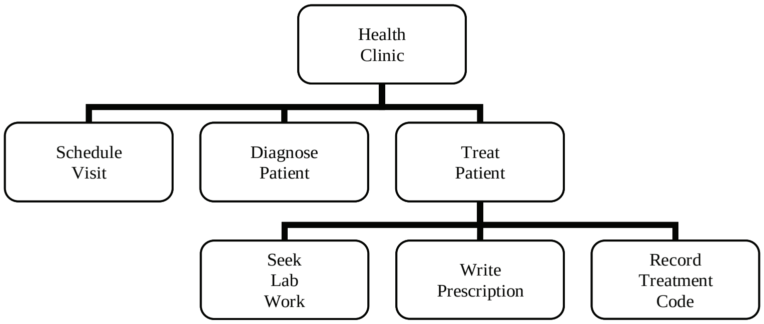
It is possible to provide a UML extension for health service modeling using typical stereotypes. Figure 1 shows the general relationships amongst some of the UML elements. A federated healthcare component performs specialty activities as its services. On the other hand, the specialty itself is decomposed to lower level services, encompassed within a medical entity. It is also similar for other levels of service/process granularity hierarchy. At the architectural level, other types of diagrams are involved, such as class diagrams with interfaces to define signatures and data types of operations, and sequence diagrams as alternative presentations of interactions (Heuval & Maamar, 2003). The Web service domain can be mapped by UML modeling concepts, providing platform independent representation as UML activity and component diagrams. Additionally, a collaboration diagram selected to represent the encapsulation of the binding mechanism as semantically precise as possible and provide all the necessary concepts and capabilities for representing integrations and collaborations of its participating parts. The diagrams, along with structured classes, can support the representation of the composition of interconnected elements representing run time instances, and the collaboration over communication links to achieve common objectives. In particular, collaborations provide the means to define common interactions between objects and other classifiers and assign roles and responsibilities to each. The interaction is similar to providing a pattern of communication between objects playing defined roles. Alternatively, the profile is equated with equivalent meta models. By defining their meta model relationships and interaction mechanisms, one can support the integration and interoperability of their models. In that way one can design complete system models having formalized interaction points and perform model transformations across multiple connected meta models (Staikopoulos & Bordbar, 2005). For example, UML and its standard profiles (CORBA, EJB, and EDOC) can be used to model PIM (Platform Independent Model) or PSM (Platform Specific Model) in the Model Driven Architecture (Brown, 2004). Design decisions can be defined by the UML profile, which provides a set of extensions to UML using the built-in extension facilities of UML, stereotypes and tagged values. The profiles provide a mechanism for managing stereotypes. The profile for healthcare would comprise the range of models derived from UML modeling. The same profile can be used across many projects. Using profiles in this manner (i.e. packages can be exchanged between models) will ensure a standardized approach to problem solving. UML extension mechanisms can help bridge between various models. Using the basics of the class diagram, the systems engineer can model the stack with relative ease. However, for the developer to implement it, he or she will need additional information. UML stereotypes can help clarify the stack requirements. In this context, stereotype is a "label" that can be used to "characterize" a model item in some way. For example, an actor

Figure 1. A sample UML representation for health processes and services (adapted from Fatolahi & Shams, 2005)



could be stereotyped as <<Patient>> <<Clinic>> or <<Service>>. A stereotype is a model element that defines additional values (based on tag definitions) and additional constraints. These can be applied to any model element. Stereotypes label a model element to denote that the element has some particular semantics. UML allows an application model to be constructed, viewed, developed, and manipulated in a standard way at analysis and design time. Just as blueprints represent the design for an office building, UML models represent the design for an application, allowing business functionality and behavior to be represented clearly by business experts at the first stage of development and away from vendor-driven preconceptions. The abstract syntax in UML's meta model is described by UML's class diagram which can represent the abstract syntax structure strictly and precisely (Jiang et al., 2005). For the purpose of health component identification, domain object analysis, and use case analysis are useful sources of input. Domain object analysis defines a domain vocabulary of the system being developed, in other words, information about health concepts in the problem area that should be handled by the system together with their attributes and relationships. Use case analysis is an effective mechanism for defining cohesive sets of features and services on the system boundary because they capture the intended behavior of the system without having to specify how that behavior is implemented. The use cases of the appropriate granularity correspond to the provider's health goals and activities, otherwise known as Elementary Health Processes (EHPs). The cases can be specified in detail according to the use case template that includes name, description, involved actors, goal in the context, scope, level, pre-condition, post-conditions, triggers, main success scenario, extensions, sub-scenarios priority, frequency, performance, etc. Figure 2 depicts a healthcare process hierarchy for this sample case. For simplicity only one thread is decomposed into its EHPs. The stereotyping helps translate the somewhat abstract class diagram into a domain specific platform independent model and platform specific model. For each use case, the use cases that precede it, follow it, perform in parallel with it or are synchronized in other ways with it should be defined. Furthermore, for each use case its super ordinate and subordinate use cases should be defined, providing a composite hierarchy of use cases, (i.e. corresponding business goals). This can be illustrated using a sequence diagram enriched to express the action semantics with the use cases on the horizontal axis of the diagram. Finally, domain information types resulting from domain analysis are cross-referenced with the use cases. In this way, for each use case the information types needed for its performance are defined. A healthcare service may be seen as a component, which in turn is defined as a self contained health process or service with predetermined functionality that may be exposed through a provider or technology interface. This indicates an implicit relationship between the notions of

Figure 2. Healthcare process hierarchy



service, process and component. One can then match the hierarchy of service-components with the hierarchy of healthcare processes in order to gain effective services. Since healthcare processes are significant components of the health delivery architecture and services are the major elements of a Web services' architecture, mapping may be seen as a bridging mechanism between the abstract health service models and the system architectures. A primary healthcare process, called a process group, may contain a series of sequencing process threads. Each thread results in a major added value for a healthcare delivery organization (called a provider), and is composed of its offspring elementary health processes (EHPs), which are the smallest meaningful units of activity for the end user, and which when complete leaves the information area in a self-consistent state. Each EHP may transform to some use cases when designing systems to support its holding thread. Therefore, a process group may decompose to a series of process threads each of which in turn may hold several EHPs. It is necessary to base the services on EHPs. An EHP can indicate which services are required by the enterprise and which of them are provided by the enterprise. Operationally, a health process may be a collection of services. The concepts are illustrated using a "Health Clinic" application that is distributed in residence of the data as well as functionality and use. Table 1 shows the service component hierarchy in the context of healthcare.

A federated health component is a set of services which are common to the various healthcare delivery organizations, including clinics, hospitals, HMOs, labs, and pharmacies. A health component system is a set of health service components assembled to deliver a healthcare solution, such as, providing quality healthcare to a patient. A health component is itself an independent concept, process or service. Distributed components and language classes are physical software components (e.g. an underlying database) and classes designed for implementation. It is sufficient to follow the hierarchy of health processes in order to record included services at each level. But this does not mean every process is a service. Identifying the specific services to be implemented using a specific technology, such as a Web service, it may be enough to verify EHPs and decompose each EHP into Derived Logical Processes (DLPs). Each DLP can be a stand-alone process that does not require human intervention. The hierarchy provides a means to package services in well-defined components that are of interest to different users at various levels (Fatolahi & Shams, 2005). Table 2 shows the generic UML stereotyping for healthcare. An EHP included by the schedule is developed here. Figure 3 shows the UML stereotyping for the SCHEDULE VISIT thread for the clinic example. It indicates how the UML stereotyping mechanism may help us in modeling the services in the healthcare processes. The diagram presents the schedule visit thread and some of the linked services. Now consider the

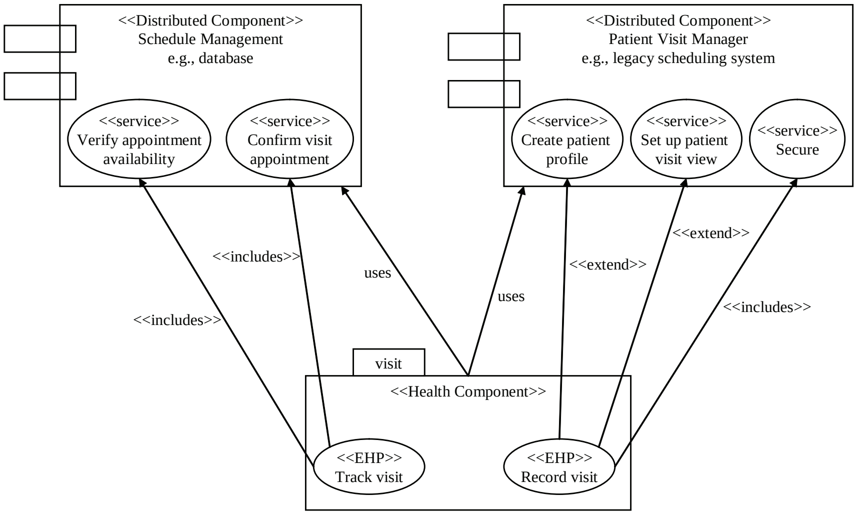
Table 1. Service component hierarchy classifies health services through a hierarchy of granularity/service (adapted from Fatolahi & Shams, 2005).

Health Service Component Granularity	Example
Federated health component	Process group – Consortium of health care delivery participants
Health component system	Process thread – Health clinic
Health component	Use case (EHP) – Process Patient Schedule
Distributed component	Distributed database
Language Class	Method – Verify schedule availability

Table 2. UML stereotyping for health care (adapted from Fatolahi & Shams, 2005)

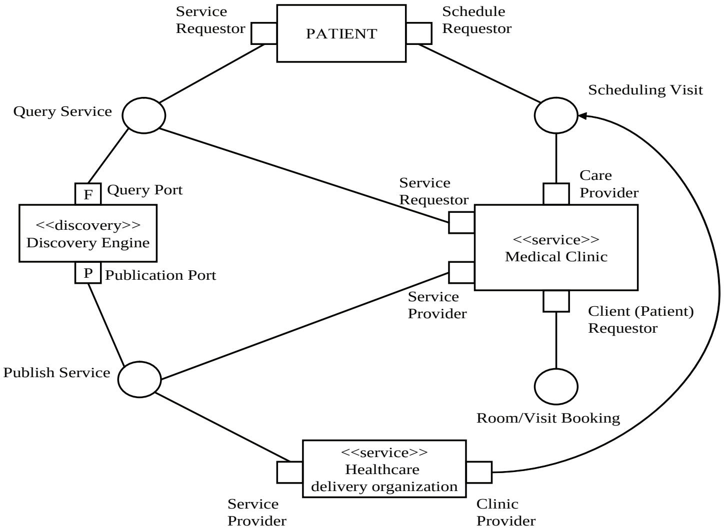
Service Component Stereotype	UML Element
Federated health component	Package
Health component system	Package
Health component	Package
Distributed component	Component (e.g., database)
Language Class	Class

Figure 3. UML stereotyping for the Schedule Visit thread (adapted from Fatolahi & Shams, 2005)



medical clinic application that serves as a manager (coordinator) of scheduling and coordinating patient visits. For simplicity, we restrict the functionality to scheduling a patient visit. For this purpose, the clinic software should be able to connect to third party (e.g. referring physician, hospital) information systems. After a patient requests a visit, the system has to query the third party systems as well as internal systems to select appropriate dates/place/location and schedule the patient visit. These requirements lead to a dynamic distributed system where new components can be brought up by the medical facility (e.g. hospitals) at execution-time. The application can be implemented as a Web service as modeled with the UML profile. Models can be differentiated at the various type levels (Baresi, Heckel, Thone, & Varro, 2004). Component diagrams can be used to show the component types of the applications, including the interfaces at the ports. Figure 4 is a partial component diagram of the health clinic example. The patient (or representative) requests to schedule a visit from the clinic. This action links to different delivery organizations. All healthcare delivery organizations need to publish Web services to accept the queries from external clinic systems in a healthcare UDDI Web services registry. When the clinic system queries third party systems, it discovers the Web services in the UDDI Web services registry, then binds the Web services at their particular Web location, and finally obtains the requested information by

Figure 4. Web services specific component diagram (adapted from Baresi et al., 2004)



execution of the Web services. The UDDI helps integrate the healthcare service across various healthcare delivery organizations in an open environment. While WSDL and SOAP describe the service interface and communication protocol once a specific service is located, UDDI enables the service consumer to reach the service provider through a multitude of Web services available. The Service Provider registers the information about the service in the UDDI Registry by publishing the service, and the Service consumer queries the UDDI Registry to discover services matching certain criteria, all through standard defined UDDI APIs (UDDI.org, 2002).

UDDI becomes a key element in Web services runtime environment and life cycle when the services are dynamic and evolving, and the binding for a service is non-deterministic. It is conceivable that service consumer will eventually discover and use the most desirable service through a streamlined find-bind-execute process without human interaction.

Additionally, the details of the port types and the interfaces may be defined by class diagrams. A partial class diagram is shown in Figure 5. The class diagram also contains stereotyped associations. These define types for links that are available to connect to the various ports. We also need to model packages of the component instances in a run-time scenario. UML collaboration diagrams can be used for this purpose. Figure 6 is an example collaboration diagram for the health clinic. Various labels can be applied to the changed instances and links during run-time. The communication features are shown by assigning messages to the link symbols. Numbers are used to indicate the sequence of the messages. The displayed specification artifacts, such as service descriptions and service requirements, are needed to enable the Web service-specific capability of dynamic service discovery (Baresi et al., 2004). An objective of the health clinic system is to provide integrated scheduling and visit services for patients by loose coupling of providers, customers (patients) and related-entities solutions already residing at their sites. Each of these can be accessed via Web service interfaces, and incoming requests are forwarded to all known services (medical; participants). Figure 7 shows a collaboration diagram modeling a hypothetical scenario to execute a query on the meta scheduling system (schedule/visit). Prior to dispatching a query, the client (patient) has to

Figure 5. Web services specific class diagram (adapted from Baresi et al., 2004)

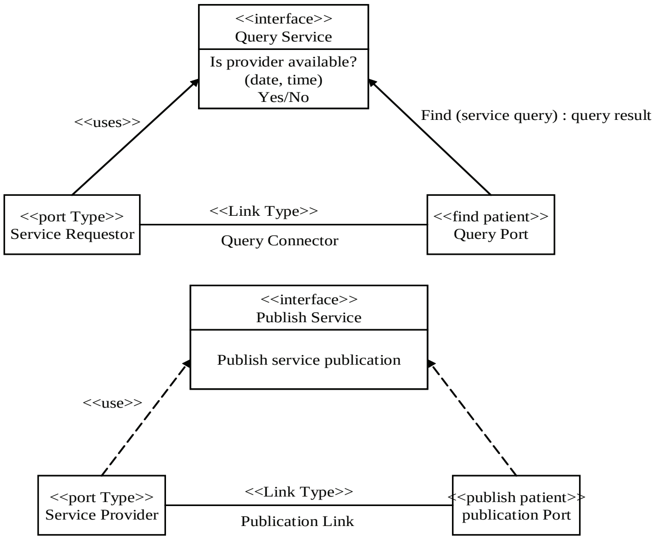


Figure 6. Web services specific collaboration diagram (adapted from Baresi et al., 2004)

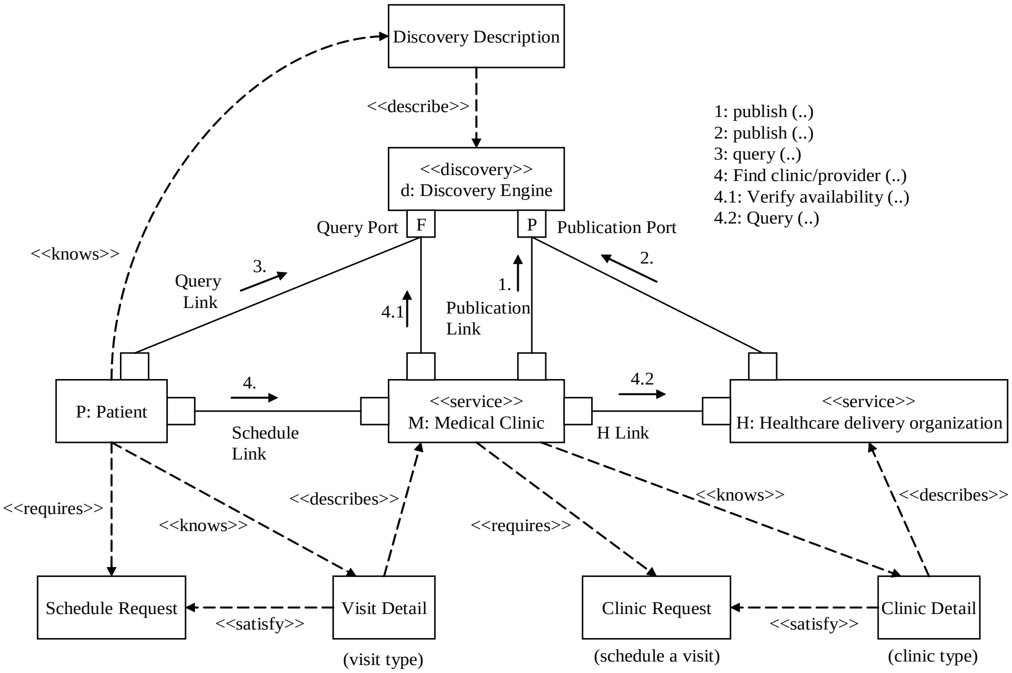

choose the local scheduling systems where the query ought to be run. Then the client retrieves a list of scheduling systems that are registered with the meta scheduling system ("discovery"), for example, the lab, and surgery. The search string is sent simultaneously to all selected scheduling systems. For this situation, a UML component diagram can identify the various components and interfaces for the given system. From the scenario in Figure 7 one can derive the UML component diagram in Figure 8 to identify the (types of) components and interfaces used in the application. The objective to develop UML profiles for healthcare frameworks is a potential definition of UML subsets incorporating extensions and annotating the artifacts. The examples represented by the various diagrams contribute to the overall development of profiles in healthcare.

CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

While the Web services paradigm is gaining attention in the development and integration of complex healthcare applications, there is an almost complete lack of modeling approaches. Web services modeling is a challenging task because the service concept further raises the level of abstraction and actually aims at narrowing the gap between the healthcare process and the software. Therefore, for the purpose of Web services modeling, the best practices from object-orientation and component-based design as well as work flow and health process modeling, must be considered and thoroughly integrated. In this article, we propose a UML profile for modeling Web services in healthcare. We describe the various components of such a profile for a hypothetical medical clinic whose interactions are characterized by distributed ness, need for interoperability, portability and scalability. Such profiles developed and standardized over time, will assist the healthcare industry in implementing robust Web services applications for a range of healthcare processes. The paradigm of Web services enables healthcare organizations to shift from tightly coupled and coarse-grained applications to more dynamic and loosely coupled ones. The UML profile outlined in this article requires further refinement especially if platform-specific details are added. The article has proposed a way to model the services components in a healthcare scenario that enable their realization and the orchestration as the primary building blocks of the Web services architecture. While the research is exploratory one can build on the concepts outlined here to develop comprehensive UML profiles for the various services in healthcare. This would advance the goal of uniform standards for interoperability as health related organizations rapidly develop electronic health record systems, clinical decision support systems and other applications. We advocate the notion of a profile along with the concept of a service component, a paradigm shift from components as static objects to components as dynamic service coordinators. In the future, specific mapping rules for transforming platform-

Figure 7. Collaboration diagram modeling executing of a query (adapted from Heckel et al., 2004)

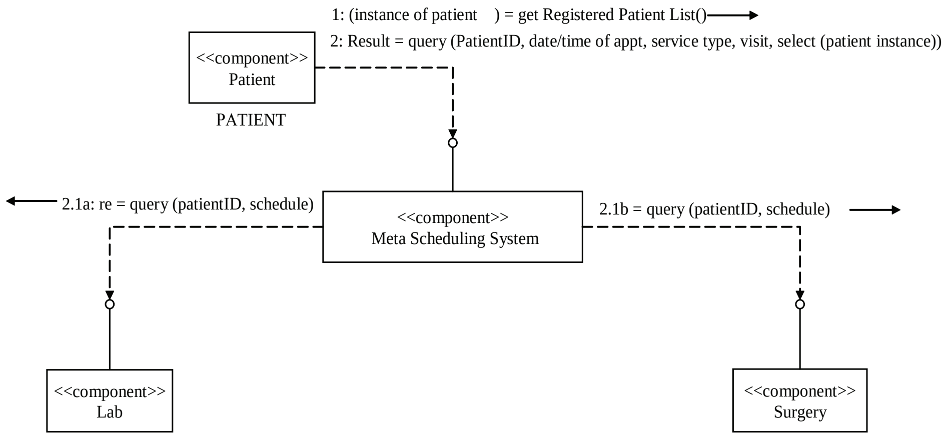

Figure 8. Partial health services architecture derived from collaboration diagram (*adapted from Heckel et al., 2004)*

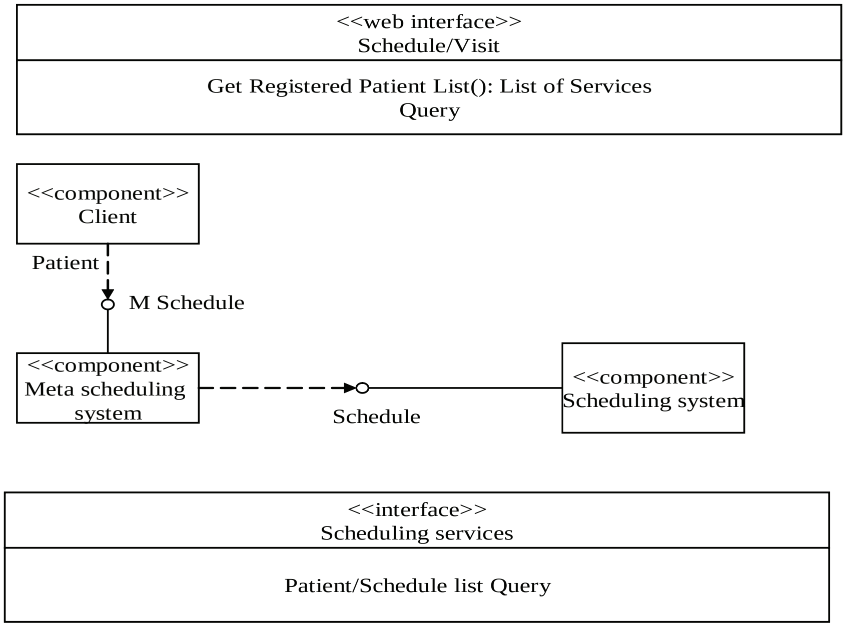

independent models into platform-specific models have to be identified (Stojanovic et al., 2004). We envision health processes as reliable resources to discover services in SOA-enabled Web services (Fatolahi & Shams, 2005) architecture for healthcare delivery organizations (for both, profit and non profit sectors). Also, in the future the UML profile approach developed here can be extended and standardized to facilitate reusability and universal application of Web services in healthcare. Additional research can provide insight into UML extensions and stereotyping in health services as well as enable definition of standards for open source development of applications in healthcare. Finally, integration with HL7 standards has to be addressed. In this way, there is incremental contribution to the advancement of global applications of information technology in healthcare. Loosely federated Web-enabled systems at this level could help track and monitor health issues, such as pandemics, on a global scale.

Chapter 2.20

Data Warehouse Design to Support Customer Relationship Management Analysis

Colleen Cunningham
Drexel University, USA

Il-Yeol Song
Drexel University, USA

Peter P. Chen
Lousiana State University, USA

ABSTRACT

CRM is a strategy that integrates concepts of knowledge management, data mining, and data warehousing in order to support an organization's decision-making process to retain long-term and profitable relationships with its customers. This research is part of a long-term study to examine systematically CRM factors that affect design decisions for CRM data warehouses in order to build a taxonomy of CRM analyses and to determine the impact of those analyses on CRM data warehousing design decisions. This article presents the design implications that CRM poses to data warehousing and then proposes a robust multidimensional starter model that supports CRM analyses. Additional research contributions include the introduction of two new measures, percent success ratio and CRM suitability ratio by which CRM models can be evaluated, the identification of and classification of CRM queries, and a preliminary heuristic for designing data warehouses to support CRM analyses.

INTRODUCTION

It is far more expensive for companies to acquire new customers than it is to retain existing customers. In fact, acquiring new customers can cost five times more than it costs to retain current customers (Massey, Montoya-Weiss & Holcom, 2001). Furthermore, according to Winer (2001), repeat customers can generate more than twice as much gross income as new customers. Companies have realized that instead of treating all customers equally, it is more effective to invest in customers that are valuable or potentially valuable, while limiting their investments in non-valuable customers (i.e., not all relationships are profitable or desirable). As a result of these types of findings as well as the fact that customers want to be served according to their individual and unique needs, companies need to develop and manage their relationships with their customers such that the relationships are long-term and profitable. Therefore, companies are turning to Customer Relationship Management (CRM) techniques and CRM-supported technologies.

In our earlier work (Cunningham, Song, Jung, & Chen, 2003), we defined CRM as a strategy that utilizes organizational knowledge and technology in order to enable proactive and profitable long-term relationships with customers. It integrates the use of knowledge management, or organizational knowledge, and technologies to enable organizations to make decisions about, among other things, product offerings, marketing strategies, and customer interactions. By utilizing a data warehouse, companies can make decisions about customer-specific strategies such as customer profiling, customer segmentation, and cross-selling analysis. For example, a company can use a data warehouse to determine its customers' historic and future values and to segment its customer base. shows four quadrants of customer segmentation: (1) customers that should be eliminated (i.e., they cost more than what they generate in revenues); (2) customers with whom the relationship should be re-engineered (i.e., those that have the potential to be valuable, but may require the company's encouragement, cooperation, and/or management); (3) customers that the company should engage; and (4) customers in which the company should invest (Buttle, 1999; Verhoef & Donkers, 2001). The company then could use the corresponding strategies, as depicted in Table 2, to manage the customer relationships. Table 1 and Table 2 are only examples of the types of segmentation that can be performed with a data warehouse. However, if used, a word of caution should be taken before categorizing a customer into Segment I, because that segment can be further segmented into (a) those customers that serve as benchmarks for more valuable customers, (b) those customers that provide the company with ideas for product improvements or efficiency improvements, and (c) those customers that do not have any value to the company.

It is important to point out that customer segmentation can be further complicated by the concept of extended households. The term *extended household* refers to the relationship that exists between companies (e.g., parent company and subsidiary). The analysis of the relationships that exist between customers (i.e., lines of potential customer influence) is known as household analysis. It is important to understand and manage extended households, because a company's decision to treat a member of one segment potentially could have a negative impact on a related customer. For example, if a customer is in a non-profitable segment, then the company may decide to increase the customer's price. However, if the company is aware that the same non-profitable customer has influence over another customer (e.g., a parent or small business) that is in a more profitable segment, then the company may decide to not increase the customer's price rather than to risk losing both of the customers. Clearly, these social networks of influence are

Table 1. Customer segments

		Historic Value	
		Low	High
Future Value	High	II. Re-Engineer	IV. Invest
	Low	I. Eliminate	III. Engage

Table 2. Corresponding segmentation strategies

		Historic Value	
		Low	High
Future Value	High	Up-sell & cross-sell activities and add value	Treat with priority and preferential
	Low	Reduce costs and increase prices	Engage customer to find new opportunities in order to sustain loyalty

important for companies to identify and manage because of the impact that they can have on the company's ability to retain customers.

Currently, however, there are no agreed upon standardized rules for how to design a data warehouse to support CRM. Yet, the design of the CRM data warehouse model directly impacts an organization's ability to readily perform analyses that are specific to CRM. Subsequently, the design of the CRM data warehouse model contributes to the success or failure of CRM. In fact, recent statistics indicate that between 50% and 80% of CRM initiatives fail due to inappropriate or incomplete CRM processes and poor selection of technologies (Myron & Ganeshram, 2002; Panker, 2002). Thus, the ultimate long-term purpose of our study is to systematically examine CRM factors that affect design decisions for CRM data warehouses in order to build a taxonomy of CRM analyses and to determine the impact of those analyses on CRM data warehousing design decisions.

The taxonomy and heuristics for CRM data warehousing design decisions then could be used to guide CRM initiatives and to design and implement CRM data warehouses. The taxonomy also could be used to customize a starter model for a company's specific CRM requirements within a given industry. Furthermore, that taxonomy also would serve as a guideline for companies in the selection and evaluation of CRM data warehouses and related technologies.

In order to objectively quantify the completeness and suitability of the proposed CRM model (and alternative models), we propose two new metrics: *CRM success ratio* ($r_{success}$) and *CRM suitability ratio* ($r_{suitability}$). The *CRM success ratio* ($r_{success}$) is defined as the ratio of queries that successfully executed to the total number of queries issued against the model. A query is executed successfully if the results that are returned are meaningful to the analyst. The *CRM success ratio* cannot be used only to evaluate our proposed CRM model, but it also can be used to evaluate other CRM data warehouse models, as well. The range of values for $r_{success}$ is between 0 and 1. The larger the value of $r_{success}$, the more successful the model. The following equation defines the CRM success ratio:

$$r_{success} = Q_p / Q_n \tag{1}$$

where Q_p is the total number of queries that successfully executed against the model, and Q_n is the total number of queries issued against the model.

The *CRM suitability ratio* ($r_{suitability}$) is defined as the ratio of the sum of the individual suitability scores to the sum of the number of applicable categories. The following equation defines the CRM suitability ratio:

$$r_{suitability} = \sum_{i=1}^{N} (\mathrm{X_i C_i}) / \mathrm{N} \tag{2}$$

where N is the total number of applicable analysis criteria, C is the individual score for each analysis capability, and X is the weight assigned to each analysis capability.

The range of values for the $r_{suitability}$ ratio is between 0 and 1, with values closer to 1 being more suitable. Unlike the $r_{success}$ ratio, which can be used to evaluate and compare the richness and completeness of CRM data warehouse models, the $r_{suitability}$ ratio, however, can be used to help companies to determine the suitability of the model based upon the contextual priorities of the decision makers (i.e., based upon the company-specific CRM needs). We utilize the two metrics to evaluate the proposed CRM data warehouse model in our case study implementation.

A brief review of CRM literature is presented in the next section. The section on schema design introduces the analytical CRM analyses requirements that the data warehouse must support as well as provides guidelines for designing the fact tables and the dimensions. The experiment, which is subsequently described with the results in the following section, tests the completeness of the model. The flexibility of the model, the utilization of the CRM analyses, as well as the initial heuristics for designing a CRM data warehouse are presented in the discussion. Finally, the research contributions and future work are discussed in the conclusions

CRM LITERATURE REVIEW

The shift in marketing paradigms from mass marketing to target marketing to the customer-centric one-to-one marketing (known as relationship marketing) is driving CRM (Bose, 2002). Mass marketing is a product-focused approach that allows companies to reach a wide audience with little or no research, irrespective of the consumer's individual needs. Unlike mass marketing, target marketing focuses on marketing to segmented groups that share a similar set of characteristics (e.g., demographic information and purchasing habits). While both approaches are cost-effective, they do not allow for personalization. On the other hand, one-to-one marketing (relationship marketing) enables companies to treat customers individually according to their unique needs. Since not all relationships are profitable or desirable, relationship marketing allows companies to focus on customers that have the best potential lifetime value. In order to identify the appropriate customer-specific approach for managing individual customers, we first must classify customers into one of the four quadrants in Table 1 and subsequently apply the appropriate strategy. In the literature, researchers use the total historical value, total potential future value, and customer lifetime value (CLV). In fact, managing the CLV is essential to the success of CRM strategies (Bose, 2002), because companies that understand and utilize CLV are 60% more profitable than those that do not (Kale, 2004). There are many ways to define and calculate those measures (Hawkes, 2000; Hwang, Jung & Suh, 2004; Jain & Singh, 2002; Rosset, Neumann, Eick & Vatnik, 2003). For the purposes of this article, CLV is the sum of the total historical value and the total potential value for each customer. The following equation defines the *total historical value*:

$$\text{Historical Value} = \sum_{i=1}^{N} (\text{Revenue}_j - \text{Cost}_j) \quad (3)$$

where j is the individual products that the customer has purchased.

In Equation (3), the historical value is computed by summing the difference between the revenue and total cost over every product (j) that the customer has purchased in the past. The cost would include such things as product cost, distribution cost, and overhead cost. Using the same calculation as defined by Hwang et al. (2004), the following equation defines the *potential future value* for a customer:

$$\text{Potential Future Value} = \sum_{i=1}^{N} (\text{Probability}_j \times \text{Profitability}_j) \quad (4)$$

where j is the individual products that the customer potentially could purchase.

In Equation (4), the profitability represents the expected revenues minus the sum of the expected costs that would be incurred in order to gain the additional revenues. The probability represents the likelihood that the customer would purchase the product. Thus, the total potential future value would be the sum of individual potential future value of each product that the customer could potentially purchase. The sum of all of the individual customer lifetime values is known as *customer equity* (Rust, Lemon & Zeithaml, 2004).

One of the goals of companies should be to increase their customer equity from one year to the next. By incorporating the ability to compute the CLV into the CRM data warehouse, companies can utilize the CRM data warehouse to determine their customer growth. Additionally, companies can use key performance indicators (KPIs) to identify areas that could be improved. Specific KPIs should relate to the goals of the organization. For example, if a company wants to minimize the number of late deliveries, then an on-time delivery KPI should be selected. Some known KPIs that are relevant to CRM include, but are not limited to, margins, on-time deliveries, late-deliveries, and customer retention rates. Other KPIs that are relevant to CRM include, but are not limited to, marketing cost, number and value of new customers gained, complaint numbers, and customer satisfaction rates (Kellen, 2002).

SCHEMA DESIGN FOR CRM

The first step in any design methodology is to understand the requirements. As such, the minimum requirements for CRM analyses are presented in the CRM analysis requirements section. The specific CRM analysis requirements as well as the need to classify customers according to the four CRM quadrants presented in Table 1 then are used to identify the specific fact tables and dimensions. The heuristics (or guidelines) for modeling the fact tables and dimensions then are explored in the design rationale for the fact tables and design rationale for the dimensions subsections.

CRM Analysis Requirements

The purpose of a data warehouse is not just to store data but rather to facilitate decision making. As such, the first step to designing the schema for the CRM data warehouse is to identify the different types of analyses that are relevant to CRM. For example, some typical CRM analyses that have been identified include customer profitability analysis, churn analysis, channel analysis, product profitability analysis, customer scoring, and campaign management.

In addition to identifying what CRM analyses the data warehouse needs to support, we also must understand how the data analyses are used by the business users. Often, understanding the business use of the data analyses provides additional insights as to how the data should be structured, including the identification of additional attributes that should be included in the model.

Once the specific types of CRM analyses as well as the intended uses of those analyses have been identified, they can be decomposed into the data points that are needed to support the analyses. Moreover, additional data points also can be identified from both experience and literature (Boon, Corbitt, & Parker, 2002; Kellen, 2002; Rust et al., 2004). It should be noted that the additional data points could include non-transactional information such as customer complaints, support calls, and other useful information that is relevant for managing the customer relationships. Furthermore, the non-transactional information could exist in a variety of formats, such as video and graphics (Bose, 2002). Such data formats are beyond the scope of this article. Table 3 identifies the types of analyses that are relevant to CRM as well as some of the data maintenance issues that must be considered. In other words, Table 3 identifies the minimum design requirements for a CRM data warehouse (DW). It should be noted that there is no significance to the order in which the items are listed in Table 3. The design rationale in the following section is based on the minimum design requirements in Table 3.

Design Rationale for the Fact Tables

The model needs to have fact tables that can be used to compute the historical and future values for each customer, because they are used to classify customers. As such, the model consists

Table 3. Minimum design requirements for CRM DWs

No.	**Analysis Type/Data Maintenance**	**Description**
3.1	Customer Profitability	Ability to determine profitability of each customer
3.2	Product Profitability	Ability to determine profitability of each product
3.3	Market Profitability	Ability to determine profitability of each market
3.4	Campaign Analysis	Ability to evaluate different campaigns and responses over time
3.5	Channel Analysis	Ability to evaluate the profitability of each channel (e.g., stores, web, and phone)
3.6	Customer Retention	Ability to track customer retention
3.7	Customer Attrition	Ability to identify root causes for customer attrition
3.8	Customer Scoring	Ability to score customers
3.9	Household Analysis	Ability to associate customers with multiple extended household accounts
3.10	Customer Segmentation	Ability to segment customers into multiple customer segmentations
3.11	Customer Loyalty	Ability to understand loyalty patterns among different relationship groups
3.12	Demographic Analysis	Ability to perform demographic analysis
3.13	Trend Analysis	Ability to perform trend analysis
3.14	Product Delivery Performance	Ability to evaluate on-time, late and early product deliveries
3.15	Product Returns	Ability to analyze the reasons for and the impact of products being returned
3.16	Customer Service Analysis	Ability to track and analyze customer satisfaction, the average cost of interacting with the customer and the time it takes to resolve customer complaints
3.17	Up-selling Analysis	Ability to analyze opportunities for customers to buy larger volumes of a product or a product with a higher profitability margin
3.18	Cross-selling Analysis	Ability to identify additional types of products that customers could purchase, which they currently are not purchasing
3.19	Web Analysis	Ability to analyze metrics for web site
3.20	Data Maintenance	Ability to maintain the history of customer segments and scores
3.21	Data Maintenance	Ability to integrate data from multiple sources, including external sources
3.22	Data Maintenance	Ability to efficiently update/maintain data

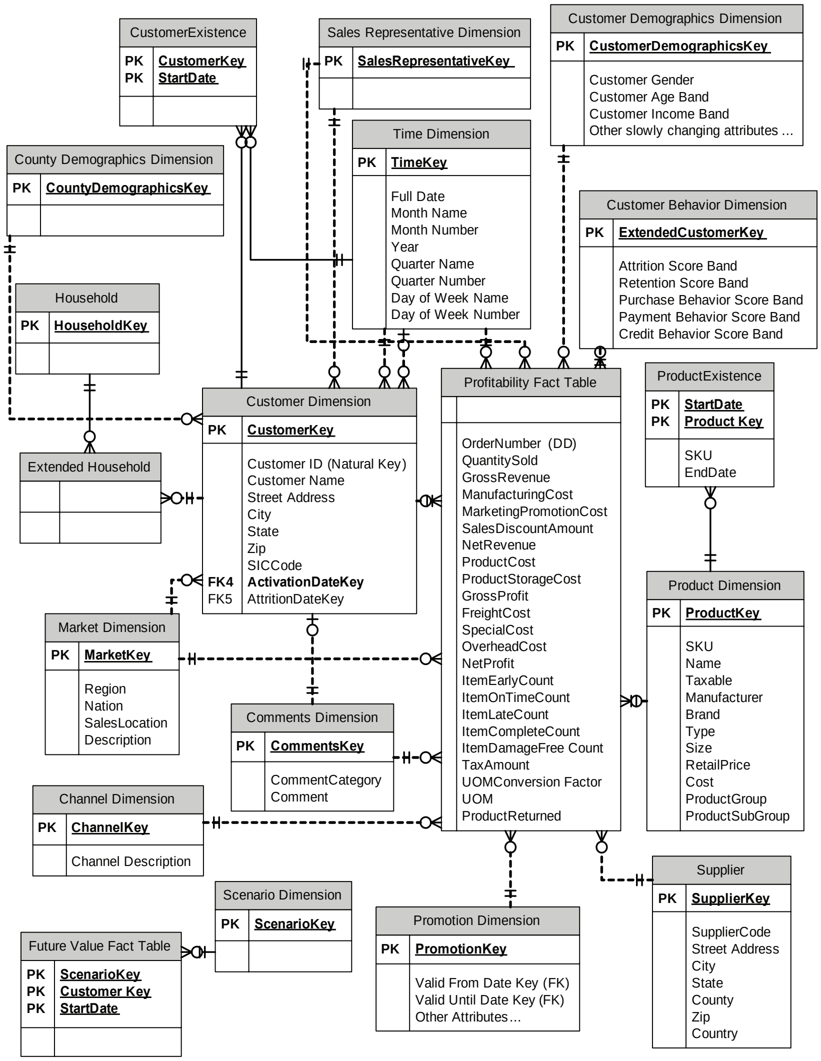
of a profitability fact table, a future value fact table, a customer service fact table, and various dimensions, which are defined in Table 4. We note that not all of the fact tables and dimensions are included in Figure 1. The profitability fact table includes the attributes (e.g., revenues and all costs—distribution, marketing, overhead, and product) that are required to compute the historical profitability of each transaction in the profitability fact table with the minimum number of joins.

Table 4. Starter model dimension definitions

Dimension Name	Dimension Definition
Channel Dimension	Stores the different modes for interacting with customers
Customer Dimension	Stores the static information about the customer
Customer Behavior Dimension	Stores the dynamic scoring attributes of the customer
Customer Demographics Dimension	Stores the dynamic demographic characteristics of the customer
CustomerExistence	Tracks the periods in which the customer is a valid
CustomerMarket	Tracks changes in the relationship between the customer and market dimensions
Comments Dimension	Stores the reasons for customer attrition and product returns
Company Representative	Stores the company representatives (sales representatives)
County Demographics Dimension	Stores external demographics about the counties
Extended Household	Represents the fact that the customer may belong to one or more extended households
Market Dimension	The organizational hierarchy and regions in which the customer belongs
Product Dimension	Represents the products that the company sells
ProductExistence	Tracks the periods in which the products are valid
Promotion Dimension	Represents the promotions that the company offers
Prospect	Stores information about prospects
Scenario Dimension	Used to analyze hypothetical up-selling and cross-selling scenarios
Supplier Dimension	Represents the vendors that supply the products
sTime Dimension	The universal times used throughout the schema
Time Dimension	Universal dates used throughout the schema

That, in turn, improves the performance when querying the data warehouse. Additionally, storing the detailed transactions facilitates the ability to compute the CLV for each customer across each product. Moreover, the model depicted in Figure 1 can be used to calculate KPIs for delivery, such as the number of on-time items and the number of damage-free items. The complement measures

Figure 1. Proposed CRM data warehouse model



are calculated by subtracting the explicitly stored KPI measures from the total quantity. These KPIs are important to track and manage, because they can help organizations to identify internal areas for process improvements and ultimately influence customer satisfaction and possibly customer retention.

The customer service fact table contains information about each interaction with the customer, including the cost of the interaction, the time to resolve the complaint, and a count of customer satisfaction or dissatisfaction. The total historical value of each customer is computed by summing the historical value of each transaction (i.e., the net revenue from the profitability fact table) and then subtracting the sum of the cost of interacting with the customer (i.e., the service cost from the customer service fact table).

In accordance with Equation 4, the future value fact table stores measures that are needed to compute the potential future lifetime value for each customer. For example, among other things, the future value fact table contains the expected gross revenue, costs, expected purchasing frequency, and the probability of gaining additional revenue. It also contains other descriptive attributes that can be used to analyze and categorize the customer's future lifetime value. The customer lifetime value, which is used to classify each customer in one of the four quadrants in Table 1, is computed by summing the historical value for each customer and the future value for each customer.

Design Rationale for the Dimensions

Dimensions are very important to a data warehouse, because they allow the users to easily browse the content of the data warehouse. Special treatment of certain types of dimensions must be taken into consideration for CRM analyses. Each of those dimension types and their special treatments are discussed in the following subsections.

Existence Dimensions and Time

Customer Relationship Management is a process. As with any business process, the CRM process needs to be changed periodically to reflect changes in and additions to the business process (e.g., organizational restructuring due to territory realignments or mergers and acquisitions, new or modified business rules, changes in strategic focus, and modified or new analysis requirements). Thus, time is an inherent part of business systems and must be modeled in the data warehouse. Traditionally, the time dimension primarily participates in a relationship with the fact tables only. Additionally, there are two ways of handling temporal changes: tuple versioning and attribute versioning (Allen & March, 2003). Tuple versioning (or row time stamping) is used in multiple ways to record (1) changes in the active state of a dimension, (2) changes to the values of attributes, and (3) changes in relationships (Todman, 2001). As such, traditional tuple versioning has limitations within the context of CRM. For example, periods of customer inactivity can be determined only by identifying two consecutive tuples where there is a gap in the timestamp. Additionally, queries that involve durations may be spread over many tuples, which would make the SQL statement complex with slow response times (Todman, 2001).

In order to alleviate the issues with traditional time stamping in the context of CRM, each dimension is examined carefully to determine if the dimension (1) contains attributes whose complete set of historical values have to be maintained, or (2) is subject to discontinuous existence (i.e., only valid for specific periods).

If either (1) or (2) is applicable, then a separate dimension is created called an existence dimension. The existence dimensions are implemented as outriggers, and two relationships are created between the time dimension and each outrigger dimension. The two relationships are formed in order to record the date period in which the data instances are valid. In doing so, this facilitates the ability to perform state duration queries and transition detection queries (Todman, 2001). State duration queries contain a time period (start date and end date) in the *where* clause of the query, whereas transition detection queries identify a change by identifying consecutive periods for the same dimension (Todman, 2001).

Careful consideration is given to this step in the design process, because the fact table only can capture historical values when a transaction occurs. Unfortunately, the reality is that there may be periods of inactivity, which would mean that any changes that occur during those periods of inactivity would not be recorded in the data warehouse. This would, in turn, impact the types of analyses that could be done, since one cannot analyze data that one has not recorded.

Mini-Dimensions

If a dimension contains attributes that are likely to change at a different rate than the other attributes within the dimension, then a separate dimension is created as a mini-dimension. The new dimensions are implemented as mini-dimensions as opposed to outriggers in order to allow the user to readily browse the fact table. One benefit of this approach is that the history of the changes in the customer's behavior scores and demographics are stored as part of the fact table, which facilitates robust analyses without requiring the use of Type 1, 2, or 3 techniques (Kimball & Ross, 2002) for the Customer Demographics or Customer Behavior dimensions.

Customer Dimension

The customer must be at the heart of the customer-centric data warehouse. As such, careful attention must be given to the design of the customer dimension, which will force attention on the customer. Direct relationships are formed between the Customer dimension and the Sales Representative, Market, Comment, and Time dimensions in order to allow the user to readily determine the most current values for the sales representative, market, activation date, attrition date, and attrition comments by simply browsing the Customer dimension without having to include a time constraint in the query statement.

Other Dimensions

There is a Household dimension as well as an extended household dimension in order to analyze the potential lines of influence that exists between customers. In accordance with the types of CRM analyses that the data warehouse must support, other dimensions are identified according to the dimensions along which the fact tables are analyzed. For example, other dimensions include the Product, Supplier, Channel, Promotion, Market, and Sales Representative dimensions in order to facilitate the CRM analyses described in the CRM Analysis Requirements section.

As a result of this approach to modeling the dimensions, the only slowly changing dimensions in the model are the County Demographics dimension, the Product dimension, the Supplier dimension, and the Customer dimension.

The model depicted in Figure 1, which is based upon the minimum design requirements and the design rationale presented in this section, is tested to determine its completeness and flexibility for CRM analyses. The experiment that is used to test the model is described in the following section.

EXPERIMENT

The purpose of the experiment is to test the completeness and flexibility of the proposed CRM data warehouse model. Our hypothesis is that the proposed data warehouse starter model has a positive impact on the ability to perform CRM analyses. The implementation, methodology, and selection of the queries that are used in the experiment to test our hypothesis as well as the results are discussed in the specific subsections that follow.

Implementation

We perform a case study to test the validity of our proposed starter model. The proposed CRM data warehouse model is implemented in SQL Server 2000 running on a Windows 2000 server. The hardware computer is a DELL 1650 database server with a single processor and 2.0 MHz. The schema is populated with 1,685,809 rows of data from a manufacturing company.

Methodology

In the experiment, a series of CRM queries are executed against the proposed data warehouse schema. The success rate of the proposed schema is computed as a ratio of the number of successful queries executed divided by the total number of queries used in the investigation. Furthermore, the proposed CRM data warehouse model is tested to determine if it could or could not perform the analyses listed in Table 3. For each analysis in Table 3 that the model could perform, it is given a score of one point; otherwise, the model is given a score of zero points. The sum of the points for the model is computed in order to determine an overall CRM-analysis capability score. The selection of the queries that are used to study the model is discussed in the following section.

Selection of Queries to Test

Since we believe that the proposed data warehouse starter model has a positive impact on the ability to perform CRM analyses, special care was taken in the selection of the queries used for testing in order to avoid any biases in the types of queries used to test the model. Stratified random sampling is used to select the specific queries for the experiment. The stratified random sampling is conducted as follows: (1) representative queries for CRM are gathered from literature and experience; (2) the queries are grouped into categories based upon the nature of the query; (3) within each category, each query is numbered; (4) a random number generator is used to select queries from each category; and (5) the queries whose assigned number corresponds to the number generated by the random number generator are selected. The specific queries that are selected are listed in Table 5. It is important to note that since the queries are randomly selected from a pool of CRM-related queries, it is possible that the $r_{success}$ ratio can be less than one for our proposed model. It is also important to note that the representative CRM queries are queries that equally apply to different industries and not queries that are specific to only one industry. This aspect of the sampling procedure is important in order to make generalizations about the characteristics of the data warehouse schema that should be present in order to perform CRM analyses across different industries.

Results

Our preliminary finding is that the proposed CRM data warehouse model can be used to successfully perform CRM analyses. Based upon the sample queries, our model has a value of 1 and 0.93 for the $r_{success}$ and $r_{suitability}$ ratios, respectively. The individual scores for successfully executing the queries against the model are listed in Table 5. The individual and cumulative scores for the suitability of the proposed CRM data warehouse model are listed in Table 6. It should be noted that there is no significance to the order in which the items are listed in the table.

The scores for items 6.1 through 6.11 in Table 6 are based upon whether or not queries are successfully executed in those categories. The scores for items 14 and 15 are determined while loading data from multiple sources and updating customer scores. Each of the queries that were successfully executed in the experiment is discussed in further detail in the following section in order to highlight the completeness and flexibility of the model.

DISCUSSION

In addition to discussing the completeness and flexibility of the model, this section also presents potential uses of the specific analyses, including KPIs. This section also describes the data quality issues pertaining to CRM data warehouses before presenting a summary of the heuristics for designing data warehouses to support CRM analyses.

Model Completeness and Flexibility

The starter model depicted in Figure 1 can be used for a variety of CRM analyses, including customer profitability analysis, household profitability analysis, demographics profitability analysis, product profitability analysis, channel profitability analysis, and promotion profitability analysis simply by including the appropriate dimensions in the query statement. Furthermore, each query can be modified to include additional measures and descriptions simply by including additional

Table 5. Sample CRM analyses

No.	Category	Analysis	Pass	Fail
5.1	Channel Analysis	Which distribution channels contribute the greatest revenue and gross margin?	1	0
5.2	Order Delivery Performance	How do early, on time and late order shipment rates for this year compare to last year?	1	0
5.3	Order Delivery Performance and Channel Analysis	How do order shipment rates (early, on time, late) for this year compare to last year by channel?	1	0
5.4	Customer Profitability Analysis	Which customers are most profitable based upon gross margin and revenue?	1	0
5.5	Customer Profitability Analysis	What are the customers' sales and margin trends?	1	0
5.6	Customer Retention	How many unique customers are purchasing this year compared to last year?	1	0
5.7	Market Profitability Analysis	Which markets are most profitable overall?	1	0
5.8	Market Profitability Analysis	Which products in which markets are most profitable?	1	0
5.9	Product Profitability Analysis	Which products are the most profitable?	1	0
5.10	Product Profitability Analysis	What is the lifetime value of each product?	1	0
5.11	Returns Analysis	What are the top 10 reasons that customers return products?	1	0
5.12	Returns Analysis	What is the impact of the value of the returned products on revenues?	1	0
5.13	Returns Analysis	What is the trend for product returns by customers by product by reason?	1	0
5.14	Customer Attrition	What are the top 10 reasons for customer attrition?	1	0
5.15	Customer Attrition	What is the impact of the value of the customers that have left on revenues?	1	0

fields from the fact table and the dimensions. Some of those queries are discussed next.

The SQL statement in Figure 2 is used to identify the most profitable customers based upon total revenue and gross margin. By excluding the time dimension, the customer profitability SQL statement identifies the customer's historical lifetime value to the company. This is an important analysis that, in conjunction with the customer's future value and the customer service interaction costs, is used to classify customers in one of the four CRM quadrants (Table 1), which subsequently can be used to determine the appropriate strategy for managing the customer.

The SQL statement in Figure 3 is used to determine the margins for each product and subsequently identifies products that potentially may be eliminated from the company's product line. The ability to be able to determine the lifetime value of each product (irrespective of market) merely by modifying the SQL statement in Figure 3 to exclude the product code further illustrates

Table 6. Sample suitability for CRM analyses scores

No.	Criteria	Score
6.1	Ability to track retention	1
6.2	Ability to identify root causes for customer attrition	1
6.3	Ability to score customers	1
6.4	Ability to associate customers with multiple extended household accounts.	1
6.5	Ability to segment customers into multiple customer segmentations	1
6.6	Ability to maintain the history of customer segments and scores.	1
6.7	Ability to evaluate different campaigns and responses over time	1
6.8	Ability to analyze metrics for website	0
6.9	Ability to understand loyalty patterns among different relationship groups	1
6.10	Ability to perform demographic analysis	1
6.11	Ability to perform trend analysis	1
6.12	Ability to perform customer profitability analysis	1
6.13	Ability to perform product profitability analysis	1
6.14	Ability to integrate data from multiple sources, including external sources	1
6.15	Ability to efficiently update/maintain data.	1

ORDER BY Sum(a.GrossRevenue) DESC;
```

the flexibility and robustness of the proposed CRM model.

The SQL statement in Figure 4 is used to determine and compare Key Performance Indicators (KPIs) for overall on-time, early, and late shipment percentages for different years.

By modifying the statement in Figure 4 to include the Channel Dimension, the performance of each channel from one year to the next is determined. The modified SQL statement can be seen in Figure 5.

The SQL statement in Figure 6 is used to determine the overall profitability of each market. By eliminating the market key from the SQL statement, the profitability for each location is obtained for each location within the organizational hierarchy that is defined in the market dimension.

The SQL statement in Figure 7 demonstrates that by including the product code from the product dimension in the previous SQL statement, the profitability of each product by market is obtained.

Figure 4. Order delivery performance query — How do early, on time, and late order shipment rates for this year compare to last year?

```
SELECT b.Year, Sum(a.ItemOnTimeCount) AS OnTime, Sum(a.ItemEarlyCount) AS
Early, Sum(a.ItemLateCount) AS Late,
Sum(a.ItemOnTimeCount+a.ItemEarlyCount+a.ItemLateCount) AS TotalCount,
OnTime/Late*100 AS PercentOnTime, Early/TotalCount*100 AS PercentEarly,
Late/TotalCount*100 AS PercentLate

FROM tblProfitabilityFactTable a, tblTimeDimension b

WHERE b.TimeKey = a.TimeKey

GROUP BY b.Year;
```

Figure 5. Order delivery performance and channel analysis query — How do order shipment rates (early, on-time, late) for this year compare to last year by channel?

```
SELECT b.Year, c.ChannelCode, Sum(a.ItemOnTimeCount) AS OnTime,
Sum(a.ItemEarlyCount) AS Early, Sum(a.ItemLateCount) AS Late,
Sum(a.ItemOnTimeCount+a.ItemEarlyCount+a.ItemLateCount) AS TotalCount,
OnTime/Late*100 AS PercentOnTime, Early/TotalCount*100 AS PercentEarly,
Late/TotalCount*100 AS PercentLate

FROM tblProfitabilityFactTable a, tblTimeDimension b, tblChannelDimension c

WHERE b.TimeKey=a.TimeKey And c.ChannelKey = a.ChannelKey

GROUP BY b.Year, c.ChannelCode;
```

Figure 6. Market profitability analysis query — Which markets are most profitable overall?

```
SELECT c.Year, b.MarketKey, b.LocationCode, b.Location, b.Description,
b.CompetitorName, Sum(a.GrossRevenue) AS TotalRevenue, Sum(a.GrossProfit) AS
TotalGrossProfit, TotalGrossProfit/TotalRevenue AS GrossMargin

FROM tblProfitabilityFactTable a, tblMarket b, tblTimeDimension c

WHERE b.MarketKey=a.MarketKey And a.TimeKey=c.TimeKey

GROUP BY c.Year, b.MarketKey, b.LocationCode, b.Location, b.Description,
b.CompetitorName, b.MarketKey

ORDER BY Sum(a.GrossRevenue) DESC;
```

The SQL statement in Figure 8 is used to determine the top reasons for product returns. In this case, the basis for the top reasons is merely the count of the number of reasons that products are returned. By first grouping the products that are returned according to the reason for their return and the product code and then including the number of returns, revenue, gross profit, and gross margin for each group, the SQL statement in Figure 8 identifies areas upon which the company should improve in order to minimize the number of returns and to improve overall customer satisfaction. Specifically, since companies have limited resources, a company can use the result set to create Pareto charts according to the most frequently occurring problems that have the largest associated gross profits. Management teams then can use the Pareto charts to determine which problems to address first with corrective actions. It should be noted that in order to facilitate quick identification of the most frequently occurring problems that have the largest associated gross profits, the SQL statement in Figure 8 includes an ORDER BY clause.

Furthermore, simply by modifying the SQL statement in Figure 8 to include the year of the transaction from the profitability fact table in the SELECT clause and the GROUP BY clause, companies can use the results of the modified query to monitor the trend of return reasons over time. Stated differently, companies can use the results of the modified query statement to monitor the impact of the corrective actions over time. Not only can the return analyses be used to monitor the impact of corrective actions, but they also can be used to identify improvement targets, which can be tied to employee (and/or departmental) performance goals.

Figure 7. Product profitability analysis query — Which products in which markets are most profitable?

```
SELECT c.Year, b.MarketKey, b.LocationCode, b.Location, b.Description,
b.CompetitorName, d.ProductCode, d.Name, Sum(a.GrossRevenue) AS TotalRevenue,
Sum(a.GrossProfit) AS TotalGrossProfit, TotalGrossProfit/TotalRevenue AS
GrossMargin

AS TotalRevenue, Sum(a.GrossProfit) AS TotalGrossProfit,
TotalGrossProfit/TotalRevenue AS GrossMargin, Count(*) AS MembershipCount

FROM tblProfitabilityFactTable a, tblTimeDimension b, tblProductDimension c,
tblCommentDimension d

WHERE a.TimeKey=b.TimeKey And a.ProductKey=c.ProductKey And
a.CommentsKey=d.CommentsKey And a.ProductReturned=Yes

GROUP BY d.CommentsKey, c.ProductCode, c.Name, d.Comment, c.ProductKey

ORDER BY Count(*) DESC, Sum(a.GrossProfit) DESC;

ORDER BY Sum(a.GrossRevenue) DESC;
```

The SQL statement listed in Figure 9 is used to determine the impact of the returned products on revenues.

The SQL statement listed in Figure 10 is used to identify the trend for product returns by customer, by product, and by reason. The results can be used to identify whether or not a problem is systematic across all customers, many customers, or a few specific customers. This query also can be used to help management make an informed decision with respect to allocating resources to address problems that lead to customers returning products. Additionally, the results can be used by the sales team to gain further insights into why their customers have returned products. The sales team potentially can use that information to work with the customer to resolve the issue(s) in cases where the customer repeatedly has returned products for reasons that cannot be considered the company's mistake. Alternatively, the sales team can use the results to identify accounts that could (should) be charged additional fees if the customer repeatedly returns products.

The SQL statement in Figure 11 is used to identify the top reasons for customer attrition. Figure 12 is used to analyze the impact of customer attrition on the total revenues. By analyzing customer attrition, companies can gain further insights into areas for improvement in order to reduce the attrition rate and thereby improve its overall company value.

Table 7 summarizes some of the possible uses for the CRM analyses that are presented in Table 5.

Data Quality

Given the range of decisions that the CRM data warehouse must be able to support and given the potential impact on companies' profitability, it is imperative that the data are accurate. The data that are used in the CRM analyses originate from disparate data sources that must be integrated into the data warehouse. Under such circumstances, the issue of dirty data arises. Analyzing dirty data, particularly in the context of systems that support corporate decision-making processes (e.g., CRM analyses and subsequent decisions), would result in unreliable results and potentially inappropriate decisions. As such, ensuring data quality within the data warehouse is important to the overall success of subsequent CRM analyses and decisions. Data quality should not be considered a one-time exercise conducted only when data are loaded into the data warehouse. Rather, there should be a continuous and systematic data quality improvement process (Lee, Pipino, Strong, & Wang, 2004; Shankaranarayan, Ziad, & Wang, 2003).

One way of minimizing data quality issues is to carefully document the business rules and data formats that then can be used to ensure that those requirements are enforced. Too often, however, thorough documentation of the business rules and data formats is not available in a corporate setting. Therefore, routine data quality audits should be performed on the data in the CRM model in order to identify data quality issues that are not addressed during the ETL process. For example, missing data can be identified during data quality audits and consequently addressed by consulting with a domain expert.

Some forms of dirty data (e.g., outliers) can be identified using data mining techniques and statistical analysis, while other forms of dirty data (e.g., missing data values) are more problematic. Although Dasu, Vesonder, and Wright (2003) assert that data quality issues are application-specific, Kim, Choi, Kim, and Lee (2003) developed a taxonomy of dirty data and identified methods for addressing dirty data based upon their taxonomy. Kim et al. (2003) identified three broad categories of dirty data: (1) missing data; (2) not missing, but wrong data; and (3) not missing and not wrong, but unusable data. They then further decompose

Table 7. Initial taxonomy of CRM analyses (S = strategic and T = tactical)

#	Decision Class	Category	Analysis	Potential Use(s)	KPI
1	S	Channel Analysis	Which distribution channels contribute the greatest revenue and gross margin?	Resource allocation	
2	S, T	Order Delivery Performance	How do early, on time and late order shipment rates for this year compare to last year?	Setting performance goals	early delivery, on-time delivery, late delivery
3	S	Order Delivery Performance and Channel Analysis	How do order shipment rates (early, on time, late) for this year compare to last year by channel?	Setting performance goals, monitoring trends	early delivery, on-time delivery, late delivery
4	S	Customer Profitability Analysis	Which customers are most profitable based upon gross margin and revenue?	Classify customers	gross margin, revenue
5	S	Customer Profitability Analysis	What are the customers' sales and margin trends?	Classify customers	gross margin, revenue
6	S	Customer Retention	How many unique customers are purchasing this year compared to last year?	Identify the threshold to overcome with new customers	unique customers/ year
7	S, T	Market Profitability Analysis	Which markets are most profitable overall?	Setting performance goals, allocate marketing resources	gross margin/ market
8	S, T	Market Profitability Analysis	Which products in which markets are most profitable?	Setting performance goals, allocate marketing resources	gross margin/ products/ market
9	S, T	Product Profitability Analysis	Which products are the most profitable?	Managing product cost constraints, identify products to potentially eliminate from product line	gross margin/ product
10	S, T	Product Profitability Analysis	What is the lifetime value of each product?	Managing product cost constraints, identify products to potentially eliminate from product line	gross margin/ product
11	S, T	Returns Analysis	What are the top 10 reasons that customers return products?	Create Pareto charts to identify problems to correct, setting performance goals	count
12	S, T	Returns Analysis	What is the impact of the value of the returned products on revenues?	Create Pareto charts to identify problems to correct, setting performance goals	count, revenue, profit
13	S, T	Returns Analysis	What is the trend for product returns by customers by product by reason?	Create Pareto charts to identify problems to correct, setting performance goals, identify problematic accounts (identify customers that may leave), assess additional service fees	count, revenue, profit

each category of dirty data. However, they did not include composite types of dirty data. They provided some suggestions to address the issue of dirty data that can be used to clean dirty data in the CRM model during the ETL process. For example, the use of constraints can be valuable for avoiding instances of missing data (e.g., not null constraints) or incorrect data (e.g., domain ranges and check constraints). It is important to point out that the ability to enforce integrity constraints on inconsistent spatial data (e.g., geographical data such as sales territory alignments) and outdated temporal data is not supported in current database management systems.

Initial Heuristics for Designing CRM Data Warehouses

Once the types of CRM analyses that the data warehouse needs to be able to support have been identified, the data points have been identified, and the granularity has been selected, the next step is designing the data warehouse model to support the analyses that were identified. Based upon our initial findings, Table 8 lists initial heuristics for designing a data warehouse in order to successfully support CRM analyses.

CONCLUSION

In this article, we first present the design implications that CRM poses to data warehousing and then propose a robust multidimensional starter model that supports CRM analyses. Based upon sample queries, our model has a value of 1 and 0.93 for the $r_{success}$ and $r_{suitability}$ ratios, respectively. Our study shows that our starter model can be used to analyze various profitability analyses such as customer profitability analysis, market profitability analysis, product profitability analysis, and channel profitability analysis. In fact, the model has the flexibility to analyze both trends and overall lifetime value of customers, markets, channels, and products simply by including or excluding the time dimension in the SQL statements. Since the model captures rich descriptive non-numeric information that can be included in the query statement, the proposed model can return results that the user easily can understand. It should be noted that such rich information then can be used in data mining algorithms for such things as category labels. As such, we have demonstrated that the robust proposed model can be used to perform CRM analyses.

Our contributions also include the identification of and classification of CRM queries and their uses, including KPIs; the introduction of a sampling technique to select the queries with which the model is tested; the introduction of two measures (percent success ratio and CRM suitability ratio) by which CRM data warehouse models can be evaluated; and the identification of the initial heuristics for designing a data warehouse to support CRM. Finally, in terms of future work, we plan to classify and test additional CRM analyses, evaluate alternative models using the same set of queries and the $r_{success}$ and $r_{suitability}$ ratios, identify

Table 8. Initial heuristics for designing CRM DWs

#	**Heuristic**	**Benefit**
1	Identify the types of CRM analyses, their uses and the data elements required to perform the analyses	The model will be able to support the intended purpose of the analyses
2	Include all attributes required to compute the profitability of each individual transaction in the fact table(s)	The ability to generate a profit & loss statement for each transaction, which can then be analyzed along any dimension
3	Each dimension that will be used to analyze the Profitability fact table should be directly related to the fact table	Provides improved query performance by allowing the use of simplified queries (i.e., support browsing data)
4	Pay careful attention to the Customer dimension	It forces attention to the customer to the center of CRM
5	Create a relationship between the Customer dimension and the Market and Sales Representative dimensions	Provides the ability to quickly determine the current market and Sales Representative for the customer by merely browsing the Customer dimension
6	Include the attrition date and reason for attrition attributes in the Customer dimension	Provides the ability to quickly determine if a customer is no longer a customer by browsing the Customer dimension only
7	Attributes that are likely to change at a different rate than other attributes in the same dimension should be in a separate dimension	Minimize the number of updates
8	Create a separate *existence* dimension for any entity that can have a discontinuous existence	Provides the ability to track the periods in which the instance of the entity is valid (needed to support some temporal queries)
9	Create a separate *existence* dimension for any attribute whose historical values must be kept	Provides the ability to track accurate historical values, even during periods of inactivity
10	Create a relationship between the Time dimension and each *existence* dimension	Provides the ability to perform temporal queries efficiently using descriptive attributes of the Time dimension
11	*Existence* dimensions should be in a direct relationship with their respective original dimensions	
12	There should always be a CustomerExistence dimension	The ability to track and perform analyses on customer attrition
13	If some products are either seasonal or if it is necessary to determine when products were discontinued, then create a ProductExistence dimension	The ability to perform analyses for seasonal and discontinued products
14	There should be a Household dimension and an ExtendedHousehold dimension	Provides the ability to perform Household analyses
15	The organizational hierarchical structure can be contained in one *Market* dimension	Provides the ability to maintain a history of the organizational changes, and the ability to perform analyses according to the organizational structure

materialized views that are relevant to CRM, and explore CRM query optimization.

Chapter 2.21

Developing a Global CRM Strategy

Michael Shumanov

ABSTRACT

While the managerial rationale for adopting customer relationship management (CRM) has been fairly well articulated in the literature, research on strategy development is scant. Moreover, reports of "CRM failures" in the popular business press have done little to inspire confidence. To date, what little research has been conducted in the area of CRM strategy development has been confined to a single country (often the U.S.). Global CRM strategy development issues have yet to be specifically addressed, particularly which elements of CRM strategy should be centralised/decentralised. The present study examines the complexities of global CRM strategy using the case of a leading financial services company. Interviews are conducted in 20 countries. Global Head Office and external IT consultant perspectives are also considered. Our findings confirm that a hybrid approach has wide practical appeal and that subsidiary orientation towards centralisation/decentralisation is moderated by firm/market size and sophistication.

INTRODUCTION

Recent advances in information technology (IT) have enhanced the possibilities for collecting customer data and generating information to support marketing decision making. CRM has been heralded by some as being the key to delivering superior business performance by focusing organisational efforts towards becoming more customer-centric and responsive (Davenport, Harris, & Kohli, 2001; Puschman & Rainer, 2001). However, others have cautioned that increasing information may actually *increase* the complexity of the decision-making process thereby adversely affecting decision-making performance (Van Bruggen, Smidts, & Wierenga, 2001).

Much of the extant academic literature on CRM has focused on identifying antecedents and consequences (e.g., Bull, 2003; Day & Van den Bulte 2002; Kotorov, 2003; Ryals & Knox, 2001). CRM has been variously conceptualised as (1) a process (e.g., Day & Van den Bulte, 2002; Galbreath & Rogers, 1999; Srivastava, Shervani, & Fahey, 1998); (2) a strategy (e.g., Croteau & Li, 2003; Verhoef & Donkers, 2001); (3) a philosophy (e.g., Fairhurst, 2001; Reichheld, 1996); (4) a capability (e.g., Peppers, Rogers, & Dorf, 1999) and (5) a technology (e.g., Shoemaker, 2001). Although there is clearly more to CRM than technology (Day & Van den Bulte, 2002; Reinartz, Krafft, & Hoyer, 2004), it is important to recognise that technology does play a central role in supporting the seamless integration of multiple customer touch points. IT also enables organisations to collect, store, develop, and disseminate knowledge throughout the organisation (Bose 2002; Crosby & Johnson, 2001). Customer knowledge is critical for successful customer relationship management (Crosby & Johnson, 2000; Davenport et al., 2001; Hirschowitz, 2001).

CRM Defined

The importance of technology in enabling CRM is exemplified by the attempts at defining the concept. CRM has been defined as the alignment of business strategies and processes to create customer loyalty and ultimately corporate profitability enabled by technology (Rigby, Reichheld, & Schefter, 2002). In a similar vain, Ryals (2002) defines it as the lifetime management of customer relationships using IT. E-CRM is defined as the application of customer relationship management processes utlising IT and relies on technology such as relational databases, data warehouses, data mining, computer telephony integration, Internet, and multi-channel communication platforms in order to get closer to customers (Chen & Chen, 2004; Fjermestad & Romano, 2003). In many respects e-CRM is a tautology in that without “e,” or technology, there would be no CRM. We therefore standardise on the term CRM throughout the paper.

As a business philosophy, CRM is inextricably linked to the marketing concept (Kotler, 1967) and market orientation, which stresses that firms must organise around, and be responsive to, the needs of customers (Kohli & Jaworski, 1990; Narver & Slater, 1990). From a capability perspective, CRM needs to be able to gather intelligence about current and prospective customers (Campbell, 2003; Crosby & Johnson, 2000; Davenport et al., 2001; Zablah, Bellenger, & Johnston, 2004) and apply that intelligence to shape its subsequent customer interactions. Furthermore, CRM processes need to acknowledge that relationships develop over time, have distinct phases, and are dynamic (Dwyer, Schurr, & Oh, 1987). Adopting this view highlights that CRM processes are best thought of as longitudinal phenomena. The interesting feature for firms is that they should interact and manage relationships with customers differently at each stage (Srivastava et al., 1998). Essentially, CRM involves the systematic and proactive management of relationships from initiation to termination across all channels (Reinartz et al., 2004). Another aspect of the relationship continuum is that not all relationships provide equivalent value to the firm. CRM requires firms to allocate resources to customer segments based on the value of the customer segment to the firm (Zablah et al., 2004; Zeithaml, Rust, & Lemon, 2001).

CRM Strategy

A high degree of CRM process implementation is characterised as where firms are able to adjust their customer interactions based on the lifecycle stages of their customers and their capacity to influence or shape the stages (i.e., extending relationships, Reinartz et al., 2004). Standardising CRM processes enables consistent execution to customers across all delivery channels. Successful CRM also requires organisational alignment (employee reward systems, organisational structure, training procedures) and investments in CRM technology. Interestingly, the level of technological sophistication of CRM technology makes no contribution to economic performance and supports the view that CRM is more than just software (Reinartz et al., 2004).

CRM can be conceptualised at three levels: (1) company wide, (2) functional, and (3) customer facing (Buttle, 2004). This study adopts the company-wide definition of CRM which views CRM as a core customer-centric business strategy focused on acquiring and retaining profitable customers (Buttle, 2004). This requires a customer-centric business culture, formal reward and recognition systems that promote employee behaviours that enhance customer satisfaction and the sharing of customer information and its conversion into useful knowledge.

Unfortunately, CRM's potential has, in many instances, failed to be realised. Successful implementation requires the adoption of a customer-centric business strategy and a redesign of functional activities, workflows, and processes (Galami, 2000; Nelson & Berg, 2000). Some organisations have begun focusing their business strategy around their customers and capturing, sharing, and applying customer knowledge to deliver superior service and customisation (Mitchell, 1998).

However, despite the rhetoric, empirical research on CRM strategy development is scarce. In particular, work on the vexing standardisation/localisation issue is lacking. In this increasingly globalised economy, it is surprising that researchers have overlooked cross-national differences and global CRM strategy issues. To address these gaps, the present study will seek to explore in depth the issues surrounding standardisation versus localisation of CRM strategy development. A case study of a leading financial services company is used to explore these issues. The paper reviews the localisation/centralisation literature, describes the study to be undertaken, and based on the findings draws a number of conclusions regarding global CRM strategy development and highlights areas worthy of future research.

GLOBAL CRM STRATEGY

In an increasingly competitive and complex market environment, multi-national enterprises (MNE's) are under constant pressure to re-assess the degree of autonomy they grant to their local subsidiaries. While headquarters are likely to have more expertise on strategic matters, local subsidiaries are likely to have more information on operational issues and be more responsive to dynamics impacting their specific market. Within a specific MNE context, centralisation refers to where decision making is vested largely with the global parent company (Cray, 1984). By contrast, decentralised organisations are defined as those where each subsidiary has a high degree of autonomy in making decisions on processes and products relevant to the needs of the local market (Edwards, Ahmad, & Moss, 2002).

There is some empirical evidence to suggest that although subsidiaries of global parent organisations may be given some autonomy in making operating decisions, strategic decision making is invariably controlled by the parent organisation (Bowman, Farley, & Schmittlein, 2000), which can be manifested through IT (Roche, 1996). Moreover, IT provides an efficient and effective decision support system to transfer information from the local subsidiary into the parent company's reporting models, increasing the capacity of headquarter management to engage in local company decision making (Clemmons & Simon, 2001; McDonald, 1996). Using a case study approach, Ciborra and Failla (2000) found that IBM failed in its vision for global CRM because of their fixation for standardisation and centralisation and the use of IT to enforce behaviours. Furthermore, they concluded that this variation in CRM adoption at the country level and unique regulatory requirements made the concept of "global CRM" tenuous at best, although they acknowledge that CRM is a "powerful weapon for centralisation" (Ciborra & Failla, 2000, p. 122).

This desire for greater parent company control is a function of perceived risk. That is, the greater the perceived level of risk, the greater the desire for active decision making (Garnier, 1982). The types of decisions likely to require parent company decision making include capital expenditure; acquisitions and divestments; and funding. A criticism of centralised decision making is that it is expensive and that local subsidiaries are unable to react quickly to changes in local market dynamics (Harris, 1992). There is some empirical evidence to suggest that organisations with decentralised decision making performed better than those organisations characterised as having centralised decision making with respect to marketing (Ozsomer & Prussia, 2000). Moreover, highly centralised organisations make less contribution to their host country in terms of investment, knowledge transfer, and management expertise than their decentralised counterparts (Fina & Rugman, 1996).

We have adopted a typology developed by Barlett and Ghoshal (1989) to classify the predisposition of organisations for a globalised/localised orientation. They describe organisations as: global, international, multi-national, and transnational. A global organisation is characterised as driven by the need for global efficiency, while having structures that are more centralised in their strategic and operational decisions. An international organisation is characterised as transferring and adapting the parent company's knowledge or expertise to foreign subsidiaries. The parent retains influence and control, but to a lesser extent than a classic global structure. A multi-national organisation manages its subsidiaries as though they were components of a portfolio of multi-national entities with headquarters exercising low control and low coordination. Finally, a transnational organisation seeks a balance between global integration and local responsiveness. This type of organisation has structures considered to be both centralised and decentralised simultaneously. Transnational firms have higher degrees of coordination with low control dispersed throughout the organisation. Using this typology, our focal firm can be characterised as a global organisation. That is, they employ structures that are more centralised in their strategic and operational decisions, and their products are homogenous throughout the world. Given a centralised structure, most of the decisions are made at headquarter level and imposed on subsidiaries.

Agency Theory

We use agency theory (Ross, 1973) as the theoretical foundation for describing the relationship between headquarters and country subsidiaries. Agency theory refers to the basic agency structure of a principal and agent who are engaged in cooperative behaviour, but having differing goals and attitudes to risk (Ross, 1973). In our research, the principal is headquarters and the agent is the subsidiary organisation. Goal differences, risk tolerance differences, and information asymmetry can create problems in agency relations (Eisenhardt, 1985). The first general problem is differences in the goals of principal and agents. Agents may act in their own self-interest at the expense of the principal. Secondly, principals and agents may have different tolerances towards risk. In the context of CRM strategy development, the principal is likely to have a lower risk tolerance than the agent. The third problem, asymmetric information arises when one party has more information than the other, or when one party prefers to keep some information private.

There are two types of agent behaviour that could be detrimental to the principal. The first, adverse selection might refer to a subsidiary's misrepresentation of its ability to undertake/implement CRM. The second moral hazard refers to the fact that the agent may not act as diligently as anticipated in carrying out the will of the principal. However, agency theory proposes that better information management systems can reduce the agency problem and provide the principal with greater control and is consistent with our earlier discussion on global CRM strategy development. Control may take the form of behaviour-based or outcome-based strategies. Both rely on the principal's ability to evaluate the performance of the agent, either on a behaviour-by-behaviour basis or at the end of the project based on its outcome (Eisenhardt, 1985).

From the principal's perspective, adopting an outcome-based control strategy is likely to be difficult given that the principal would need to wait until the long-term outcomes became known. Consequently, a behaviour-based control strategy may be preferred by the principal in CRM strategy development. The degree of knowledge that the principal (headquarters) has about the agent (wholly owned subsidiary) in terms of market characteristics, customer profile, and processes, enables headquarters to more effectively monitor and control a subsidiary's behaviour (Kirsch, 1996). This is likely to mitigate the risk of subsidiaries acting in their own self-interest at the expense of the entire organisation. Agency theory (Ross, 1973) is therefore useful in addressing our research questions: what aspects of CRM strategy should be centralised/localised? and what are some of the complexities of cross-national CRM strategy development? Another fundamental concept is the level of involvement between the principal and agent in implementation. For instance, if the agent is able to customise the CRM implementation to reflect their country's requirements, then the principal has less ability to control the behaviour of local country CRM managers compared to where the local subsidiary is required to implement a standardised CRM solution. However, the control dichotomy needs to be balanced to avoid implementation failure particularly where headquarters does not have an in-depth understanding of local market conditions. Furthermore, where a standardised implementation is imposed, it is important to consider the level of knowledge and dynamic learning mechanisms that will need to be created in the local subsidiary to address system failures.

We also examined the channel coordination literature (i.e., Frazier, 1999; Frazier & Rody, 1991; Hunt & Nevin. 1974), which describes the relationship between buyer and seller involving a distribution channel. However, given that this research seeks to examine the relationship between headquarters and its subsidiaries, agency theory offers a more robust theoretical foundation with respect to CRM strategy development. The channel coordination literature relates more to relationships characterised as involving a distribution channel, rather than describing the parent-subsidiary relationship.

METHOD

Data Collection

Understanding both substantive and methodological context permits the reader to put the research into context and thus derive deeper meaning from the findings (Johns, 2001). Data were derived using the case study method and utilising a multi-sample longitudinal research design (Yin, 1994). Case studies enable the development of deep insights into respondent beliefs and assist in theory development (Beverland, 2001). Bonoma (1985), Hirschman (1986), and Deshpande (1983) have all advocated for greater application of qualitative research methods in marketing. In order to avoid cueing subjects into a desired response, respondents were asked fairly general questions on the topic in order to elicit themes (Strauss & Corbin, 1992). Specifically, two "grand tour" questions (McCracken, 1988) were asked. The first related to issues surrounding local subsidiary decision-making empowerment in relation to CRM strategy. The second, on what CRM processes and systems should be centralisation versus decentralisation. Each participant was also sent a copy of the final transcript for comment. Any comments were noted and the results adjusted accordingly (Johnston, Leach, & Liu, 1999). The research questions were then e-mailed to sample 1 respondents with a statement thanking them for participating in the initial depth interviews and reiterating the purpose of the research. This was broadly described as seeking to gain an understanding of global CRM strategy development complexities with the aim of sharing the eventual findings across the whole group. In order to cross validate the results using a different group of respondents, we e-mailed the same two research questions to a second sample of respondents coupled with a statement describing the research. The objective was to assess the robustness of the initial sample findings with a separate sample of respondents (Deshpande, Farley, & Webster, 1993).

Two rounds of interviews were conducted with managers having a functional responsibility for CRM in their respective national subsidiary. Whether CRM respondents were responsible for CRM strategy or implementation was dependent on the level of the respondent within the organisation. Invariably, more senior respondents were responsible for strategy formulation. We had a mix of both strategic and operational CRM respondents (see Tables 1 and 2). The first sample consisted of CRM representatives from the following subsidiaries: Australia, Belgium, Germany, Italy, Netherlands, Spain, Switzerland, United Kingdom, and United States. To improve construct validity, interviews were also conducted with the internal strategy department at headquarters and with external consultants assisting in CRM strategy formulation. This provided a strategic level view of the vision for CRM from a Group/HQ perspective (Deshpande, 1983; Johnston et al., 1999). Details of first round respondents are presented in Table 1.

The first round of interviews was conducted by one of the authors over the telephone (Holbrook, Green, & Krosnick, 2003) and recorded/transcribed in order to assist in thematic analysis. The transcribed data was then edited and any additional data was integrated to develop a case summary. Details of second-round respondents are presented in Table 2. Australia, Germany, Netherlands, Spain, and Switzerland were repre-

sented in both samples, although in this case an alternative respondent, having responsibility for CRM, was interviewed.

FINDINGS

In reporting our results, we quote actual statements made by respondents in order to improve the validity of the findings for the reader (Eisenhardt, 1989; Yin, 1994).

Perceived Complexities of Global CRM Strategy Development

The general consensus of both samples suggested that they are limited in their ability to make strategic decisions. "*[Subsidiaries] get a very strong framework from headquarters.*" Most respondents also anticipate that strategic decision-making is unlikely to become more devolved. Some respondents noted a distinction between strategic decision-making in terms of IT and operations: *"I must say that the CRM project on the IT side is very much directed by the project group at head office. On the other hand, nobody asks us if CRM processes are in place and actively managed"* and "*CRM initiatives particularly system related are being governed on a global or regional basis [and the subsidiary] probably does not have an overriding influence on it.''* An exception to this is country X, where the different stage of CRM development in that market has meant that "*[head office] kind of gave us the ability to operate outside of their purview.*"

Respondents in both samples noted cultural differences and maturity of markets as contributing to the complexity of global CRM strategy development. For instance, "*local cultural differences make it difficult to offer standardised CRM tools.*" Another respondent noted "*no one central system can accommodate all of the differences that exist.*" And another: "*what works great in one country may not work at all in another* *country.*" Another perceived complexity was the capacity to meet all the different subsidiary requirements. "*The number of countries and the differences in market size and maturity creates another layer of complexity.*" And "*you have to deal with a lot of market specifics—market-specific business processes and market-specific system adaptations.*" Process concerns were also articulated, "*…existing local IT systems and related business processes cause issues when trying to overlay a global IT system.*" Interestingly, hardly any respondents considered software-related issues as potential barriers to CRM strategy development, which may reflect their view that CRM is more than just software. However, one respondent noted, "*fractured information flows between head office and local subsidiaries results in misinformation regarding CRM developments.*" And another respondent (in the second sample) raised the issue of cross functionality: "*CRM can't be implemented easily because it is cross functional.*" Some respondents also noted that "*country-specific legislation also needs to be considered.*"

Standardised Across Markets or Tailored to Local Market Requirements?

On the question of whether CRM processes and systems should be centralised, or decentralised, a "hybrid" approach has practical merit. That is, embracing a centralised CRM IT system which can then be configured by subsidiaries to meet local market requirements. The perceived benefits of this approach are that it is cost and resource efficient. Nearly all agreed that there were considerable advantages to centralisation. For example, "*If you just let every country do what they wanted, it would be chaos. Everybody would come up with unique solutions, there would be double investments and duplication of effort, there would no cooperation and I think the organization would suffer.*" And "*centralise as much as possible and localise as little as possible.*" A small market perspective was that "*we feel that some sort of centralisation in one country can very much benefit smaller countries due to budget constraints impeding their ability to develop their own systems.*" The general consensus was that decentralisation would be inefficient in terms of resource utilisation, costs, and duplication of effort. On the other hand, they did recognise that complete centralisation would lead to a situation of inflexibility. "*If you do everything on a central basis, one size fits all, then you are going to end up with inertia of the organization—think global act local.*" There was some dissension on whether centralisation was more cost efficient than localisation. "*From a high level perspective [centralisation] might be cheaper, but down the road, one country will have a couple of hundred requirements, another country will also have another couple of hundred and the question is whether it is going to be worth it. The money that you and everyone is going to spend for changes will be [the] same as having a local solution.*" The answer seems to be somewhere in the middle. "*In my opinion, I think it makes sense to develop them centrally and to adapt to local requirements. Each market is different and has different cultures, has different issues and so to develop things centrally makes sense because of development costs. But each market has to adapt them locally.*" And, "*You may need to develop some tools that are able to have some consistency at its core, but which can then be configured to meet local needs, because its in the local market where you have got to survive.*" And "*a centralised CRM tool is cost efficient and easy to update if you want to further develop the tool. If it is decentralised, then each country may spend a lot of financial resources doing that. The negative thing is that it doesn't take into account the local needs of the market.*"

Another perspective viewed lack of market-specific information as a potential barrier to centralisation. *"My perspective is that markets know more what they need than the central department. I think the processes are not that different from country to country, but the key integration points are different for each market and are not well understood by headquarters. I think that when you try and bring a group approach to a specific problem its not going to work."* Another respondent noted the possibility for resistance, *"…what I can see, there is high resistance [to a centralised tool] from the markets because they want a lot of customisation which is not allowed and that causes a lot of problems."* Similarly, *"I think that CRM processes should be decentralised because of the respective market idiosyncrasies and it is important to set common objectives and standards and pursue them. In my opinion, centralisation is much more expensive [compared to localisation] because of the customisation costs."* One respondent noted that performance measurement also needs to be standardised in order to enable comparability. *"Success measurement KPIs need to be defined so that the performance of one market can be objectively compared against another market."*

One respondent suggested a set of guiding principles or framework could be utilised to assist in providing some direction, but ultimately subsidiaries would be responsible for decision making given their more intimate understanding of the market. *"I think there needs to be a strategic framework which is applicable for all subsidiaries all over the world and you can act within this framework to bring in your own experience, bring in your market-specific issues."* Another respondent noted that an alternative to the centralisation-decentralisation dichotomy is clustering markets based on similar characteristics and then applying a common approach. *"It might be a European solution for say all European countries, 'an Americas solution' for North and South America and so forth."*

Global Strategy

Local subsidiaries are often not empowered to make strategic decisions with respect to CRM. This may be a function of the perceived risk (Garnier, 1982). This finding is consistent with Bowman et al. (2000) who found that strategic decision making was controlled by the parent company. There also appears to be some dissension on whether the organisation has achieved a global strategy for CRM. *"Is there one [a global strategy]? To my mind we have only managed to derive some more or less binding rules for the subsidiaries, which tell them the 'do's', and 'don'ts' in treating their customers. A concise strategy focused on retention and acquisition to my mind does not yet exist."* In summing up, one respondent noted that, *"CRM is really about the business first and the business processes. The system should be designed to support this, not the other way round."* A number of large market respondents noted that there should be a global platform for knowledge management. *"We need to capture the key learnings from each market and leverage off these for the next country."* And *"lets stay connected and learn from each other."*

Cross-National Differences

In comparing differences between countries a clear pattern begins to emerge: two countries are demonstrably more advanced in terms of CRM implementation than the other 18, who are largely still in a passive "data collection" phase, not yet using customer data in their marketing strategies to anywhere near its full potential. The two advanced countries, by contrast, are well ahead of the curve—using advanced customer analytics for segmentation purposes to proactively manage customer relationships. The other interesting dynamic within this context is the fact that Head Office has largely allowed the advanced country "to get on with it" and granted them a high degree of autonomy. Among the other 18, there is another fairly obvious partition, between more advanced and less advanced. We say obvious because the split is fairly predictable and is driven by country size, stage of economic/social development, and market size. Basically, mature versus developing economies.

There also appears to be a feeling that the group strategy favours large markets and the needs of smaller subsidiaries in emerging markets are subordinated. *"There needs to be more attention paid to the smaller [market] solution and strengthening central support."* And *" from the point of view of small markets, you might think that decisions are sometimes based on the big market."*

DISCUSSION

Most respondents recognised the many advantages of standardisation. They could see the merit in having a universal strategic framework to guide the CRM process. They acknowledged that IT systems should be standardised to avoid resource duplication and any possible re-inventing of the wheel. This was particularly evident in smaller and/or less developed markets. However, a number of problems with standardisation were also acknowledged. These included inability to factor into account cultural differences/idiosyncrasies, country-specific legislation, and complexities arising from the inherently cross-functional nature of CRM. Thus, somewhat predictably, calls for a hybrid approach can de deduced from the data. However, based on the strength of arguments and also drawing on the literature, we conclude that local adaptation needs to be well justified and should be viewed more as the exception rather than the norm.

Theory-Building and Managerial Implications

This paper makes at least two significant contributions to the extant CRM literature. First, given the lack of empirical research in the area, it extends on earlier work on the complexities of global CRM strategy development (Ciborra & Failla, 2000; Massey, Montoya-Weiss, et al. 2001). Findings confirm that there is a lack of clarity regarding what the important antecedents are to global CRM success. The more mature markets in this study seem to have a better developed understanding of the importance of these dimensions and invest resources in enhancing their competencies in these areas. Second, we have shed some light on the perennial standardisation/adaptation question and have provide a preliminary framework of what elements may be amenable to centralisation and which to localisation. For global CRM managers and strategists, the findings suggest that a centralised approach has merit. Indeed, the majority of CRM functionality could well be centrally located, with the more customer-centric elements driven at the subsidiary level. The benefit of this approach is that it improves control and coordination while reducing transaction costs (Clemmons & Simon, 2001).

Limitations and Future Research

A number of limitations of this research are noted. First, the non-random selection of respondents introduced an element of judgement into the sampling process. Furthermore, for the majority of subsidiaries, a single informant may not accurately represent the entire view of the organisation. However, it was felt that the manager identified as responsible for CRM activities was the most qualified to respond to in-depth interview questions. Another limitation of this study is that it only involves a single organisation in a single industry and therefore the results may not be generalisable to other organisations or industries. The researchers attempted to mitigate the limitations of the sample by utilising two respondent samples (Deshpande et al., 1993). A problem also arises in attempting to find a suitable second informant in small subsidiaries, and some initial respondents may object to having a cross-validation process. Finally, stringent university "Ethics in Research Involving Humans" guidelines prevented us from identifying verbatim quotes with individual respondents because that would compromise respondent anonymity.

A number of directions for future research have emerged from this exploratory study. First, a study examining global CRM strategy development across industries would be useful to test the generalisability of these findings. In addition, further research is required to examine the relative importance of those global CRM factors we have identified and test whether there are some other factors which contribute to global CRM complexity, which have been overlooked in the current study. Also further work is required to quantify the cost-benefit of localisation versus centralisation. It is not clear whether the inflexibility that a centralised CRM tool mandates compensates for the anticipated cost benefits. It may be that the costs of local market customisation erode these cost benefits. An interesting stream for future research would be to attempt to develop a framework that provides organisations with some insights into the required sequencing of CRM activities consistent with stage of implementation in order to build a solid foundation for the development of further CRM capabilities. Finally, from a cross-cultural perspective, the applicability of a stage model to global CRM implementation is worth considering.

Chapter 2.22

Building Complex Adaptive Systems:

On Engineering Self-Organizing Multi-Agent Systems

Jan Sudeikat[1]
Hamburg University of Applied Sciences, Germany

Wolfgang Renz
Hamburg University of Applied Sciences, Germany

ABSTRACT

Agent oriented software engineering (AOSE) proposes the design of distributed software systems as collections of autonomous and pro-active actors, so-called agents. Since software applications results from agent interplay in multi-agent systems (MASs), this design approach facilitates the construction of software applications that exhibit self-organizing and emergent dynamics. In this chapter, we examine the relation between self-organizing MASs (SO-MASs) and complex adaptive systems (CASs), highlighting the resulting challenges for engineering approaches. We argue that AOSE developers need to be aware of the possible causes of complex system dynamics, which result from underlying feedback loops. In this respect current approaches to develop SO-MASs are analyzed, leading to a novel classification scheme of typically applied computational techniques. To relieve development efforts and bridge the gap between top-down engineering and bottom-up emerging phenomena, we discuss how multi-level analysis, so-called mesoscopic modeling, can be used to comprehend MAS dynamics and guide agent design, respectively iterative redesign.

INTRODUCTION

AOSE (Weiß, 2002) is a prominent approach to the development of complicated distributed software systems. *Agents*, that is, autonomous and pro-active entities, are proposed as a basic design and development metaphor. Since highly dynamic and distributed application domains lend themselves to be understood as collections of collaborating actors, the agent metaphor provides appropriate design abstractions (Jennings, 2001). As the actual software applications result from agent interplay, they allow *decentralized* coordination mechanisms that promise the purposeful construction of systems that self-organize, that is, establish and maintain structures without external control, justifying intensive research activities (e.g., Kephart & Chess, 2003; Müller-Schloer, 2004). Awareness is rising that MAS implementations comprise the inherent potential to exhibit complex systems dynamics, for example, *criticality*, *phase transitions* (Parunak, Brueckner, & Savit, 2004) and *emergent* phenomena (Serugendo, Gleizes, & Karageorgos, 2006) have been observed.

The need to handle complex system dynamics in MASs is attracting increasing attention in AOSE research, as the rising phenomena complicate and challenge conventional top-down development efforts. So state Henderson-Sellers and Giorgini (2005):

> *...To alleviate this concern of an uncontrolled and uncontrollable agent system wreaking havoc, clearly emergent behavior has to be considered and planned for at the system level using top-down analysis and design techniques. This is still an area that is largely unknown in MAS methodologies… (p. 4)*

It has been found that these dynamics can be embedded implicitly in top-down designs, leading to unexpected synchronizations and oscillations that impair system performance of MASs, composed of agents that individually perform as intended (Mogul, 2005; Moore & Wright, 2003; Parunak, & VanderBok, 1997). Simulations are required to identify these phenomena and empiric practices dominate development approaches (e.g., De Wolf & Holvoet 2006; Edmonds, 2004).

In this chapter, sources for CAS phenomena in MASs are discussed. Particularly, we give an overview on current best practices for the development of self-organizing dynamics in MASs, leading to a novel classification of implementation approaches. While these practices have been classified phenomenological, insights in underlying mechanisms are required (Maes, 1994) to guide the utilization of emergent dynamics in software.

Current approaches to the construction of MASs can be distinguished between top-down development *methodologies* and bottom-up, *experimentation-based* prototyping procedures. Engineering procedures address the purpose-, cost- and time-oriented construction of applications and typically rely on iterative, top-down procedures that start from system requirements, which are agreed with stakeholders, and refine these to implementable system designs (cf. *Toward Development Methodologies* and *Summary* sub-sections). When engineering efforts target complex system dynamics, the design of applications that reliably exhibit the nonlinear system behaviors is inherently intricate (Edmonds, 2004), forcing elaborate simulation cycles conducted by experts. In order to mediate between both development paradigms a CAS inspired multi-level, *mesoscopic* modeling approach is presented and demonstrated that can be used to *redesign* MASs, enforcing the intended dynamics. Complex systems and complexity scientists as well as AOSE practitioners find a discussion of the particular challenges that MAS development efforts face established solutions.

This chapter is structured as follows. In the next section software-engineering approaches for agent-based systems are briefly introduced, followed by a discussion of relationships between MASs and CASs. Afterwards, engineering approaches to self-organizing dynamics in MASs are discussed. In the fifth section, these are classified and in the sixth section a multi-level modeling approach is presented, supporting iterative cycles of bottom-up analysis and top-down (re-)design. Finally, conclusions and prospects for future work are given.

AGENT-ORIENTED SOFTWARE ENGINEERING

AOSE proposes agents as a basic design and implementation metaphor for complicated distributed software systems. Agents are understood as autonomous and pro-active entities that are situated in an environment and collaborate with each other in so-called MASs, that is, sets of agents (Jennings, 2001). Different notions of agency exist that are supported by dedicated agent architectures, guiding agent implementation. These range from purely *reactive* mechanisms (e.g., Brooks, 1986), to *cognitive* models inspired by psychology and philosophy that address rational agent behaviors (e.g., Rao & Georgeff, 1991).

Agent-based application development is facilitated by dedicated programming languages and middleware platforms (recently reviewed by Bordini et al., 2006; Braubach, Pokahr, & Lamersdorf, 2006), directly supporting different theories of agency for application programmers. Agent platforms provide dedicated middleware platforms that offer specific services, for example, agent communication and coordination, to MAS developers utilize to construct MASs in general-purpose programming languages.

Three general software-engineering approaches to MASs can be distinguished (Müller, 2004), which comprise *agent-oriented, organizational*, and *emergentist* approaches. Agent-oriented approaches focus on the design of individual agents, typically biased towards certain agent architectures and organizational approaches that facilitate the specification of static organizational structures in the MAS. Corresponding methodologies guide MAS development from the initial examination of system requirements to the actual agent implementation. They commonly provide tailored development *processes* and modeling *notations*, supported by design *tools* (Henderson-Sellers & Giorgini, 2005; Sudeikat, Braubach, Pokahr, & Lamersdorf, 2004). These top-down approaches are opposed by bottom-up emergentist procedures that particularly focus on self-organizing dynamics. They distinguish carefully between *micro*-level agent implementations and *macroscopic* observable system-wide phenomena, providing heuristic design guidelines (Brueckner & Czap, 2006) and MAS analysis techniques (e.g., De Wolf, Holvoet, & Samaey, 2005).

SELF-ORGANIZATION: COMPLEX SYSTEM DYNAMICS IN MAS

Industrial as well as academic research initiatives intend to utilize self-organizing dynamics for the construction of robust and scalable applications. Both properties require purely *decentralized* coordination of entities, so that the absence of single points of failure (robustness) as well as the coordination of increasing numbers of entities (scalability) is ensured. The terms *autonomic computing* (Kephart & Chess, 2003) and *organic computing* (Müller-Schloer, 2004) have been coined to express visions of future adaptive IT systems that configure and maintain themselves according to high-level policies.

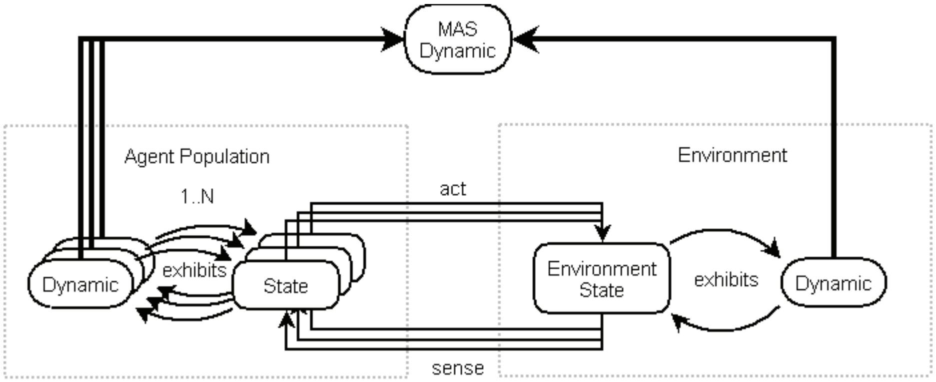
To enable these properties IT research targets the construction of adaptive processes that give rise to and maintain configurations without external control. This *self-organizing* behavior is distinct from *emergent* phenomena, that is, novel artifacts that rise from microscopic interactions (De Wolf & Holvoet, 2004). Since development efforts aim at these two complex system phenomena via *modular* and *hierarchical* structures of artificial *autonomous* entities, the resulting software systems have the potential to exhibit CAS dynamics, for example, *criticality* and *phase transitions* (Parunak et al., 2004). However, they are distinguishable from CASs observed in nature, as *self-organized criticality* and *edge of chaos* phenomena are typically absent.[2] These phenomena result from *critical* points—configurations where system properties change suddenly—that are approached and maintained by the system itself. In MASs, critical points can be identified but are commonly controlled via fixed, tunable parameters (Parunak et al., 2004).

CASs are typically defined in terms of sets of autonomous actors that interact (Bar-Yam, 2002), and computational tools have been proven valuable to give insights in their intricate dynamics (e.g., Rauch, 2002). The typically applied simulation tools need to be distinguished from general-purpose AOSE technologies (Drogoul, Vanbergue, & Meurisse, 2002). While simulation tools allow the interleaved execution of simple program models in observable environment models, AOSE provides tools to the decomposition of computational systems in truly distributed and autonomous actors.

Figure 1 presents a canonical view on MASs. A number of agents execute concurrently and interact (act/sense) with an environment that exhibits its own dynamic. Abstracting from the applied agent architectures, agents maintain execution states that are altered by environment perception and reasoning dynamics inside individuals, that is, stochastic processes in adaptive agents or reasoning processes in cognitive agent architectures. The exhibited microscopic dynamics give rise to macroscopic phenomena, that is, self-organization and emergence.

Bonabeau, Dorigo, and Theraulaz (1999) identified four basic principles for the design of *swarm* intelligent systems: (1) *multiple interactions* among the individuals, (2) *positive feedback,* (3) *negative feedback,* and an (4) *increase of behavior modification*. Multiple interactions as well as positive and negative feedback generate nonlinearities responsible for complex system behaviors. Furthermore, increase of behavior modification introduces, for the systems under consideration, a *slaving* principle proposed in the 1970s by Haken (2004). The presence of feedback loops enforces that results of agent actions continuously influence agent behavior, leading to collective adaptation. According to our canonical MAS model, self-organization results from two basic ingredients. First, agents sense their (local) environment; and secondly, they adjust their behaviors to adapt to perceptions. From the abstract view on MASs in Figure 1, it becomes apparent that MASs inherently allow for these two components. It depends on the application domain and implementation details if agent interdependencies result in feedback loops that steer the system. Top-down development approaches have to either prevent their occurrence by restricting agent behaviors or to anticipate their rise from MAS designs.

Figure 1. A canonical view on multi-agent systems. Agents sense and modify (act) their environment. In addition, agents and their environment exhibit their own dynamics, leading to macroscopic system dynamics.



When self-organizing properties are *intended* in MASs, system design forms a paradox in itself, that is, design requires developers to revise agent and environment implementations in a way that ensures the rise of the intended macroscopic artifacts (Sudeikat & Renz, 2006). Assuming that the constituent agents are properly implemented, that is, behave according to predefined rules, developers need to ensure that these rules actually lead to the intended dynamics. Due to nonlinearities and the complexity of the intended phenomena, it is a major challenge how to break the intended phenomena down into individual, microscopic agent models. Tools are needed to bridge the gap between the micro- and macro-scales of MAS implementations. In the following section, we examine current AOSE best practices to address this challenge.

ENGINEERING SELF-ORGANIZING MAS

After numerous successful applications of self-organization in MASs have been reported (Brueckner & Czap, 2006; Serugendo, Gleizes, & Karageorgos, 2006), there are notable efforts to compare and classify the utilized mechanisms. These provide MAS models that guide collective agent behavior adjustment. Adjustment design can be used to create adaptive system behaviors, for example, *phase transitions*, finally leading to self-organizing structures and emergents. Mechanisms have been categorized according to (1) the applied computational techniques (De Wolf & Holvoet, 2006; Mamei, Menezes, Tolksdorf, & Zambonelli, 2006; Serugendo et al., 2006), (2) the intended system properties (De Wolf & Holvoet, 2006a); and (3) their sources of inspiration (e.g., Hassas, Marzo-Serugendo, Karageorgos, & Castelfranchi, 2006; Mano, Bourjot, Lopardo, & Glize, 2006). Development processes support their application and formal tools have been proposed to analyze and anticipate MAS behaviors.

Template Architectures

Following Serugendo et al. (2006), five coordination mechanisms, based on *direct interactions, stigmergy, reinforcement, cooperation,* and *generic architectures* are currently utilized for the construction of self-organizing MASs. Mechanisms based on *direct interactions* rely on environments that allow agents to directly sense information of other individuals and environment objects. A prominent example is the adaptive configuration of structural and/or spatial aspects in MASs via *gradient-fields* or *co-fields* (Mamei, Zambonelli, & Leonardi, 2004). Spatial and contextual information is represented by computational fields originating from agents and/or environment objects. Fields are propagated by the environment, allowing agents to directly sense field gradients and infer information to act coherently, for example, to arrange themselves in spatial formations.

Stigmergy-based coordination is particularly inspired by biological systems where individual efforts stimulate corresponding actions of other agents (Grasse, 1959). Numerous insect species rely on so-called *pheromones*, chemical substances that denote specific insect behaviors, sensible to population members and gradually evaporating when released to the environment. When insects exhibit specific behaviors they distribute corresponding pheromones, therefore communicating their behavior. For example, when a termite builds a wall its building brick is distributing a dedicated pheromone that stimulates other termites to drop bricks nearby, leading to unique nest structures. Corresponding MAS implementations utilize *digital pheromones* (Parunak, 1997). Their evaporation provides a means of inter-agent communication and ensures that obsolete stimuli disappear gradually when their reinforcement stops.

Adaptive behavior of whole MASs can also be achieved by mechanisms that use *reinforcement* of individual adaptive behaviors. Corresponding agent implementations adapt agent behaviors based on individual stochastic processes (e.g., Weyns, Schelfthout, Holvoet, & Glorieux, 2004). Perceived environment states provided feedback on the success or failure of agent actions. This feedback is used to enforce the usage of behaviors that have been successfully applied, commonly supplemented with stochastic perturbations allowing agents to try less common behaviors.

Collective coherent MAS behaviors can also rise from agent *cooperation*. These mechanisms design agent implementations to agree on cooperative scenarios with other individuals. The sum of the local cooperative behaviors leads to the globally observed system functionality. Examples include the *organization self-design* approach from Ishida, Gasser, and Yokoo (1992) and the *adaptive multi-agent systems* (AMASs) theory (Gleizes, Camps, & Glize, (1999), which lead to the ADELFE development methodology (Bernon, Gleizes, Peyruqueou, & Picard, 2003). The methodology and corresponding tool support (Bernon, Camps, Gleizes, & Picard, 2003) guide agent design in terms of *cooperative* and particularly *noncooperative* scenarios. Agents are designed to perceive and resolve the latter ones in order to ensure that the system itself maintains the intended functionality.

Finally, *generic agent architectures* have been developed to allow modification of the MAS structure at run time. Agents can change the MAS structure directly, for example, in *holons* and *holarchies* (Koestler, 1967) or reason about and modify MAS *meta-models* at run-time (e.g., Dowling & Cahill, 2001), resulting in MAS architectures that can adjust themselves according to environmental influences.

Independent from the previous classification, De Wolf and Holvoet (2006) have examined and cataloged decentralized coordination mechanisms. They distinguish between *stigmergy, co-fields, market-based, tag-based,* and *token-based* coordination. *Stigmergy* (digital pheromones) and *co-field* (gradient fields) mechanisms correspond to the aforementioned outlined classification by Serugendo et al. (2006). *Market-based* coordination denotes agent collaboration in virtual markets where agents negotiate prices of resource access and/or service offers. This coordination scheme is established to control MAS resource allocation, since market dynamics adapt to demand and supply changes, typically leading to equilibrium states. *Tag-based* coordination is typically used for team formation and relies on tags attached to individuals. These can be viewed and modified by population members, indicating trust and reputation information. Based on this information, agents can decide team formations and role adoptions. Finally, *tokens* can be used to represent special conditions, roles, or permissions, for example, resource access. Agents need to possess the corresponding token to adopt roles or use resources and pass the token to other individuals. The rules for token distribution control MAS configuration and adaptation.

Toward Development Methodologies

The basic principles that enable self-organizing processes in *stigmergic* MASs are well understood and lead to heuristic development guidelines. Early design principles have been given by Parunak (1997), were expanded and revised by Parunak and Brueckner (2004), leading to a classification of basic principles given by Brueckner and Czap (2006), regarding the design of suitable *agent populations*, appropriate *agent interactions* that ensure information flows, leading to positive and negative feedback loops and the *emergence of desired function* via behavioral diversity inside agents and local fitness measures.

The coordination mechanisms described in the previous section provide means to implement MASs according to these guidelines. Due to the well understood dynamics, a trend towards their *reconstruction* in self-organizing MASs can be observed (discussed by Sudeikat & Renz, 2006). Development teams (1) identify a well understood coordination mechanism and (2) map its constituent parts to the actual application domain. Finally, the (3) behavior of prototype implementations is examined and parameters—controlling agent and/or environment properties—are adjusted. In this respect, the usage of coordination mechanisms as *design patterns*, that is, reusable design examples (Gamma, Helm, Johnson, & Vlissides, 1995), has been proposed by De Wolf and Holvoet (2006b). Initial guidelines on the selection of these patterns based on system requirements have been given (De Wolf & Holvoet, 2006a), in terms of a look-up table relating intended system properties to suitable coordination mechanisms. While this methodological stance reflects current development trends, it raises concerns similar to the application of traditional design patterns, that is, how to combine patterns properly, leading to quality architectures.

General-purpose methodologies usually do not consider the rise of emergent and self-organized structures (Henderson-Sellers & Giorgini, 2005). An exception is the ADELFE methodology that provides an extended version of the *rational unified process* (Kruchten, 2003), tailored to the design of adaptive MASs composed of cooperative agents. ADELFE provides tool support guiding the development process (Bernon, Camps, 2003) and a development life-cycle that stresses the identification of cooperation failures (noncooperative situations) and the equipment of agents with procedures to recover from these. Accordingly, MASs provide the intended, adequate functionality when all constituent agents provide their designated (sub-) functionalities, that is, *cooperate*. The inherent focus on cooperative mechanisms impairs support for other coordination schemes.

Since the inherent nonlinearities in self-organizing MAS dynamics impair formal specifications and subsequently render reductionist, top-down development approaches, impractical (Edmonds & Bryson, 2004), typical development procedures adopt an empirical stance and regard development as iterations of experiments. Therefore, Edmonds (2004) proposes a tailored combination of *engineering* and *adaptation* procedures for MAS development. While engineering procedures address the construction of systems by design and implementation activities, examine adaptation procedures the available (prototype) implementations and fine-tune system parameters. Edmonds (2004) argued that complicated dynamics require the adaptation phase to revise the *theory* developers have about the system behavior. The theory leads to testable hypotheses that can be checked by scientific experiments. Only when the theory is thoroughly validated developers can make assumptions about system reliability.

Another example for an experimental approach to MAS design has been given by De Wolf and Holvoet (2005). They adjusted the incremental and reductionist *unified process* (Jacobson, Booch, & Rumbaugh, 1999) in order to revise MAS implementations. In their approach architectural design concerns the selection of an appropriate coordination mechanism for the identified system requirements. Testing is adjusted to address macroscopic properties via system simulations.

Gershenson (2006) proposes a conceptual framework for the description of self-organizing systems. In concordance to ADELFE, his approach provides a measurement of the *satisfaction* of the system under consideration, in terms of a weighted sum of the goal satisfaction of individual agents. The weights have to be evaluated via experiment. The aim of corresponding design efforts is to construct systems that autonomously maximize agent satisfaction, leading to maximal system satisfaction. MAS designs rely on the introduction of so-called *mediators* (Heylighen, 2003) that arbitrate among individuals, therefore minimizing *interferences* and *frictions* (Gershenson, 2006). The conceptual framework facilitates the identification of suitable domain entities and strategies, supporting system designs that intend equilibrium states via mediating agents.

Formal Methods

Since development practices depend on experimentation procedures to analyze (nonlinear) system behaviors, formal computer science tools promise to speed up MAS simulations. Formal specifications can be used to simulate abstract models of agent implementations. Two usages can be distinguished. First, formal models can be derived from actual MAS implementations (e.g., described by Sudeikat & Renz, 2006). The derived models then allow predicting system behaviors that are expected to emerge under different parameter values and initial conditions. Secondly, abstract specifications of MAS designs can be used as *proof-of-concept* allowing validating that an initial design allows the rise of the intended dynamics.

Applied models utilize mathematics, particularly systems of *differential equations* and transition systems, that is, *process algebra* (Viroli & Omicini, 2005). Most work on formal specifications of self-organizing processes addresses *swarm robotic* systems, mathematical approaches for these systems were reviewed by Lerman, Martinoli, and Galstyan (2004) and formal specification languages were examined by Rouff, Hinchey, Truszkowski, and Rash (2006).

Mathematical treatment of complex, nonlinear system dynamics typically models the rate of change of macroscopic observables (see e.g., Haken, 2004). Temporal development of discrete systems is represented by difference equations, but typically continuous functions can be assumed, leading to sets of coupled and nonlinear, first-order differential equations. These are well established to describe self-organizing system dynamics in various disciplines (Haken, 2004), for example, chemical reaction systems or population dynamics of biological ecologies. Lerman and Galstyan (2001) established these equations to model homogenous MASs composed of reactive agents and presented a structured process to derive these equations from microscopic agent modes (Lerman & Galstyan, 2004). Assuming an underlying time-continuous Markov processes, MAS dynamics can be modeled by rate equations, describing in quantitative terms mean occupation numbers of individual agent states. Sudeikat and Renz (2006a) exemplified how similar, phenomenologic models can be derived for MASs composed of cognitive agent when an underlying stochastic process can be assumed to govern MAS dynamics.

Process algebra is a prominent formal tool to describe, model, and verify concurrent and reactive systems (Milner, 1989). Subjects are described as *transition systems*, that is, as sets of states, actions, and transition relations (S → S'), caused by actions. Stochastic extensions to this algebra have been given (e.g., by Priami, 1995) that annotate activity rates to channel definitions and make process activities subject to delays. These extensions transfer the underlying transition systems to Markov transition systems (Brinksma & Hermanns, 2001). Activity rates define how the probability of state transitions increases in time. Interpreter implementations are available for large-scale simulations (e.g., Phillips, 2006).

Rouff et al. (2006) examined conventional and stochastic process algebra as well as logic-based approaches, concluding that stochastic process algebras are suitable to model concurrent system dynamics while the latter formalisms are more suitable to verify agent internal reasoning. Stochastic algebras have been applied to model complex biological and chemical processes, for example, ant colonies (Sumpter, Blanchard, & Broomhead, 2001) and have been applied to self-organizing MAS dynamics (Gardelli, Viroli, & Omicini, 2005, 2006). Gardelli et al. (2006) utilized stochastic algebra specifications for quantitative, large scale simulations of abstract MAS designs. These allowed illustrating, that intended MAS designs enable the rise of intended system dynamics and facilitate the examination of system parameters and macroscopic behavioral regimes. Having examined these regimes in abstract MAS designs, developers face the challenge to enforce similar macroscopic system parameters in the MAS to-be. While the relation between stochastic algebras and MAS implementations has not been examined yet, Sudeikat and Renz (2006a) provided an initial tool support to derive process terms semi-automatically from annotated implementations.

Summary

Development efforts for self-organizing systems intend complex system dynamics which in turn complicate top-down development procedures. Therefore, current development efforts rely on template architectures and prototype/simulation approaches. While experience and heuristics guide the MAS design, methodologies support application development, for example, via enforcing the distinction between *engineering* and *adaption* (Edmonds, 2004), the promotion of a certain coordination scheme (Gershenson, 2006), or the identification of suitable template architectures (Serugendo et al., 2006). Open research questions concern how the applied coordination schemes influence each other and how they can be combined without interferences in real-world scenarios. In order to relieve simulation procedures, formal tools have been proposed. These promise computationally cheap simulations of large numbers of autonomous processes on a macroscopic scale. Therefore, they can be applied to both facilitate the analysis of available systems (Lerman & Galstyan, 2004) as well as to examine abstract MAS designs and their support for the intended dynamics (Gardelli et al., 2006). The abstract nature of these models facilitates examinations of distributed coordination mechanisms and self-organizing dynamics, but gives developers limited insight into the intended agent designs. Instead the derived models form a kind of requirements engineering for self-organizing MASs since the identified parameter ranges define properties that final agent designs have to bring by. For example, the simulation parameters for an intrusion detection system from Gardelli et al. (2006) comprise the probabilities that certain agent types interact. While simulations can ensure that a MAS composed of accordingly behaving agents will perform well, it is up to the developers to ensure consistent behavioral regimes in MAS implementations.

Software projects are commonly carried out in interactive sequences of development phases, comprising the analysis of system *requirements*, system *analysis*, *design*, *implementation*, and *testing* of the resulting software (Kruchten, 2003). System requirements express the intended functionality of the software system to-be. A detailed examination of the intended functionality guides system analysis, defining the system architecture, which is refined in the design phase until the implementation is enabled. In the last phase resulting implementations are tested. Figure 2 shows the support of these development phases by the here discussed techniques and procedures. The classified coordination mechanisms (SO-Mechanisms, cf. *Template Architectures* sub-section) reduce requirements and system analysis to the identification of an appropriate pattern, mapping this template architecture to the application domains guides MAS design and implementation. Formal tools (cf. *Formal Methods* sub-section) have been applied to simulate abstract MAS models and derive mathematical models from MAS implementations. This allows examining behavioral regimes of intended MAS designs (analysis) and implementations (test). The available methodic development approaches (SO-process, cf. *Toward Development Methodologies* sub-section) focus mainly on system analysis and design in simulation-based procedures, broadening test to simulation. The specific ADELFE methodologies is considered separately (cf. *Toward Development Methodologies* sub-section), since it provides a complete development cycle supported with notation and tools, but focusing on the *cooperation* coordination mechanism.

Figure 2. The relation between the discussed techniques for MAS development and general software engineering phases. Design and implementation relate mainly to established coordination mechanisms; requirements engineering and testing are merely unsupported.

Specific Methodologies (section 4.2; ADELFE)	O	X	X	X	O

X : Supported O : Minor Support - : Not Supported

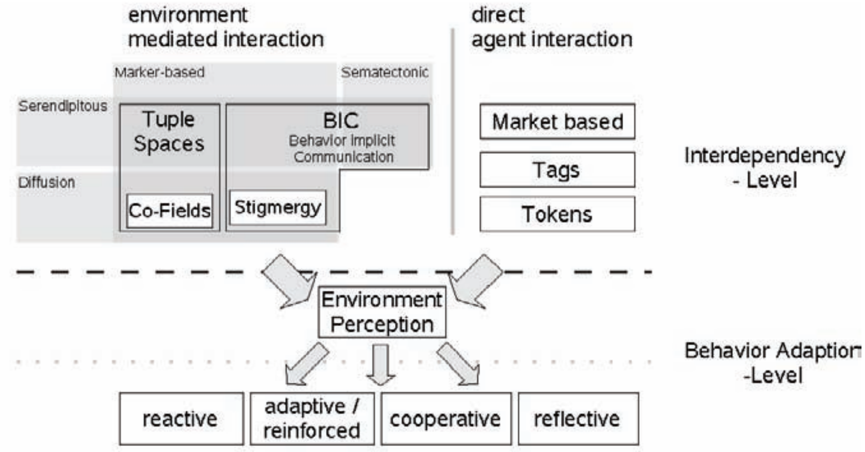
This examination highlights the lack of *requirements engineering* and *testing approaches* to self-organizing MASs. While simulation-based development procedures are currently revised, testing refers to the automated validation of specification that defines how the system under development should behave. It is a major challenge for general-purpose AOSE research to move from experimentation to testing procedures. This transition will be possibly supported by suitable means to describe and analyze the requirements for self-organizing systems.

A CAS-BASED CLASSIFICATION OF COORDINATION MECHANISMS

In the *Self-organization—Complex System Dynamics in MAS* section it has been found that complex system dynamics originate from entities that (inter-) act autonomously, but are correlated by positive and negative feedback from their environment. Agent reasoning, adjusting agent behaviors according to the available local information and the spread of this information in the MAS are two basic ingredients to self-organizing dynamics (cf. *Self-organization—Complex System Dynamics in MAS* section). The here discussed mechanisms are field tested and well understood, but their support for both of these ingredients has not been examined yet. Therefore, we differentiate in the following between interdependency- and behavior adaption-level mechanisms. While the former ones describe how information propagates to individuals from the environment and other agents, the latter ones provide blueprints for agent implementation, specifying how agents use the provided local information to select appropriate behaviors. Figure 3 displays this classification. It turns out to be that the identified coordination mechanisms form disjoint sets, supporting either feedback loops or behavior selection.

Interdependency-level mechanisms are distinguished between *direct* interactions of agents (right) and indirect interactions that are *mediated* by a (virtual) environment. The prominent stigmergy and co-field approaches are both examples for mediated interactions, since agents communicate implicitly via environment changes and virtual fields. The *environment* propagates information from anonymous individuals, and agents use these for behavior adjustment. Mamei et al. (2006) provide a fine-grained classification scheme of mediating mechanisms that inter alia concern the propagation of information and the introduction of dedicated representations. Infor-

Figure 3. Coordination mechanisms for self-organizing MAS. These provide techniques to implement agent interdependencies and selection between different agent internal behaviors.



mation propagation can either rely on *diffusion* or on agents that wander a shared data space where they encounter *serendipitously* novel information. Coordination mechanisms require the introduction of explicit data items (*marker-based*) or agents infer implicit information from the perceived environment (*sematectonic*). *Behavior implicit communications* (BICs), introduced by Omicini, Ricci, Viroli, Castelfranchi, and Tummolini (2004) relates to the fact that agents do not necessarily need to engage in communication to spread information. Sole observation of other agents' behavior can be used by individuals to infer their states, enabling coherent agent coordination, similarly enforced and degraded as in stigmergy systems. BICs describe both marker-based and sematectonic coordination and stigmergy can be regarded as specialization. Co-field implementations rely on specific *tuple spaces* (e.g., reviewed by Mamei et al., 2006), that is, a standard coordination model, based on tokens that explicitly represent the distributed information. As tuple spaces and BICs support serendipitous mechanisms, specific frameworks support the spatial diffusion of markers (e.g., digital pheromones and tuples) in virtual environments. Diffusing tuples are used to construct co-fields (Mamei, Zambonelli & Leonardi, 2004) while stigmergy denotes mediated communications between individuals via the modification of either serendipitous or diffusing environment elements. Evaporating digital pheromones are a prominent example (Brueckner & Czap, 2006). It is to note that sematectonic data spaces contradict diffusing approaches.

Direct agent interactions take place between distinguishable agents, either exchanging messages/tokens or modifying tags. Message exchange enables negotiations for *market-based* coordination and transmitted *tokens* represent permissions to play certain roles, for example, access resources. *Tag*-based coordination also provides a direct interaction approach, since their modification requires direct interaction with a known individual (cf. *Template Architectures* sub-section).

Individual *behavior adaption* is controlled by the employed agent architectures, ranging from purely *reactive* mechanisms to, *adaptive, cooperative,* and *reflective* architectures. Reactive agent models respond directly, knee-jerk to sensor perceptions, possibly deciding between behaviors categorized in priorities (Brooks, 1986; cf. *Agent-oriented Software Engineering* section).

Adaptive, cooperative, and reflective agent models correspond respectively to *reinforcement*, *cooperative* mechanisms and *generic* architectures, as identified by Serugendo et al. (2006) which support run time (re-)configuration (cf. *Template Architectures* sub-section). The term *reflective* is introduced to replace the term *generic*, characterizing the general feature of these systems that they explicitly enable MAS reconfiguration to be triggered by individual agents.

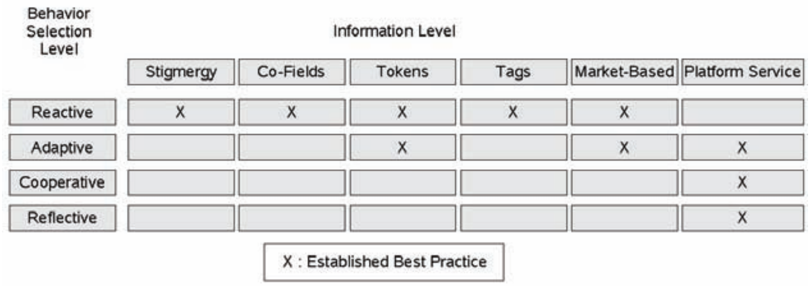
In principle, all combinations of interdependency and behavior adaption mechanisms are conceivable, however only specific combinations of agent architectures and interaction schemes are utilized. Figure 4 presents employed best practices. In this matrix the previously discussed interdependency-level mechanisms are supplemented with *platform* (communication) *services*, since some agent architectures do not require dedicated information propagation techniques, but can be implemented using generic message services.

The literature review revealed a trend that these practices focus either on environmental dynamics, steering simple reactive agent models or on more sophisticated agent designs (adaptive, cooperative, and reflective), revised to emerge collective, adaptive system behaviors (cf. Figure 5). Exceptions are token- and market-based coordination that applies adaptive agent implementations as well. This observation indicates that the combination of coordination mechanisms in MAS applications is unexplored and agrees to the previously described focus of methodologies and heuristics on specific mechanisms.

CAS-INSPIRED MAS ANALYSIS: TOWARDS MULTI-LEVEL MODELING OF MASS

Complex system dynamics are inherently nonlinear and it has been argued that their complexity impairs top-down design procedures (Edmonds, 2004). Therefore, intended system dynamics are typically anticipated, utilizing the established coordination mechanisms (cf. *Template Architectures* to *Formal Methods* sub-sections). In the following, a CAS-inspired, multi-level modeling approach to MASs is presented, showing how self-organizing processes can be explained by examining coarse-grained agent contributions to macroscopic phenomena. When constructing self-organizing MASs, developers typically have to understand and catalogue exhibited agent behaviors, forming ontologies of agent contributions to system-wide phenomena. So-called *mesoscopic* modeling, introduced by Renz and Sudeikat (2005a, 2006), aims to aid these efforts. This analysis view does not replace but supplement

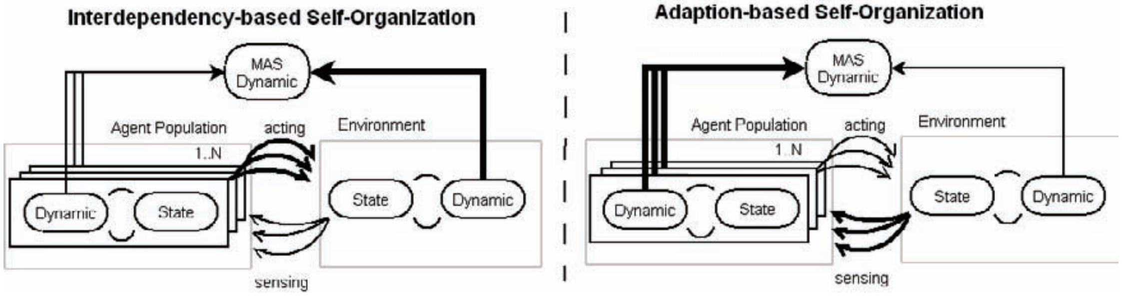
Figure 4. Established combinations of interdependency and behavior adaption mechanisms. Sophisticated information propagation schemes rely on simple agents, while complex agent models utilize generic platform message services.



Behavior Selection Level	Information Level					
	Stigmergy	Co-Fields	Tokens	Tags	Market-Based	Platform Service
Reactive	X	X	X	X	X	
Adaptive			X		X	X
Cooperative						X
Reflective						X

X : Established Best Practice

Interdependency-based coordination focus on environment dynamics to coordinate rather simple agents. Adaption-based mechanisms control system dynamics via collective adaption of individuals.



the available software engineering methodologies and toolsets (cf. *Engineering Self-organizing MAS* section).

Mesoscopic Modeling

Multi-level descriptions are appropriate tools to study CASs. Taking inspiration from established efforts to understand CAS behaviors (e.g., Haken, 2004), we propose intermediate—mesoscopic—description levels to mediate between top-down and bottom-up development. This modeling notion allows relating system behaviors to individual agent behaviors, facilitating bottom-up analysis of prototype implementations and their topdown (re-)design (cf. *Applying Mesoscopic Models—MAS Redesign Support* sub-section).

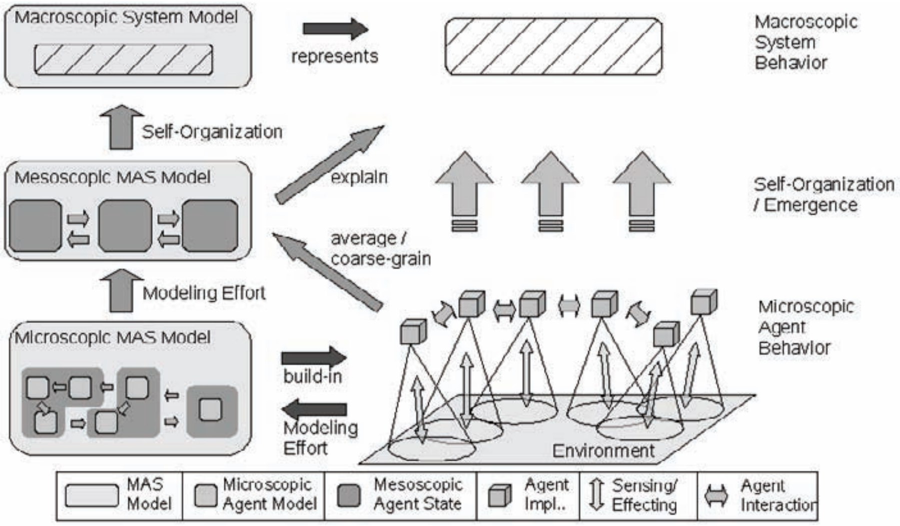
M*acroscopic* models describe the systems behavior space. Points in this space denote MAS configurations, in terms of behaviors observable in the sense of functional system requirements. Trajectories in this space represent system reconfigurations and their corresponding dynamics. Since designers intend specific macroscopic phenomena when conceptualizing MASs, it is necessary to foresee the principally possible system configurations. This helps to distinguish *intended* structures and/or emergents from *unintended* ones and the possible transitions between them. Since developers typically can not anticipate the complete MAS behavior space at design time, this model is subject to incremental revision and requirements engineering activities (Sudeikat & Renz, 2007).

The purpose of a *microscopic* modeling level is to provide sufficient details to guide agent implementation. Resulting models describe the available behaviors and the selection process that underlies agent adjustment, typically biased towards the applied agent architecture.

Transitions between qualitatively different macroscopic configurations can be explained by mesoscopic models (Renz & Sudeikat, 2005a, 2006) that introduce intermediate artifacts, abstracting from microscopic agent behaviors (cf. Figure 6). Abstraction is done by merging multiple microscopic agent behaviors and replacing them by a few abstract states, so-called *hidden* agent states, which are not directly observable in the behavior of the individual agents but average out short time fluctuations of the microscopic agent actions. This approach is inspired by similar modeling methods developed in physics to describe phase transitions in equilibrium as well as in far-from-equilibrium systems, see for example, Haken (2004).

Appropriate abstraction is a considerable modeling effort, requiring classifying and merging agent states that contribute to macroscopic dynamics in similar ways. The introduced mesoscopic

Figure 6. The relation of MAS implementations (right) and mesoscopic modeling (following Sudeikat & Renz, 2006)



states resemble *roles* agents play in respect to the exhibited macroscopic system dynamics. The resulting models are distinct from macroscopic models since they still include the underlying mechanisms causing the short-time behavior of the self-organization process (Renz & Sudeikat, 2006). It has been found that these models are useful to mathematically describe these processes that result from distributed coordination mechanisms in MASs. When appropriate agent states have been identified, system reconfiguration can be expressed by rate equations (Sudeikat & Renz, 2006a) and process algebra (Sudeikat & Renz, 2006b), requiring estimation or measurement of relevant transition rates for typical environmental conditions.

Figure 6 relates the three description levels to each other (left) and the MAS implementation they model (right). Microscopic agent (inter-) actions (bottom) give rise to macroscopic MAS configurations (top). Mesoscopic descriptions capture averaged agent behaviors. These exhibited behaviors explain how agents contribute to rising structures.

Applying Mesoscopic Models: MAS Redesign Support

In bottom-up development procedures MAS prototype implementations are tuned by simulation. This typically focuses on parameter adjustment (cf. *Toward Development Methodologies* subsection), a non-trivial task that requires extensive simulation (De Wolf et al., 2005). Procedures for the purposeful adjustment of prototypes and mechanisms have yet found minor attention (e.g., by Gershenson, 2006) but could relieve developers from costly simulation cycles. In addition these procedures provide vocabulary and tools to bridge the gap between bottom-up and top-down engineering. Sudeikat and Renz (2006) showed how the identification of agent contributions to the observable macroscopic structures (mesoscopic roles) can guide MAS redesign, that is, the purposeful modification of agent and environment implementations to enforce intended macroscopic structures. Here, two redesigns are exemplified, namely, reimplementation of adaptive minority game players and collectively clustering ants.

Case Study I: Minority Games

The so-called *minority game* (MG) (Challet & Zhang, 1997) is a socio-economically inspired setting to examine inductive reasoning in populations of adaptive agents. In a round-based game, an odd number of agents have to make repeatedly binary decisions (1 or 0) and agents in the *minority* group get rewarded. In order to increase their reward, agents need to conform to the next minority decision, while their only source of information is a limited memory of the past round results.

Renz and Sudeikat (2005, 2005a) redesigned a stochastic adaptive agent population, where agents adjust their probability to alternate their previous selection. Successful agents increase their likelihood to change, while unsuccessful agents tend to stick to their previous selection. It turned out that these agents—in specific parameter regimes—can play *optimal* and *fair*, that is, enter a behavioral regime where population reward is maximized and agents get awarded in turn.

A mesoscopic model classifies three behavioral regimes, namely, supplier *loyal*, *alternating*, and *undecided* agents. Optimal behavior occurs when agents synchronize into two distinct alternating groups. In this case the agent with the smallest alternation probability adopts a so-called *emergent role* (Renz & Sudeikat, 2006). Its selection determines which group will win and loose respectively, since the alternating groups are equal sized. This role was named *Schwarzer Peter* (get the short straw in German speaking countries) and solely arises from game dynamics. Since *Schwarzer Peter* agents force other individuals to loose, eventually this role will be adopted by other (less successful) agents.

Besides a mathematical treatment, the mesoscopic model guided agent *reimplementation*. The continuously changing strategies of the stochastic MG were replaced by deterministic transitions between three agent states, representing the mesoscopic behaviors. By means of self-organization, deterministic state transitions lead to similar, optimal behavior in a controlled and predictable way (Renz & Sudeikat, 2005a, 2006).

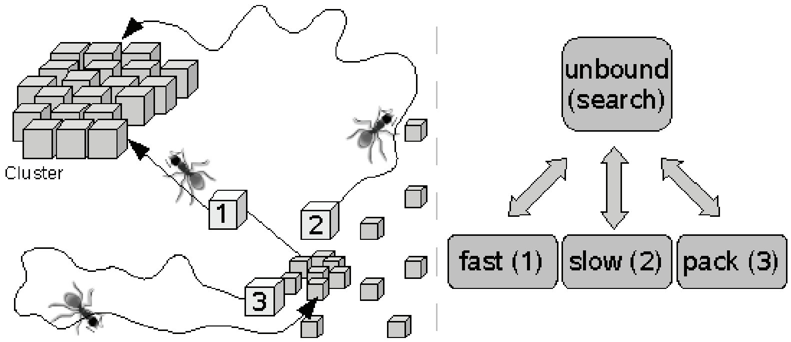
Case Study II: Collective (Ant) Sorting

Ants achieve global structures of grouped items (eggs, larvae, etc.) by continuously transporting items to similar ones nearby (Parunak, 1997). These *brood-sorting* mechanisms are well studied and have been applied to sort and cluster large scale data in open environments with streams of incoming items (Parunak, Weinstein, Chiusano, & Brueckner, 2005). A naive implementation comprises reactive agents that walk an environment (torus) in Brownian motion, inhabited by a number of randomly distributed items. Agents execute a searching behavior either to find items to pick up (when unbound) or to drop at another item (when bound to an item).

Figure 7 denotes the mesoscopic system description. Ants contribute to cluster formations in three distinct ways. They move items from the grid to a cluster after (1) a comparatively short walk, (2) they carry a comparatively long walk, or (3) they pick up items and release them on the same cluster. The length of a walk is related to the environment size and item density. From the mesoscopic system description (Figure 7), it was inferred that the short walk behavior (1) is to be amplified to enhance clustering efficiency. This increase is achieved by two redesigns, focusing on agent movement and the inhabited environment.

A first redesign replaced the Brownian motion with a stiffened random walk behavior. When agents have gained a high velocity, the average deviation to their current heading is reduced. Therefore, the trajectories of individual agents stiffen over time, resulting in a mean velocity increase. The second redesign increases agent's probability to drop items. It is enforced that items are dropped on top of encountered items. Released items adopt the heading of the encountered item and move (fall) till they reach an empty grid cell.

Figure 7. The transportation behaviors of sorting ants (left). Agent movement can be (1) comparatively direct (2), indirect, or (3) may also let agents pick up and drop items at the same cluster. These behaviors correspond to mesoscopic transportation velocities (right; from Sudeikat & Renz, 2006).



What results are *elongated structures* of aligned items. The elongated shape increases the cluster surface, therefore increasing the probability to be encountered by stiffened walking agents. The obtained improvement has been quantified by Sudeikat and Renz (2006).

Mesoscopic models provide a novel vocabulary that depends on the application domain and allows us to reason about MAS behaviors. Their application poses a non-trivial modeling effort, but the resulting system abstraction can be formally specified, allowing developers to anticipate the effects of changes. Mesoscopic models describe how agents contribute to the globally observable structures. Mesoscopic states describe roles agents play in relation to the system structure, for example, fast and slow moving agents are *roles* agent play in relation to the global transport behavior toward a cluster. Therefore, the derivation of mesoscopic models relies inherently on the identification of contributions to global artifacts and different views on the same MAS are possible. Based on these models are two redesign strategies principally possible. (1) The MG case study exemplifies how intended system behavior can be controlled and adjusted by resembling the identified mesoscopic states directly in agent implementations. The wanted, emergent system behavior observed in the stochastic MG can now be obtained by self-organization in the mesoscopic model (Renz & Sudeikat, 2006). (2) In the case of collective (ant) sorting (Sudeikat & Renz, 2006) an increase in sorting efficiency was achieved solely by identifying an agent behavior to be amplified and corresponding adjustment of reactive agent models and environment objects representing the mesoscopic states explicitly. During these redesign efforts the mesoscopic models do only change when analysts gain novel insights in the agent contributions to structures. The estimation of transition rates between identified roles, that is, mesoscopic states, relies on environmental changes.

CONCLUSION

In this chapter we justified that AOSE research has to address the possible rise of emergent and self-organized phenomena in MASs. Design efforts may introduce them unintended, or revise agent and environment interactions to ensure their rise. In addition, we argued that the development of MASs—particularly ones with self-organizing properties—can be regarded as the challenge to construct CASs, leading to the question how both research areas can endorse each other. While MASs, that is, agent-based modeling, is an established tool for CAS research, corresponding analysis techniques only play a minor role in AOSE research.

Established techniques and methodologies to design and implement self-organizing MASs have been reviewed and classified according to their focus on collective *agent behavior adjustment* or *agent interdependency propagation*. Both are suitable to design self-organizing MASs and are currently applied rather independently from each other. In order to mediate between top-down development approaches and bottom-up experimentation procedures, mesoscopic modeling—a CAS-inspired multi-level analysis approach—has been discussed and it has been exemplified how the gained insights in system dynamics can be used to redesign agent implementations, enforcing the rise of intended structures. While simulations of the final implementations are necessary, representations of mesoscopic models allow the anticipation of (re-)design results. We expect the proposed modeling approach, together with the novel classification of MAS designs to stimulate the analysis of MAS implementations, allowing developers to examine and compare underlying mechanisms. In order to combine design heuristics and simulation procedures and top-down engineering practices, tools, and models for the examination of self-organizing MASs are necessary. The typically applied computational techniques to the construction of self-organizing MASs are catalogued and have been classified in this chapter (cf. *A CAS-based Classification of Coordination Mechanisms* section). Commonly agreed taxonomies of self-organizing phenomena and their causes are essential to revise prediction techniques and (semi-) automated analysis tools in order to move from MAS *simulation* to *testing* MASs for intended phenomena. This transition is crucial for purposeful engineering practices.

We expect the rising awareness that self-organization is a generic, inherent feature of MAS implementations (cf. *Self-organization—Complex System Dynamics in MAS* section) and that it will affect general-purpose AOSE practices. Tool support for MAS *analysis* by simulation and *construction* by adjusting template architectures will become more and more crucial. Since mesoscopic modeling facilitates the anticipation of system behaviors, it is a topic of future research how these can be introduced in structured development processes.

Chapter 2.23

Challenges in Developing a Knowledge Management Strategy:

A Case Study of the Air Force Materiel Command

Summer E. Bartczak
University of Central Arkansas, USA

Jason M. Turner
Air Force Institute of Technology, USA

Ellen C. England
ISN Software Corporation and Kaplan University, USA

ABSTRACT

It is widely acknowledged that knowledge management (KM) strategy is a desired precursor to developing specific KM initiatives. Strategy development is often difficult due a variety of influences and constraints. Using KM influences as a foundation, this case study describes issues involved in developing a KM strategy for the Air Force Material Command, including issues to be considered for future strategy development such as leadership support and understanding, conflicts with IT organizations, funding, technology usage and configuration, and outsourcing.

INTRODUCTION

Enablers, barriers, and influences of KM have been grouped into three broad categories: internal managerial influences, internal resource influences, and external environmental influences

(Holsapple & Joshi, 2000, 2002). Managerial influences "emanate from the organizational participants responsible for administering the management of knowledge" (Holsapple & Joshi, 2000, p. 239); resource influences include human, financial, knowledge, and material resources that make KM a reality (p. 241); and environmental influences affect what "knowledge resources should or can be acquired in the course of KM, as well as what knowledge manipulation skills (e.g., human or technical) are available" (p. 242).

KM strategy is also generally regarded as essential to implementation and should be guided by organizational strategy (Zack, 1999). Earl (2001) provides a taxonomy of strategic starting points, seven "schools of knowledge management" and key attributes of each. Yet despite such insight, little is known about KM strategy within the military (Bower, 2001; Plant, 2000). Difficulties stem from the unique context in which KM must be implemented including culture, organization, and operating environment. Because of these unique attributes, an investigation of military KM may prove telling theoretically and practically.

CASE BACKGROUND

Headquartered in Dayton, Ohio, Air Force Material Command (AFMC) employs 85,000 military and civilian employees worldwide. AFMC has "cradle-to-grave" oversight for all aircraft, missiles, and munitions. The Directorate of Requirements (DR) is home to AFMC's Knowledge Management program.

In the early 1990s, AFMC/DR developed a repository of acquisitions regulations, process descriptions, and other miscellaneous information. The repository soon expanded into the Defense Acquisition Deskbook program and was managed by an interservice Joint Program Office. AFMC/DR continued updating Air Force (AF) documents within Deskbook; however, this did not require DR's entire budget. As a result, it was decided the excess funding was to be used for the development of an additional KM application that helped to document and disseminate overarching AF lessons learned.

AFMC/DR was also developing Web-based training for acquisitions personnel due to impending talent drains as more civilian personnel retired. To improve AFMC's preparedness, Deputy Director Robert Mulcahy became a KM champion. He consolidated deskbook, lessons learned, and web-based training into one KM system in order to provide better capture and dissemination of critical workforce knowledge.

Mulcahy assigned Randy Adkins to lead the consolidated AF knowledge management (AFKM) program. Initially, the AFKM program centered on the use of commercial KM processes and technologies for solving specific customer problems. Soon, however, the now-consolidated KM system grew beyond its original three components; by 2000, two new modules were added: the AFMC Help Center and Community of Practice (CoP) workspaces." The Help Center provided search capabilities for information across AFMC web sites; the CoP workspaces fostered information exchange, collaboration, and problem solving. The AFKM Hub/home page was a portal-like entrance into the entire system.

RESEARCH METHOD

AFMC was one of the first AF organizations to embrace KM; the AFKM team also faced significant challenges determining future directions for their efforts. It was therefore likely key issues impacting KM strategy development might be identified in this context. Additional case research was also needed to bridge the gap between KM theory and practical advice (Jennix, 2005, p. vii). Given these factors, an exploratory case study methodology was used.

Holsapple and Joshi's (2000, 2002) KM influences framework provided three foundational constructs for “analytic generalization” (Yin, 1994, p. 31); these factors—managerial, resource, and environmental—could be examined as potential barriers to KM strategy development. Considerations for design quality were made in accordance with Kidder and Judd (1986) and Yin (1994); however, internal validity was not addressed due to the study’s exploratory nature.

Data included interviews, field notes, and physical traces. Open-ended interviews were taped and transcribed, then reviewed and approved by respondents. Twelve individuals were interviewed providing a cross-section of organizational leadership, the AFKM team, and AFKM customers. Transcripts were first searched and categorized according to a priori KM influence (and emergent) categories and themes. Resultant data was combined with field notes (capturing impressions about the interviews and observations of individual/organization dynamics) and physical traces (e.g., documents, Web sites, organizational charts, budget records, advertising media, etc.) to form a robust understanding of the case.

FINDINGS

The AFKM effort exhibited many of Holsapple and Joshi’s (2000, 2002) influence factors; however, the military environment provided some unique constraints that further exacerbated the negative influences. On the whole, this study revealed a variety of latent and emergent issues that should be considered for any KM strategy development; key issues are discussed below.

Leadership Support and Understanding

Mulcahy had been a staunch supporter for KM efforts. David Franke replaced Mulcahy in 2000, and a new Director of Requirements was also appointed. Both were open to KM concepts and the AFKM program, but neither was as educated or enthused about KM as Mulcahy. Adkins indicated that Franke didn’t see KM as needing emphasis above other AFMC programs, thereby increasing the difficulty of securing exposure and backing necessary to compete for scarce resources. Furthermore, few other individuals had much of an idea of what KM was about. Although it was easy to communicate the importance of individual applications (e.g., lessons learned, document repositories, corporate yellow pages), it was more difficult to explain comprehensive KM concepts. Adkins realized “learning about KM” took time, but the ignorance of those upon whom he relied for support threatened the program’s survival before it had a chance to prove itself on a large scale.

Conflict with the IT Organization

Dealing with AFMC’s information technology (IT) organization was a continual challenge because it perceived its role as providing technology solutions for the customer, as did AFMC/DR. Additionally, a conflict arose when the IT organization mandated LiveLink® as AFMC’s only authorized collaboration tool. LiveLink® directly conflicted with CoP development and was generally more sophisticated than was needed by the average customer. While Adkins’ team had a wealth of KM knowledge and system development expertise, the IT organization was the authorized policy maker, and continued conflicts risked AFKM being changed, dismantled, or absorbed.

Funding

A $600,00 budget cut loomed that would eliminate six personnel impacting AFKM systems development workload distribution. Furthermore, many AFKM customer-specific applications had been developed without charge. Without such assistance, some customers would never get their

KM efforts off the ground and AFKM's support practices would have to be re-evaluated

System Usage Concerns

Despite rave customer reviews about AFKM systems, Adkins was disturbed by low usage rates. Access metrics showed usage generally rising, and yet it was a small portion of what it could be. Publicity capmpaigns did little overall; it was clear the AFKM system tools were still in their infancy and the low usage statistics didn't help the team adequately justify the benefits or budget.

Technological Challenges

The AFKM team became so efficient at developing technology solutions that they could develop a "CoP in a box" with a few minor customizations in only a few days. Instead of providing content (i.e., deskbook, lessons learned), the team now provided software frameworks, in which customers added information and knowledge. However, a new AF portal was decreed the de-facto access point for all AF information and knowledge. This raised the question of how to design future applications. Adkins' team was heavily involved in the technology of CoPs, but the community-based capabilities of the AF portal might change everything.

Outsourcing KM

With so many issues impacting AFKM; Adkins needed a strategic vision and implementation roadmap to guide future development. Adkins' foremost concern was the development of a strategic vision and plan. He needed documents that would provide starting points for decision-making and describe how to proceed to the envisioned business environment.

Unfortunately, AeroCorp's recommendations captured the complexities of AFMC's environment, and yet were so broad and involved it was difficult to determine a starting point. AeroCorp also had difficulty developing concise methodologies or "blueprints" that addressed the enormity of what AFMC needed to do to evolve into a true knowledge-sharing organization. In particular, AeroCorp applied integrated definition (IDEF) modeling to KM. IDEF modeling was developed for systems engineering and often depicts "as-is" enterprise processes and information requirements; it did not serve as a user-friendly methodology for fully explaining or depicting strategic KM needs.

After seeing the initial draft of the IDEF model, it was clear the process was "over-engineered." After a year of waiting, the promised roadmap was too unfamiliar and complicated for Adkins and others to practically implement. Faced with an impending budget cut, AeroCorp would likely not have an opportunity to make necessary changes. At this point, Adkins had no good answers.

LESSONS LEARNED

Adkins understood he needed a strategic vision to guide AFKM's direction and decision-making. When outsourcing KM strategy met with limited success, he rescoped and refocused the team on a few key areas under their immediate control. From 2002 forward, the AFKM team:

1. promoted CoPs as a key technique for KM across the AF,
2. provided enterprise Web search capabilities across AFMC and selected AF sites,
3. used a process approach for delivering CoP capability.

The team's strategy became one of building momentum by providing rapid KM services ("CoPs in a box") and following up with training and implementation support; leadership could observe successes at the grassroots level. Since the change in strategy, AFKM has enjoyed remarkable success. The AFKM Web site, now called AF Knowledge Now, continues to expand its capabilities and customer base. In 2004, Adkins secured key support from the AF Chief Information Officer; Adkins' team was dubbed the AF Center of Excellence for Knowledge Management, and AF Knowledge Now was integrated into the AF portal.

IMPLICATIONS AND CONCLUSION

This study highlighted some real-world examples of such barriers and several issues to be considered for strategy development: many of the same factors that act as barriers to implementation may also impede KM strategy development. This study highlighted some real-world examples, such as barriers and several issues to be considered for strategy development:

- KM is hard to define and communicate to others.
- KM initiatives must be championed and supported at the highest levels of any organization.
- KM strategy development is not easy, yet it is critical to the success of any KM initiative.
- Outsourcing KM can be very risky.
- Focusing on specific KM efforts is important for countering negative KM influences.

Despite rising awareness of KM and its benefits, we are reminded that such issues may well play out in any organization, military or otherwise, and should be accounted for preemptively during KM strategy development to improve the chances of improving long-term organizational performance.

Chapter 2.24

A Multi-Agent System for Optimal Supply Chain Management

Hyung Rim Choi
Dong-A University, Korea

Hyun Soo Kim
Dong-A University, Korea

Yong Sung Park
Catholic University of Busan, Korea

Byung Joo Park
Dong-A University, Korea

ABSTRACT

Supply chain management recently has been developing into a dynamic environment that has to accept the changes in the formation of the supply chain. In other words, the supply chain is not static but varies dynamically according to the environmental changes. Therefore, under this dynamic supply chain environment, the priority is given not to the management of the existing supply chain but to the selection of new suppliers and outsourcing companies in order to organize an optimal supply chain. The objective of this research is to develop a multi-agent system that enables the effective formation and management of an optimal supply chain. The multi agent system for optimal supply chain management developed in this research is a multi agent system based on the scheduling algorithm, a cooperative scheduling methodology, which enables the formation of an optimal supply chain and its management. By means of active communications among internal agents, a multi-agent system for optimal supply chain management makes it possible to quickly respond to the production environment changes such as the machine failure or outage of outsourcing companies and the delivery delay of suppliers.

This research has tried to suggest a new direction and new approach to the optimal supply chain management by means of a multi-agent system in dynamic supply chain environment

INTRODUCTION

Many companies have tried to introduce SCM (supply chain management) in an effort to enhance competitiveness amid severe competition caused by market globalization. Now, the participating companies in the supply chain are not fixed but rather are dynamically being changed in response to the environmental changes. Under such a dynamic SCM, it is very important to determine with whom to cooperate in order to solve these problems coming from environmental changes. Instead of seeking to optimize the existing supply chains, this study has focused on optimizing the supply chain itself. The optimization of an existing supply chain can be efficient to a fixed supply chain, but it is difficult for a dynamic supply chain to respond flexibly under the environment that its member is always changing. When a company joins an existing optimal supply chain, or when a company, which is currently joining a supply chain, has to transfer to another supply chain, they have to change their systems or processes in order to join in the new supply chain. However, this is not an easy job. The optimization of a supply chain is not made only once. Rather, it is to be made continually in response to diverse environmental changes. That is, it needs to be made on a real-time basis.

By the way, the supply chain, which consists of a lot of companies, is likely to meet with various complex problems for entire optimization, and these problems bring a significant influence on making the optimal supply chain. For example, machine failure of one participating company affects not only its related member companies but also the whole supply chain that the company belongs to. Therefore, this problem must be coordinated or adjusted not as a problem of one company, but as a problem of whole supply chain. To this end, each member of the supply chain has to cooperate and exchange information between members on a real-time basis. A multi-agent system can provide a useful tool for this purpose. Many preceding studies have emphasized that the multi-agent system is the best way in solving many complicated problems under diverse environmental changes (Bussmann, 1999; Choi, Kim, Park, & Park, 2004; Fox, Barbuceanu, & Teigen, 2000; Julka, Karimi, & Srinivasan, 2002; Shen & Norrie, 1998; Shen, Norrie, & Kremer, 1999). Also, this is an efficient way of exchanging and sharing information without integration of its applications among companies. That is to say, it enables relevant companies to move smoothly to another supply chain without changing their systems and processes. Accordingly, only by the transfer of the agent alone, which represents the relevant company, cooperation, and information exchange among members within the supply chain can this be made possible.

In this study, we developed an integrated scheduling method in order to organize and manage an optimal supply chain and a multi-agent system in order to solve the various problems occurring on a real-time basis in the optimal supply chain. The integrated scheduling method enables the scheduling for the entire supply chain in cooperation with related members in a supply chain, thus it is possible for a manufacturing company to make scheduling by taking into consideration the production environments of outsourcing companies and the delivery status of suppliers. And the multi-agent system shares the information on production environment and supply capacity of both outsourcing companies and suppliers, making it possible to respond to the dynamic environmental changes such as a delay in supplying parts or raw materials, power stoppage, or machine failure of the outsourcing companies for an optimal supply chain management.

BACKGROUND

A multi-agent system has been considered the best way to solve complicated problems under the diverse environmental changes (Shen et al., 1999). In fact, it is not easy for manufacturing companies to be flexible for dynamic changes. A number of researchers have attempted to apply agent technology to manufacturing enterprise integration, supply chain management, manufacturing planning, scheduling, and control (Bussmann, 1999; Maturana & Norrie, 1996; Parunak, 1987; Parunak, Baker, & Clark, 1997). This trend is well described in Shen et al.'s studies on agent-based production system (1999). Shen et al. developed in their studies many production-related agents with diverse functions and configurations. Their studies mainly focused on making new a manufacturing system using an agent technology for automation and efficiency in the process planning and scheduling. Also, the AARIA (Autonomous Agents for Rock Island Arsenal) project of Intelligent Automation company (Baker, Parunak, & Erol, 1997), ABCDE (Agent-Based Concurrent Design Environment) system developed by KSI (Knowledge Science Institute) of University of Calgary (Balasubramanian & Norrie, 1995), a virtual manufacturing agent made by LIPS institute of the University of Texas at Austin (Chuter, Ramaswamy, & Baber, 1995) and MASCOT (Multi-Agent Supply Chain cOordination Tool) agent of Intelligent Coordination and Logistics team of Carnegie-Mellon University (Norman, David, Dag, & Allen, 1999) are representative studies that have used a multi-agent system for development of intelligent manufacturing system.

While making intensive studies on the intelligent manufacturing system by means of an agent system, the scope of this research has been extended to the study on a multi-agent system for supply chain management. Shen et al. (1999) emphasized that there are a lot of complexities and changes in the manufacturing environment under supply chain, and that the agent system can be the best way for effective supply chain management. Also, they said that a multi-agent system can be the best method to integrate the activities of suppliers, customers, and business partners with internal activities of a company (Shen & Norrie, 1998). Meanwhile, more active research has been done on the agent-based supply chain models. Wu, Cobzaru, Ulieru, and Norrie (2000) suggested a new method that one participating member is connected via a Web system to the agents of its related business partners in the manufacturing, distribution, and service field. When an event happens, each agent cooperates to organize a virtual cluster to solve a specified problem. Julka et al. (2002) suggested an SCM model based on an agent while emphasizing the importance of a more flexible and efficient system. Shen et al. (1999) divided production management into five divisions such as design, process planning, scheduling, marketing, and coordination. And then they established a mediator agent for each division and a mediator agent for each mediator agent. Through this mediator-based multi-agent system, they suggested the possibility that if the scope of manufacturing activities within a factory is extended to its suppliers or business partners, an effective SCM could be established. MetaMorph II system suggested by ISG has a mediator-based multi agent structure, suggesting a supply chain network model where the agents for suppliers, business partners, and customers are connected to the mediator of the system via Internet (Shen et al., 1999).

Most existing research has tried to solve the complex and difficult problems, which cannot be solved by individual application programs, by means of mutual cooperation among agents. That is to say, the existing studies have focused on solving various problems occurring within a supply chain by way of communicating among agents. But this study has tried to organize an optimal supply chain by means of communicating among agents, while focusing on maintaining and managing the optimal supply chains. The existing studies and this study are similar in the sense that both have made use of a multi-agent system, but differences between them are in where and how the multi-agent system has been used. Also, it can be said that the studies on the optimization of supply chain by means of a multi-agent system have not yet been made much.

A METHOD FOR OPTIMAL SUPPLY CHAIN MANAGEMENT

Organization of Optimal Supply Chain

This study focuses on the following problems: How to organize an optimal supply chain under the dynamic supply chain environment? When environmental changes have occurred to the optimal supply chain, how to respond to it? As an object of our research, this study chose a molding company among many make-to-order manufacturers. When a molding company tries to select a supplier and an outsourcing company, such factors as delivery date, cost, and productivity are to taken into consideration. In particular, owing to its industrial characteristics, the due date is the most important factor. A molding company is a typical make-to-order manufacturer, and so if it fails to meet the due date required by a customer, it is impossible for the company to sell its product. Also, as most products of the molding companies are standardized, their price and quality are almost the same, thus showing no much difference. Because of this, instead of the price and quality, the delivery date becomes a critical factor in choosing a supplier or an outsourcing company.

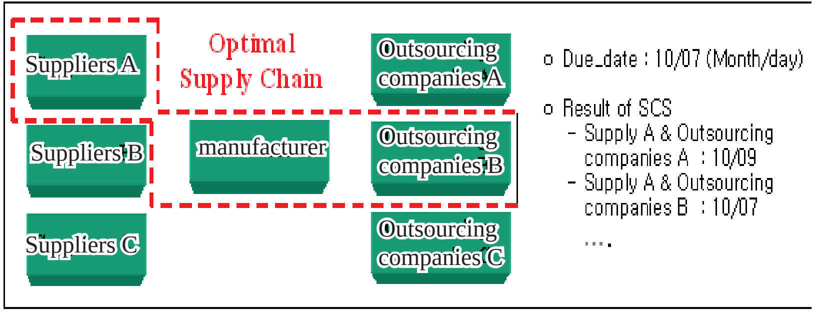
When there are many outsourcing companies and suppliers, as illustrated in Figure 1, this study has selected the supplier and outsourcing company that can meet the due date demanded by customers in order to organize an optimal supply chain.

If an outsourcing company participating in the optimal supply chain is unable to perform operation due to its machine failure, or a supplier fails to provide the specified parts on the due date, the manufacturer has to reorganize the supply chain. Like this, when environmental changes occur, it is absolutely necessary to automatically obtain, exchange, or share information in order to speedily respond to the sudden environmental changes.

An Integrated and Dynamic Scheduling Method for Optimal Supply Chain Management

This research uses genetic algorithm to establish integrated and dynamic scheduling. This algorithm integrates process planning and scheduling in order to consider alternative machines of outsourcing companies and operation sequences, and also can perform rescheduling in response to the changes in the production environment. Traditionally, process planning and scheduling were

Figure 1. Optimal supply chain



achieved sequentially. However, the integration of process planning and scheduling brings not only best effective use of production resources but also practical process planning without frequent changes. Choi, Kim, Park, and Park (2004) have proved that this integration of process planning and scheduling is far superior to the sequential process of planning and scheduling in the aspect of completion time of jobs.

We used a genetic algorithm with flexible representation structure for the integrated and dynamic scheduling method. Genetic algorithm enables integrated scheduling, considering alternative machines of outsourcing companies and operation sequences. Also, it enables rescheduling when changes have been made to the suppliers, outsourcing companies, and producer. In order to design genetic algorithm, first of all, the attribute of the problem should be analyzed, and then the presentation proper to the problem, performance measure, genetic operator, and genetic parameter should be decided. The following is genetic algorithm for the establishment of integrated scheduling considering alternative machines and operation sequence under the dynamic situation.

Representation

To achieve integrated production plan through genetic algorithm considering alternative machines and operation sequences, first of all, the problem should be represented in chromosome. The representation should be made in the way that all the processing sequence, alternative operation sequences, and alternative machines could be decided. First, to represent processing sequence, the pattern to repeat the number of the job as many as the number of operation is used. One gene means one operation, and in the represented order it will be allocated to the machines. For example, the problem of three jobs and three machines is represented in sequence as shown in Figure 2. The threefold repeated number in the first row is the number of the job, and the reason that each job number has been repeated three times is that each job has three operations. The first repeat of the job number means the first operation of the job, and the second repeat means the second job operation. If the job number continues to represent the number of job operation, this chromosome will always maintain its feasibility. The second row is the random numbers that will be used to decide alternative operation sequence. As each job is done in the one-operation sequence, each job produces the same random number within the number of maximum alternative operation sequence. For example, as job 2 in Table 1 has three alternative operation sequences, the random figure has to be produced within three. The third row has the random numbers to decide the alternative machine, producing them within the number of maximum alternative machines. In Table 1, the second operation of job 1 is to be done in the M2 but also can be done in the M1 and M3. In this case, the number of machines that can handle the second operation of job 1 is 3. As there are no more alternative machines than this in Table 1, the random figures for all alternative machines will be produced within three. The index in the last row means the repeat number of job numbers, namely showing the ordinal operation of each job.

Selection Method

The seed selection is used as a way of selection (Park, Choi, & Kim, 2001). Seed selection, as a way of individual selection that is used in the propagation of cattle and the preservation of the individual, has been introduced to the evolution of genetic algorithm. If the random value of the individual, which belongs to the father among parents, comes within the figure of probability (0.9), the best individual will be selected from within superior individuals from ranking population. But, if not, the individual will be randomly selected from among the entire group. The mother will be selected randomly among the entire group, but in this case, first two individuals will be selected randomly, and then the better individual based on the value of probability will be selected. These will be used as parents, and then returned to the individual groups, so that they will be used again later.

Genetic Operator

Crossover operator should maintain and evolve the good order relationship of chromosome. The crossover operator used in this research has a process as follows:

① Produce a random section
② Insert all the genes inside the random section into parent 2
③ All genes with the same index as the genes in the random section will be deleted in parent 2
④ It will be corrected according to the alternative operations sequence of the initial job number to make alternative operation sequence coincide to the same job number
⑤ These processes will be performed alternating parent 1 and parent 2

The position of insertion is just before the gene where the random section has started. If in parent 1 the random section starts in the fourth place, then the position of insertion will be before the fourth gene in parent 2. This crossover operator produces two children. After two offspring are evaluated, the better one will be sent as a next generation. The mutation operator gives a change to the chromosome, thus maintaining diversity within the group. This research uses the mutation operator based on the neighborhood searching method (Park et al., 2001).

Table 1. Alternative machines and alternative operation sequences of each job

Job 1	Operation sequence 1 (alternative machine)	M1	M2	M3
		(M3)	(M1)	
			(M3)

Objective Function and Replacement

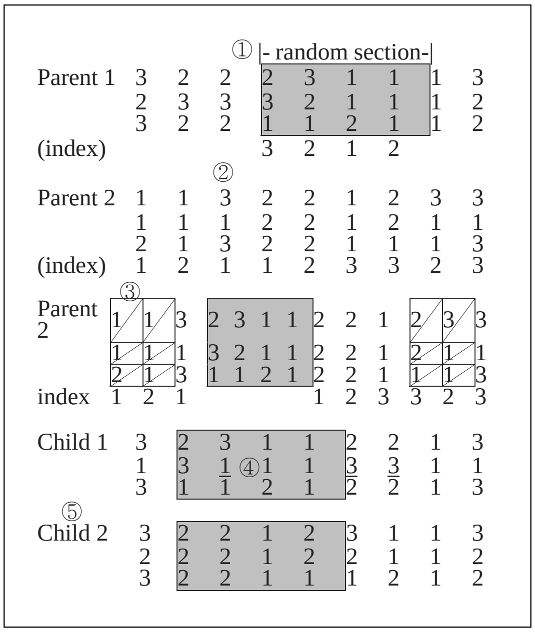
The minimum makespan in the scheduling often means the highest efficiency of a machine. When a chromosome is represented as a permutation type, the makespan is produced by the process that assigns operations to the machines according to sequence of gene from left to right, while maintaining the technological order of jobs and considering its alternative operation sequence and alternative machine. The process is shown in Figure 3. The next generation will be formed by the selection among the current generation and with the help of genetic operator. The new individuals will be produced as many as the number of initial population and form the next generation. By using elitism, bad individuals will be replaced with good individuals. Also, because of crossover rate and mutation rate, some individuals will be moved to the next generation without getting through the genetic operator.

Genetic Algorithm for Dynamic Scheduling

The genetic algorithm suggested in this paper reflects the dynamic changes in the suppliers and outsourcing companies along with the production changes of the producer. When the changes of production environment have happened in suppliers or outsourcing companies—the acceptance of new orders, machine failure, outage, and the absence of the worker in duty—all these changes will be reflected in the rescheduling. For example, when a machine cannot be operated for 10 hours because of its failure, or a supplier cannot keep the lead-time, thus delaying 10 hours, the integrated scheduling will reflect the usable time of each machine and the possible starting time of each job. Figure 4 shows the process of rescheduling when a new order has been accepted at the time of t1.

In the process of rescheduling, the remaining jobs and the new jobs to be done by the new orders will be considered in the new production planning. It also considers the starting time of jobs and the usable time of machines. The starting time of jobs can be changed by the delay of supply or the operation delay of its prior process. The usable time of machines, as shown in the black shade of Figure 4, can be changed by when the machine has already been allotted to other job, machine failure, and the absence of the worker on duty. All these dynamic changes will be reflected in the rescheduling (Park, 1999). In the rescheduling process, the chromosome is to be modified, and a new objective function is to be produced in response to the environmental changes. Based on this rescheduling, a new supplier or an outsourcing company is to be selected, and the information of rescheduling is to be transmitted through the multi-agent system. In order to solve several problems simultaneously, the genetic algorithm in this study has been represented in a chromosome and has been designed for better evolution, so that it can more effectively solve the complex problems of integrated scheduling. Like this, the strong point of genetic algorithm lies in its approach based on the problem-centered chromosome design. Also, thanks to its flexible representation, speedy performance, and excellent performance capability, the genetic algorithm makes it possible to reflect in the rescheduling all the information about suppliers and outsourcing companies, which comes from the multi-agent system on a real-time basis. In this respect, the genetic algorithm is considered to be best suited to the dynamic supply chain management.

Figure 3. The example of crossover



A MULTI-AGENT SYSTEM FOR OPTIMAL SUPPLY CHAIN MANAGEMENT

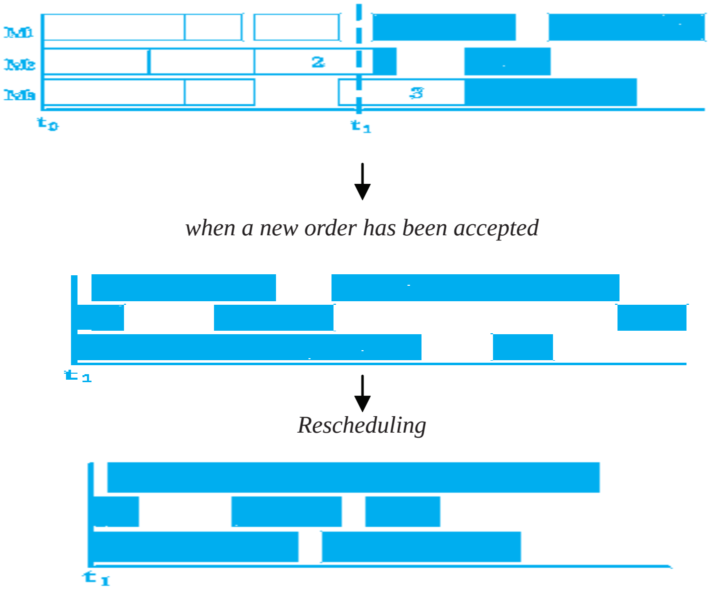
The Whole Structure of a Multi-Agent System

The key factor in the development of a multi-agent system is how the roles should be assigned to each agent. In the multi-agent system, one agent doesn't perform all functions. Rather, each agent has an individual function, and so they mutually communicate with each other to jointly solve complicated matters. Because of this reason, how to classify each agent is a key factor to designing a multi-agent system. For the development of a multi-agent system, all the activities from a customer's order to manufacturing were reviewed, and then these activities were assigned to each agent. Each agent is given a specified function so as not to have many functions.

As illustrated in Figure 5, the multi-agent system can be divided in two subsystems: virtual manufacturing system and SCM system. The virtual manufacturing system is composed of an inventory analysis agent, manufacturability analysis agent, process planning agent, and scheduling agent. This system makes a decision on whether it will be able to manufacture or not, makes scheduling in consideration of the production environments of both suppliers and outsourcing companies, and makes a decision on the necessity of parts or materials through inventory analysis. This activity is directly related to the selection of suppliers. The SCM system consists of an outsourcing management agent, supplier management agent, outsourcing company communication agent, supplier communication agent, and registry server agent. This system organizes and manages the optimal supply chain based on the integrated scheduling that is the result of virtual manufacturing.

Based on the exact scheduling, the virtual manufacturing system makes a decision on whether it can manufacture within the due date. The SCM system's main function is to respond to the manu-

Figure 4. Example of dynamic scheduling



facturing environment changes occurring in the optimal supply chain. To this end, the mediator of the manufacturing company has to exchange information on a real-time basis with both the supplier's and outsourcing company's agent. The multi-agent system has a mediator-centered structure. All the agents are connected to the mediator, which takes control of each agent, and also are responsible for smooth information exchange with suppliers and outsourcing companies.

Function of Each Agent

All agents own their basic function to communicate with each other, and each one has diverse kinds of engines according to his role.

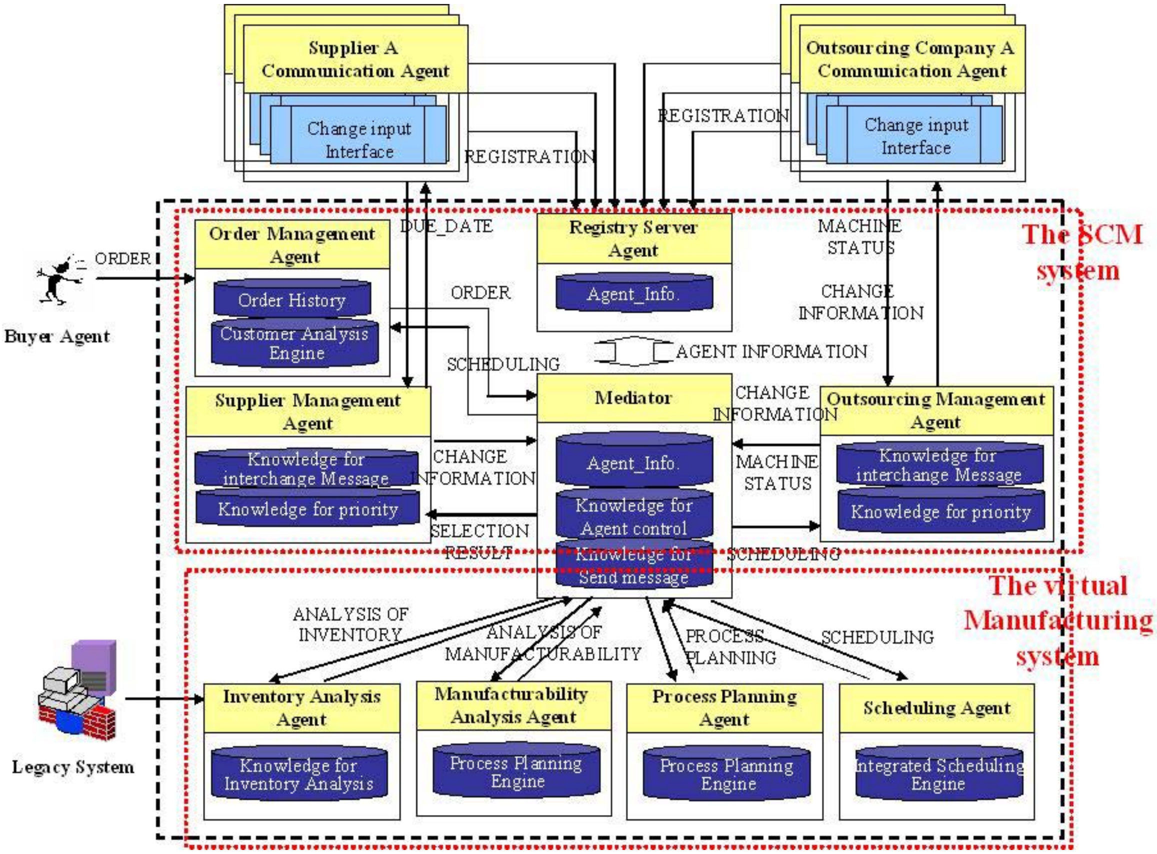
Mediator

The mediator plays the role of controlling and coordinating the message exchange among agents within the system. The agent in charge of controlling and coordination is necessary in order to perform harmoniously the various jobs of many agents, to remove the bottlenecks occurring within the system, and to prevent the collision between each agent. For this purpose, the mediator has a knowledge base for agent coordination and message exchange as well as information on each agent.

For example, when the SMA (supplier management agent) received from the SCA (supplier communication agent) the information on production environment change, that is, "The material delivery from the supplier is delayed," the mediator is to send this information speedily to the SA (scheduling agent) so that it may make rescheduling according to the production environment changes. The roles of mediator are as follows:

- Message transmission between internal agents
- Function control of internal agents
- Function of filtering the messages
- Knowledge of mediator's behaviors
- Knowledge of internal agents

Figure 5. Structure of multi-agent system of an optimal supply chain



The mediator is in charge of controlling and coordinating each agent, and has diverse knowledge base to help the message exchanges between agents, which are illustrated in Table 2.

As illustrated, the knowledge is expressed in the form of rules. Case 1 shows that when OMA (order management agent) receives an order, the mediator is to send the message asking the MAA (manufacturing analysis agent) to make a decision whether it can be produced or not. See Case 1.

Case 2 shows that when it receives the message that it can produce the ordered product from MAA, the mediator is to send PPA (process planning agent) the message asking for scheduling. See Case 2.

Diverse messages from internal agents converge to the mediator. The mediator is to perform the function of operating its system smoothly, so that it can remove bottlenecks and prevent collisions between each agent. This study adopted the FIFO (first in first out) method in handling the messages. If messages from the agents come to the message queue, those messages will be handled in sequence.

Registry Server Agent

Buyer agent, outsourcing company agent, and supplier agent are to be registered in the registry server agent (RSA). Registered agents are to obtain position information from RSA so as to be able to communicate to his or her partner agent. The agents registered in the RSA can be candidates for the participating member of the

Table 2. The knowledge in the mediator

Knowledge of agent role	Knowledge of subagent composition Knowledge of subagent role
Knowledge of message exchange	Knowledge of job handling procedures Knowledge of how to handle the contents of message
Knowledge of problem solution	Knowledge of how to handle message in case of no answer Knowledge of how to express in time of trouble

optimal supply chain. In principle, the optimal supply chain needs to be organized through communication with the agents of all the suppliers and outsourcing companies. But in reality, for mutual communication among agents, each agent has to obtain information about his or her partner agent. For this reason, only the agents who can communicate via RSA can be candidates for the optimal supply chain organization.

The outsourcing companies and suppliers have to register the information on their agent's position and basic data of their companies. The basic data of the companies includes their name and role. Their role is whether they are outsourcing companies or suppliers. Outsourcing company and supplier have a different role. Because of this, they have to register additional information besides basic data. That is, the outsourcing company has to provide information on machines and facilities, and the supplier has to include information on the parts and materials that it can provide. In particular, in case of an outsourcing company, as an outsourcing company executes some parts of an ordered product, information on its production facilities such as a mill or a drill has to be registered.

Order Management Agent (OrderMA)

An order management agent receives orders and confirms them. It keeps order information and analyzes and classifies buyers through data mining and statistic analysis.

Case 1.

```
[ case 1 ]
 rule name  Accept Order
if   contents_name = order
then send product_width and product_length and product_height and raw_material and part_width and part_length and part_height to ManufacturabilityAnalysisAgent
```

Case 2.

```
[ case 2 ]
 rule name  Accept ManufacturabilityAnalysisResult
if   contents_name = ManufacturabilityAnalysisResult and
 ManufacturabilityAnalysisResult = yes
then send use_for and model_name and number_of_part and process_time and product_width and product_length and product_height and raw_material and part_width and part_length and part_height to Process Planning Agent.
```

Supplier Management Agent

A supplier management agent provides the information on the environmental changes in the suppliers to the inside system and also transmits the information on supply schedule to the suppliers. This agent also keeps the suppliers' priority on the basis of their capability and confidence. This data will be used at the time of selecting suppliers when they all can keep the same due date.

Outsourcing Management Agent (OMA)

An outsourcing management agent provides the information on the machine situation of outsourcing companies for the sake of scheduling, and also, based on the scheduling, it makes a decision on the necessity of outsourcing. The criteria for the decision-making are whether the outsourcing company can keep the due date or not. When the producer cannot keep the due date for itself, this agent sends the message containing the necessity of outsourcing. The following is the agent's action knowledge represented in the form of IF-THEN, saying, "If the due date based on the production planning is not satisfactory, inform the mediator of the necessity of outsourcing." Here, Last_time is the finishing time of the last operation in the production planning.

```
IF  Last_time > due_date
Then send  yes_message  to  Mediator
```

This agent has the priority information on outsourcing companies, and this information will be used for selecting outsourcing companies.

Inventory Analysis Agent (IAA)

An inventory analysis agent analyzes the inventory level and makes a decision on the purchase of materials. The information on the inventory level is to be secured from the inside of the system. The inventory analysis agent makes a decision based on the purchase necessity analysis knowledge.

Manufacturability Analysis Agent (MAA)

Based on the information on products and parts, MAA checks up the constraints related to the manufacturing process in order to make a decision on its manufacturability. Constraints usually come from the size and weight. In case the size of an ordered product is too large or the weight is too heavy, the small manufacturer cannot produce it. For example, if the size and weight surpass the capacity of the cranes of the manufacturer, it cannot execute the order. The judgment on manufacturability can be made by the knowledge base. This knowledge base includes information on various kinds of size and weight as well as the cases making it impossible to execute an order. The knowledge in Box 1 shows how the judgment on manufacturability can be expressed in JESS, that is, a language of java-based rule expression.

Process Planning Agent (PPA)

A process planning agent performs the role of process planning. This paper used CBR (case-based reasoning) based on a process planning engine. The reason is that if the products of order-based producers are similar, the same process will be used (Kolodner, 1993). Choi, Kim, and Park (2002) have proved the availability of this methodology by applying it to molding industry.

Scheduling Agent

A scheduling agent performs the role of scheduling based on a genetic algorithm-based engine, considering alternative machines and operation sequence. This agent plays the critical role in the multi-agent system, and based on this scheduling, the supplier and outsourcing company will be selected.

Box 1.

"The mold size of cavity plate is a>600, b>270, c>400, it is impossible to execute the order."

```
 (constraint_rule_002
        (size_a     ?a)
        (size_b     ?b)
        (size_c     ?c)
  =>
  (if (&& (>=?a600) (>=?b270) (>=?c400)))
   then (assert (manufacturability  no)))
```

Supplier and Outsourcing Company Communication Agent

A supplier and outsourcing company communication agent performs the role of communications between multi-agent system and suppliers and outsourcing companies. For the establishment of scheduling, the supplier communication agent provides the possible due date of raw materials, and the outsourcing company communication agent provides the information on the machine situation. These two agents provide multi-agent systems with the information on the production environment changes through user interface.

The Process of the Multi-Agent System

The process of the multi-agent system is composed of the followings: the process of scheduling for self-production, the process of scheduling for selecting outsourcing company, the process of scheduling for selecting supplier, and the process for rescheduling in case the production environments of suppliers and outsourcing companies have been changed. If necessary, based on the rescheduling, the supplier and outsourcing company should be reselected.

The Process of Scheduling for Self-Production

Figure 6 shows the case that a producer can make for order-based products at his own factory without the help of suppliers and outsourcing companies. The producer establishes the scheduling for accepted orders, and provides the result to the buyer agent.

The Process of Scheduling for Selecting Outsourcing Company

Figure 7 shows the case that if a producer cannot meet the required due date by self-production, he has to select an outsourcing company.

The outsourcing management agent analyzes the necessity of outsourcing based on the scheduling, and if necessary, it asks for the information on the machine situation of outsourcing companies. Based on this information on machine situation, the scheduling agent establishes rescheduling. Based on this rescheduling and outsourcing company priority, the outsourcing management agent selects an outsourcing company.

The Process of Scheduling for Selecting Supplier

Figure 8 shows how to select the supplier in case that the producer doesn't have enough inventory

Figure 6.The process of scheduling for self-production

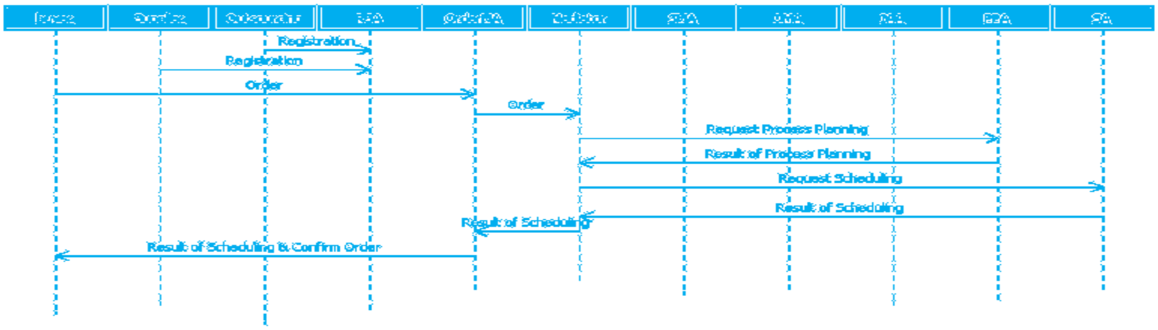


Figure 7. The process of scheduling for selecting outsourcing company

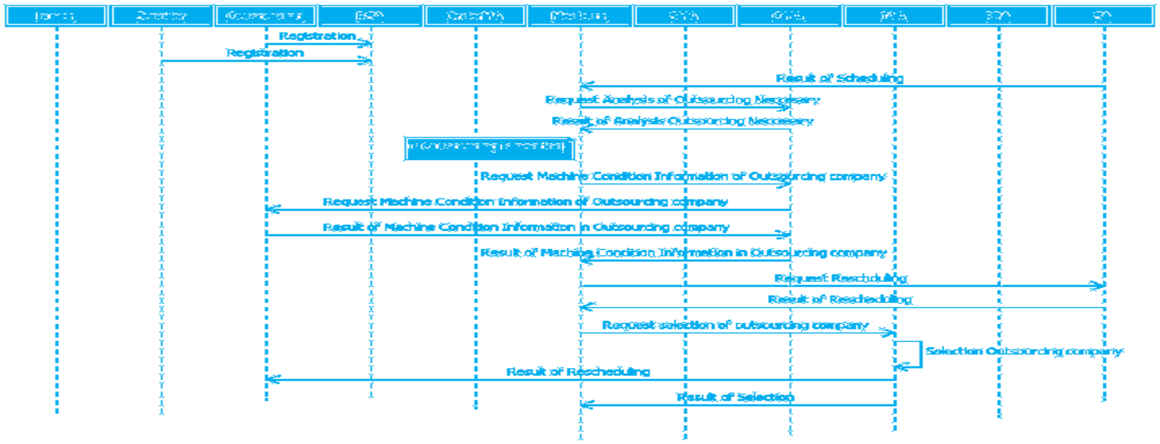

Figure 8. The process of scheduling for selecting supplier

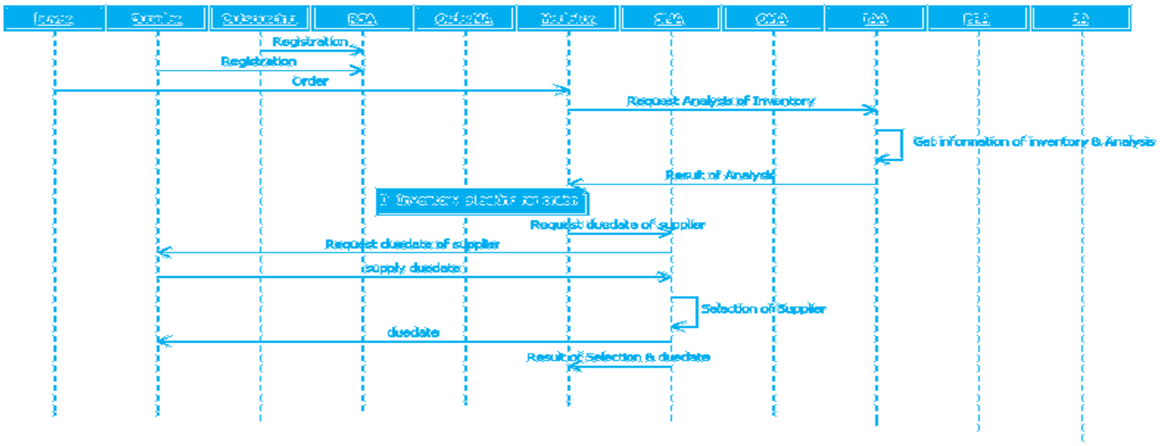

of raw materials. The inventory analysis agent analyzes the inventory of the inside system and required raw materials for orders. If it thinks the supplier should be selected, the supplier management agent will ask the suppliers for a possible due date, and based on this information, it will select a supplier.

The Process of Rescheduling for Production Environment Changes

Figure 9 shows how to respond to the changes in the production environment. When there are changes in the production environments of outsourcing companies, the outsourcing communication agent provides this information to the outsourcing management agent. And based on this changed production environment, the scheduling agent achieves rescheduling, and the outsourcing management agent analyzes this rescheduling. However, if this rescheduling cannot meet the required due date, other outsourcing company should be selected.

To testify to the availability of the above processes of the multi agent system, this research adopts a molding company as a case study.

CASE STUDY OF MULTI-AGENT SYSTEM

Case Definition

In order to test the validity and practicality of the multi-agent system developed by this study, we made a prototype and applied it to real field cases. We visited the small "J molding company," the domain of this study, and reviewed and analyzed the facilities of the factory and its field situation. J molding company has such machines as a large mill, medium and small mill, drill, and lathe to perform milling, drilling, grinding, and electric discharge machining. Meanwhile, due to the constraint of facility of this company, there are some molds that cannot be manufactured. That is, the cranes of this company cannot handle the mold exceeding the weight of five tons. But there are no other difficulties in the resources, like manpower or machines, and in technologies. The knowledge base of MMA defines the constraints and uses them in judging manufacturability. The J molding company was maintaining a close relationship with its outsourcing companies and suppliers while outsourcing some part of milling and electric discharge machining.

Figure 9. The process of rescheduling for production environment changes

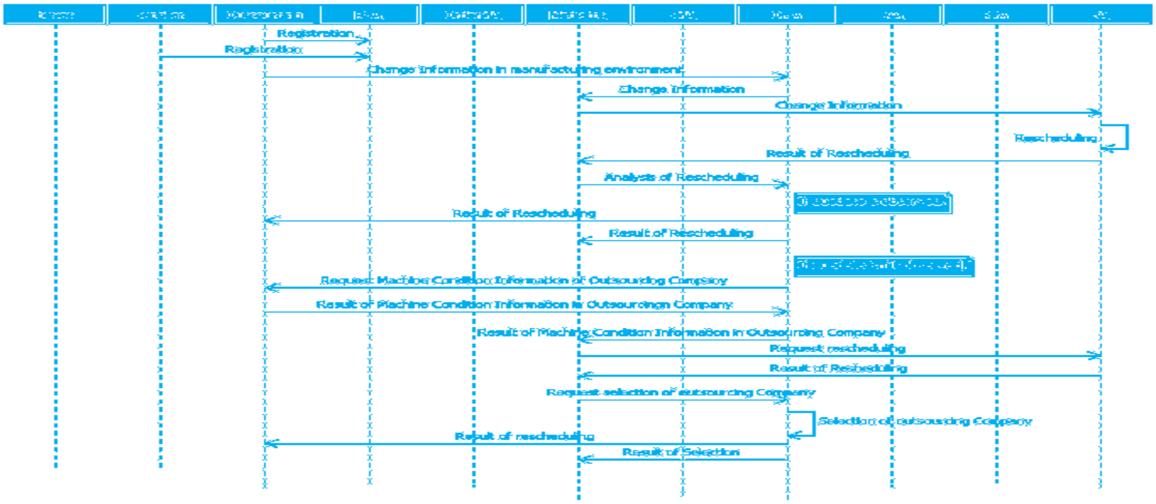

Figure 10. Supply chain of J molding company

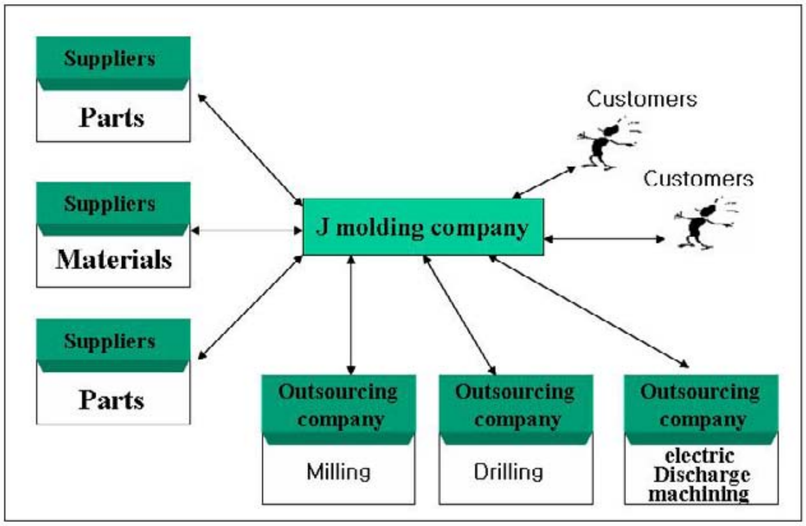

As illustrated in Figure 10, J molding company has a supply chain consisting of material suppliers, outsourcing companies, and customers. Also, in order to meet the due date of the order, it tries to organize an optimal supply chain. The company keeps a good business relationship with three outsourcing companies and three suppliers. This case study is for the mold production of a "cake box."

Case Study

The case study has two stages: The first stage is how to organize an optimal supply chain according to the procedures as illustrated in Figure 11. The second stage is how to respond to the environmental changes such as a machine failure or power stoppage after organizing an optimal supply chain.

As illustrated in Figure 11, the organization of an optimal supply chain needs two steps: The first step is to perform virtual manufacturing for an ordered product. The second step is to select an optimal supplier and outsourcing company according to the result of virtual manufacturing.

Step 1. Virtual manufacturing
If the mediator receives from OMA a message that a client order "cake box" within six days from order date, it sends necessary information to the MAA so as to make judgment on manufacturability.

If the mediator receives a "yes" message from MAA, it sends order-related information to the PPA and SA so that both agents may prepare for process planning and scheduling respectively.

The mediator sends scheduling information from SA to the OMA to make a decision on whether there it is necessary to outsource.

"Makespan 61" is the result of scheduling for an ordered "cake box" mold. This means that if the factory operates eight hours per day, it takes eight days. In this case, as the customer's due date request is within six days from his or her order date, J molding company cannot satisfy the customer's due date. Accordingly, the OMA sends the message of outsourcing necessity to the mediator.

Step 2. The organization of an optimal supply chain
In order to select an optimal outsourcing company that can meet the due date, the mediator asks OMA

Figure 11. Procedure for organizing an optimal supply chain

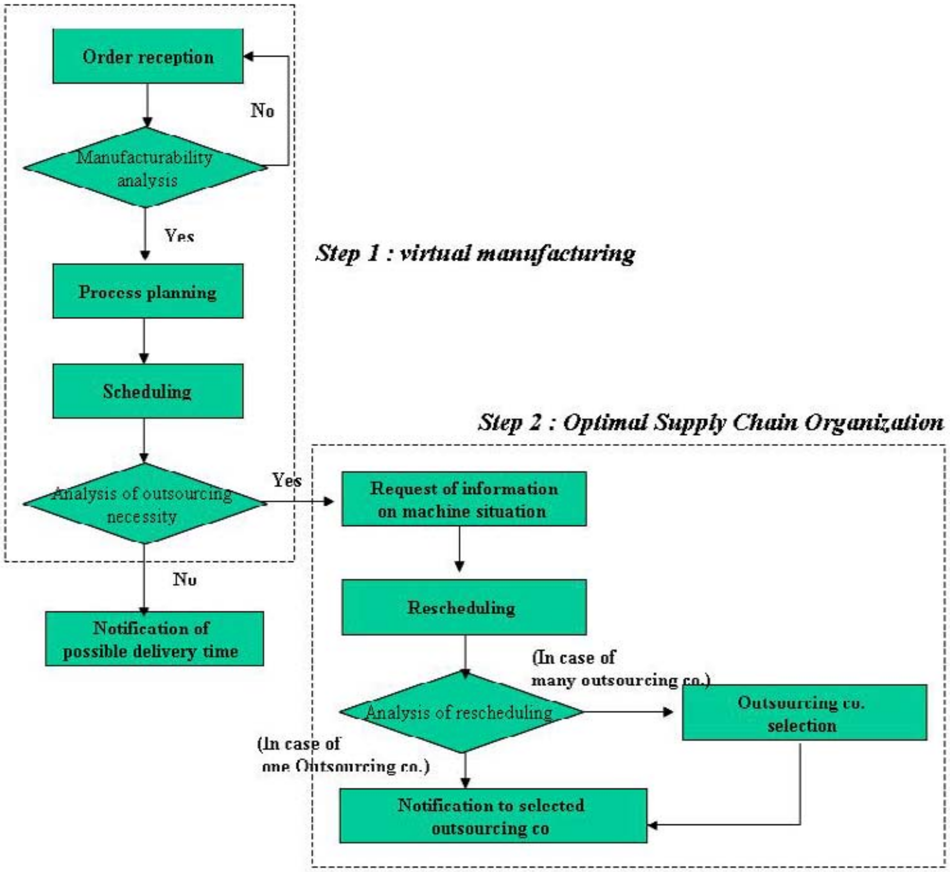

Figure 12. Manufacturability analysis-related message interface

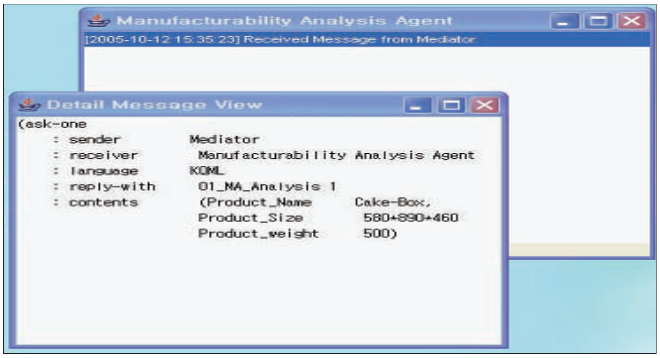

```
[2005-10-12 15:35:23] Received Message from Mediator
```

```
(ask-one
    : sender        Mediator
    : receiver       Manufacturability Analysis Agent
    : language      KQML
    : reply-with     01_MA_Analysis 1
    : contents       (Product_Name      Cake-Box,
                     Product_Size        580*890*460
                     Product_weight      500)
```

for the information on the machine situation of outsourcing companies registered in the RSA.

OMA asks the OCCA (outsourcing company communication agent) of each outsourcing company for the information on machine situation, which includes the machine schedule. If the machine is now in operation, that machine cannot be used for another order until the current operation is over. When the mediator receives the following information on machine schedule from outsourcing companies, it sends this information to the SA so that it may prepare for rescheduling.

- A outsourcing company: two units of mill are now not in operation. (AM 1 0, AM 2 0)
- B outsourcing company: one unit of mill can be used after six hours. (BM 6)
- C outsourcing company: one unit of mill can be used after three hours, and another one unit is now not in operation. (CM 3, CM 0)

As illustrated in Figure 17, rescheduling was made by considering outsourcing companies' machine situation. As a result of rescheduling, in case of A and C outsourcing companies, possible due date is October 18, 2005, thus satisfying customer's request. But B outsourcing company's possible due date is October 20, consequently not meeting the requested due date. This means that A and C can be a participating member of the optimal supply chain. Therefore, the mediator asks OMA to choose one company between these two outsourcing companies. Based on the priority information, OMA chooses A outsourcing company, and then notifies the mediator and OCCA of it.

By selecting A outsourcing company, the optimal supply chain for a "cake box" mold was organized. In this case study, the case of selecting a supplier was excluded, but the supplier also can be selected in the same way as the above-mentioned outsourcing company. Meanwhile, the optimal supply chain is not fixed, rather it can be changed in response to the changes of a manufacturing

environment. But even if such environmental changes take place repeatedly, an optimal supply chain can be organized in the same way as the first organization of an optimal supply chain. As illustrated in Figure 19, this study performed the tests for two kinds of environmental changes. The first environmental change is: A outsourcing company, which is chosen as a member of the optimal supply chain, is unable to work because of milling machine failure. The second one is: A supplier becomes unable to provide the parts within the requested date. Figure 19 shows the process to solve the environmental changes.

The above two environmental changes can affect J molding company in the following two ways: one is that the delay of work doesn't directly affect the due date requested by the customer, and the other is that it affects the due date. In the

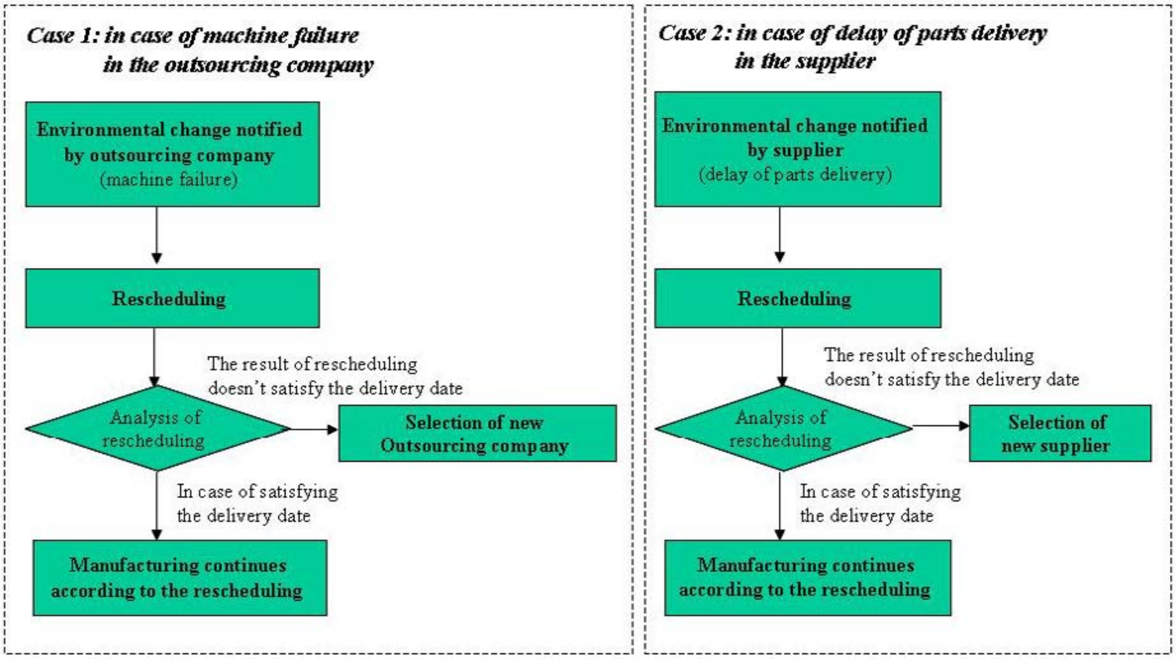
Figure 19. The test procedures of optimal SCM cases



first case, the company's manufacturing activity will be continued according to the rescheduling, but in the second case, it has to reselect a new outsourcing company or supplier.

As shown in the above tests, the optimal supply chain can be reorganized in response to the dynamic changes in the manufacturing environment, so that the manufacturing company may smoothly maintain and manage its optimal supply chain.

Review of Case Study

In order to test the validity and practicality of the developed multi-agent system, this study produced a prototype performing key functions and applied it to the field for case study. Unfortunately, the multi-agent system has not yet commercialized because of many difficulties in realizing its knowledge base. Likewise, the multi agent system's prototype made by this study is not enough to be commercialized, and so we couldn't measure the performance and effect by means of application. Instead, as a way to test its validity and practicality, we had interviews with the experts in charge of scheduling at the make-to-order manufacturing companies, including the J molding company and 15 software developers related to agent development. The experts in charge at the make-to-order manufacturing companies testified to the validity of the multi-agent system, and those software developers evaluated the systemic performance of the multi-agent system. Evaluation was performed on a five-point scale on the next major items.

- *Experts in charge at the make-to-order manufacturers*
    - Is the scheduling of this system correct and accurate?
    - Is it reasonable that the optimal supply chain consisting of suppliers and outsourcing companies focused on due date for supply chain organization?
    - Does the work process for calculating the possible due date reflect well the reality?
    - Does this system smoothly react to the environmental change occurring in the supply chain?
- *Software developers*
    - Is communications among agents smoothly performing?
    - Is the role of each individual agent well assigned? And is the multi-agent structure appropriate?
    - Is the handling speed of the system satisfactory?
    - Is the agent development method reasonable?
    - Is there any serious mistake in the system?

As a result of evaluation, the experts in charge at the make-to-order manufacturers gave a score of 3.8 on the overage, and software developers gave a score of 4.2. The experts in charge gave a relatively higher score to the capability to react to the environmental changes and well-reflected work process, but a somewhat low score to the accuracy of scheduling. This seems to come from the fact that the current algorithm is not fully enough, because of the complex scheduling of the molding industry. However, they put a high value on the automation of scheduling and the possibility of job handling without human intervention and believed that commercialization of the multi-agent system will be able to bring cost reduction and productivity improvement. They also added that many efforts were being made to maintain a solid relationship with outsourcing companies and suppliers that satisfy the due date. These efforts mean that the core point of satisfaction of due date in the organization of optimal supply chain has validity. The agent software developers, who gave a higher score, seem to value the current high level of agent development. The evaluation team as a whole rated the validity and practicality of the multi-agent system very high. In particular, they have paid attention to the new approach to SCM.

FUTURE TRENDS

Owing to the characteristics of the domain of this research, we organized an optimal supply chain based on the satisfaction of due date. From now on, however, further research on the optimal supply chain, which has two different objectives, or considers two key factors simultaneously, will be made. Many companies consider the problem of price to be very important as well as due date. For example, when we consider the two factors of price and due date simultaneously, as the due date is the same but the price is different like Figure 20, it is easy to select its business partner. But as shown on the right side of Figure 20, if the price and due date are respectively different, it is not easy to evaluate them because the two have different worth. Therefore, the method to evaluate due date and price simultaneously has to be developed.

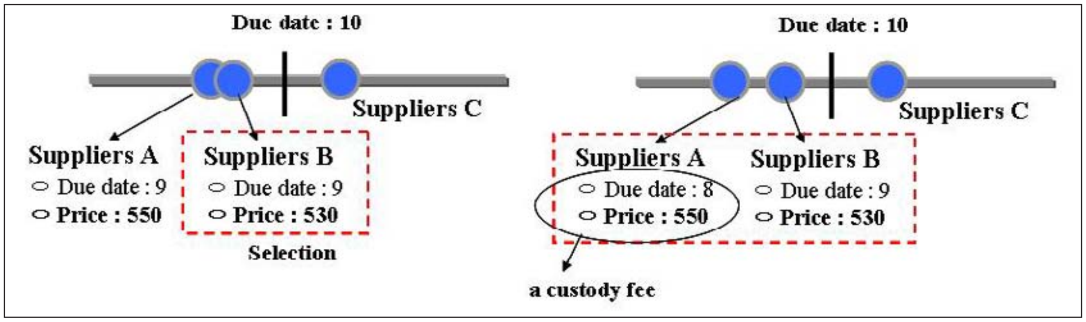
Furthermore, as due date and price have a trade-off relationship, negotiation is possible. That is, the following negotiation can be made: Instead of lowering the price, the due date can be lengthened, or if an earlier due date is required, the price will be higher. In these cases, a new negotiation protocol as well as a new negotiation method needs to be developed.

CONCLUSION

Owing to the increasing importance of quick response to the rapid changes of business environments, the supply chain also needs dynamic changes according to its environmental changes. In the dynamic supply chain environment, it is a key factor to decide who to cooperate with for effective manufacturing. This study developed a system to efficiently select an optimal business partner under the dynamic supply chain environment. To this end, this study developed an algorithm for both scheduling and rescheduling, which is to be made by taking into consideration the manufacturing environments of both suppliers and outsourcing companies. Also, by using a multi-agent system, this study made it possible to organize and manage an optimal supply chain on a real-time basis in response to the dynamic changes in the supply chain environment.

Like this, instead of trying to optimize an existing, fixed supply chain, we have tried to organize a new supply chain that can dynamically respond to the environmental changes, so that it can bring diverse effects such as cost saving, productivity enhancement, and speedy job handling. These

Figure 20. Evaluation of due date and price



effects are well presented in the results of our case study.

Finally, we expect that this multi-agent system will be usefully applied to the complex supply chain environment and also have expectations that the agents realized in the wrapper method through a new development framework will be used in diverse fields.

Chapter 2.25

Integration of Global Supply Chain Management with Small to Mid-Size Suppliers

Asghar Sabbaghi
Indiana University South Bend, USA

Ganesh Vaidyanathan
Indiana University South Bend, USA

ABSTRACT

The purpose of this chapter is to develop a conceptual insight and an integrated framework to global supply chain management through strategic aspects of business philosophy as it pertains to the small- to mid-sized supplier. Primary consideration is given to characteristics of the integrated supply chain and the necessity of adaptation in managing the supply chain in order to attain competitive advantage. A review of the current literature and an analysis of the supply chain in changing global markets emphasize the relative importance of strategically managing the supply chain process given the limited resources of the small- to mid-sized firm. It is argued that managing the supply chain through the development of market specific strategies allows the small to mid-sized firm to be anticipatory as opposed to being reactive in its strategic planning, which can greatly benefit customer satisfaction levels and thus enhance the performance of the firm.

INTRODUCTION

Supply chain management (SCM) as a strategy for competitive advantage has gained prominence in both large and small organizations. An understanding of the supply chain management concept from the perspective of suppliers and, in particular, small and medium enterprises (SMEs) is crucial to the study of vertical integration of global SCM. This understanding will better formulate internal business strategies of suppliers by supporting both the objectives of the supply chain and their own businesses. About 80% of the supply chain members are SMEs, and a major impact and savings may well be found with the SMEs within the supply chain (Smeltzer, 2002). By taking advantage of their position and criticality in the supply chain, SMEs can add value and contribute to the vertical integration essential in the supply chain. This creates advantages not just for themselves, but also for other members within their supply chain.

By some definitions, a supply chain is a network of facilities that performs the functions of procurement of material, transformation of material to intermediate and finished products, and distribution of finished products to customers (Lee & Billington, 1995). The supply opportunity analysis technique (SOAT) moves away from a reactive to a proactive mode by taking (determining) the suppliers' perspective (Bhattacharya, Coleman, & Brace, 1995). When customers demand customized products, products often become increasingly complex. In addition, the development and manufacturing of such products demand even greater resources that need to be shared by the supply chain members. In addition, the development and manufacturing of such products by the original equipment manufacturing (OEM) partners require supply chain members to increasingly share available resources as virtual partners (Rota, Thierry, & Bel, 2002). To the suppliers, these virtual partnerships can provide both opportunities of growth and threats of becoming obsolete from the supply chain. A supplier is usually involved with multiple customers and therefore in several supply chains. The supplier receives both firm orders and forecast orders. To be successful, the supplier needs to negotiate these firm orders and the forecast orders with its suppliers. To deliver customized products with short delivery times and high due-date observance, to plan for the supplier's own raw material requirements, it is important for the customer to effectively share information (Rota et al., 2002).

The transformation from reactive to proactive procurement parallels a transformation in relationships between suppliers and buyers. Suppliers have developed partnerships with customer firms. This partnership has turned into collaborative relationships or strategic alliances (Burt, Dobler, & Starling, 2003). The rising cost of product development, globalization, and shorter product lead times have been cited as important reasons for supplier collaboration (Bruce, Fiona, & Dominic, 1995; Helper, 1991; Lamming, 1993). The involvement by partners has a positive impact on strategic purchasing, and strategic purchasing has a positive impact on a firm's financial performance (Masella & Rangone, 2000). Even though there are many benefits from this collaborative or alliance network between suppliers and customers, there are obstacles. Trust plays a critical role in such collaborative or alliance relationships between suppliers and customers (Burt et al., 2003). However, such collaborations and alliances enable information flow across the supply chain.

To answer questions such as why a supplier was not treated according to its capabilities or why did engineering think it had capabilities when it did not, the characteristics of the suppler has to be clearly articulated (Nellore, 2001). Developing visions for suppliers can help OEMs to create clear expectations and thus better the core capabilities of the buyer and supplier firms (Nellore, 2001). OEMs also increase supplier involvement in product development and the share of inbound just-in-time (JIT) deliveries. However, while suppliers increase their outsourcing and globalization of production and product development activities, OEMs do not (von Corswant & Fredriksson, 2002). By outsourcing certain activities to specialized suppliers, companies can focus on those products and activities that they are distinctively good at (Venkatesan, 1992). This specialization, enabling a reduction of the capital base, implies improved return on invested capital (Quinn & Hilmer, 1994) and the possibility to benefit from economies of scale. However, outsourcing means that important activities are placed outside the boundaries of the firm (Richardson, 1972). In addition, coordination of these activities demands vast resources, and many companies therefore strive to reduce their supply bases (Cousins, 1999). A cooperative strategy between OEMs and suppliers is needed to ensure efficient coordination of these activities. Information flow enables such cooperative strategies.

A significant portion of product nonconformance costs can be directly attributed to variation in supplier processes. To mitigate the effects of variation in the near term it may be tactically prudent to assess tolerances to influential supplier processes. Such tolerance allocation strategies tend to be adversarial in nature, since the cost associated with a nonconforming product is principally borne by suppliers via scrap and repair costs, not to mention costs associated with safety stock increases, and so on. However, a more appropriate long-term strategy for reducing nonconformance costs is to consider ways to achieve a reduction of variation in supplier processes (Plante, 2000). Variance reduction of a supplier's processes requires knowledge of what influences the process variation so that appropriate improvement action can be undertaken in an informed manner. Gaining such knowledge requires that organizations invest in and commit to continuous learning (Plante, 2000). Companies such as Raytheon finds that 50% to 70% of its product costs are represented by outside purchases, with a majority of the material dollars spent on a few key parts provided by a few key suppliers. To address this conundrum, the Raytheon Six Sigma with Suppliers process was created, providing a set of tools and resources to help reduce supplier costs. The Raytheon Six Sigma with suppliers process has six steps (visualize, commit, prioritize, characterize, improve, and achieve), including an intense two-day workshop, which requires a heavy involvement and commitment by the supplier. Information flow between suppliers and customers can enable acquisition and use of this process knowledge to reduce supplier costs.

Measures related to quality, cost, delivery, and flexibility have been used to evaluate how well the suppliers are performing. Companies track supplier performance over time to detect problems early. It is imperative for even small businesses to establish performance measures (Knechtges & Watts, 2000). Performance cannot be measured solely by past or current levels of sales and profitability but should also include quantitative indicators of how the firm will do in the future. A recent study showed that in a supply chain, the supplier management practices adopted by first-tier suppliers affected second-tier suppliers' performance. Second-tier suppliers' performance consequently influenced both first-tier suppliers' quality and delivery performance (Park & Hartley, 2002). As performances of suppliers are evaluated regularly and frequently, these problems can be mitigated easily and at an earlier stage. The implementation of a successful supplier performance measurement system not only clarifies supplier understanding of performance expectations, consequences for poor performance, and rewards for performance excellence, but it also provides documentation of actual supplier performance. Supplier performance metrics can be used for a wide range of continuous improvement efforts. For example, they can be the basis for a establishing a proactive supplier development process, or making critical decisions when rationalizing the supply base, or even for determining how to distribute costs over several suppliers to better manage risk. Information flow of performance plays a critical part for maintaining supplier relationships. Supplier process, performance, strategy, and relationships can be made effective and efficient using information technology. Given the symbiotic relationship existing between supplier and customer, all participants of the global supply chain need to be educated and trained to facilitate IT adoption (Kirby & Turner, 1993).

In the next section, we present the characteristics, opportunities and challenges for SME companies and suppliers in general. Based on that discussion, we illustrate a conceptual framework consisting of five dimensions for suppliers in the third section. The remaining sections expand these five dimensions. The final section presents a summary and conclusions of the five dimensions.

Small- to Medium-Sized Companies: Their Characteristics, Opportunities, and Challenges

Small and medium enterprises (SMEs) have played a significant role in the global supply chain management in various countries and in the landscape of global business competition (Chapman, Ettkin, & Helms, 2000). As reported by the U.S. Small Business Administration (USSBA, 1999), SMEs are an integral part of the renewal process that pervades and defines market and economies. New and small firms play a critical role in experimental and innovation that leads to technological changes and productivity growth. With the emergence of the new technologies, new products, new services, new markets, and new management concepts, the pattern of competitive advantage for companies—particularly for small- to medium-sized organizations—has changed and has subsequently led to new opportunities and new challenges. There is no universally accepted definition of a small and medium enterprise (SME). In the literature, the definition of SME varies based on the number of employees, ownership of the shares capital investment, or financial turnover, among others (Reed, 1998; Taylor & Adair, 1994).

In order to better understand the strategic roles of SMEs in the global business, it is important to recognize their inherent characteristics. SMEs are often independently owned and operated and closely controlled by the owners/managers who are the principal investors and decision makers having entrepreneurial behavior. The attitude and expression of values (cultural and personal) of owners can play a significant role in the adoption of new technology and strategy development (Stansfield & Grant, 2003). The decision maker, often an entrepreneur or small network of associates, formulates attitudes based on perception of its environment. The entrepreneur's attitudes influence his/her own behavior, such as decision making, and thereby have a direct impact on the SME's capability. They also influence an employee's attitudes and behaviors and thus affect the internal environment through the organizational culture factor, and further indirectly affect the SME's capability through that mechanism.

SMEs are also characterized by an absence of standardization and formal working relationships, having a flat organizational structure. Thus, they have a more organic organizational structure when compared to a more bureaucratic structure in large firms (Ghobadian & Gallear, 1996). These characteristics make SMEs more flexible to environmental changes (Levy, 1998; Storey & Gressy, 1995) as well as incurring lower overhead expenses and thus are perceived more innovative. Consequently, they have the potential of playing a significant role in global competition. In particular, SMEs who possess/exhibit entrepreneurial behavior can use the new information technologies as the strategic tools to generate new products and services, and as driving force behind new processes, new forms of business organization, new scope for consumers, and new market opportunities and supply chain management.

The characteristics of an SME can determine the strategic opportunities and challenges available to these companies, particularly in the area of supply chain management. The entrepreneurial behavior of SMEs differentiates them from larger companies in supply chain management, particularly in a cross-cultural dimension and global market. While SMEs' managers are more sales oriented, they do not have a well-developed overall strategic plan. According to Dodge and Robbins (1992), 64% of SMEs that failed did not have a business plan. SME managers tend to rely on their tacit knowledge rather than systematic techniques in supply chain management planning activities, such as vendor selection (Park & Krishnan, 2001). The competitiveness of an SME is defined by its flexibility to environmental changes and dependent on its owner/manager (OECD, 1993), since the adoption of a strategic planning approach is affected by its ownership structure (O'Regan & Ghobadian, 2002). However, they may have limited resources required for efficient supply chain management and find themselves encountering more barriers due to increased competition at national and international levels, particularly when they do not have the resources to meet the demands of their trading partners in the supply chain. SMEs that are subsidiaries of larger organizations may be able to access resources from their parent organizations (O'Regan & Ghobadian, 2002) and be able to overcome these challenges of limited resources. However, they are typically responsible for their local strategies and limited flexibility in their national and international strategies. Furthermore, as managers of SMEs are usually holding multiple roles as entrepreneur, and owner/manager, the management focus tends to be operational rather than strategic. However, in order to take advantage of supply chain management as a means for competitive advantage and succeed, these companies need to take a strategic approach of supply chain management. In particular, SMEs are challenged to balance their short-term operational focus with long-term strategies and technological innovations. This in turn requires greater financial and technical resources. The lack of resources required for effectiveness and efficiency is another major challenge for SMEs in adopting appropriate strategies for their supply chain management, particularly in their quest for global competition.

Small to medium suppliers are less resourceful and often play niche roles within the supply chain as a commodity supplier, collaboration specialist, technology specialist, and problem-solving supplier (Kaufman, Wood, & Theyel, 2000) as shown in Table 1. The supplier topology divides along two dimensions: technology and collaboration. By dividing these dimensions into high and low categories, Kaufman et al. (2000) create four distinct supplier strategies. The top left quadrant

Table 1. Strategic supplier typology

	Low Collaboration	High Collaboration
Low Technology	**Commodity Supplier** • Spot market supplier • Low cost, low price priorities • Little or no differentiation	**Collaboration Specialist** • Detailed control parts supplier • Uses a closed network in each industry • Can be in many industries to maintain customer product information
High Collaboration	**Technology Specialist** • Proprietary parts supplier • Innovation in product technology used to produce high barriers to entry • First mover advantages • Uses design capabilities for competitive advantage	**Problem-solving Supplier** • Black box supplier • High differentiation • Cost less important • Small runs, high process and labor flexibility

defines suppliers who use standard technologies and relate to customers through standard market contracts. These suppliers compete on the basis of low cost. These suppliers can be replaced since switching costs are low. These commodity suppliers design and sell parts to their customers as specified by their customers. The top right quadrant describes collaboration specialists. These suppliers use standard technologies that meet customer specifications and delivery schedules. However, these firms develop enhanced collaborative techniques to fulfill current and to anticipate future customer needs. These suppliers use vendor managed inventory (VMI) strategy. The collaboration essentially requires accurate and timely information. They reduce the customers' internal monitoring or administrative costs.

The suppliers in the lower right quadrant are the problem-solver suppliers. They help their customers to avoid costly investments in specific resources. They employ both advanced technologies and collaborative methods in promoting innovative design and manufacture of supplied parts. The bottom left quadrant defines the technology specialists. They supply proprietary parts using advanced technologies. However, they have weak relationships with customers and the customers benefit from acquiring high technology parts without having to invest in resources. These different suppliers can also be classified as subcontractors who are connected to their customers through supply networks and play coordinating roles between both domestic and foreign players (Andersen & Christensen, 2005).

The common theme in this four dimensional topology is information technology (IT). Information technology is perceived as a critical enabler for efficient exchange of information between the SMEs and the members of supply chain management, and to improve organizational performance and enhance competitive advantage. However, due to resource constraints, SMEs place lower priority on IT investments. Thus, SMEs differ from large companies in their supply chain management practices and technology. Large companies have a greater scope of operation and thus are more likely to be involved in diverse markets. They can spread costly new systems over large units of production, and have internal technical development and maintenance capabilities (Smeltzer, 2001). SME managers and, in particular, small business entrepreneurs, tend to lack or not value many of the basic skills needed to adopt and implement networked processes. They are not operationally inclined or concerned with issues of managing their supply base methodically. They are keen to sell more. Larger firms have invested time and money in implementing their enterprise resource planning (ERP) and e-commerce strategies, including e-procurement and online selling, integrating with these firms can be frustrating. SMEs must develop the business planning skills to identify, select, and implement the supporting technology. Particularly, SMEs must adopt an integrated system such as ERP, e-commerce, and e-procurement systems to support their supply chain management and be able to "pull through" from downstream customers.

In the context of Porter's framework of competitive advantage strategies, and given the characteristics, opportunities, and challenges facing SMEs, the competitive success of these companies may not critically depend on price leadership or differentiation strategies but on how they are unique and critical to their trading partners (Quayle, 2002). In this context, SMEs could focus on meeting ultimate customers' needs, strive to supply quality products/services, and add value to meet the demands of their supply chains. Thus, it is essential that SMEs can link their business strategies to that of the supply chain. The organic organizational structure of SMEs should enable them to develop strategic alliances with their trading partners in the supply chain so that they are able to leverage the skills and expertise of supply chain partners to gain strategic advantage for the whole chain.

Conceptual Framework

Forrester (1958) viewed a supply chain as part of industrial dynamics, alternatively known as system dynamics and management system dynamics; it is broadly defined as the application of feedback thinking and control engineering concepts to the study of economic, business, and organizational systems. System dynamics is concerned with problem solving in living systems that bring together machines, people, and organizations. It links together the system theory and the control theory so that we are able to generate added insight into system dynamic behavior and, particularly, into the underlying causal relationships in the context of global performance of the system and internal control. In this context, supply chain is defined as a system of business enterprises that link together to satisfy customer demands and to provide value to the end customer in terms of product and services. We can discern a distinct generic procedure as part of the production/operation process in a supply chain that is called an echelon. In their most basic form, materials/goods flow from one echelon to the next until they reach the end customer. In reality, however, supply chains do not exist in isolation, but form part of a network of supply chains satisfying different demands.

Figure 1. Integration framework for supplier network

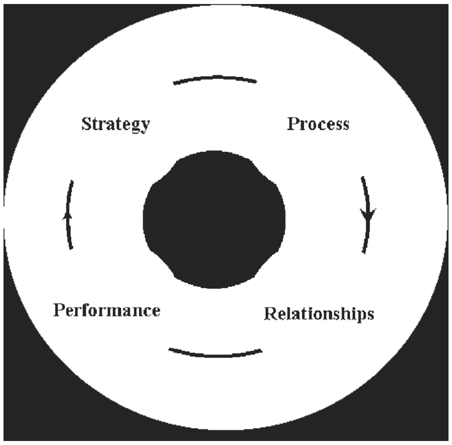

Figure 1 describes a framework for suppliers in the global integrated supply chain. The four major dimensions of the framework include strategy, process, partnership, and performance. These dimensions are enabled by the fifth dimension, global information flow. The ultimate goal in supply chain management is to create value for the end customers and the firms in the supply chain network. To accomplish this, firms in the supply chain network must integrate all their supply chain process activities both internally and with other firms in the network. This integrated supply chain process needs a supply chain strategy. The strategic fit requires the firm to achieve a balance between its responsiveness and its efficiency in its supply chain that best meets the requirements of its competitive strategy. The supply chain performance of the firm with respect to its supply chain strategy is in terms of its responsiveness and efficiency (Chopra & Meindl, 2004). Furthermore, to create value for the supply chain network, it is critical that suppliers and customers develop strong relationships and partnerships based on a strategic perspective. Good supplier relationships are a key ingredient necessary for developing an integrated supply chain network (Wisner, Leong, & Tan, 2005). Good supplier and customer relationships and a great supply chain strategy are not enough to create value in an efficient, integrated supply chain process. The supportive role of information technology is essential along with the use of information technology to measure the supply chain performance. This provides the firm with the ability to make decisions about supply chain improvements. It is generally accepted in the literature that today's forward thinking managers use an integrated approach to managing their business by using quantitative and technological tools to bring together multiple facets of the business including, but not limited to, procurement, inventory management, manufacturing, logistics, distribution, and sales. It has been argued that the next century's paradigm for addressing challenges from increasingly demanding customers and global competition will rely on the effective use of information sharing and inventory control to streamline operations and coordinate activities throughout the supply chain. The conceptual integrated framework of the supply chain network brings collaboration and information sharing to fruition. The collaboration and information sharing results in reduced supply chain costs, greater flexibility to respond to market changes, less safety stock, higher quality, reduced time to market, and better utilization of resources (Wisner et al., 2005).

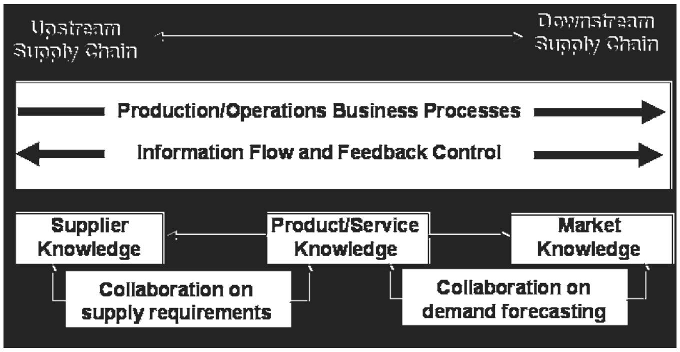
Integrated Process

According to the Global Supply Chain Forum, supply chain management is defined as the integration of key business processes from end user through original suppliers that provides products, services, and information that add value for customers and other stakeholders (Croxton, Garcia-Dastugue, & Lambert, 2001). This definition identifies eight key processes as the core of supply chain management. The eight processes include: (1) customer relationship management, (2) customer service management, (3) demand management, (4) order fulfillment management, (5) manufacturing flow management, (6) supplier relationship management, (7) product development and commercialization, and (8) returns management. These processes transcend the length of the supply chain cutting through firms and functional silos alike. These processes also provide a framework for various aspects of strategic and tactical issues present in the supply chain processes. The integration of such processes would allow successful management of the supply chain for the suppliers as well.

Figure 2 shows a relatively simple and generic supply chain that links a company with its suppliers upstream and its distributors and customers downstream. Upstream supply chain includes the organization's first-tier suppliers and their suppliers. Such a relationship can be extended in several tiers all the way to the origin of material. Downstream supply chain includes all the processes involved in delivering the product or service to the final customers. Thus, there are physical flows in the form of raw materials, work-in-process inventories, and finished products/services, between supply chain echelons, from suppliers/vendors to manufacturers to distributors and retailers, and to consumers. Supply chain also includes the movement of information and money, and the procedures that support the movement of a product/service. Managing these physical and informational flows effectively and efficiently requires an integration approach that promotes organizational relationship and fosters the sharing of strategic and technological efforts (Sabbaghi & Sabbaghi, 2004).

Figure 2. Integrated supply chain process



An effective supply chain management has required an integrated approach and collaboration among the various tiers of suppliers and retailers, and has led to information sharing relations. In 1995, a pilot project between Wal-Mart, Warner-Lambert, Benchmarking Partners, SAP, and Manugistics led to the concept of collaborative planning, forecasting and replenishment (CPFR) (Cooke, 1998). Skoett-Larsen, Thernoe, and Anderson (2003) have defined three levels of CPFR: (1) basic CPFR collaboration that only involves few business processes and a limited integration with trading partners, (2) developed CPFR collaboration that is characterized by increased integration in several collaboration areas, and (3) advanced CPFR collaboration that deals with synchronization of dialogue between the parties in addition to data exchange. While in basic CPFR, the supply chain partners will usually choose a few key processes relevant to precisely their form of collaboration with customers and suppliers, in developed CPFR the parties start to coordinate data and information exchange by making agreements about the type of information sharing and exchanges. In advanced CPFR, the collaboration will be expanded to coordinate processes within forecasting, replenishment, and planning. The planning processes may in turn be decomposed into collaboration on production planning, product development, transport planning, and market activities.

CPFR is a set of norms and procedures created by the Voluntary Inter-industry Commerce Standards (VICS) Association to drive companies toward common business planning procedures and to search for efficiency in the supply chain while establishing standards to facilitate the physical and informational flow. The CPER model is part of the integration mechanism among these processes and a valuable technological innovation tool to support the implementation of various types of transactions among the supply chain companies. These norms would provide the foundations for companies in the supply chain to collaborate in sharing data and information, in forecasting and ordering, in better production and distribution, and to achieve a global optimum of cost and services. Successful collaboration and implementation of CPFR norms would enhance the partnership in a supply chain. This would lead to lower costs, improved product or service quality, better customer service, quicker project results, reduced cycle time/lead time, and improved value to customers. Furthermore, managing business processes requires both internal and external knowledge about the company's operations and its strategies, as the development of effective behavior standards influences operational processes among the partners in the supply chain. Thus, given the constant need for innovation in organizational processes and corresponding information technology, CPFR can be viewed as a tool for competitive advantage in the supply chain.

The effective competitiveness of supply chain between supplier and customer partly depends on the effectiveness and efficiency of the flow of order and information between various parties in the supply chain. Participating organizations need to adopt an appropriate business model and culture that facilitate inter-organizational integration, sharing of skills and knowledge, and enable change in response to market forces. The challenge at the front end, before the order, is to have relationships with suppliers over time using as much electronic technology as possible to be able to source product availability in real time, to meet the customers' requirements. At the back end, the challenge is to understand and identify the best way to integrate with all their suppliers. This requires system standardization that allows suppliers to easily connect into their IT systems to improve not only their data communication facilities but also improve their business processes and facilitate collaboration between partners. This can be supported by the use of an integrated enterprise-wide information system such as enterprise resource planning (ERP) system. Enterprises, particularly SMEs within a supply chain, must then be evaluated as to added value in this process provided to customers and by their working relationships and partnerships to improve their performance and competitiveness. Where material and component suppliers are regarded as partners in the activity of satisfying customers, the adversarial approach to supplier auditing is not appropriate. All aspects of the supplier's business process, from receiving and reviewing an order, through manufacture to delivery, needs to be reviewed by the auditor to ensure that they meet minimum acceptable standards and to identify opportunities to improve. The auditor acts as an independent observer in reviewing the SCM system. This method aims to identify opportunities for improvement in the customer-supplier relationship that will improve quality, delivery, and service (Saunders, 1994).

In a move to remain competitive, many OEMs have resorted to outsourcing a large amount of design and manufacturing work. In so doing, they have repositioned themselves as customer-focused market players instead of design and manufacturing experts. This repositioning has consequently led to an increased reliance on the Tier 1 suppliers. With increased reliance comes increased pressure. Because of these new market changes, today's suppliers are facing a significant shift in responsibilities: while their share of the design and development responsibilities has increased, there is a concomitant expectation that costs will decrease. Furthermore, suppliers have multiple OEMs and consequently need to respond to multiple process integration. There is an increased focus on suppliers becoming leaner, as well as a push for heightened investment in rigorous processes that focus on innovation in close collaboration with OEM customers. A significant factor contributing to the length of product development is the time and process required in responding to design changes. Communicating design changes in language relevant to or understood by both the manufacturer and supplier is difficult, time consuming, and expensive. Evaluating the impact of change, reaching agreement on options, and implementing the change can take months due to the back and forth communication between all parties involved in the project. This complex communication process involves exchanging and remastering design information in a variety of formats during product design, analysis, and change. This can be improved by using a collaboration tool that shares design intelligence between these departments, dramatically shortening the time to communicate change, evaluate tradeoffs, and make decisions. Engineering supply chain collaboration also results in early problem detection, saving time and money for all involved, and making it easy to tie and integrate processes from various OEMs and respond to them individually.

SMEs need to identify a number of factors that can impede external process integration along the supply chain, causing information distortion, longer cycle times, stock-outs, and the bullwhip effect, resulting in higher overall costs and reduced customer service capabilities (Wisner et al., 2005). Failing to see the big picture and acting only in regard to a single department within the firm or a single tier in the supply chain can create quality, cost delivery timing, and other service problems. To overcome this silo mentality, firms must strive to align their supply chain processes and strategy to the overall vision of the supply chain network. The inability to easily share information from all the members of the supply chain is a common process integration problem. Using information technology, one of the dimensions discussed in this chapter, can solve this problem. Successful process integration between the members of the supply chain requires trust. Trust and commitment may be improved by collaborating on a small scale, better communication, and going for a win-win situation. Lack of process knowledge within the firm and among partners can lead to the downfall of supply chain activities. Educating and training the employees can improve their process knowledge. Finally, reducing the length of supply chain, making demand data available to suppliers, improving order batching efficiency, reducing price fluctuations, and eliminating short gaming can improve the supply chain integrated process (Wisner et al., 2005).

Integrated Strategy

The integration of business processes in supply chain management from suppliers would add value first to original equipment manufacturers (OEM) and finally to their customers. This integrated strategic process is enhanced through the use of logistics management. According to the Council of Logistics Management (Cooper, Lambers, & Pagh, 1997), logistics management is defined as the process of planning, implementing, and controlling the efficient, cost-effective, flow and storage of raw materials, in-process inventory, finished goods, and related information flow from point-of-origin to point-of-consumption for the purpose of conforming to customer requirements.

The scope of the supply chain management expands further upstream to the source of supply and downstream to the point of consumption, involving the integrated strategic process. The need for integration of information systems, planning, and control activities exceeds the level of integration necessary in the management of logistics alone (Cooper et al., 1997).

Although not all efforts toward integration are successful, companies are increasingly using an integrated, strategic approach not only to manage the supply chain, but as a general philosophy in managing the business due to the perceived benefits of improved performance (Tan, 2001). In fact, one study completed in 1998 supports a positive impact to performance by correlating supplier performance and firm performance (Tan, Kannan, & Handfield, 1998). The study summarizes literature available to that point. The study also concludes that a company's customer relations and purchasing practices—as major components of supply chain management strategy—have a positive impact on the effectiveness of supply chain management as a whole. Furthermore, through empirical analysis, the same study lays a foundation for the premise that additional practices of concurrent engineering, customer focus, strategic alliances, and quality-driven production improve the strategic management of the supply chain management function as a whole (Tan et al., 1998).

However, in slight contrast to these findings, companies should be further interested in the firm's overall performance and their ability to attain competitive advantage, as opposed to merely positively impacting the supply chain management strategic process. Since the concept of supply chain management as a strategic tool for business planning is relatively new, there is less clear data on the effect of "overall" performance of the corporation given a successful supply chain management strategy. A statistical study on the impact of purchasing and supply chain management of activities relating to corporate success was published in 2002 (Ellram, Zsidisin, Siferd, & Stanly, 2002) that attempted to answer many of the questions concerning overall firm performance by stratifying companies into three categories using a number of different financial and benchmarking criteria. The results determined that above-average firms showed no increased use of supply chain management processes when compared to average and below-average firms and that below-average firms had higher perceptions of actually practicing this strategic process. The reasons for this are partially explained by realizing that firms with average and below-average performance levels may be facing market pressures and declining profitability and must seek ways to improve performance and lower costs. In other words, above-average performing firms may not seek the advantages of strategically managing the supply chain given the relative success of the corporation despite additional opportunities to increase the firm's performance.

These results heavily support many of the underlying principles developed later in this analysis when looking closer at the scarce resources available to the small firm and any attempts at using supply chain management as a replacement for corporate strategy, as some of the supply chain management literature suggests. Although many companies are moving toward such strategies due to the far-reaching effects of overall customer satisfaction, supply chain management should not be confused with, and cannot make up for, broader corporate strategy and the need for managing effective strategic processes in areas such as marketing, financing, and distribution, just to name a few (Ellram et al., 2002).

Small- to medium-sized firms are confronted with the issue of scarce resources to a greater extent than are larger corporations. In fact, often in such companies, it is the same individual(s) developing the strategic initiative, which means focusing too heavily on any one strategic area, inclusive of supply chain management, may actually lead the company to greater risk. Product and technology life cycles have shortened significantly and competitive product introductions make life cycle demand difficult to predict. At the same time, the vulnerability of supply chains to disturbance or disruption has increased, not only to the effect of external events such as wars, strikes or terrorist attacks, but also to the impact of changes in business strategy. Many companies have experienced a change in their supply chain risk profile as a result of changes in their business models, for example, the adoption of "lean" practices, the move to outsourcing, and a general tendency to reduce the size of the supplier base. A research study (Christopher & Lee, 2004) suggests that one key element in any strategy designed to mitigate supply chain risk is improved "end-to-end" visibility. It is argued that supply chain "confidence" will increase in proportion to the quality of supply chain information. Rather, it is the balance of strategic planning and execution within these organizations that is the common denominator among successful firms of small- to mid-size. Consequently, it is the successful management of the supply chain for any firm in context of its overall business strategy that can provide it with a competitive advantage, but doing so with a poor business strategy or a weak marketing plan is not likely to provide the firm an advantage in the marketplace.

It is clear that the uncertainty of global market conditions leave companies on the edge with respect to their strategic thought process in all aspects of strategic planning; yet it is the responsibility and opportunity of the enterprise to interpret, comprehend, and even predict circumstances relevant to the global market that determines its effectiveness. Global supply chain management provides a key element to understanding these conditions of uncertainty and is one of the primary reasons that the strategy is being so well accepted across organizations of all types and sizes. However, some unique problems and opportunities arise for smaller companies who are able to redefine, adapt, and redesign the supply chain. Managing each defining component of the supply chain is difficult for the small to mid-sized entity due to scarce resources. However, given the knowledge base and the in-depth understanding of the supply chain processes by limited individuals in the smaller firm, it seems reasonable to change and make necessary adjustments to the supply chain management processes.

For the smaller corporation, supply chain performance is based on the flexibility of the management strategy practiced by the entity to reduce the level of risk provided by factors of global market uncertainty. A company's performance in the marketplace has been specifically linked to flexibilities involving volume, product launch, and target markets (Vickery, Calantone, & Droge, 1999). This empirical study looks at the furniture trade and is extremely relevant given the trend toward overseas production and a declining U.S. market for producers. It reveals that companies able to adapt to changing market conditions performed more favorably in terms of financial measures and marketability by exhibiting performance in areas of volume flexibility and product launch flexibility over all others. Volume flexibility is the ability to increase or decrease aggregate production of a good or service, and launch flexibility refers to the ability to introduce new products, as well as variations of existing products, involving the entire supply chain. Both provide excellent examples of ways small companies should be able to pursue competitive advantages, given their ability to control these processes initiating with the need to do so. In other words, they do not require direction from other "functional" departments, but rather respond to immediate needs of the market as opposed to reacting too late. Clearly, flexibility can be used as a strategic tool for the smaller enterprise.

Partnerships

Partnerships are business relationships based on mutual trust and openness as companies share risks and rewards leading to such an advantage (Muskin, 2000). The ability of a firm to extend beyond traditional corporate boundaries by working with partners will increase efficiencies and success.

Traditionally, in the market economy, products and services are produced to meet the forecasted demand. Firms in a supply chain are tightly integrated and focused on high-volume, maximum utilization of working capital, and cost efficiency in their supply of products/services. The optimum competitive decision is often accepted as achieving economies of scale and/or economies of scope. Productive processes are arranged so as to optimize the utilization of production and distribution capacity. In this economy, sharing technology and expertise with customers or suppliers was considered risky and thus unacceptable. There has been much emphasis on in-sourcing and vertical integration in supply chain strategies and little emphasis on outsourcing and cooperative and strategic buyer-supplier partnership (Sabbaghi & Sabbaghi, 2004). For example, in the computer industry, companies such as IBM or Digital Equipment Corporation tended to provide most of the key elements of their own computer systems, from operating system and application software to the peripherals and electronic hardware, rather than sourcing bundles of subsystem modules acquired from third parties. Products and computer systems typically exhibited closed, integral architectures, and there was little or no interchangeability across different companies' systems, keeping existing customers hostage. Each company maintained technological competencies across many elements in the chain and emphasized the value of its overall systems-and-service package, determined to stave off competitors who might offer better performance on one or another piece of the package.

The supply chain strategy in the market economy has been designed to "push" products to the customer based on forecasted demand. It focuses on supporting a tightly integrated enterprise geared toward mass production of goods at the lowest possible price. The production processes across the supply chain are synchronized for efficient utilization of all resources. Information technology, however, acts as an enabler for operational optimization across the supply chain by offering better forecasts that are customer driven in addition to robustly synchronizing the sourcing, production, and processes across the supply chain to achieve optimal performance, even if the forecasts are not perfect. For example, in car manufacturing, cars are traditionally manufactured to match forecasted demand that lacks much customer input.

However, in the new information economy, also called the Internet economy or the Web economy, the focus is exclusively on customer needs. To this end, the firms collaborate in a network of trading partners, each specializing in one or more core competencies (be it shipping, manufacturing, marketing, billing, order entry, or procurement services) and divesting itself of non-core activities beyond those associated with sourcing, manufacturing, or distributing products/services. In this network economy, information technologies, digital networking, and communication infrastructures provide a global platform over which people and organizations interact, communicate, collaborate, and search for information. The Internet has created more sophisticated customers who demand innovative, personalized products/services delivered at their convenience. It has also expanded the very definition of the word "customer," so that it now includes employees, distributors, suppliers, business partners, and shareholders. As a result of these changes, a company's competitive position in this Internet economy depends on its ability to deliver customized, relevant, highly responsive service to every participant in these networks of economic relationships. This new economy has led to the rapid emergence of business networks and new business models within and outside the firm to satisfy the strategic need for competitive flexibility. In this new economy, the supply chain is geared toward the customer "pulling" products customized to their specific needs, and the firm's resources are organized to meet the unpredictable demand patterns of the customer. Therefore, the benefits of supply chain management integration promote organizational relationships that in turn foster the sharing of information technology and strategic efforts.

Partnership in supply chain management, in this network economy, has led to the development of various cooperative arrangements among various supplier and retailers. Jagdev and Thoben (2001) identify three types of collaboration and partnership between independent companies:

1. supply chain type of collaboration based on long-term collaboration where the participating companies in the supply chain must operate synchronously to meet customer demands;
2. extended enterprise type of collaboration, most integrated form of collaboration, where the information and decision systems and respective production processes are integrated; and
3. virtual enterprise type of collaboration, as a short-term collaboration where the participating companies, without system integration, are loosely related to bundle their competencies to meet customer demand.

The type of partnership would determine the effective strategies that SMEs may consider and the perceived value added in the supply chain. For example, in vendor-managed inventory system, the responsibility of stock management is handed over to the supplier (Hvolby & Trienekens, 2002). This would make it possible for the supplier to adjust production and distribution planning to changes in consumer demand. In this system, SMEs as the suppliers would be able to access the retailer's information systems to view stock levels and future requirements. On the other hand, advanced planning systems (APSs) make it possible to include suppliers and customer relations in the planning procedure to optimize the whole supply chain on a real-time basis (Kennerly & Neely, 2001). They would support collaborative planning among several partners in a network by shared access to information about known and expected material requirements and resources (Hvolby & Trienekens, 2002).

Quantity flexibility (QF) contract is an arrangement between supplier and retailer that responds effectively to the demand fluctuations over time and divides the risk of excess capacity. A retailer in this model is committed to purchasing a percentage of its forecasted demand. However, the supplier is committed to delivering more than the forecast. For example, if they agree to a 25% of QF contract, the retailer is committed to purchase 75% of the forecast while the supplier is committed to delivering up to 125% of the forecast should the retailer need more than forecast. If demand turns out to be low, the supplier is protected by the lower limit, whereas if demand turns out to be high, the retailer can take advantage of that upside by knowing that the supplier has some additional capacity. Thus, both supplier and retailer can be better off in a QF contract.

As another type of arrangement, revenue-sharing contracts between suppliers and retailers, for example, in the video rental industry, would allow retailers to increase their stock of newly released movies, thereby substantially improving the availability of popular movies. Under a typical revenue-sharing contract, a supplier charges a retailer a wholesale price per unit plus a percentage of the revenue the retailer generates from the unit. This revenue-sharing model has been practiced for quite some time in the distribution of films to theaters, where the studio charges the theater a small up-front fee and then takes a certain fraction of the box-office revenues. Cachon and Lariviere (2005) examined the revenue-sharing contract model in supply chain management where the partnership between supplier and retailer would improve the performance of any supply chain toward a global optimization. They have cited Blockbuster, a video rental chain, as a successful case to illustrate the effectiveness of revenue-sharing strategy in collaborative supply chain management.

Traditionally, video rental stores have to spend typically $60 to purchase a tape from a distributor and then rent that tape to customers for $3 to $4. However, demand for new releases drops dramatically after the first few weeks, and video retailers have a hard time making any money on the rentals. Consequently, they can only afford to buy a few cassettes to accommodate that initial surge in demand. Customers consistently complained about the poor availability of new release videos. Blockbuster decided in 1998 to enter into revenue-sharing agreements with the major studios. The rental company agreed to pay its suppliers 30 to 45% of its rental income in exchange for a reduction in the initial price per tape from $60 to $8. The introduction of revenue-sharing model at Blockbuster coincided with a significant improvement in performance in the supply chain. It has been reported that Blockbuster's market share of video rentals increased from 24% in 1997 to 40% in 2002 after a revenue-sharing contract was adopted (Warren & Peers, 2002). The increase in the industry's total profit due to revenue-sharing strategy has been estimated at 7% (Moretimer, 2000). However, there are some limitations and drawbacks in revenue-sharing model. The first is that it is administratively burdensome compared with the straightforward wholesale price-only contract. Revenue sharing takes an organizational effort to set up the deal and follow its progress. If profits are only increasing by a very small percentage so that the revenue sharing does not cover the extra administrative expenses, then there is no incentive for the retailer to enter into a revenue-sharing contract. The second limitation, according to Cachon and Lariviere (2005), is when the retailer actions influence demand. Specifically, it is assumed that the retailer can increase demand by exerting costly effort, and that this effort is non-contractible. If a retailer is taking in only a small fraction of the generated revenue, this may not be sufficient incentive to improve sales. On the other hand, a supplier wants the retailer to buy the right quantity and to sell at a higher rate. The model may help to make sure the retailer buys the right quantity, but it may hurt its sales effort.

Collaborative computer-based information systems have become a major trend in today's business (Grossman, 2004). SCM evolved with the aim of integrating disparate functions like forecasting, purchasing, manufacturing, distribution, sales, and marketing into a harmonious ecosystem that would envelop the company's suppliers and customers. SCM promised to align all participants to act in unison to serve the end customer. Collaboration would enable managers to stop optimizing their individual silos to work together with partners—both internal and external—to achieve efficiency and effectiveness across the value chain. A truly collaborative partnership would encompass multiple customers and suppliers. OEMs would regularly communicate product availability, supply plans, and product content changes to distributors and other channel partners. Based on upstream forecasts and product changes, the channel partners would communicate demand requirements to manufacturing service providers. In this fashion, members of the outsourced supply chain would be assured of accurate, up-to-date information to help them make decisions that elicit common, supply chain-wide benefits. While collaborating, there is distinction between big and small companies; it is between big, aggressive, large muscled organizations and agile, flexible, adaptable organizations that can survive in an environment of rapid change, constant uncertainty, and disruptive technologies.

Involving suppliers early and giving them influence over design is associated with greater contributions of suppliers to cost reduction, quality improvement, and design for manufacturability (Liker, Kamath, & Wasti, 1998). Increasing competitive parity in the areas of cost and quality has forced global manufacturers to seek other sources of competitive advantage, with new product development rapidly becoming the focal point in the quest for sustained growth and profitability. The essence of today's new product development strategies is the simultaneous development of the new product and the accompanying manufacturing process such that quality is enhanced, costs reduced, and lead times shortened. The implementation of the integrated product development (IPD) process has come to depend on the use of multi-functional teams. Supplier involvement promotes better resource utilization, the development and sharing of technological expertise, and network effectiveness (Birou & Fawcett, 1994). Evaluation and monitoring of performance metrics are key aspects of the integration process, partnerships, and strategy. In the next section, we will discuss how customers evaluate suppliers' performance, how SMEs respond to their customers' evaluation actions, and the impact of these performance evaluations.

PERFORMANCE

Buying firm respondents who reported their firms' supplier development efforts to be satisfactory were more likely to have a proactive philosophy regarding suppliers' performance, put more effort and resources into their supplier development efforts, and exhibit a greater willingness to share information with their suppliers than their counterparts, who were generally dissatisfied with their firms' supplier development results (Krause & Ellram, 1997).

On its Global Procurement Web site (http://ch0107.whirlpool.com/SRM/generalhelp.htm), Whirlpool provides a list of requirements for potential companies wanting to become a Whirlpool supplier. All Whirlpool suppliers are required to pass a supplier quality audit. These requirements are based on ISO 9000, QS 9000, and ANSI/ASQC Q90-94 standards. They are to ensure the best cost, quality, manufacturing efficiency, and continuous innovation in design and manufacturing. All Whirlpool suppliers are to meet the Integrated Supply Management (ISM) guidelines as a common process for doing business using electronic communication. Whirlpool is also committed to establishing and maintaining a capable, qualified, competitive, and diverse supply base providing minority-owned, disadvantaged, and small businesses. Whirlpool also provides each supplier with the plan year's forecast, profit plan volume, and cost to be used later for total cost productivity targets.

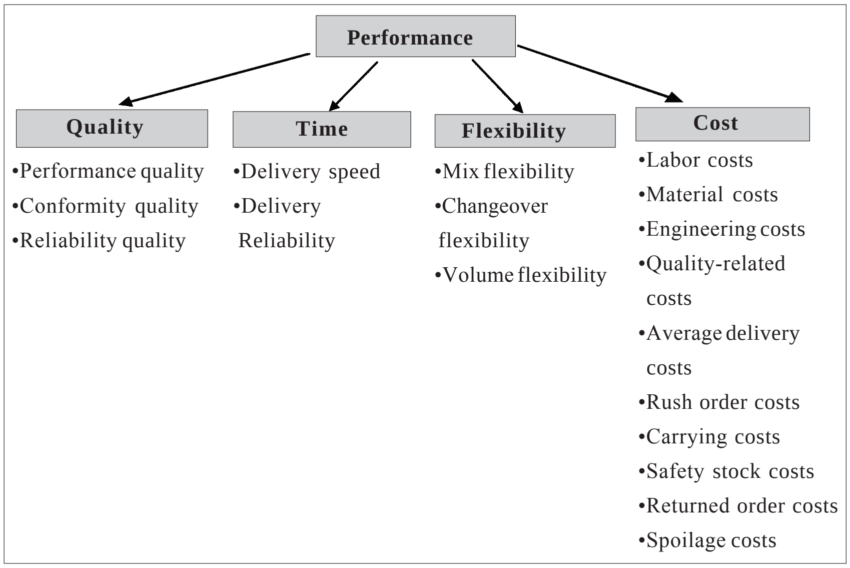
Information provided by the supplier performance will be used to assess efficiency in the supply chain (Wisner et al., 2005). FedEx not only has performance scorecards for its suppliers but also has developed a Web-based "reverse scorecard" that allows suppliers to provide constructive performance feedback to enhance the customer-supplier relationship.

A supplier's service level is, in general, insufficient for the manufacturer to warrant the desired service level at the customer end. The method by which the supplier achieves its service level to the manufacturer also affects the customer-service level. Procedures and metrics must be in place to collect and report performances of the eight processes that were discussed earlier in the integrated process section of this chapter. To assure that the integrated process is supporting the integrated strategy and the working relationships of partners, performance is continuously measured using metrics for each of the eight processes. These performance measures need to be both internal and external. As process integration improves across the supply chain, the overall performance will improve. Over time, under-performing suppliers and unsuitable customers will be eliminated. Suppliers can then concentrate on establishing beneficial relationships and forming strategic alliances to create a win-win situation.

As shown in Figure 3, evaluating and responding to the results of supply chain performance metrics and measurements have a huge impact on business performances. Four generic performance factors have been identified by Bozarth and Handfield (2005) as relevant to the supply chain management. These factors include quality, time, flexibility, and cost, as illustrated in Figure 3. Performance quality includes the basic operations characteristics of the product or service, conformance quality questions whether the product was made or service was performed to specifications, and reliability quality explores whether the product or service will perform consistently over a period of time and without failing or high maintenance costs. Time has two basic characteristics: speed and reliability. Delivery speed refers to how quickly the supply chain can fulfill a requirement, while delivery reliability refers to the ability to deliver products or services when promised. The ability to produce a wide range of products and services is the mix flexibility, while changeover flexibility questions the ability to provide a new product with minimal delay, and volume flexibility is the ability to produce whatever volume the customer needs. Cost categories include labor costs, material costs, engineering costs, quality-related costs, average delivery costs, rush order costs, carrying costs, safety stock costs, returned order costs, and spoilage costs (Bozarth & Handfield, 2005; Wisner et al., 2005).

In a study by Purdy, Astad, and Safayeni (1994), automotive supply organizations were interviewed regarding their perceptions of the effectiveness

Figure 3. Supply chain performance factors



of a North American automotive certification program. The major findings were that:

- suppliers viewed preparing for the performance evaluation as the most important aspects of the process;
- the evaluators detected only a small percentage of the suppliers' significant business and manufacturing problems;
- suppliers perceived an overemphasis on procedures and documentation on the part of the evaluators; and
- suppliers felt that the performance evaluation did not accurately reflect their effectiveness.

The same study concluded that the supplier evaluation program reflected the management style of the large bureaucratic customer organization, which was not necessarily appropriate for the size and nature of the supplier's business. Further, good performance on the evaluation did not directly correspond with further business contracts (Lyn et al., 1994). In today's world, definition of quality revolves around customer satisfaction, quality of product and service, timely delivery, and cost/price (Mehta, 2004).

INFORMATION TECHNOLOGY

Information technology (IT) offers huge potential for large suppliers as well as SMEs to achieve effective SCM mechanisms. In today's global marketplace, organizations are faced with ever-changing customer requirements and intensifying competition. To succeed, companies are looking at streamlining their supply chain through the successful deployment of Information Technology. Supply chain management expands the notion of integration beyond a single company to encompass all related trading partners in the supply chain. Suppliers, customers, third-party logistics providers, distribution centers, and relevant government agencies share the information and plans necessary to make the chain more efficient and competitive.

Manufacturers increasingly rely on IT to streamline their business processes. By integrating business processes across the supply chains, companies can quickly move information and materials to their trading partners and respond quickly to market changes. Internet technology is considered to be the most promising network infrastructure for supply chain connectivity. By having an integrated network infrastructure, companies can now manage their operations anywhere by accessing information using the Internet. Most companies are positioning IT as one of the key components for enhancing supply chain management, and they want to be updated regularly on new technologies that they can apply in their work.

Achieving integration in the global supply requires an enormous commitment by all members of the supply chain. In order to exploit competitive advantages by forming strategic alliances and partnerships and facilitating these relationships, companies must exchange information through increased communication and cooperation. The level of integration companies strive for now and in the future can only be possible through significant advances in information technology, which, in the past, has been costly and available only to larger companies with budgets that could support such endeavors. It has been argued that this helps explain the trend toward vertical integration as opposed to increasing horizontal communication efforts between suppliers, manufacturers, distributors, and customers. Information flow and sharing are essential in all components of supply chain. Supply chain information flow integrates all the facets of logistics as well (Vaidyanathan, 2005).

Although companies utilize technological tools such as electronic data interchange (EDI), and enterprise resource planning (ERP), there are still many issues arising from incompatible systems (interoperability) that drive inefficiencies. Additionally, as new technology develops, such as wireless networks, which still lack standard protocols, the problem does not appear to be going away too fast. This can be a major issue for the small- to mid-sized company, given budget restraints and the aggressive nature of larger budget companies to incorporate new technologies and information systems. Therefore, despite companies feeling they are actively sharing information with their supply chain partners, there continues to be inefficiencies and waste throughout the supply chain. The problem is further intensified when looking at partnerships on a global scale due to the traditional issues of cultural barriers and communication differences.

Internet technology has been increasingly used to enhance global supply chain through electronic commerce functionalities. Many Internet-based systems have been designed and developed for SCM to interconnect suppliers and customers. A four-phase migration model with technical, security, and financial requirements as a plan for the migration of the procurement process onto the Internet has been proposed by Yen and Ng (2003). The first part of the migration is the digitization of data in a local area network (LAN) to manage the information storage and retrieval within the company. The second phase is deployment of communication infrastructures such as EDI. The third phase is the installation of electronic commerce front-end system to implement procurement business processes such as Web sites and search engines. The fourth phase is the integration of vertical portal, that is, information processing with third-party service providers for financial transactions and logistics.

Small- and medium-sized enterprises are different than large enterprises in three primary ways that hinder e-commerce adoption (Smeltzer, 2002). SMEs seldom have mature technology. They usually emphasize product development and survival rather than supply chain integration. The large enterprises have costlier, mature integration software as well as internal technical development and maintenance capability (Smeltzer, 2002). Some of the large companies have integrated SMEs in their supply chain. As a $41 billion retailer, Sears has successfully connected every one of its 7000 suppliers by using a targeted technology, a proven process, and dedicated resources provided by a supply chain integration service (Smeltzer, 2002). The question confronting these suppliers is often not whether they should use SCM systems, but rather how they can take advantage of these systems and benefit from their use (Subramani, 2004).

Suppliers use IT for many reasons that include: requests for quotation (RFQ) received electronically by suppliers, support documents such as detailed part drawings and quality specifications accessed online, electronic transmission of purchase orders, shipment notifications, scheduling delivery windows at warehouse loading docks, electronic payment, electronic notification of changes, and inventory alerts based on preset triggers to communicate stocking levels of products in warehouses (Subramani, 2004).

Internet technology with its communication infrastructure has enhanced SCM initiatives. Companies are taking advantage of this technology and moving their procurement functions such as sourcing, negotiating with suppliers, payment, and other transactions onto the Internet. Such electronic procurement (e-procurement) results in control, flexibility, and cost savings. This provides suppliers with the ability to become proactive in doing their business. By implementing the supply chain onto the Internet, both suppliers and the customers will face both challenges and opportunities. Such challenges and opportunities include careful planning of the ways that people integrate changes and the benefits that the Internet can bring to the business, such as reduction in overall costs, respectively (Srinivasan, Reeve, & Singh, 2000). A large academic bookseller, Co-op Bookshop, launched electronic commerce and faced difficulties when competing globally. The lesson learned from this launch is that a company should study the existing customers and markets before it deploys e-commerce on the Internet (Loebbecke, Powell, & Gallagher, 1999).

E-procurement is more than putting purchasing decisions online; its functions also include linking suppliers and buyers into the purchasing network and rethinking of business processes such as transactions (Fisher, 2000a). With efficient information, such product information is structured by electronic catalogs with which e-procurement can form a good basis in order to attract more buyers to the shopping site (Avery, 2000a). Shell Services International launched its e-procurement service as a cost-cutting driver, and its electronic catalogs contain a broad list of suppliers ranging from huge contract partners to small chemical producers with which Shell has pre-negotiated discounts and service contracts. When a purchasing order is received, it will be automatically forwarded to the appropriate suppliers (Fisher, 2000b). E-procurement could reduce costs and cycle time by fostering a better relationship between buyers and sellers with a vertical supply chain Avery (2000b). The introduction of an e-procurement system in Texas Instruments has reduced the number of transactions in which purchasing was involved and replaced the internally based catalog system, saving a significant amount of cost (Atkinson, 2000a). The Texas-based Burlington Northern Santa Fe Railway planned to apply e-procurement for strategic sourcing and SCM, as it believed that collaboration with its suppliers could be facilitated in order to achieve full contract discount pricing (Atkinson, 2000b).

Yen and Ng (2003) classified the impact of electronic commerce in the procurement process into buyer and seller, and then further divided it into individual and inter-organizational categories. Individual and inter-organization classifications represent the internal efficiency and external impact, respectively. With *sourcing*, buyers can search for quick and complete information of materials from suppliers' online electronic catalogs while purchasing is enhanced. During *quotation* and *negotiation*, sending inquiries with the electronic and automated inquiry forms to suppliers can save time, and, in return, suppliers could direct the forms with quick and customizable responses, facilitating communication between buyers and sellers. With automated, synthesized, and modifiable *order placement*, cost and time are saved while purchase records can be viewed in a quick and timely fashion. Suppliers can benefit from efficient and error-free profiling management and more accurate demand forecasts in order to improve overall profitability. Again, communications between buyers and sellers can be enhanced while time is saved. Electronic *transactions* can take place without the need for physical forms of payment that are restricted by geographical and currency barriers. Suppliers can benefit from secure real-time collection of payment while the risk of unsuccessful receipt of payment is lowered, resulting in improved profitability. With *delivery*, uncertainty of receiving time is reduced by separated logistics and shipment, while information flow or communication between suppliers and logistic third parties is facilitated.

Electronic data interchange (EDI) is a way of conducting inter-organizational transactions electronically (O'Callaghan & Turner, 1995). The key components of EDI are: the electronic transfer of data, the use of standards, and the exchange of data with minimal human intervention. An event in a customer company's operational processes, for example, a purchase order, may trigger a computer application that generates an electronic message which is sent to, received, and processed by another computer application in a supplier's company. This message will trigger another event in the receiving supplier organization, for example, the delivery of products. Enabled by standardization of the message exchange, this communication takes place without human intervention. The organizations involved have to agree on contents, grammar, and organizational actions resulting from the message exchange. SMEs can improve their competitiveness by integrating their systems with their suppliers or other trading partners. Existing approaches to integration like EDI might help SMEs to overcome part of the integration problems, but they have their limitations (Themistocleous & Chen, 2004).

The Dutch coordination center for EDI reported that around 25.000 out of a potential 400.000 companies in the Netherlands are currently using EDI. The number of users has grown by 10.000 companies since 1994, but despite this relatively high growth in the number of EDI users, the current number still falls short of expectations (van Heck & Ribbers, 1995). In the U.S., for instance, Oakie (1997) reports that only 100,000 out of a potential 1.9 million companies are currently participating in EDI. Therefore, the adoption and implementation of EDI is still not prevalent. There are different reasons for this apathy to the adoption of EDI. One of the difficulties in EDI adoption is that its full benefit can be reached only if enough critical mass is achieved. To transact EDI messages, one needs to have partners who also are willing to adopt EDI. The other reason is that some EDI implementations are costly. One of the critical factors is the availability of EDI standards. The use of commercially available standards reduces the development costs and time and decreases the risk linked to the new EDI application (Krcmar, Bjÿrn-Andersen, & O'Callaghan, 1995). SMEs will adopt EDI if EDI message formats are available, if they decrease the risk linked to the new EDI standards, and if they reduce the development cost and time (van Heck & Ribbers, 1995). As more competitors and trading partners become EDI-capable, small firms are more inclined to adopt EDI in order to maintain their own competitive position (van Heck & Ribbers, 1995).

Another medium of e-procurement is the use of electronic business-to-business (B2B) commerce marketplaces. While there are many advantages to the use of B2B marketplaces, there are many disadvantages as well. The potential decrease in product quality is a big issue for B2B participants. Expectations will vary from one buyer to another, and the definition of quality will vary across suppliers. B2B may not be of interest to suppliers since the forced price reduction of supplies by new suppliers trying to gain a share of the market will hurt the supplier's margins and strain their ability to stay in the market (http://www.primetechnologywatch.org.uk).

Rovere (1996) argues that the role of SMEs should be investigated with regard to innovation and regional development studies with a focus on industrial districts. This argument is based upon the increasing importance of flexible organizations in today's economic environment, with the main elements of the flexible specialization model being networks of small firms, flexibility of equipment, and human resources. Rovere further argues that these ideas must be thoroughly considered in defining an IT diffusion policy for SMEs. The relatively inexpensive availability of IT products and services serves to create many new business opportunities for SMEs. If flexible production capabilities do indeed lie within the environs of networked SMEs, IT increases in importance to ensure the platform to allow for efficient information flow within and outside of SME networks.

Another problem posed to the SSM for the SMEs is integration. Enterprise resource planning (ERP) systems are an integrated software solution to manage a company's resources and to integrate all business functions, such as planning, inventory/materials management, sales and distribution, finance, human resources, and services. The complexity of ERP systems and the non-flexible nature of ERP solutions, combined with their high cost of implementation have impeded many companies' quest for integration. The major problem with ERP is integration, as ERP packages are not designed to tie up other autonomous applications (Cingil, Dogac, & Azgin, 2000). As a result, autonomous and heterogeneous applications coexist in companies with ERP systems, and integration problems have not been addressed. Therefore, the use of ERP systems no longer supports or leads to competitive advantages for organizations, especially SMEs (Themistocleous & Chen, 2004).

According to the United Nations report on e-commerce and development (avaliable at http://www.unctad.org/en/docs/ecdr2004ch2_en.pdf), SMEs in Latin America have recognized the need to increase their capacity to differentiate their products and services, and to link electronically with their customers and suppliers. However, none of the enterprises surveyed had advanced beyond the first stage of information and communications technology (ICT) adoption. For example, while most of them were on a local area network (LAN) and some of them used the Internet for looking up information, none used EDI or an Intranet, and very few communicated with clients via electronic mail, preferring to use the telephone or fax.

According to a study conducted by the World Wide Worx (http://www.theworx.biz/download/Exec%20Summary%20%20SME%20Survey%202003.doc), investment in information technology is having a major impact on the competitiveness of small and medium businesses in South Africa. Among the key findings of the survey was that SMEs are spending a higher proportion of their turnover on IT each year. In 2001, 47% of SMEs spent more than 1% of turnover on IT; in 2002, 48%; and in 2003, 49% expect to spend more than 1% of their turnover on IT. According to a Canadian net impact study (http://www.netimpactstudy.com/ca/pdf/release_final.pdf), 50.2% of Canadian SMEs are currently using or implementing the Internet. The same study concludes that a firm with $10M in revenues, with a 20% gross margin and 10% net margin, can achieve increases in net profit of up to 154% in a “best case” scenario, that is, if these average changes in revenues and costs were realized together.

In a recent survey, Deloitte Research undertook an exploratory study of IT purchasing by SMEs (available at http://www.deloitte.com/dtt/research/0,1015,sid%253D16418%2536cid%253D632D63293,00.html) in an effort to understand decision making in different stages of the information technology purchase process. The resulting study identifies the key factors impacting technology purchase decisions by small and medium enterprise owners. In particular, it found that: SMEs need information and help to manage their IT growing pains; price isn’t necessarily the bottom line when considering IT purchases; and vendor Web sites and reputations are extremely important in the minds of SME decision makers when looking for information and making purchase decisions.

Various forms of SCM applications are arising among the enabling technologies. Prominent vendors in SCM applications market include i2 Technologies, SAP, Oracle, and Invensys, which produce a range of hardware and software components that span communication, optimization, and modeling systems.

SMEs are becoming increasingly dependent on information technology to operate efficiently, serve customers effectively, and work with partners and suppliers more collaboratively. Faced with all the challenges and opportunities of competing in a fast-paced environment, growing companies must be especially confident that their networks can support business evolution. Building an effective network foundation is integral to, and an operational insurance policy for, achieving e-business transformation. It is vital that SMEs focus their attention on the critical success factors that drive growth in their particular market. They cannot afford to expend precious time re-architecting, re-learning, and managing networks. Network infrastructures should be the invisible plumbing that enables the transport of company information and communications and enables efficient processes.

CONCLUSION

The subject of global supply chain management is an important new frontier for businesses choosing to participate in the new global economy. The inherent processes range from raw material supplier to end-user and involve literally all functions in between. Consequently, the integration of these processes is crucial to achieving supply chain management success, which is only facilitated by adequate information exchange between partners within the supply chain—a task not easy to accomplish due to issues of interoperability. Yet, the ability for companies to successfully implement strategic relationships relies on their ability to develop or maintain an effective partnership strategy, as it is not always necessary to enter into full-scale partnerships with all suppliers perceived to be partners within the chain. Additionally, in today's uncertain global economy and associated issues of security and trust, many companies continue to re-evaluate their partnerships and foster those relationships that are more likely to lead to a competitive advantage. The literature emphasizes the importance of trust in developing such partnerships, as firms will attempt to reduce risk by not entering into partnerships lacking trust. However, the need to leverage the resources of the supply base and revenue sharing cannot be overlooked, and companies will pursue such relationships. In a changing world, the subject of truth and ethics is important when discussing supply chain management strategy.

Most discussions of supply chain management are presented in abstract terms and in ways that apply to product and service organizations alike. However, most small companies, and even larger corporations, focus on niche markets. Niche markets are where managers will correctly argue that profits are created and realized; therefore, the goal of many organizations is to develop business and market strategies to exploit these opportunities in the market. Similarly, as this chapter has detailed, it has been shown that an affective supply chain management strategy can benefit these very initiatives.

More specifically, the smaller firm in the supplier role has unique opportunities to develop business, market, and supply chain management strategies that are unique from those of the larger established companies. Realizing that the "buying" company within the supply chain—or end-user—is actively pursuing competitive advantage through marketing of its unique product or service, the small company is often better positioned to adapt to the needs of the customer. More precisely, the level of information available to key members of the smaller supplying organization and its integrated partners provide market opportunities that may not exist to larger corporations.

Supply chain management strategies, because of the unique circumstances of specific markets, can not be characterized as "one size fits all." In fact, global supply chain strategies are contingent upon market characteristics and business strategy, which seek to attain higher-level customer responsiveness at less total cost to the supply chain as a whole. Nowhere are the unique characteristics more prevalent than in the small- to mid-sized corporations, as each of these types of corporations seeks competitive advantage through management of the supply chain and, more specifically, management of the supply chain for a specific niche market.

Moreover, there are some unique obstacles and challenges in managing the supply chain given the scarce resources of the small- to mid-sized supplying company. More specifically, because of the involvement of so few within the supply chain management process in the smaller firm, there is greater responsibility for those individuals to manage this very important strategic process given the unique opportunities to exploit niche markets. The ability of a small firm to offer flexibility in terms of volume and product differentiation provides the competitive advantage businesses of all size pursue. Supply chain management strategy, then, is applicable to all sized firms and has unique characteristics for smaller entities. To maximize the Internet and supply chain management, SMEs must be included. The SMEs need to have the information technology capability to fully integrate into the supply chain. Only then will the supply chain management be effective to save time, decrease costs, improve relationships, and maximize overall responsiveness.

Chapter 2.26

A Methodology for Developing Integrated Supply Chain Management System

Yi-chen Lan
University of Western Sydney, Australia

Bhuvan Unhelkar
University of Western Sydney, Australia

ABSTRACT

Integrated Supply Chain Management (ISCM) involves the linking of suppliers and customers with the internal business processes of an organization. ISCM solutions allow organizations to automate workflows concerning the execution and analysis of planning, sourcing, making, delivering, returns handling, and maintenance, to name but a few. Many of today's ISCM systems use primarily Web technology as the supporting infrastructure. Undoubtedly, the electronic (Internet-based) ISCM systems deliver the enterprises with a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer patronage, and enable thorough planning abilities. However, there has been significant customer backlash concerning the inability of software vendors to deliver easy integration and promised functionality. Although various researchers have suggested strategies to overcome some of the failures in operating ISCM systems, there appears to be a lacunae in terms of architectural investigations in the analysis stage. The methodology proposed in this chapter seeks to resolve these gaps and provides a fundamental framework for analyzing ISCM systems.

INTRODUCTION

This is the age of communication based on Internet technologies. As a result, enterprises are able to conduct inter- and intra-organizational activities efficiently and effectively. This efficiency of communication has percolated in all arenas of organizational activities, including customer relationships, resource planning, and, in the context of this discussion, supply chains. Given the cost of logistics and their importance in order fulfillment process, organizations may want to capitalize on this opportunity to communicate in order to reengineer their supply chain operations that would sustain them in the globally competitive and challenging world of electronic business. With this invigorated growth of e-business, software vendors and consultants have been promising businesses the utopian Internet-based supply chain systems that would provide them with the capability to respond in real-time to changing product demand and supply and offer an easy integration functionality with backend information systems (PeopleSoft, 2002; Turner, 1993).

Although a number of Internet-based supply chain systems (or integrated supply chain management systems—ISCM systems) are available for adoption, enterprises do not guarantee to implement the systems in conjunction with their existing information systems. Furthermore, the ISCM systems may not fulfill the connection and implementation requirements among participants in the supply chain.

After the e-commerce hype had dissipated, surveys undertaken in 2001 tend to paint a different picture as to the success of these implementations. Smith (2002) concludes that at least 15% of supply chain system implementations during 2001 and 2002 were abandoned in the US alone. Although several reasons can be identified as the cause of implementation failure, the main problem rests with the fundamental analysis of ISCM operations and requirements.

The purpose of this chapter is to debunk some myths proposed by vendors with regard to the implementation of Integrated Supply Chain Environments (ISCE) and propose an analysis methodology for Integrated Supply Chain Management systems.

First, the chapter will examine some of the available literature regarding ISCE. The fundamentals of ISCE—technologies and processes—will be investigated in some detail. Vendors were quick to promote the benefits of ISCE yet were not so forthcoming as to possible barriers and other issues to watch for. Both of these also will be discussed in this chapter.

Second, an analysis methodology is proposed, which intends to address some of the issues identified previously and construct a theoretical model for enterprises to adopt in the analysis phase of developing ISCM systems. This chapter concludes with a future research direction in investigating technological issues of ISCM systems operation.

INTEGRATED SUPPLY CHAIN MANAGEMENT OVERVIEW

ISCM involves the linking of suppliers and customers with the internal supply processes of an organization. Internal processes would include both vertically integrated functional areas, such as materials, sales and marketing, manufacturing, inventory and warehousing, distribution, and, perhaps, other independent companies involved in the supply chain (i.e., channel integration). Customers at one end of the process can potentially be a supplier downstream in the next process, ultimately supplying to the end user (Handfield et al., 1999; Turner, 1993).

ISCM Solutions

While, in many cases, ISCM systems are still in their infancy, the concept of establishing information flows between points in the supply chain has been around since the 1980s. Through Electronic Data Interchange (EDI), customers and suppliers have communicated supply data through direct dial-up interfaces and other mediums (Zieger, 2001). However, the ability for the Internet to create a common communication infrastructure has made integration much more cost-effective. ISCM has promised to deliver the right product to the right place at the right time and at the right price (Comptroller, 2002).

From the supply chain software development perspective, there are generally four large vendors identified; namely, Oracle, SAP, PeopleSoft, and Ariba, and a multitude of medium-sized vendors in the ISCM solution space (Armstrong, 2002). All claim that ISCM will enable the enterprise to respond in real time to changes in demand and supply.

For instance, current ISCM solutions allow organizations to automate workflows concerning the execution and analysis of the following business activities (Comptroller, 2002; Gledhill, 2002; Peoplesoft, 2002):

1. **Planning:** Demand and supply planning, manage planning infrastructure.
2. **Sourcing (buy-side):** Strategic sourcing, eprocurement, services procurement, catalog management, collaborative contract/ supply management, e-settlements/vendor payments.
3. **Making (in-side):** Product life cycle management, demand planning, production management, production planning, flow production, event management.
4. **Delivering (sell-side):** Inventory, order management, promotions management, warehouse management, transportation management, delivery infrastructure management, e-bill payment, scm portal.
5. **Returns handling (from customers)**
6. **Maintenance**

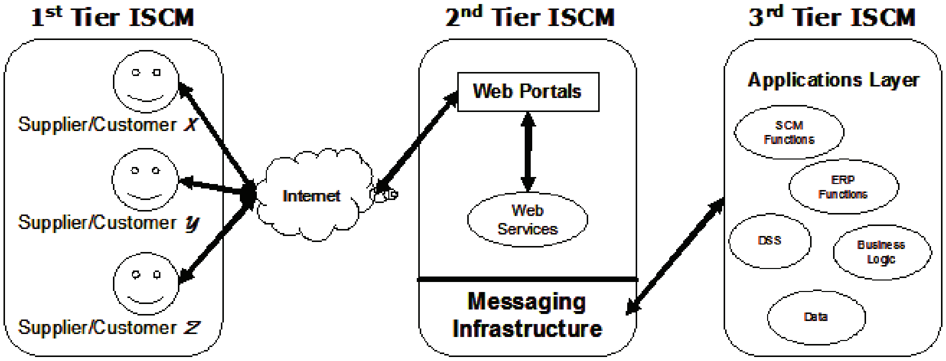
ISCM Systems Architecture

Turner (1993) stated that information systems would be the enabler of integrated logistics. Armstrong (2002) affirms that Turner's view has come to fruition. Many of today's ISCM systems primarily use Web technology as the supporting infrastructure (Dalton et al., 1998). It is not uncommon in these instances to develop a three-tier or n-tier network architecture in order to provide robust support for ISCM systems.

For example, Advanced Software Design Inc. (2002) illustrated the three-tier ISCM integration architecture (Figure 1) in use by the US Department of Defense (DoD). Suppliers and customers access the DoD ISCM through the use of Web portals (the first tier of the ISCM). Web portals provide the necessary Web services to establish a common graphical interface for the DoD's stakeholders in accessing supply chain data. Customers, suppliers, distributors, and delivery agents can access custom information and services supplied by the ISCM. Supplier services could include access to business-to-business (B2B) marketplaces, support, and other push/pull supplier functionality. Alternately, customers can customize the site in order to access catalogs from the organization and external suppliers; customer transaction details; and other product, customer, and technical support.

The portals are supported by a messaging infrastructure (second tier), which provides the

Figure 1. ISCM integration architecture



link to the underlying applications layer (third tier). The applications layer is independent of any particular interface (e.g., portals) and contains the necessary business logic and data access in order to perform operations. This includes access to SCM functionality, ERP systems, and decision support systems. Data and business logic also are stored independently.

The software architecture is constructed mostly in a Web-based environment that involves HTTP, server-side Java, and XML. ISCM systems are generally no different than other business applications but still require some interfacing with old technologies, such as aging ERPs and legacy systems (Zieger, 2001).

Benefits of ISCM Systems

ISCM delivers the enterprise with a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer patronage, and utilize more thorough planning abilities (Turner, 1993). The benefits of ISCM systems are categorized into a number groups, including financial, customer, planning, production, and implementation. Each of these groups is further discussed in the following subsections.

1. Financial

   Cost Reduction: In some manufacturing organizations, the cost of the supply chain can represent 60-80% of their total cost base (Cottrill, 1997). One of the core benefits of driving efficiency through the supply chain is cost reduction. ISCM allows the organization to maximize profitability through reduced customer service, administration, and inventory costs. Less staff is required to maintain the supply chain, and order/inventory details can be made available to customers directly without human intervention (Comptroller, 2002; Cottrill, 1997; Gledhill, 2002). Some organizations have quoted 25% cost reductions per transaction, despite a 20% increase in orders (Turner, 1993).

   Quality Financial Information: Another benefit is the improvement and reliability of financial information. ISCM systems maintain centralized databases that are linked to other enterprise systems (e.g., ERP, CRM) providing integrity, consistency, and real-time data access to managers so that they can manage the supply chain with an organizational perspective (Comptroller, 2002; Turner, 1993).

2. Customer

   Retention: Supply chain systems, through customer portals, provide customers with an instantaneous and holistic view of the progress of their transactions within the organization. This level of service (coupled with benefits derived from production) result in higher customer satisfaction levels and, in turn, improve the firm's ability to attract new customers and, more importantly, retain them. Organizations have achieved customer service levels of 97% following the introduction of ISCM systems. This retention translates into greater revenue (Bergert, 2001; Comptroller, 2002; Cottrill, 1997; Gledhill, 2002; Turner, 1993).

   Behavior: The ability to capture customer transactions and preferences online provides the organization with the facility to track their behavior and, in turn, customize products and services to cater to them (Bragg, 2002).

   Promise: Because of the level of workflow automation and inventory statistics, organizations are able to provide accurate estimates of when orders will be filled at the time of ordering. This is known as capable-to-promise (CTP) capability. This capability allows the organization's customers to plan more effectively (Gledhill, 2002).

3. Planning

   Companies with ISCM systems have the ability to mathematically and graphically observe the performance of the supply chain, giving the manager the power to plan and make things happen (Turner, 1993). ISCM systems provide the organization with the capabilities to derive more accurate demand planning with improved precision, create shorter planning and production cycles, establish one central data repository for the entire organization, and facilitate enhanced communications through rapid information dissemination (Bragg, 2002; Comptroller, 2002; Gledhill, 2002).

4. Production

   ISCM provides the ability to holistically manage the supply chain, allowing managers to respond dynamically to any situation that may arise so as to minimize its impact on production.

   Inventory Management: By measuring the level of inventory and analyzing turnover, supply chain systems can improve turnover by reducing the need for safety stocks and the risk of retailer out-of-stocks. Inventory items need to be numbered consistently in order to facilitate measurement and tracking. These benefits reduce the overhead required to store high inventory levels (Cottrill, 1997; Gledhill, 2002). Turner's (1993) research claimed a 37% reduction in inventory levels as a result of ISCM implementation.

   Efficiency: ISCM systems measure the performance of the supply chain through the generation of supply chain metrics. This allows process quality issues to be tracked and rectified, isolates bottlenecks in the process, and measures lead times so they can be aligned with available capacity in order to maximize plant utilization. All of this ensures quicker time-to-market for the firm's products (Bragg, 2002; Comptroller, 2002; Gledhill, 2002).

   Other efficiency benefits include no data rekeying through simplified automated order placement, order status inquiries, delivery shipment, and invoicing (Bragg, 2002; Gledhill, 2002). ISCM implementations have resulted in a 50% overtime reduction for some organizations (Turner, 1993).

5. Implementation

   Consultants promise responsiveness and Plug & Play integrations. However, documented examples of supply chain failures by organizations such as Siemens AG, Nike, OPP Quimica, and Shell are evidence that the implementation of ISCM systems is not as easy as vendors claim. Claims of rapid integration and seamless linking seem to significantly underestimate the effort required to integrate ISCM with the rest of the enterprise (Oakton, 2003).

   For Nike, i2 ISCM software required a significant degree of customization in order to integrate the software to the rest of the organization. Customization to enterprise software comes with great risk and significant cost for ongoing maintenance. Nike's summation of the software was that it just didn't work. OPP Quimica (a Brazilian chemicals company) required the use of third-party integration software in order to assimilate i2 to the rest of the enterprise architecture. Shell's implementation proved problematic with the need to tie 85 ERP sites to a single SCM platform (Smith, 2002).

Issues and Barriers in ISCM Analysis

Similar to the hype attached to Enterprise Resource Planning (ERP) applications, there has been significant customer backlash concerning the inability of software vendors to deliver easy integration and promised functionality (Smith, 2002). Turner (1993) believes that "few companies claim to have fully implemented SCM and have sustained the benefits proposed ISCM would create" (p. 52). In fact, Fontanella (2001) indicates that only 25% of ISCM users are utilizing the full suite of supply chain applications and that only 12% of users are receiving data from inbound suppliers and customers—far from an integrated supply chain.

Many of these issues stem from a failure to undertake thorough analysis in the following key areas.

- **Focus on transaction systems over strategic systems to manage supply chains:** Organizations are not taking a strategic view of ISCM systems. More so, they tend only to focus on transactions systems (e.g., inventory control, order processing, etc.), which provide little visibility of the enterprise (Fontanella, 2001; Turner, 1993).
- **Failure to preempt change to business processes:** In a majority of implementations, analysis has focused on the technical aspects of integrating ISCM systems with the remaining architecture. One area that has been neglected is the effect on business processes. Organizations expect staff either to just accept change or to customize the software. Both of these options are generally flawed. In order to reap the cost savings from ISCM systems, significant analysis must be conducted regarding process reengineering in order to ensure collaboration and to continue to sustain benefits (Fontanella, 2001; Mol et al., 1997; Turner, 1993).
- **Failure to appreciate geographical, relational, and environmental considerations between buyer and supplier:** The nature of ISCM (especially with multinational corporations) involves transacting across the world—24 hours a day, seven days a week, 360°. Analysts fail to appreciate the geographical, relational, and environmental inhibitors for ISCM implementations of this scope (Mol et al., 1997).

  Cross-borders logistics, culture, language and economics, and regulatory climate are just some considerations that can affect the integration of business processes between regional offices and external organizations, creating communication issues throughout the supply chain. One ill-performing participant in the supply chain will affect the performance of the entire supply chain (Strausl, 2001).
- **Failure to accurately identify the costs and benefits of ISCM implementation:** Many implementations have been classified as failures because of ISCM system's perceived inability to reap benefits and produce cost savings, as expected. However, in many cases, it is the initial analysis of cost and benefits that has been flawed. Because of the nature and scope of ISCM implementations, it is difficult to accurately quantify attributable cost reductions from ISCM, because they could be derived throughout the supply chain and be complicated to calculate. In the same light, determining benefits share similar traits, with some having the additional complication of being intangible (e.g., benefits of a central database) and, therefore, difficult to quantify (New, 1994).
- **Insufficient capability:** The implementation and support of ISCM systems can be rather complex and, therefore, demands sophisticated resources and incremental implementations. Unfortunately, during the planning and analysis phases of implementation projects, organizations have failed to properly appreciate the level of complexity involved, resulting in significant under-resourcing. As a result, many organizations have suffered material cost overruns and delayed go-live times (Fontanella, 2001).

PROPOSED METHODOLOGY FOR ISCM SYSTEMS ANALYSIS

Due to the extent of failed ISCM system implementations, it is imperative to construct an appropriate analysis and development methodology that can be adopted as the roadmap for enterprises flourishing in ISCM systems development and operations. The proposed methodology demonstrates an overall picture for constructing an ISCM system from recognizing problems and analyzing requirements to the implementation and operation. It embraces eight phases:

1. Identifying information management structure
2. Identifying connecting components
3. Ensuring appropriate business processes
4. Establishing and developing interfaces
5. Developing new business processes
6. Confirming strategic alignment
7. Implementing ISCM systems
8. Testing efficacy of implementation

Following is a discussion and culmination of those eight phases within the proposed iterative framework.

Identifying Information Management Structure

Given the global nature of supply chain systems and their level of required integration, a common ICT (information and communication technology) infrastructure must be able to extend around the globe, to support open and rapid communication, and to integrate easily with the architecture of not just the organization but also the architecture of customers and suppliers. This will be conducive to information sharing (Comptroller, 2002).

The enterprise's information systems architecture must be properly analyzed to ensure that it satisfies the needs of ISCM systems and can support security boundaries, largely distributed database operations, and event-driven applications. The architecture needs to be durable, flexible, and embedded with the appropriate middleware in order to integrate as easily as possible (Zieger, 2001). It also must be sufficiently robust in order to cater to firewalls and other security measures and have 24/7 global access and redundant systems and processes in order to handle events when ISCM systems need to be off-line for maintenance, emergency, and recovery purposes.

In accordance with these criteria, the Internet-based structure can be considered the most appropriate platform to satisfy these requirements. Nevertheless, participants in the supply chain have various capability and maturity levels in information management structure. Hence, prior to adopting the Internet technology for integration, the existing information management structure of each participant must be determined.

Identifying Connecting Components

One of the most critical functions of supply chain management is to ensure the effective integration of information and material flows through the system. This includes understanding the value added to products and its related information flows (inputs and outputs) as it progresses through the supply chain (Michael-Donovan, 2002). This embraces analysis of the supply chain's real costs and cost and performance drivers (Seirlis, 2001).

Turner (1993) identifies some of the key components that need to be functionally integrated. These components also are considered the connecting components (or connecting business functions) among participants in the supply chain. These components include order management, customer service, invoicing, forecasting, distribution requirements planning (DRP), warehouse and inventory management, manufacturing planning, production control (MRPII), and integrated logistics.

Ensuring Appropriate Business Processes

In order to enhance the supply chain processes, it is important to understand what happens currently. Generally, supply chain processes may include the procurement, production, ordering, delivery, and inventory paths, both within the company and external parties.

First, analysts should analyze the supply chain processes and be able to appreciate the company's mix of products, end configurations, volumes, life cycles, channels, customer segments, and delivery outlets (Tyndall et al., 2002).

Each process then should be prioritized and broken down into its subprocesses, identifying each of its sources, outputs, transformations, timings, resources utilized, and requirements. This also would be an opportune time to gather metrics concerning each of the processes in order to establish a baseline for identifying problems and to measure future process improvement.

Additionally, any opportunities to benefit from quick-wins should be taken advantage of at this point (Michael-Donovan, 2002).

Establishing and Developing Interfaces

Once architectural issues have been resolved and data requirements have been determined, a structure needs to be established to enable common linkages between data providers and data recipients of the ISCM (i.e., customers and suppliers) and linkages within ISCM processes. This will require the need to ascertain whether there are any missing links and to determine how the data required will be sourced or provided and in which format.

The emerging technology for interface communications is XML (eXtensible Markup Language). XML uses HTML tags to enable the definition, transmission, validation, and interpretation of data. However, effort for this task should not be underestimated (Zieger, 2001). Significant resources may be required in analyzing sources from ERP and antiquated EDI systems. It has been suggested that third-party interface tools (e.g., Informatica & Brio) can be used to ease the transition for these types of systems (Zieger, 2001).

Developing New Business Processes

After conducting a detailed analysis of existing supply chain processes and identifying any inefficiencies and/or gaps in the process, a proposal should be created for the design of new processes. Not only should new processes cater to anticipated ISCM processing, but they also should be sufficiently visionary in order to accommodate other strategic initiatives (i.e., CRM, Supplier Management, Knowledge Management).

The new supply chain should be modeled in a manner so that supply chain blueprints can be generated (Comptroller, 2002; Zieger, 2001). Tyndall et al. (2002) suggest an iterative approach to process design, whereby a process is broken down into stages and then defined, analyzed, executed, assessed, and then redefined. This cycle continues until the appropriate performance expectations have been achieved. This process can become quite complex and convoluted, once organizations begin to incorporate backend systems and the processes of other organizations.

Based on metrics determined during the initial business process review, goals should be set for process improvement.

Confirm Strategic Alignment

At the completion of most of the analytical work, it is important to revisit some of the groundwork that would have been completed during the planning phase activity in the traditional SDLC.

It has been included in this framework to highlight the importance of ensuring an alignment between business strategy and expectations with the outcomes of the ISCM implementation—supply chain strategy is interdependent on the business strategic direction.

Analysts need to confirm that value is being delivered through ISCM by conducting a critical analysis on proposed benefits and costs in order to ensure that they are still realistic (Tyndall et al., 2002). In order to prevent misalignment of resources and skillsets, analysts also need to confirm that the business problem still can be solved with its current complement of staff.

Implementing ISCM Systems

This phase involves determining what activities will need to be undertaken to facilitate implementation of ISCM system—creating an action plan.

There are a number of factors that should be considered in this final phase of the methodology, such as setting up communication standards, developing business operation procedures, and establishing training programs.

Furthermore, this phase should be expanded to incorporate activities that can assist in the detailed analysis of implementation risks of the system. Conducting analyses in areas such as change management is one example. Inability to manage the implementation of change has been a key factor in project failure. Any enterprise system places great strain on the organization to adapt in order to reap the benefits. Change management involves more than simply conducting user-training programs but involves a continuing consultative relationship with end users to secure buy-in.

CONCLUSION AND FUTURE CHALLENGE

This chapter endeavors to propose an analysis and development methodology for ISCM systems. The discussion started with review and investigation of the current ISCM solutions and architectures, and identified a number of benefits, issues, and problems regarding the implementation of ISCM systems. Based on the examination of existing ISCM status, the proposed methodology for ISCM systems analysis is constructed by an eight-phase development framework. The methodology tends to illustrate a systematic roadmap for enterprises in developing ISCM systems.

The future challenge for enterprises in operating and maintaining ISCM systems stressed the overall maturity of technological availability and the flexibility of business processes aligning with the ISCM architecture.

Section III

Tools and Technologies

This section presents extensive coverage of the technology that informs and impacts strategic information systems. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support the emergence and advancement of strategic information systems. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Chapter 3.1

Intelligent Agents in Decision Support Systems

Gloria E. Phillips-Wren
Loyola College in Maryland, USA

INTRODUCTION

Internet-based, distributed systems have become essential in modern organizations. When combined with artificial intelligence (AI) techniques such as intelligent agents, such systems can become powerful aids to decision makers. These newer intelligent systems have extended the scope of traditional decision support systems (DSSs) to assist users with real-time decision making, multiple information flows, dynamic data, information overload, time-pressured decisions, inaccurate data, difficult-to-access data, distributed decision making, and highly uncertain decision environments. As a class, they are called intelligent decision support systems (IDSSs).

Although various AI techniques such as artificial neural networks, genetic algorithms, case-based reasoning, methods from expert systems, and knowledge representation have been successfully incorporated into IDSSs, intelligent agents are one of the more promising AI research fields with broad applicability to IDSSs. Although there is no universally-accepted definition of an agent, the definition given by Woolridge (2002) is often cited as authoritative:

> *An agent is a computer system that is situated in some environment and that is capable of autonomous action in this environment in order to meet its design objective.*

Woolridge (2002) adds the capabilities of *reactivity, proactiveness*, and *social ability* for an intelligent agent, although many researchers, including the DSS community, do not make a distinction. Reactivity means that an intelligent agent can perceive the environment and respond to it as it changes. Proactiveness implies that it is able to take the initiative to meet its design objective. Social ability means that it can interact with other agents and possibly humans to perform such tasks as negotiation and cooperation. Delivery of these capabilities imposes demanding requirements on the part of the agent designer since the environment may change during execution of the software program and initial assumptions may no longer be valid, and yet the agent's goal remains the same. In complex environments, teams of agents or multi-agent systems have been developed that attempt to balance goal-direction with reaction to the environment. Agents, intelligent agents, and multi-agent systems are active areas of research both in themselves and in application to IDSSs.

The objective of this article is to review characteristics of intelligent agents and their applications to intelligent decision support systems. The article is organized as follows. In the second section we provide a background on intelligent agents and IDSSs. In the third section we discuss intelligent agents within IDSSs and provide examples of applications. In the final section, we examine future research trends.

BACKGROUND

Simon (1997) described the decision making process as consisting of three phases: intelligence, design, and choice. A fourth phase, implementation, was added by later researchers (Forgionne, 1991). The decision maker acquires information and develops an understanding of the problem during the intelligence phase. During the design phase the user identifies criteria, develops the decision model, and investigates alternatives. An alternative is selected during choice and the user acts on the decision during the implementation phase. A similar four-step decision making process is recognized by researchers for defense decisions and is called the observe, orient, decide, act (OODA) loop (Phillips-Wren & Jain, 2007).

Decisions are often characterized by the degree of structure involved in the decision (Turban & Aronson, 1998). A structured decision is deterministic with a known solution, while an unstructured decision is on the other end of the continuum with decisions with little or no agreement on the solution. In the middle are semi-structured decisions and this is the area where DSSs are most effective at providing support by using computing to assist with the decision. Semi-structured decisions are those that require some human judgment and at the same time there is some agreement on the solution method. Examples of support for decision making are mathematical models and statistical methods. In general, a DSS consists of input, processing, output, the user, and computing resources. Inputs include the database(s) needed for the decision and model base(s) that supply the models needed to evaluate and/or predict potential outcomes. During processing the model(s) is evaluated and a feedback loop to the input permits multiple what-if scenarios and alternatives. In output, the user is presented with alternatives and sometimes recommended courses of action. The user and computer are considered part of the system.

A DSS with embedded AI techniques is referred to as an 'intelligent decision support system.' What is intelligence in the context of DSSs? Turban and Aronson (1998) defined an IDSS as a DSS exhibiting some or all of the abilities that are indicative of 'intelligent behavior':

- Learn or understand from experience.
- Make sense out of ambiguous or contradictory messages.
- Respond quickly and successfully to a new situation.
- Use reasoning in solving problems.
- Deal with perplexing situations.
- Understand and infer in ordinary, rational ways.
- Apply knowledge to manipulate the environment.
- Think and reason.
- Recognize the relative importance of different elements in a situation.

The characteristics of intelligent agents given by the collective AI community (Bradshaw, 1997; Huhns & Singh, 1998; Jennings & Woolridge, 1998; Woolridge, 2002; Jain, Chen, &, Ichalkaranje, 2002; Russell & Norvig, 2003; Padgham & Winikoff, 2004; Design-Ireland, 2007) are comparable:

- **Autonomous:** Capable of working without human supervision.
- **Adaptive:** Ability to learn and change behavior as their knowledge base increases.
- **Proactive:** Ability to take an initiative on its own.
- **Reactive:** Responds to changes in its environment.
- **Communicative:** Ability to communicate with other systems, agents and the user.
- **Cooperative:** As an advanced capability, ability to act in coordination with other agents.
- **Mobile:** Ability to travel throughout computer systems to gain knowledge or perform tasks.
- **Goal-Directed:** Ability to work toward achieving a specific goal.
- **Persistent:** Ability to persist and maintain state over long periods of time.

It appears that intelligent agents can deliver the necessary behaviors within IDSSs.

As organizations increasingly deploy IDSSs on networked computers and within distributed systems, intelligent characteristics can be provided by multi-agent systems (Huhns & Singh, 2006). A multi-agent system "consists of a number of agents, which *interact* with one another, typically by exchanging messages through some computer network infrastructure" (Wooldridge, 2002). The agents in multi-agent systems may act on behalf of users or even other agents with differing goals and objectives. Successful interaction then requires cooperation, coordination, and negotiation between agents, and sometimes between the human user and agents, that do not share the same beliefs, goals, or interests. Agents can dynamically create teams and multi-agent systems are said to create an "artificial social system" (Woolridge, 2002) involving agent architecture, cooperation among agents and with humans, human-like learning, and trust.

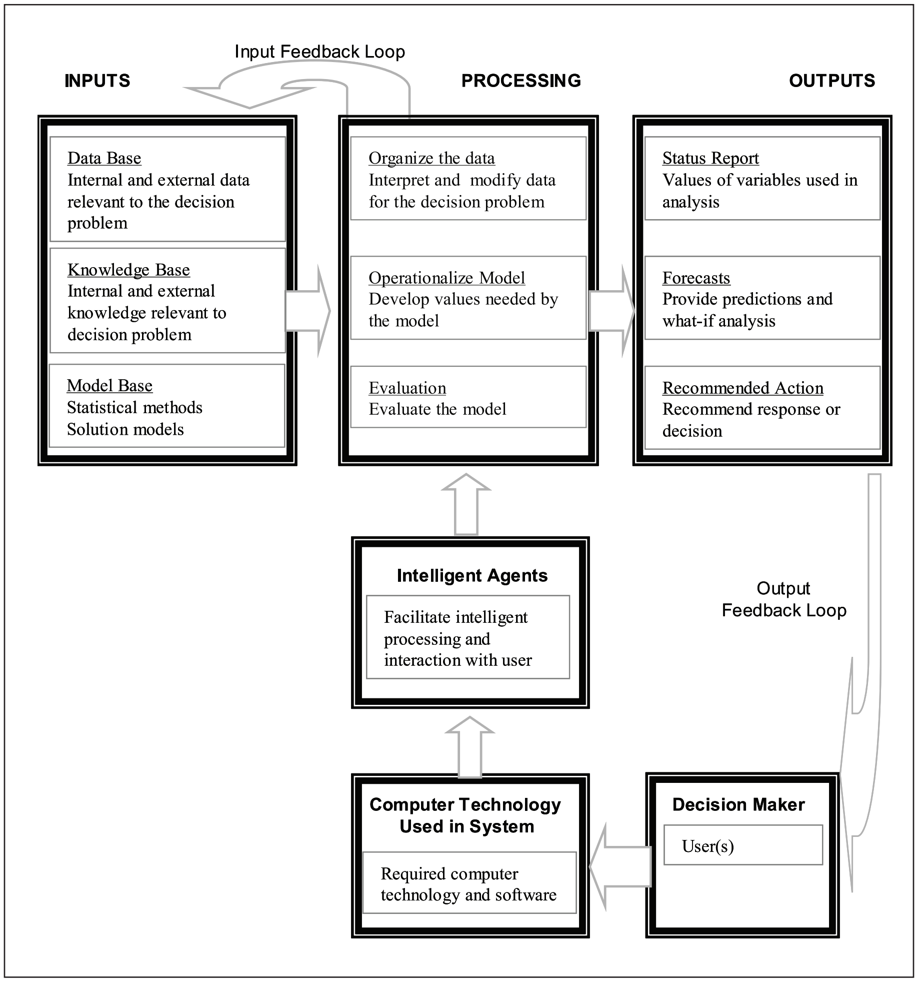
INTELLIGENT AGENTS IN DECISION SUPPORT SYSTEMS

Support for Decision Making

Recent advances in intelligent agents and multi-agent systems have led to a noticeable increase in the number of IDSS applications over the past several years. "Agent-based computing has already transformed processes such as automated financial markets trading, logistics, and industrial robotics. Now it is moving into the mainstream commercial sector as more complex systems with many different components are used by a wider range of businesses. Organisations that have successfully implemented agent technologies include DaimlerChrysler, IBM and the Ministry of Defence" (Sedacca, 2006).

Various frameworks have been proposed for IDSSs. For example, Linger and Burnstein (1997) provided two layers in their framework, a pragmatic layer that is associated with the actual performance of the task and a conceptual layer that is associated with the processes and structure of the task. Figure 1 illustrates a framework for an IDSS implemented with intelligent agents. The input has a database, knowledge base, and model base, some or all of which may utilize intelligent methods. Data directly relevant to the decision problem is contained in the database, for example, values for the states of nature, courses of action, and measures of performance. Problem knowledge, such as guidance for selecting decision alternatives or advice in interpreting possible outcomes is contained in the knowledge base. The

Figure 1. Framework of an intelligent decision support system implemented with intelligent agents



model base is a repository for the formal models of the decision problem and the approaches (algorithms and methodologies) for developing outcomes from the formal models (Phillips-Wren et al., 2006). Intelligent agents may autonomously perceive, obtain and develop needed data, knowledge, or models.

Processing involves organizing problem inputs, structuring the decision problem and decision model, using the decision model to simulate policies and events, and determining the 'best' problem solution. Intelligent agents may assist in these tasks by using knowledge drawn from the knowledge base to perform appropriate actions and present the results to the user.

During processing, status reports, forecasts, recommendations, and explanations may be created (Phillips-Wren et al., 2006). Status reports may reveal relevant states, courses of action, and measures of performance and show the current values for these problem elements. Intelligent agents could anticipate the need for status reports and communicate with the user. Forecasts may report the states and actions specified in the simulations and the resulting projected values for the measures of performance. Intelligent agents can assist these processes by anticipating requirements for the analyses such as variable values and acquiring them from appropriate databases. The recommendations may suggest values for the actions that best meet the measures of performance. Explanations will justify the recommendations and offer advice on further decision making, and intelligent agents could communicate with the user depending on user preferences. Such advice may include suggestions on interpreting the output and guidance for examining additional problem scenarios.

Input feedback from the processing provides additional data, knowledge, and models that may be useful for future decision making. Intelligent agents could anticipate the need for feedback and obtain the needed values of the variables autonomously. This feedback can be provided dynamically to update the models and inputs in real time without external intervention. Output feedback is used to extend or revise the original analyses and evaluations, and intelligent agents could interact with the user to refine or evaluate the decision further. Multi-agent systems could distribute the IDSS over multiple networks for collaboration between multiple decision makers while maintaining the functionality discussed.

In general, intelligent agents and multi-agent systems are being implemented in IDSSs for tasks such as obtaining values to quantify uncertainty and assess risk, providing up-to-date information in real-time, enabling collaborative decisions, evaluating consistency between data sources, handling routine decisions, monitoring and alerting the decision maker as problems arise, bringing together data from different media types or sensors, and expanding the knowledge set to include more information from more sources. The AI community is "shifting from inward-looking to outward-looking" (Mackworth, 2005) and intelligent decision support is poised for significant advancement. For example, in engineering designs of buildings, early research focused on AI to aid design processes such as computer-assisted drafting. Current efforts use AI as "the glue that holds larger *systems* together

Table 1. Decision process and dteps vs. intelligent agent and multi-agent system characteristics

DECISION PROCESS	**DECISION STEPS**	**INTELLIGENT AGENT AND MULTI-AGENT SYSTEM CHARACTERISTICS**								
		AUTONOMOUS	ADAPTIVE	PROACTIVE	REACTIVE	COMMUNICATIVE	COOPERATIVE	MOBILE	GOAL-DRIVEN	PERSISTENT

	Task Monitoring	√							√	√

using reasoning *systems* that represent or manage processes, information, and interaction devices that use conventional procedural programming; effectively blurring the boundaries between AI and non-AI" (Maher, 2007).

Characteristics of intelligent agents and multi-agent systems support the decision process and decision steps as shown in Table 1. The decision making process includes the phases of intelligence, design, choice, and implementation discussed previously. The phases can be further refined into decision steps to clarify the actions that take place in each phase (Turban & Aronson, 1998) with one such refinement (Mora, Forgionne, Cervantes, Garrido, Gupta, & Gelman, 2005; Phillips-Wren et al., 2006) shown in Table 1. Characteristics of intelligent agents and multi-agent systems are then related to the decision steps in Table 1 to demonstrate the actions that can be performed by agents on behalf of the user or other agents. The comparison demonstrates that intelligent agents and multi-agent systems can support the tasks in decision making. However, they can not replace the human user who remains part of the IDSS as shown in Figure 1. The user maintains the final decision on accepting or not accepting the recommended course of action and implementing it, as well as interacting with the system to provide user-specific domain knowledge or preferences.

Applications of Intelligent Decision Support Systems

Several examples of applications of IDSSs with intelligent agents are shown in Table 2 to illustrate the depth and breadth of recent research efforts. Many other examples can be found in the literature (see, for example, Phillips-Wren & Jain, 2005).

A more detailed illustration is given by an application of intelligent agents for the non-expert who seeks information in a technical field (Wang et al., 2006; Phillips-Wren, 2006). An Internet-

Table 2. Sample applications of agent-based IDSSs

Industry or Research Area	**Sample Applications**		
	Author	Year	Brief Description
Securities Trading	Wang, Wang, Xu, and Kit	2004	Minimize transaction risk by aiding business exception management (i.e., monitoring, investigation, and reconciliation of transaction errors) with agents. Currently multiple organizations, human activities, and automated processes are involved. Web-enabled, agent-based, decision support to address dynamic, complex, and distributed processes. Result is faster, more accurate, and more flexible business exception management.
Electronic commerce	Lee and Park	2003	IDSS for Web-based, make-to-order (MTO) semiconductor manufacturing environment. During industrial manufacturing processes, various sampling methods such as spectroscopy are used to judge the quality of the final product. IDSS utilizes intelligent agent to autonomously generate available customized sampling methods and provides performance information to the customer. The customer then selects a process sampling method that is most suitable to their particular situation.
Planning and control	Santos, DeLoach, and Cox	2006	A multi-agent, distributed IDSS was developed to assist a commander on the battlefield with mission planning and execution. The environment is complex, distributed, collaborative, and dynamic with competing goals and user preferences. Agents assist in retrieving, analyzing, synthesizing, and distributing information to the decision maker.
Strategy	Li	2007	Web-enabled, multi-agent IDSS was developed to assist users in marketing strategies, competitive strategies, and associated electronic commerce strategies.
Healthcare	Sissons, Gray, Bater, and Morrey	2007	Agent-based IDSS to bring best-practices into oncology to develop an individual patient's treatment by examining objective research in order to suggest treatment.

based, suicide prevention Web site (PSN, 2006) was developed for the U.S. National Institute of Mental Health to, in part, provide an interface to the U.S. National Library of Medicine (NLM, 2007). A portion of the Web site involves information retrieval for the user from medical research literature. Agents persist in autonomously and proactively locating remote information by moving between resources, retrieving information, and communicating with the user.

Users of the Web resources are intermediaries between a person who may be suicidal and medical information that could be helpful in preventing suicide. Much of that information is contained in databases at a centralized location, namely, the U.S. National Library of Medicine. The difficulty for users is that the databases are large, mix various types of medical information, are constantly updated, and are catalogued according to medical terminology using a MeSH® system whose keywords are developed, and whose articles are categorized, by medical subject area specialists (NLM, 2007). Users, on the other hand, are generally non-experts without medical training who are generally unfamiliar with the specialized terminology. Access to needed information on suicide is greatly hampered and likely impossible without assistance. The amount of available information makes generalized information searches ineffective. One database alone, Medline, lists over 15 million references from more than 5,000 biomedical journals published in the United States and 80 other countries (NLM, 2007). Intelligent agents can provide an appropriate interface to the databases for this category of non-expert users.

Previous research (Wang, 2006) has shown that the information search process used in information retrieval corresponds to the decision making process as shown in Table 3. The similarities in the processes together with characteristics of intelligent agents and multi-agent systems shown in Table 1 suggest that an IDSS implemented with intelligent agents may be able to aid the user in locating the desired information.

Within the Web site, an agent-based IDSS was developed to allow a user to register, save, and update personal data that describes the type of suicide information of interest. User terminology describes in lay terms the type of suicide information that is desired. By registering these search preferences, the user initiates an intelligent agent that autonomously monitors the technical databases at the National Library of Medicine, seeks new information as the databases are updated or the user search preferences change, and reports new information to the user electronically as it

Table 3. Steps in the decision making process compared to the information search process (Wang, 2006)

Decision-Making Process	**Description**	**Information Search Process**
Intelligence	Recognize problem; Gain problem understanding; Seek and acquire information	Task Initiation Topic Selection
Design	Develop criteria; Specify relationships; Explore alternatives	Prefocus Exploration Focus Formulation
Choice	Evaluate alternatives; Develop recommendations; Make decision	Information Collection
Implementation	Weigh consequences; Implement decision	Search Closure

becomes available.

Intelligent agents in the technical information retrieval process are autonomous, proactive, communicative, mobile, goal-driven, and persistent. Intelligent agents autonomously communicate with remote databases at the National Library of Medicine on behalf of the user. They are mobile between the user, the Web site containing the user's search preferences, and the National Library of Medicine. Intelligent agents proactively search for new information without further user direction. They are goal-driven to find new information for the user by translating the user's interests into technical terms in accordance with the MeSH®, identifying new information, and contacting the user. Intelligent agents are unique in information retrieval since they infer the user's technical medical interests based on a non-technical description.

FUTURE TRENDS

The area of IDSSs, and especially implemented with intelligent agents and multi-agent systems, is an active and growing research area. As distributed systems continue to become more pervasive with globalization and networked applications, agent-based IDSSs will be able provide assistance for complex, real-world decision making problems.

The future presents research challenges in the application of intelligent agents and multi-agent systems to IDSSs, particularly in the interfaces between humans and machines. The challenge is to design robust human-agent teams, human-like agents, trust-based agent models, emotion-based agents, agent communication, cooperation models, and self-creating agent architectures. Adaptive IDSSs that personalize for different users and perceive user intent in action or language are actively being pursued.

One of the biggest challenges in this research field remains trust in autonomous systems in general, and in IDSSs in particular. Future research will need to address questions such as: What decisions are we willing to allow machines to make autonomously? What actions will we allow them to take and under what conditions? What security do we need in place? What checkpoints need to be implemented in systems? How much do we really trust them to act in our best interests?

CONCLUSION

Intelligent agents and multi-agent systems are sufficiently mature to offer significant promise in intelligent decision support systems. Such systems have the potential to transform business and personal decision making, particularly in distributed, network-centric environments.

KEY TERMS

Decision Support System (DSS): An information system that utilizes database and model-base resources to provide assistance to decision makers through analysis and output.

Intelligent Agent: A software program with the ability to act autonomously on behalf of a user or other agents to achieve a goal.

Intelligent Decision Support System (IDSS): A decision support system with embedded artificial intelligence techniques exhibiting some or all of the abilities indicative of intelligent behavior.

Multi-Agent System: A system of intelligent agents that work together to meet their design objectives.

Semi-Structured Decision: Decisions in the middle between structured and unstructured decisions, requiring some human judgment and at the same time with some agreement on the solution method. Area of focus for most DSSs.

Structured Decision: A deterministic decision with a known solution.

Unstructured Decision: Decisions with little

Chapter 3.2
Agents and Multi-Agent Systems in Supply Chain Management:
An Overview

Pericles A. Mitkas
Aristotle University of Thessaloniki, Greece

Paraskevi Nikolaidou
Aristotle University of Thessaloniki, Greece

ABSTRACT

This chapter discusses the current state-of-the-art of agents and multi-agent systems (MAS) in supply chain management (SCM). Following a general description of SCM and the challenges it is currently faced with, we present MAS as a possible solution to these challenges. We argue that an application involving multiple autonomous actors, such as SCM, can best be served by a software paradigm that relies on multiple independent software entities, like agents. The most significant current trends in this area are shown, focusing on potential areas of further research. Furthermore, the authors believe that a clearer view on the current state-of-the-art and future extension will help researchers improve existing standards and solve remaining issues, eventually helping MAS-based SCM systems to replace legacy ERP software, but also give a boost on both areas of research separately.

INTRODUCTION

This chapter discusses the current state-of-the-art of agents and multi-agent systems in supply chain management (SCM). The growing complexity of the supply chain has increased the need for effective supply chain management, which may raise profit and reduce stock at a minimal cost. However, SCM is a complex problem of distributed nature and it often involves sensitive data that companies may be reluctant to reveal. Multi-agent systems (MAS) appear to be an ideal solution to this problem, as they can handle complex and distributed processes in an effective way. Considerable ongoing research efforts on MAS have yielded a wide variety of prototypes and applications although the adoption of agents by the software industry proceeds at a cautious pace. Agent-based solutions for the SCM problem abound in the literature underlining the significant interest in this approach and its huge potential.

Section 1 provides a general description of SCM and explains the reasons that make effective SCM critical, both within a single company and across the chain. Section 2 discusses the main problems that SCM is currently faced with and section 3 explains the reasons why MAS are an ideal solution to this problem. Section 4 describes the various approaches and current trends and focuses on current problems that arise and areas that need further research. Finally, section 5 presents the main conclusions.

Current Trends in SCM

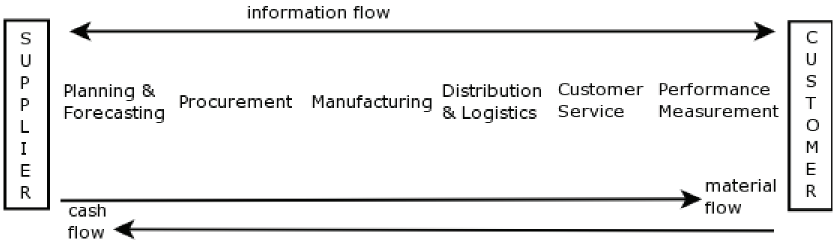
According to Stanfield (2002), "supply chain management deals with the management of materials, information and finance in a network consisting of suppliers, manufacturers, distributors and customers" (p.11). Practically, according to Kim, Tannock, Byrne, Farr, Cao, and Er (2004), "the activities involved in the material flow are to deliver to the end-user via procurement of raw materials, manufacturing, distribution and customer service" (p.10). All these activities must be managed using suitable information flows. This is easily illustrated in Figure 1.

The above factors cause increasing emphasis to be placed on integrating, optimizing and managing the entire supply chain from component sourcing, through production, inventory management and distribution to final customer delivery. Recent technological advances have facilitated this job, replacing approximate estimations by human experts by more precise calculations, as managing the supply chain is a complex task with increased sensitivity on small changes.

Increasing competition has emphasized the need for more flexible, robust and powerful supply chain management. The current trend in production is changing "from mass-production to customisation, and from technology and product-driven to market and customer-driven" (Kim et al., 2004, p.9). Bielli and Mecoli (2005) state that "current scenario in production and logistics fields must accomodate globalization, needs for increasing quality of goods, rapid changing in market demand, customer-service policies, flexibility of production processes, e-business and e-commerce" (p.147).

Many companies see the need for complete visibility into their supply chain as the starting point for managing them and many solutions are already implemented in this area. The next stage is to go further and implement solutions that are designed to change business practices and make supply chains more efficient.

Figure 1. Flows in the supply chain (Adapted from Speckman, Kamauff, & Myhr, 1998)



SCM PROBLEMS

Managing the supply chain is an extremely complicated task, which requires correct coordination of distributed heterogeneous information. Each part of the chain plays a different role in the functionality of the entire chain and it is difficult to conceive a suitable model, especially when the latter is designed to be more generic rather than to describe a particular chain. "The speed and accuracy required to increase the company's profit, as well as the current trends for customisation and flexibility, require the adoption of 'just-in-time' practices" (Stanfield, 2002, p.11). However, these practices not only require a totally transparent chain, but also increase its sensitivity on real-world problems, such as delays, specification changes and compromises. The most important problems of SCM are discussed below.

Bullwhip Effect

As explained by Kombrough, Wu, and Zhong (2001), a very well-known phenomenon in SCM is the so-called bullwhip effect, where the variance of orders amplifies upstream the supply chain. Figure 2 illustrates this effect.

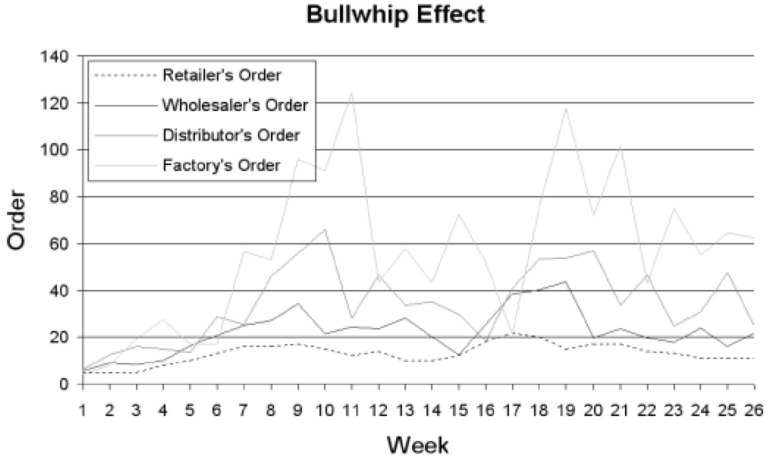
Such results are commonly observed in real-life situations. Small fluctuations on one end of the chain often become surprisingly large on the other end, hindering the flawless functionality that one would expect from a well-designed supply chain. As a result, there is a growing interest in efforts to eliminate the bullwhip effect, or at least minimize it.

Kombrough et al. (2001) state that the bullwhip effect can be minimized under the assumption that all divisions of the supply chain work as a team. Yung and Yang (1999) claim that information sharing and, more generally, coordinating information and planning along the supply chain can minimize the bullwhip effect. Ganapathy and Narayanan (2003) suggest simulation methodologies to lower demand amplification, but this, of course, requires extensive collaboration between the different levels of the supply chain system.

Coordination

It is also necessary to discuss the importance of correct timing and coordination in SCM. The most immediate consequence of incorrect coordination is a bottleneck effect, where products are accumulated in one part of the chain, while there is a shortage at its end. This can lead to products eventually becoming useless, or can force a modification of the manufacturing and

Figure 2. The bullwhip effect



supplying process, with immediate impact on product quality, cost and competition.

Ganapathy and Narayanan (2003) present time delay, added together with delays from other levels, as the major cause of the bullwhip effect. Chan and Chan (2004) state that one common weakness is the assumption of deterministic demand. Facing uncertain demand, retailers prefer to place an order late in most cases in order to gather enough time to collect more information. However, this leads to insufficient production times and hence increased production cost.

MAS AS A SOLUTION

Generally speaking, the best way to define software agents and distinguish them from other software entities is to do so based on some common attributes that they have. As stated by Ta, Chai, and Liu (2005), agents' main characteristics are autonomy, sociability, capacity for cooperation, capacity for reasoning, adaptive behavior and trustworthiness. One can easily understand that all of these capabilities are, not only necessary, but also vital to SCM.

However, there is still not a commonly accepted definition on what an agent might be. Wan (2004) states that an agent is merely an object with initiative. Of course, initiative is an important feature of an agent, but one can easily understand that there's more in an agent than initiative. Other authors, such as Caglayan and Harrison (1997), define an agent as "a software entity that accomplishes a specific task, usually on the Internet, according to the user's requirements". This definition, though commonly used, is also too vague and does not give a complete picture of agents.

A multi-agent system (MAS) is a system, in which many agents communicate and interact. This interaction may be either cooperative or selfish. According to Sycara (1998), the main characteristics of a MAS are:

- Each agent has incomplete information or capabilities to solve the problem
- There is no global control on the system
- Data is distributed
- Computations are asynchronous

As explained earlier, SCM is a problem of distributed nature, which requires processing of heterogeneous data in an intelligent way. Resource allocation is crucial to the supply chain's functionality and negotiation and cooperation between the parts of the supply chain are necessary. This shows that MAS are an ideal solution to this problem, since they are designed for distributed problem solving and negotiating.

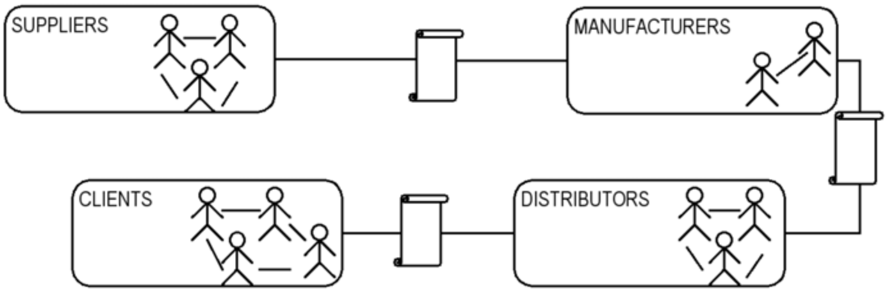
According to Wu, Ulieru, Cobzaru, and Norrie (2000), since SCM is fundamentally concerned with coherence among multiple, globally distributed decision makers, a multi-agent modeling framework based on explicit communication between constituent agents (such as manufacturers, suppliers, retailers and customers) seems very appealing.

"Agent technology may facilitate the integration of the entire supply chain as a networked system of independent echelons, each of which utilizes its own decision-making procedure" (Jiao, You, & Kumar, 2006). Ulieru and Cobzaru (1999) argue that "agents are suitable for integrating supply chain functions because they can extend applications like production, distribution and inventory management functions across supply chains spanning various organisations without the need for additional interfaces, especially when a common infrastructure is used."

STATE-OF-THE-ART

MAS are still a new research area, not yet fully adopted by industry. As a result, the agent-based solutions for SCM to be found today are relatively limited. A simplistic approach would be to merely simulate the supply chain by substituting

Figure 3. Simplistic MAS modeling of a supply chain



each part of it by an agent, as in Figure 3. This solution increases the chain's performance, but it does not totally exploit the huge potential of agents and MAS.

Various Approaches

Negotiation and Cooperation

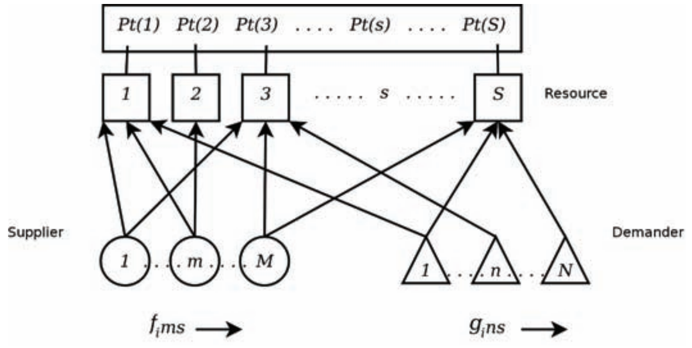
The most common approach on agent-based SCM is negotiation and cooperation. Many people, like Kaihara (2001, 2000), have discussed bidding mechanisms. One strategy (2001) is based on market-oriented programming, whose mechanism is shown in Figure 4. *Pt(S)* is the price of resource *s* at time *t*, while *ftms* and *gtns* represent the supply function of supplier *m* and the demand function of demander *n* on resource *s* at time *t*.

Agent activities in terms of products required and supplied are defined so as to reduce an agent's decision problem to evaluate the trade offs of acquiring different products in market-oriented programming. Kaihara defines several functions that formulate agents' strategy for the resource allocation in SCM, taking into account the budget constraints of each agent.

Kaihara (2000) discusses the advantages of double-auction mechanisms. He formulates supply chain as a discrete resource allocation problem with supply/demand agents and demonstrates the applicability of economic analysis. Finally, he introduces an agent-based double auction algorithm based on market mechanisms and demonstrates that it can provide several advantages on resource allocation.

Lou, Zhou, and Chen (2005) give a definition of *agile SCM* and discuss coordination mechanisms for both self-interested and cooperating agents. "The *agile supply chain* is an operational strategy focused on inducing velocity and flexibility in a supply chain" (p. 171). The two differences between an agile supply chain and a normal supply

Figure 4. The bidding mechanism proposed by Kaihara (Adapted from Kaihara, 2001)



chain are (a) speed, which is the ability to respond quickly to the changing of customers' requirements, and (b) flexibility, namely the ability of reconfiguring quickly according to changing. The coordination mechanism in ASCM is shown in Figure 5.

The main doctrine of the coordination mechanism for cooperating agents is "as decentralized as possible, as centralized as necessary", and the reasoning process is shown in Figure 6.

As shown in Figure 5, coordination for self-interested agents is done at two levels, namely strategic-level coordination and operational-level coordination.

Chan and Chan (2004) introduce a coordination framework for distributed supply chains by using the distributed constraints satisfaction problem (DSCP). They propose a coordination framework by adopting the DSCP philosophy for distributed supply chains, which are modeled by MAS, subjected to uncertainties. In their simulation, they demonstrate that the proposed mechanism outperforms traditional stochastic modeling.

Chan and Chan (2005) perform a comparative analysis of negotiation-based information sharing in agent-based supply chains. They model a distributed make-to-order (MTO) manufacturing supply chain as a MAS. In this case, information can only be exchanged through negotiation in the agent-based framework. In their simulation results, they show that partial information sharing has comparable performance in terms of total cost and fill rate against full information sharing based on negotiation. Considering the associated

Figure 5. Coordination mechanism in multi-agent based ASCM

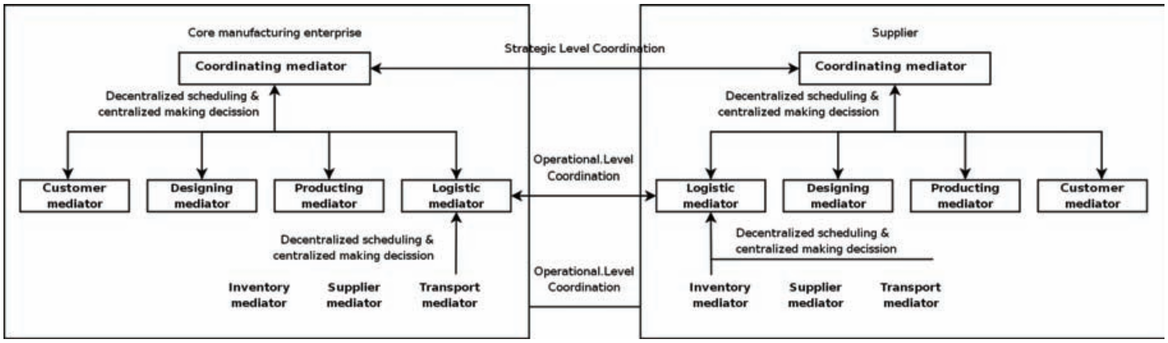


Figure 6. Reasoning process for cooperating agents

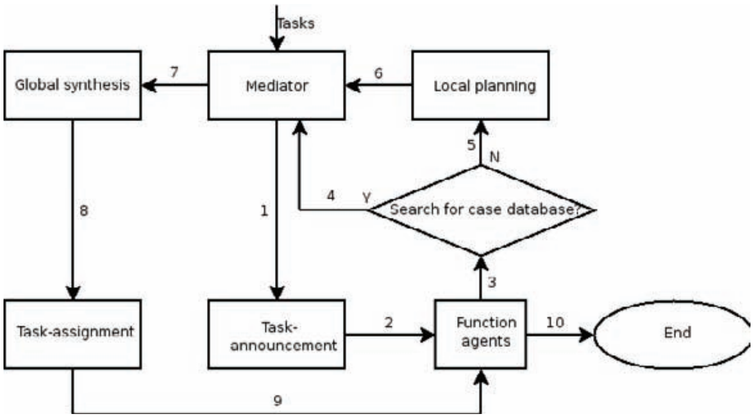

Figure 7. Classifications of DDM systems (Adapted from Schneeweiss, 2003)

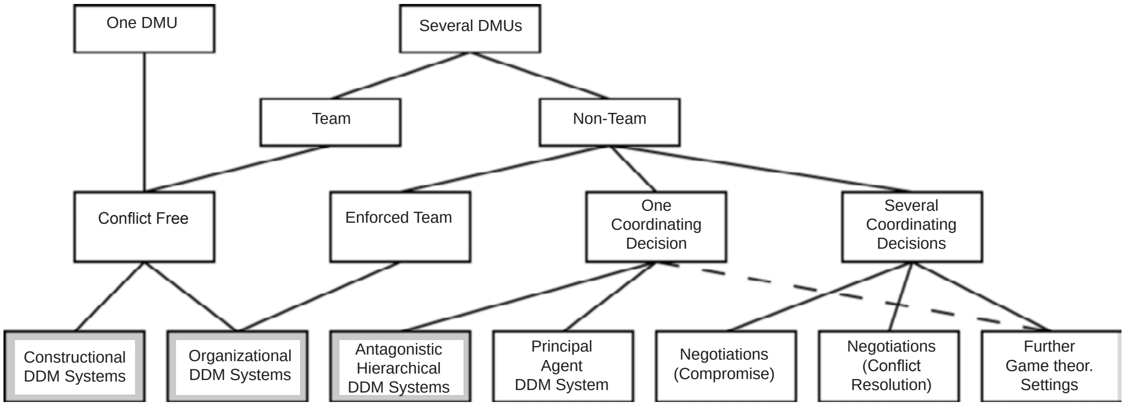


cost and limitations to achieve full information sharing, they prove that partial information sharing is more practical in real applications.

Sauer and Appelrath (2003) present an approach using teams of cooperating agents in a hierarchical as well as heterarchical way. Traditional hierarchical implementations lack incorporation of feedback from lower levels and possibilities of reactive scheduling, so the authors use a hierarchical and heterarchical approach. To simplify the generation of such a hierarchy of agents, they develop and describe a framework for scheduling agents and they use an example to illustrate how it is used to build teams of cooperating agents.

Distributed Optimisation / Resource Allocation

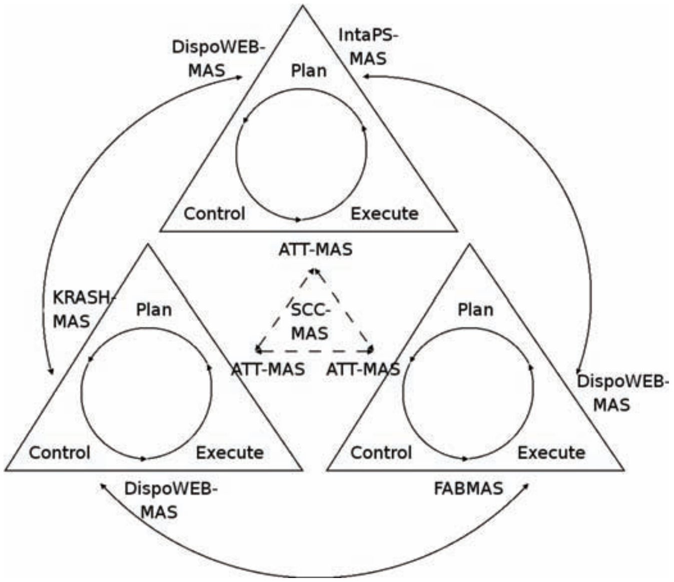
SCM is also often seen as a *distributed optimisation* and *resource allocation* problem. Schneeweiss (2003) describes a unified approach on distributed decision-making (DDM) by providing a general theoretical framework for it and characterizing the main directions or approaches in DDM in view of the general features of such a framework. He classifies DDM settings as shown in Figure 7 and discusses a general coordination scheme, showing how it might be specialized for particular DDM problems.

Silva, Sousa, Sa da Costa, and Runkler (2004) use ant colony optimization (ACO) for the supply chain. This algorithm builds a so-called “pheromone matrix”, an indirect record of the optimization steps, that is manipulated at all times during the optimization process. This concept is presented for a supply chain system with a logistic, a supplying and a distribution subsystem. After describing the general ACO framework, they implement the algorithm for each of the optimization problems and then they introduce the framework for the multi-agent platform, where the communication protocol is based on pheromone matrices updating.

Frey, Stockheim, Woelk, and Zimmermann (2003) discuss a MAS architecture based on production planning and control. They are integrating many individual projects: DISPOWEB for SCM scheduling, KRASH, IntaPS and FABMAS for shop floor production planning and control, and ATT/SCC for proactive tracking and tracing services. The integration is made by providing interfaces and gateways between these systems, as shown in Figure 8.

Smirnov, Sheremetov, Chilov, and Cortes (2004) use genetic algorithms (GA) for resource allocation. The proposed approach considers configuring as: (1) coalition formation and (2) product and resource allocation tasks in a multi-

Figure 8. Integration of the MAS projects by Frey et al. (2003)



agent environment. Their first approach uses GA to find a suboptimal solution applying the theory of games with fuzzy coalitions. Their second approach uses genetic algorithms directly and constraint satisfaction problem solving for resource allocation tasks. They use FIPA-compliant agents using ontologies for task description.

Moyaux, Chaib-draa, and D'Amours (2004) use game theory to analyze collaborative strategies in a forest supply chain. They use collaboration in an attempt to reduce the bullwhip effect, under the assumption that each company is one single agent using one of three ordering schemes, where each ordering scheme represents a level of collaboration. They run a simulation to evaluate each company's inventory holding and backorder costs and use the outcome of this simulation to build a game in the normal form, which is then analyzed using Game Theory. They identify two Nash equilibria incurring the minimum cost of the supply chain, both of which include collaboration between companies: collaborating companies have no incentive to stop collaboration.

Symeonidis, Kehagias, and Mitkas (2003) describe a multi-agent SCM system that acts mostly as a recommendation engine. It uses data mining techniques to discover new customer trends and dynamically incorporate the extracted knowledge into the company selling policy. Agents can be periodically retrained to improve their knowledge. In the paper, the architecture and development details of this system are presented and their application is demonstrated on a real test case.

Simulation of the SCM / Particular Assumptions

Another area of research is simulation of the SCM and/or particular frameworks. Web services, for example by Mi, Jianjun, Zunping, Yinsheng, and Binyu (2005) or by Hassan and Soh (2005), is a very commonly used technology. Mi et al. (2005) define a strategy for aggregating the agents, both normal and mobile agents, into the Web service architecture and the functionalities for them to control the business conducts. They also devise a UDDI ranking frame based on analysis of supply chain activities, deploying Web Service-oriented technologies and protocols for modeling, managing and executing business-oriented functionalities. Their framework is illustrated in Figure 9.

Figure 9. UDDI-based Web service framework

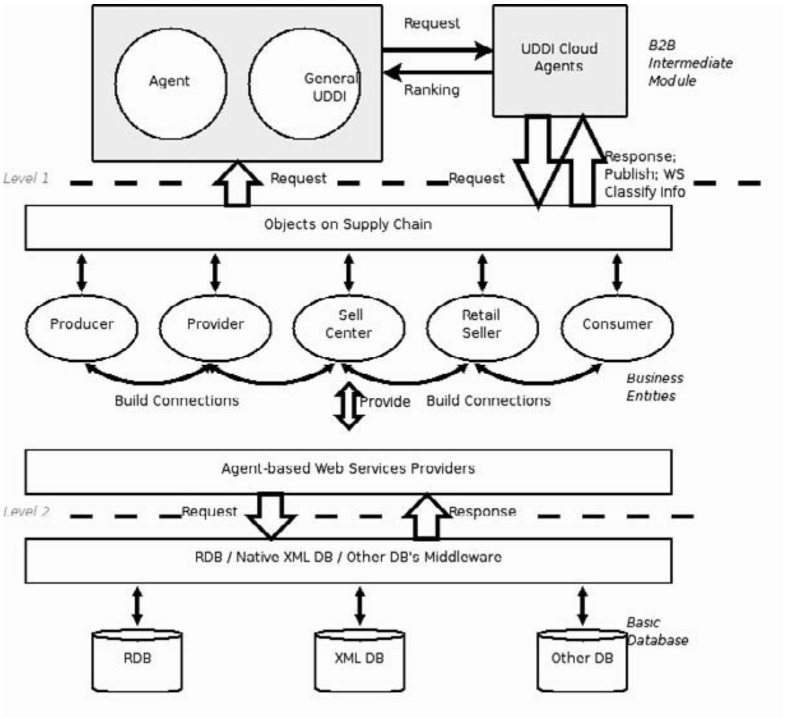


Figure 10. Structure of an agent as proposed by Hassan and Soh (2005)

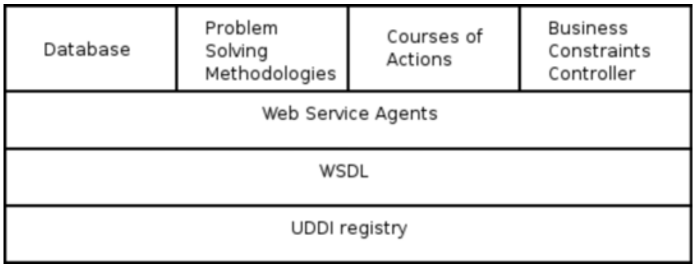


Hassan and Soh (2005) propose an agent structure to provide more agility to the supply chain in an attempt to overcome its traditional problems. They focus on two aspects of SCM: removing inefficiencies in supply chains by real-time knowledge sharing and automated supply chain configuration by negotiating methods being used by agents. They argue that Web services are not only easier to implement, but also take care of the problems of legacy application connectivity. Figure 10 shows how an agent is structured and placed in the supply chain net.

Web services are also examined by Maximilien and Singh (2005). The authors present a multiagent framework for dynamic Web services selection. Based on their trust model (2005) and on their architecture for autonomic Web service selection (2003), they provide a basis that incorporates providers' offering advertisements and consumers' preferences, but also enables the gathering and sharing of ratings of services. Based on the requirement that "trust should be self-adjusting", their application uses a service agent, which selects the suitable implementation of a particular service, according to the customer's policy. Their results show that the agents' trust assignments are dynamically adjusted, enabling agents to select the best policies, according to consumers' needs.

Qing and Renchu (2001) provide a review of modeling methodologies and model a distribution system in a supply chain. They consider the following approaches to modeling supply chain systems: (a) simulation-based method, (b) network design method and (c) rough-cut method. However, these traditional models are based on mathematical and statistical tools and rely on the assumption of linearity, while many phenomena in a supply chain are of non-linear nature. They model a distribution system based on a MAS, with agents configured as manufacturer, distributor, transporter, retailer and customer interconnected through the network.

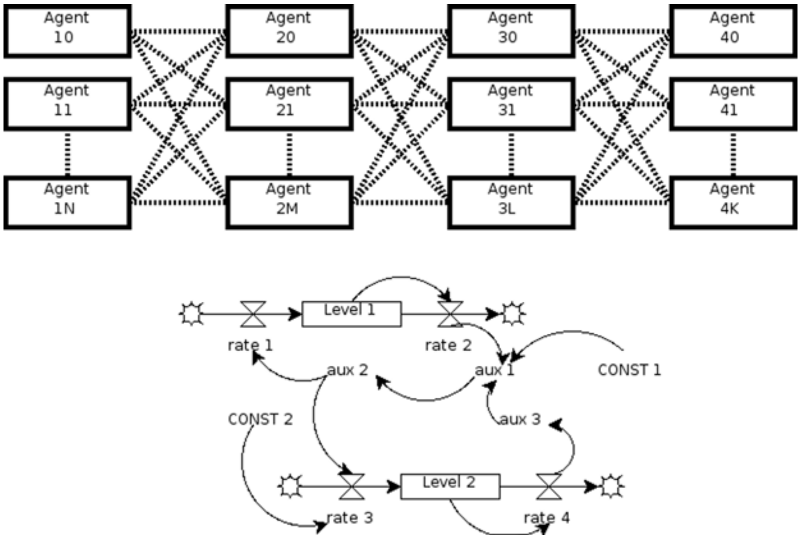
Schieritz and Groessler (2003) perform a study integrating agent-based and system dynamic modeling and make a distinction between the macro and micro level of a supply. Their approach discusses the strengths and weaknesses of system dynamics and discrete agent-based modeling and integrates these two methodologies. They model a supply chain with two levels of aggregation, as shown in Figure 11.

The macro level shows a network of agents that are potential supply chain participants, while the micro level shows the internal structure and functionality of each agent.

Giorgini, Kolp, and Mylopoulos (2006) propose architectural styles for MAS, which adopt concepts from organizational theories. They start by presenting organizational styles identified in Organization Theory and in Strategic Alliances. They detail the structure-in-5 and the joint venture as organizational structures and present four case studies, two for each structure. Each case study describes an existing company. They continue by presenting the software qualities that characterize MAS architectures and demonstrate the application of the two organizational styles they described using the classical mobile robot case study. They conclude by presenting a framework to select architectural styles with respect to their identified software quality attributes, based on a requirements-driven methodology.

Li and Feng (2003) propose a J2EE-based multi-agent platform, decomposing each function of the supply chain into groups of various agent

Figure 11. Macro and micro level of supply chain



types. In their platform, each group is formed by a scheduling agent which supervises several vertex agents. The enterprise's internal supply chain behavior is simulated by interaction among groups, while behaviors of different enterprises are coordinated by interaction among platforms. They think of their platform as "an effective tool for building the virtual organization of enterprises", designed to meet businesses' requirements for project information sharing, process integration and coordination of decisions.

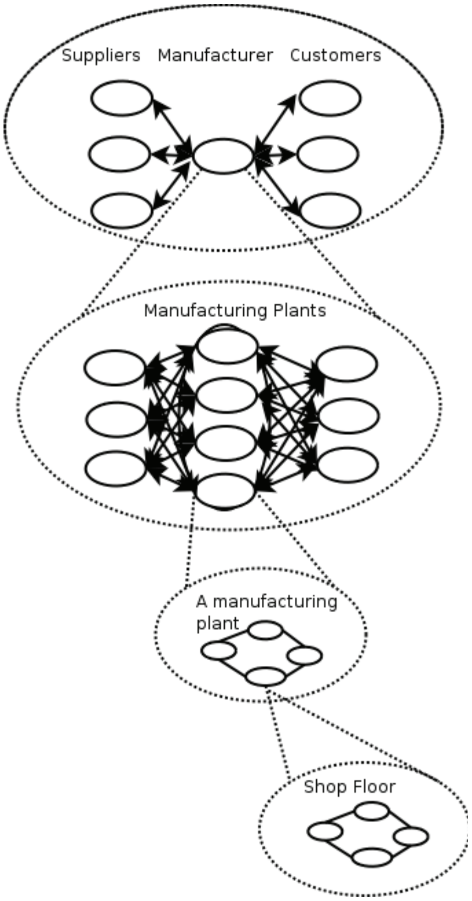
Nissen (2000) proposes a set of techniques and tools, aiming to integrate agent design for the supply chain into e-commerce. He models the enterprise supply chain process at user, supplier and contractor levels and designs the agents structure from above using Grafcets. Subsequently, he analyzes the supply chain of an operational enterprise and deploys a supply chain agent federation to demonstrate its effective performance along the supply chain. He states that his work facilitates the process of agent development, giving end users the potential to develop their own agents in an e-commerce context.

Goh and Gan (2005) construct a framework based on the requirement to enable dynamic interoperation of units within a supply chain. They argue that effective coordination of activities within the supply chain is inevitable for manufacturing excellence. To address this need, they identify the core requirement for activity coordination and construct a framework based on the requirement to enable dynamic interoperation of units within a supply chain for successful global manufacturing. Figure 12 illustrates their proposed framework.

Decision Making and Learning

Another approach on agent-based SCM is *decision making and learning.* Sheremetov and Rocha-Mier (2004) deal with collective intelligence as a framework for SCM. They consider a large multi-agent system where there is no centralized control and communication, but also, there is a global task to complete. Their proposed framework is focused on the interactions at local and global levels with the agents in order to improve the overall supply chain business process behavior. Learning consists of adapting the local behavior of each entity with the aim of optimizing a given global behavior. They use reinforcement learning algorithms at the local level and a Q-neural algorithm to optimize the global behavior. Their work demonstrates that the SCM problem is a good experimental field for the investigation and application of the Collective Intelligence theory.

Figure 12. The framework proposed by Goh and Gan (2005)



Guo and Mueller (2004) use knowledge models with historical and context information. Their approach is threefold: first, they develop a multi-agent architecture and learning algorithms that enable us to combine background models learned from history data with context-related knowledge about the current situation. Second, they use a large real data set to show that adding situated knowledge actually improves the performance of a supply chain decision support system. Third, for their settings they evaluate the degree to which agent-assisted decision support is actually usable/sufficient to improve human decision-making and to support automated decision-making in dynamic supply network management scenarios.

Simek, Albayrak, and Korth (2004) use reinforcement learning (RL) algorithms for procurement agents. They use the well-known Q learning algorithm of reinforcement learning in evaluating production orders within a SCM framework and making decisions. They introduce their SCM model and show that RL performs better than traditional tools for dynamic problem solving in daily business, but also show some cases where RL fails to perform efficiently.

Kwon, Im, and Lee (2005) use optimization and case-based reasoning (CBR) models on a Web services-based platform. They think that, despite the advancement of optimization techniques, this approach has not been fully extended to addressing more complicated problems such as revenue maximization and stochastic dimension. They compare the performance outcomes of the prototype system, which uses linear programming and mixed integer programming, with their optimization model shown in Figure 13 using a variety of scenarios.

Zhang and Xi (2005) discuss a decision support system for partner choice and measurement in a supply chain. Their study presents a perspective and technical framework based on decision support system and agents. This framework is shown in Figure 14. The model they propose exhibits basic characteristics of agents, that is, intelligence, flexibility, integration and collaboration, and it provides a technical support on partner choice decision and assessment.

Agent-Based SCM for Particular Supply Chains

Many researchers have modeled agent-based SCM systems for a particular supply chain, or under other particular assumptions. For example, Liu, Zhang, and Hu (2005) discuss a supply chain for a motorcycle corporation, Xue, Shen, and Wang (2005) present a framework for construction supply chains, and Yi, Kim, and Kim (2002) use a MAS simulation for a harbor supply chain.

Figure 13. MAS with CBR models on a web services-based platform

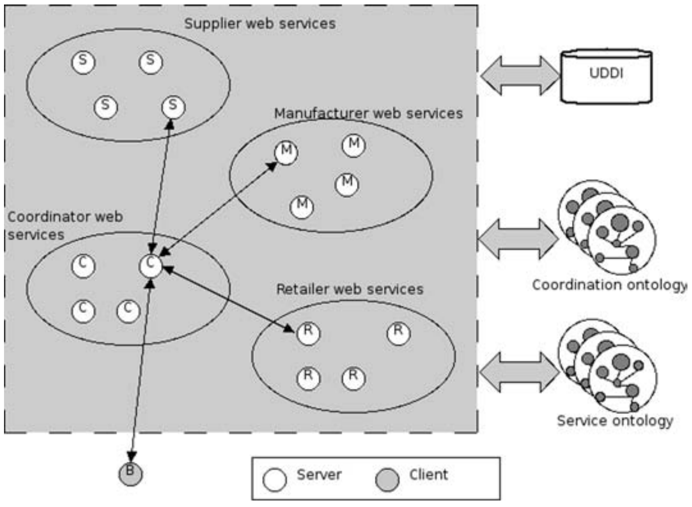


Figure 14. Decision support system for partner choice

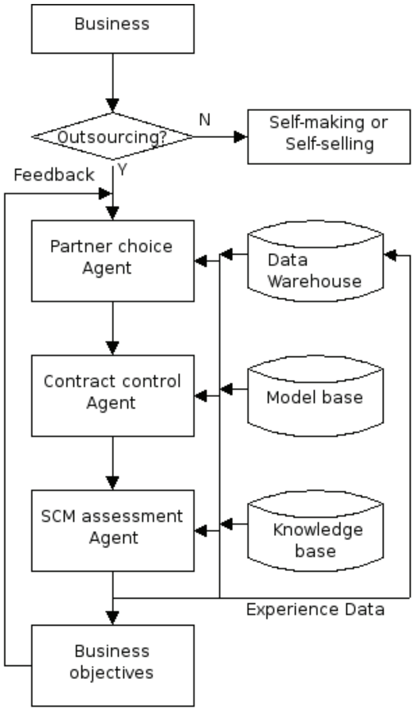

It is also worth mentioning some different approaches on the view of the supply chain. For example, Mangina and Vlachos (2005) emphasize the role of sales and marketing on a food supply chain, modeling it as illustrated in Figure 15. Unfortunately, though sales and marketing is undoubtedly a very important factor in SCM, it usually seems to be ignored in most traditional and newer SCM models.

Shuwang, Ren, Zhifeng, and Guangfu (2003) introduce the concept of a green supply chain, aiming to reduce or eliminate environmental impacts of products in their life cycle by preventing excess consumption of resources. The green supply chain is shown in Figure 16.

Bonura, Corradini, Merelli, and Romiti (2004) emphasize quality control, an important aspect that again seems to be missing from most supply chain models in bibliography. More precisely, they define the extended supply chain, to take quality control into account, as shown in Figure 17.

Figure 15. A food supply chain according to Mangina and Vlachos (Adapted from Mangina & Vlachos, 2005)

Figure 16. The green supply chain

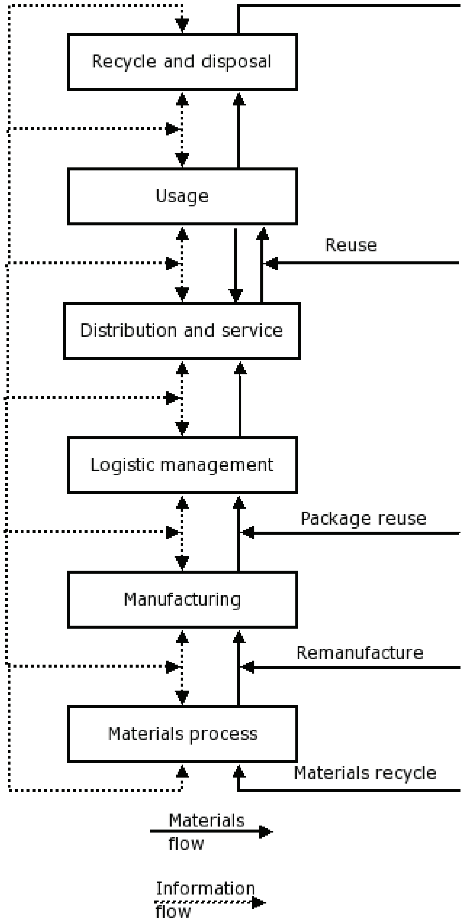

Figure 17. The extended supply chain

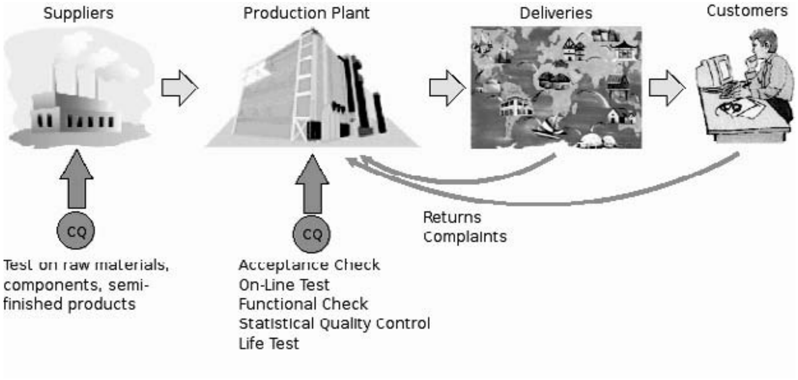


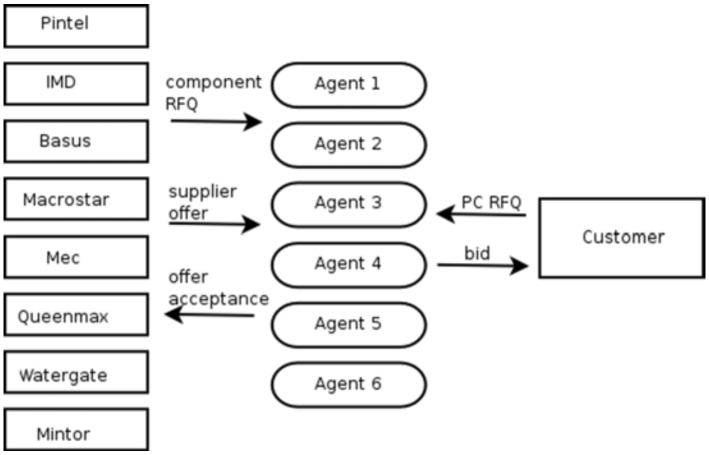
Failures in assembled products may be detected at many points of the product life, therefore an early diagnosis could depend on the retrieval of all significant information recorded along the extended supply chain. The basic idea proposed in this work is to define a society of Autonomous Agents created to support the traceability of components information in a federated enterprises environment.

Trading Agent Competition

Finally, the trading agent competition for SCM (SCM TAC) has given an important boost on SCM research. As described by Kiekintveld and Wellman (2005), in the TAC/SCM scenario, "six agents representing PC assemblers operate in a common market environment over a simulated year. The environment constitutes a supply chain, in that agents trade simultaneously in markets for supplies (PC components) and the market for finished PCs. Agents may assemble for sale 16 different models of PCs, defined by the compatible combinations of the four component types: CPU, motherboard, memory, and hard disk."

Figure 18 diagrams the basic configuration of the supply chain. The six agents (arrayed vertically in the middle of the figure) procure components from the eight suppliers on the left, and sell PCs to the entity representing customers, on the right. Trades at both levels are negotiated through a request-for-quote (RFQ) mechanism, which proceeds in three steps:

Figure 18. The TAC SCM game



- Buyer issues RFQs to one or more sellers
- Sellers respond to RFQs with offers
- Buyers accept or reject offers; an accepted offer becomes an order

Arunachalam and Sadeh (2004) provide a description of the 2003 SCM TAC, while Zhang and Zao (2004) discuss an economic model for it. They consider that the most important issues in the TAC SCM game are "daily production, product pricing and market-clearing price prediction" (p. 63), then differentiate the quantity competition (defined as a variation of Cournot model) and price competition (extension of Bertrand game). They argue "the results of their paper provide the solution to the decision-making problem of TAC SCM" (p.63).

Kiekintveld and Wellman (2005) analyze the 2004 SCM TAC, discussing differences in agents' behavior and strategic interactions, as well as the different ways that the agents responded, as these are the most important factors that shaped market prices and determining agents' classification in the competition.

Jordan, Kiekintveld, Miller, and Wellman (2006) compare the results of the 2005 competition to the games played in previous years by considering market efficiency, sales competition, and the bullwhip effect. They present a way to measure and compare market efficiency in the game to find "statistically significant increases in intra-tournament market efficiency, whereas agents are generally decreasing in manufacturer market power" (p. 99).

Borghetti, Sodomka, Gini, and Collins (2006) present a way to evaluate TAC SCM agents' performance, using benchmarking tools that manipulate market environments based on market pressure. They claim that these tools can be used to inspect agents' behavior and check for possibly unwanted behaviors under special conditions, and use them for their agent MinneTAC.

Of course, many publications have been made about specific TAC agents, for example MinneTAC by Gini, Ketter, Kryzhnyaya, Damer, McGillen, Agovic, and Collins (2004), Botticelli by Tschantz, Benisch, Greenwald, Grypari, Lederman, and Naroditskiy (2004), or TacTex05 by Pardoe, Stone and VanMiddlesworth (2006). Toulis, Kehagias, and Mitkas (2006) present their agent Mertacor, which participated in the 2005 TAC and finished third in the final round. This agent is based on "a combination of OR, statistic and heuristic modeling techniques" (p. 1198). Its main advantages are its robust inventory management system and flexible learning models that correctly captured the dynamics of the TAC market, while heuristics also played an important role.

Overall Problems

According to Goh and Gan (2005), the fundamental issue of a supply chain, namely "interoperation among suppliers, manufacturers and customers" (p. 330), is still not addressed. Smooth negotiation and coordination mechanisms, optimization to generate optimal solutions, developing adaptive systems and emphasizing on a real-time information sharing and updating are significant, but not sufficient to enable global manufacturing when the fundamental issue is not addressed.

Jiao et al. (2006) observe that "most current MAS approaches assume that a fixed number of entities share a common target in a closed environment" (p. 239). However, on a real-case global manufacturing supply chain, this is not always the case. Not only each supply chain entity has its own interests, but also there is no obligation for any company to remain within the supply chain for a certain period of time. Moreover, all agents should be loosely coupled and not coordinated by any central controller.

However, even after having considered the aforementioned problems, the huge potential of agents and MAS is still not exploited. Agents are powerful decision-making entities, capable of taking over complex tasks. On the other hand, when it comes to SCM, their usage is still mostly limited to recommendation rather than autonomous functionality.

Another area of research on SCM MAS can deal with evaluating and increasing the agents' intelligence. Very little research has been done on intelligence itself (Sheremetov & Rocha-Mier, 2004) and nobody has addressed the issue of possibly evaluating it, even in specific environments or benchmarks. The trading agent competition is a benchmark only for single agents. It evaluates their performance under very particular conditions, which are quite distinct from real-life situations. On the other hand, SCM requires intelligent solutions, as it deals with critical and complex problems.

The supply chain can be so sensitive that even very small deviations or fluctuations on one part can badly influence, not only this particular part, but also the whole chain. Current solutions have limited capability to learn from their past (especially in an unsupervised way), which is essential in an efficient MAS. Apart from this, efficiency is usually evaluated in terms of increased profit, which might be the desired result and an easily measurable quantity, but it is a rather short sighted approach and can only relate to the structure and the essence of the MAS by experimenting or trial-and-error. The real problem, however, is the agents' intelligence itself, as well as the intelligence of the whole MAS. This issue is usually not faced and the MAS intelligence, or even its performance, is hardly evaluated in depth. As a result, one can easily see the need for research on this topic.

CONCLUSION

Current trends in SCM demand customization, high quality, flexibility and customer-service policies in a highly competitive environment. This has emphasized the need for more flexible, reliable and powerful SCM systems. Agent-based technology, with its inherent capabilities for distributed problem solving, flexibility and handling large amounts of data, provide an ideal solution to this problem. However, this technology is still a large area of research, which shows the lack of not only a commonly deployed system, but also of a unified approach on this area.

The most important areas of research today are negotiation and cooperation, distributed optimization and resource allocation, decision making and learning, as well as particular frameworks and simulation. Many researchers have modeled SCM systems based on a particular supply chain or suggested enhancements to the supply chain, such as the green supply chain or, more commonly, the agile supply chain.

However, most SCM products today are designed to be used in only one company, and they are designed for recommendation rather than making their own decisions. On the other hand, no evaluation is made on the agents' performance and intelligence. This indicates a large potential for future research on this area, promising fruitful results.

Chapter 3.3

Application of Agent-Base Technology as Coordination and Cooperation in the Supply Chain Based E-Business

Golenur Begum Huq
University of Western Sydney, Australia

Robyn Lawson
University of Western Sydney, Australia

ABSTRACT

This chapter explores the utilization of a multi-agent system in the field of supply chain management for electronic business. It investigates the coordination and cooperation processes, and proposes and discusses a newly developed model for an enhanced and effective cooperation process for e-business. The contribution made by this research provides a theoretical solution and model for agents that adopt the enhanced strategy for e-business. Both large organizations and SMEs will benefit by increasing and expanding their businesses globally, and by participating and sharing with business partners to achieve common goals. As a consequence, the organizations involved will each earn more profit.

INTRODUCTION

Today's Internet-connected world has created an enormous revolution among business organizations. Nowadays, running a global business electronically is one of the most important emerging issues. Many researchers and software developers have been investigating and developing software tools and mechanisms that allow others to build distributed systems with greater ease and reliability for conducting e-business. When a computer system acts on our behalf, it needs to interact with another computer system that represents the interests of another party, and these interests are generally not the same. In this context, Wooldridge (2002) specifies:

> *It becomes necessary to endow such systems with the ability to cooperate and reach agreements with the other systems, in much the same way that we cooperate and reach agreements with others in everyday life. This type of capability was not studied in computer science until very recently.* (p. 3)

Traditional purchasing and selling for business-to-business (B2B) and business-to-consumer (B2C) have been conducted through different complex processes involving negotiation, as well as cooperation and coordination. It was quickly realized that e-commerce represents a natural, and potentially very lucrative, application domain for multi-agent systems. Artificial intelligence (AI) has been largely focused on the issues of intelligence in individuals, but surely a large part of what makes us unique as a species is our social ability. Not only can we communicate with one another in high-level languages, we can cooperate, coordinate, and negotiate with one another. As many species have a strong social ability (e.g., birds) like this, we also need cooperation and coordination in multi-agent systems to conduct fruitful, successful, and sustainable e-business.

It has been found that cooperation and coordination are important issues in conducting e-business. In recent years, there have been many research studies in e-business negotiation, but there is little work in e-business negotiation through cooperation and coordination. For example, large organizations mostly have enough products to sell. On the other hand, small and medium enterprises (SMEs) that are suffering from a lack of capital cannot compete with large organizations. However, some SMEs want to purchase products from large organizations and sell them to their customers. Another example is supply chain management (SCM) where at each and every stage (for instance, procurement of material, transformation of material to intermediate and finished goods, and distribution of finished products to customers) cooperation and coordination are needed. In these cases, they can cooperate with each other by exchanging products, and a deal between them can be made because both participants are able to "fine-tune" their profit. That means they can work together to achieve particular goals.

Therefore, if we can perform this type of activity electronically, it will be easier and faster, and, at the same time, very complex issues can be avoided. To perform these activities electronically using a cooperation and coordination process, models need to be investigated for performing flexible and reliable tasks. Many different disciplines including sociology, political science, computer science, management science, economics, psychology, and system theory are dealing with fundamental questions about coordination in one way or another. Furthermore, several previous writers have suggested that theories about coordination are likely to be important for designing cooperative work tools (Finnie, Berker, & Sun, 2004; Holt, 1988; Winogard & Flores, 1986). Therefore, it is possible to develop computer-supported cooperative work with the prospect of drawing on a much richer body of existing and future work in the application of multi-agents in supply chain based e-business.

The main objective of this chapter is to explore the operation of a multi-agent system in supply chain management for electronic business. It focuses on the coordination and cooperation processes, and discusses a newly developed model for an enhanced and effective cooperation process for e-business. The main contribution of this research is a theoretical solution and the model for agents that adopt this strategy for their e-business transactions. Both large organizations and SMEs will benefit, as the strategy will enhance their global business by participating and sharing with other businesses to achieve common goals. As a consequence, the organizations involved will be more profitable and competitive.

The chapter is organized as follows: first, factors in conducting e-business are discussed.

Then agent-based technology is outlined as a multi-agent system that is necessary for a supply chain system. A definition/theory of coordination is introduced, and some related work on coordination and cooperation is reviewed. The next section discusses cooperative problem-solving processes. Then a theoretical model and architecture on coordination and cooperation is explained in the context of trading agent competition supply chain management (TAC/SCM). The concluding section provides an overview of the chapter.

FACTORS IN CONDUCTING E-BUSINESS

The following factors have been identified in conducting e-business:

General Problems

- **Finances:** It has been found that some SMEs do not have enough resources to conduct e-business; however, they are particularly interested in being involved. Therefore, large organizations and SMEs have a good opportunity to work together to conduct global e-business.
- **Price war:** When a buyer seeks goods through an Internet catalogue, for various reasons, the price of some products are too cheap, while others are too expensive. As a result, customers feel a level of confusion about making the right decision.
- **Postpurchase/local customer service:** It has also been found that if somebody buys goods from the Internet, the company may not have a local retailer in that city. In this case, if any problem is found with the goods, postpurchase/local customer service becomes a complex issue to solve. As a result, some customers are not interested in buying goods from the Internet. Therefore, currently, local retailers need to stock similar goods. Moreover, to conduct e-business globally, many retailers need to participate. For that reason, cooperation is required for transactions with large organizations and with SMEs.
- **Lack of a pricing strategy:** In the real world, a pricing strategy is an important issue. To develop an effective pricing strategy, sometimes an incentive like a discount is needed. This is possible when a manager thinks its time to give a discount via a special promotion or to clear old stock. It is also possible to implement a pricing strategy in the online world.
- **Lack of customer satisfaction:** From the above points, customers can feel dissatisfied.

Problems in Supply Chain Management

- **Lack of information sharing:** Information sharing is one of the most significant issues in SCM and plays an important role. As for example, a retailer such as K-Mart may place huge orders for a particular product for their planned promotion. If suppliers had prior knowledge of this promotion, they also could plan for a production increase.
- **Lack of information access limitation and lack of transparency:** At times, users are unable to find an exact outcome due to restricted access to some information. This results in a lack of transparency. As a result, it obstructs making the right decision within the right time frame.
- **Lack of sharing the benefits of coordination equitably:** The coordination benefits are not being shared equitably in the supply chain, which is a challenge (Chopra & Meindl, 2003, p. 503). Consequently, if agents agree to work together, the problem can be resolve accordingly.

- **Lack of agreement to work together:** Agreements are not generally found in real-world SCM. This is due to one stage of the supply chain having objectives that conflict with other stages that generally have different owners. For this reason, the main objective of each owner is to maximize its own profit. As a result, this diminishes the overall supply chain profit. Today, the supply chain is comprised of potentially hundreds or even thousands of independently owned enterprises. For instance, Ford Motor Company has thousands of suppliers from Goodyear to Motorola. To make an overall profit for the supply chain, the partners need to reach an agreement for working together. This can lead to the overall profit being maximized. Therefore, each participant in the cooperative venture will benefit accordingly.
- **Lack of communication among business organizations/supply chains (level of product availability):** Good communication can yield good results. Companies in the supply chain often do not communicate through the various stages of the supply chain and are unwilling to share information. As a result, companies become frustrated with the lack of coordination.
- **Timely manner:** Sometimes, some information is not accessible in a timely manner. Therefore, this can obstruct the right decision being made in a timely fashion.
- **Lack of use of technology to improve connectivity in the supply chain.**
- **Lack of trust:** Because of the above obstacles, trust is decreased and frustration appears at various stages of the supply chain, making coordination efforts much more difficult. On the other hand, high levels of trust involve the belief that each stage is interested in the other's welfare and would not take actions without considering the impact on the other stages.

If the organizations work together electronically towards some shared common goal, then there is a possibility that the problems defined above can be fully or partially overcome.

Benefits of Conducting E-Business

The following are the expected benefits in conducting e-business when organizations work together:

- **Reasonable and flexible price:** If different organizations work together, they will be able to sell goods at a reasonable and leveled price. An e-business can easily alter the price of the products in one entry of the database, which is linked to its Web site. According to current inventories and demand, this type of ability allows an e-business to increase revenues by adjusting prices. Airline tickets are a good example where low-cost available tickets are shown on a Web site for flights with unsold seats. This can reduce the price war between competitors.
- **Reliable product:** By working together, it is also possible to sell reliable products to customers.
- **Globally available and less transportation cost:** Because organizations can work together globally, then the goods can also be available globally. For example, a customer in Thailand can place an order on the Internet. If there is a warehouse situated in Thailand for that item, then it is easier to get the item; otherwise the seller would need to ship the item. In the case of limited stock, it might not be profitable to have an item available globally when there are high transportation costs. Consequently, by globally working together, organizations can earn more profit and lower transportation costs.
- **Reduce operational cost:** Operating costs can also be decreased if a manufacturer is using e-business to sell directly to customers,

as there are fewer supply chain stages for the product as it makes its way to a customer.

- **Reduce delivery time:** If a warehouse exists locally, then this will also lower the delivery time, in addition to delivery costs.
- **Enhanced customer service locally:** If a problem arises for the product, then it can be serviced locally. As a result, a customer will feel more confident in buying further products.
- **Fewer inventories:** E-business can reduce inventory levels and costs by improving supply chain coordination and creating a better match between supply and demand. For example, Amazon.com requires fewer inventories than local retail bookshops. As a result, e-business reduces inventory cost.
- **24-hour access from any location:** Customers are able to place their order any time day or night and from any location through the Internet. Therefore, it is possible for an organization to increase sales.
- **Maximum profit:** All of the above points have the potential to maximize profit for organizations.
- **Expansion of business:** By working together, large organizations have the opportunity to expand their business with the cooperation of SMEs. Thus, SMEs also have the opportunity to share tasks with large organizations. Ultimately, through collaboration, organizations can collectively increase their profits.
- **Duplication of work:** Reducing the duplication of work can save both time and money. For example, a pricing strategy for a product can be negotiated electronically, and then can be used for the collaborating organizations.

In summary, factors in conducting e-business can be categorized as general problems associated with the operation of the organization (finances, pricing strategy, and customer service), and more specific problems in managing the supply chain (lack of information sharing and access, and lack of agreement to work together). To examine the supply chain further in an electronic context, the use of agent-based technology is investigated.

AGENT-BASED TECHNOLOGY

Agent-based technology has emerged as the preferred technology for enabling flexible and dynamic coordination of spatially distributed entities in a supply chain. Authors have defined agents from different perspectives. The main focus of this chapter is a discussion of software intelligent agents, and the definition presented is adapted and based on Wooldridge and Jennings (1995). An agent is a computer system that is situated in a particular environment, and is capable of *flexible autonomous actions* in that environment in order to meet its design objectives. Autonomy is a complicated concept, but it can be simply explained that the system should be able to perform without the direct intervention of humans (or other agents). At the same time, it should have control over its own actions and internal state. The meaning of *flexible actions* is that the system must be:

- **Responsive:** Agents should be able to perceive their environment, which may include the physical world, a user, a set of agents, or the Internet and can respond timely according to changes that occur in it.
- **Proactive:** Agents cannot only perform based on their environment, but should also be able to exhibit opportunistic, goal-oriented behavior by taking the *initiative* according to their intention.
- **Social:** Agents should be able to interact with one another as humans do, based on their own problem solving ability to help others with their activities, as required.

Therefore, if the above characteristics exist in a single software entity, then we can consider it is an intelligent agent that provides the capability of the agent paradigm. This paradigm is different from the software paradigm, for instance, object-oriented systems, distributed systems, and expert systems.

Multi-Agent Systems

By using agent-based systems, the key abstraction used is that of an agent. It might be conceptualized in terms of an agent, but implemented without any software structures corresponding to agents at all. A situation exists with an agent-based system, which is designed and implemented in terms of agents. Again, a collection of software tools exist that allow a user to implement software systems as agents, and as societies of cooperating agents.

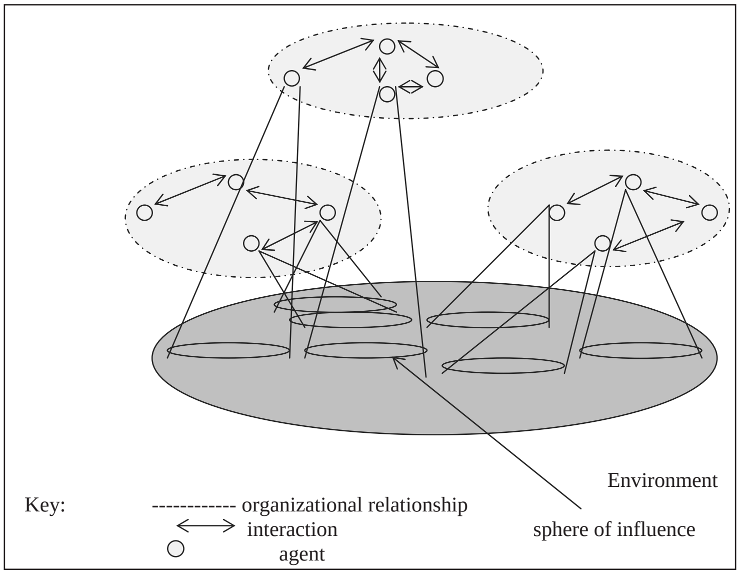
There is no such thing as a single agent system. Therefore, we should always consider the system of agents as a multi-agent system, where the agents will need to interact with each other and cooperate as required. Jennings (2000) illustrates the typical structure of a multi-agent system (see Figure 1). The system consists of a collection of agents that are able to interact with each other by communication. The agents perform their activities in the environment and different agents have different "spheres of influence," and have control over, or at least are able to, influence different parts of the environment. In some cases, the spheres of influence may coincide or may require dependency relationships between the agents. For instance, two robotic agents have the ability to move through the door, but they may not be able to move simultaneously. Another example might be "power" relationships, where one agent is the "boss" of another agent.

Dependency Relations in Multi-Agent Systems

In multi-agent systems, the agents need to be dependent in some way to be able to perform their tasks. The basic idea of such dependency was identified by Sichman and Demazeau (1995) and Sichman (1994) and there are a number of possible dependency relations:

- **Independence:** In this case, no dependency exists between the agents.

Figure 1. Typical structure of a multi-agent system (Jennings, 2000)



- **Unilateral:** This type includes one agent depending on the other agent, but not vice versa.
- **Mutual:** Both agents depend on each other according to the same goal.
- **Reciprocal:** The first agent depends on the other for a goal, while the second agent depends on the first agent for another goal. These two goals may not be same, and mutual dependency implies reciprocal dependence.

The above dependency relations may also be qualified by whether or not they are *locally believed* or *mutually believed*. The locally believed dependency is when the agent believes the dependency exists, but may not believe that the other agent is aware of it. The mutual belief is when one agent believes that the dependency exists and the other agent is aware that this dependency exists.

The suppliers, manufacturers, retailers, and consumers are all in a supply chain related network, which needs proper, efficient, and timely coordination, cooperation, and negotiation. Therefore, overall benefits will be achieved when applying multi-agent systems to improve efficient performance among these entities.

In summary, the use of a multi-agent system has emerged as a flexible and dynamic method for coordination of spatially distributed entities in a supply chain. Efficient performance is possible between business partners in an online environment through coordination and cooperation.

DEFINITION/THEORY OF COORDINATION

We all have a common understanding about coordination and cooperation from our everyday lives. At times, we need to coordinate and cooperate with others for a variety of reasons. When we watch a winning soccer or cricket team or high-quality synchronized swimming, we notice how well the program is organized. In contrast, we could spend hours waiting to return something, or when we thought we had booked an airline ticket that had already been sold, or when a company repeatedly fails to make its expected profit, then we may become very aware of the effects of poor coordination. The dictionary definition of coordination is: *the act of working together harmoniously*. It is essential that an intention to work together "harmoniously" includes handling conflict as well as cooperation.

Malone and Crowston (1990) specified that computer science does not deal primarily with people; however different computational processes must certainly "work together harmoniously," and as numerous researchers have pointed out, certain kinds of interactions among computational processes resemble interactions among people (e.g., Fox, 1981; Hewitt, 1986; Huberman, 1988; Miller & Drexler, 1988; Smith & Davis, 1981). Malone and Crowston's (1990) observation is not completely correct, due to the fact that software developers implement computational processes according to user requirements. Therefore, it is possible to develop software agents, which will perform coordination tasks for human beings in order to facilitate e-business.

Literature Review: Cooperation and Coordination

Finnie, Berker, and Sun (2004) proposed a multi-agent architecture for cooperation and negotiation in supply networks (MCNSN), which incorporated a learning capability for some agents, and discusses the issues that need to be addressed for coordination, cooperation, and negotiation. They mainly concentrate on case-based reasoning (CBR) as a framework for learning the best strategy between buyers and suppliers and also focus on customer relationship management (CRM). They did not concentrate on business-to-business (B2B) cooperation and coordination.

Beck and Fox (1994) developed the mediated approach to coordinate the supply chain, which has a global perspective and gathers information on commitments from other agents when there is an event disrupting supply. They conducted an experiment, which showed that the mediated approach has a better performance than the negotiation approach. Although the multi-agent approach in SCM has received considerable attention, a number of unresolved questions remain in cooperation and negotiation in supply networks (Schneider & Perry, 2006). A multi-agent system (MAS) was considered by Finnie and Sun (2003) in such a way that only some agents had the CBR capability.

Several reasons have been identified for multiple-agent coordination (Jennings, 1990; Nwana, 1994):

- **Dependencies between agents' actions:** Interdependencies occur when goals undertaken by individual agents are related, either because local decisions made by one agent have an impact on the decisions of other community members (selling a commodity depends on a salesperson for customer service and customers), or because there is a possibility of a clash among the agents (two cars may simultaneously attempt to pass on a narrow road, resulting in the risk of a collision). Ultimately, dependencies prevent anarchy or chaos and coordination is necessary among the agents to achieve common goals.
- **Meeting global constraints:** Commonly, some global constraints exist that a group of agents must satisfy if they agree to participate. For instance, a system of agents allocating components to organizations may have constraints of a predefined budget. Similarly, if one organization fails to sell their products for some reasons, then other organizations can coordinate to minimize the problem.
- **Distributed expertise, resources or information:** All agents may not have the same capability, but have different resources and specialized knowledge in various areas. For example, treating a patient in the hospital requires different expertise (anaesthetists, surgeon, heart specialist, neurologist, ambulance personnel, nurse, and so on), resources (equipment like an x-ray machine and ultra sound machine) and information (different reports) to diagnose the patient. In this type of case, it is not possible to work individually. Therefore coordination and cooperation are both necessary to solve the entire problem.
- **Efficiency:** When an individual agent works independently, time can be a factor. If another agent helps to finish that work, then it can be completed twice as fast. For instance, if two people plant 50 seedlings each, then 50% of the time is saved.

Nwana, Lee, and Jennings (1996) specified that coordination may require cooperation, but it would not necessarily need cooperation among all agents in order to get coordination. This could result in disjointed behavior, because for agents to cooperate successfully, they must maintain models of each other as well as develop and maintain models of future interactions. If an agent thinks that other agents are not functioning correctly, then disjointed behavior may still give a good result. Coordination may be completed without cooperation. For example, if somebody drives very close towards your lane, you might get out of the path, which coordinates your actions with the other person, without actually cooperating. To facilitate coordination, agents need to cooperate with others by sending communication messages. This results in agents having the opportunity to know the goals, intentions, outcomes, and states of other agents.

In summary, coordination and cooperation are practiced daily in physical world transactions, and the notion of creating a similar environment in the virtual world is not a trivial problem. Electronic cooperative problem solving using a multi-agent system is a complex challenge to address.

COOPERATIVE PROBLEM SOLVING

In the context of cooperation in multi-agent systems, Franklin and Graesser (1997) offer a cooperation typology (see Figure 2) with a number of characteristics. If each agent pursues its own agenda independently of the others, then it is termed an independent multi-agent system. There are two types of independent multi-agent systems: (a) discrete and (b) emergent cooperation. The discrete system involves agents with agendas that do not have any relation to each other. Therefore, discrete systems do not have any cooperation. Becker, Holland, and Deneubourg (1994) specified that the puck gathering robots form an independent system, each moving in a straight line until an obstacle is encountered according to its agenda, it then backs up and goes in another direction. From an observer's point of view, this puck gathering is an emergent behavior of the system, as it looks like the agents are working together. However, from the agents' point of view, they are not working together. The agents only carry out their individual tasks.

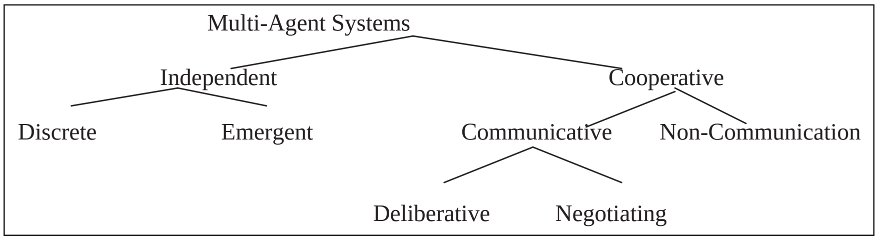
On the other side of the independent system is the agent who is cooperating to its own agenda with other agents in the system (*cooperative systems*). This type of cooperation can be either communicative or noncommunicative. Communicative systems intentionally communicate with the other agents by sending and receiving messages or signals. The noncommunicative systems are those in which the agents coordinate their cooperative activity by observing and reacting to the behavior of the other agents, for example, lionesses on a hunt (Franklin, 1996). Intentional communicative systems are divided into two categories: (a) *deliberative*, where agents jointly plan their actions to achieve a particular goal; and such cooperation may, or may not entail coordination; and (b) *negotiating*, where agents act like deliberative systems, except that they have added challenge of competition.

Doran and Palmer (1995) offer a viewpoint that specifies cooperation as a property of the actions of the agents involved. Thus, given a multiple-agent system in which the individuals and the various subgroups therein may be assigned one or more goals, possibly implicitly, then cooperation occurs when the actions of each agent satisfies either or both of the following conditions:

1. Agents have an implicit common goal (cannot be achieved in isolation) and actions tend towards that goal.
2. Agents carry out actions that enable or achieve their own goals, and also the goals of the other agents.

This definition does not require that the goals be explicit within the agents. For instance, two robots carrying a large object jointly, which is an example of the definition of the variant (1) assume that both have the goal of the moving object. If

Figure 2. Cooperation typology (Adapted from Franklin & Graesser, 1997)



two robots are building two towers separately with different colored bricks, then if one of the robots finds colored bricks that match the other robot, it passes them to the other robot, which is an example of the variant (2). Therefore, agent developers need to know the more specific tasks and choices of actions to cooperate and achieve the intended goal.

The Cooperative Problem Solving Process

Wooldridge and Jennings (1999) developed a model that consists of four main stages:

a. **Recognition:** Where an agent is identified for potential cooperation.
b. **Team formation:** Where the agent applies for assistance.
c. **Plan formation:** Where the newly-formed collective agents attempt to prepare a joint contract.
d. **Execution:** When members of the team play out the roles they have negotiated.

Some questions arise in regard to the above stages:

1. Are the agents performing their task properly?
2. Has an agent left or decommitted in the middle of its task?
3. If it has, then who will complete that task?
4. Who will coordinate these tasks?

Gaps in the cooperation process have been recognized, and this research has identified that two more stages are necessary. The additional stages consist of *monitoring* and *post-execution evaluation* to support the completion of the cooperation activity. The monitoring stage will provide progress reports of the agents' tasks, and the evaluation stage will generate the overall result of the cooperative work. These six stages, four identified by Wooldridge and Jennings (1999) and two identified by this research, are discussed in the following section.

Recognition Stage

This stage commences when an agent in a multi-agent environment realizes that it has a common goal, and identifies the potential for cooperative action. Reasons for recognition include when an agent thinks that it is not able to complete the goal in isolation, or believes that cooperative actions can achieve that goal. For example, a supplier agent has excess goods in stock, but cannot sell these without the help of proper buyers. Therefore, cooperation is needed to achieve the goal. Alternatively, a large company may be able to achieve its goal but does not want to in isolation. This large company believes that if another company works with it, then it would be more beneficial. For example, a small company does not have enough capital to do business properly and a large company does, and wants to expand its business globally. This large company is looking for another company so that it can achieve its goal. Therefore, if the small company and large company work together, then the cooperative actions can provide good results for both companies more quickly and more accurately.

In regard to the above situation, the authors categorize the agents in the following manner:

Definition 1. Types of the agents

a. **Able agent:** Those agents that prefer to work with the group.
b. **Unable agent:** Any agent that does not prefer to work with a group.
c. **Partially able agent:** Those agents that prefer to cooperate and commence to do work, but cannot complete the task.

If an agent has the ability to do the task in the environment, then it is favorable to complete the task.

Theorem 1. An Able agent finishes its task if and only if the environment (*En*) is favorable, which can expressed from the definition as:

$Able_{ag}\ Favourable\ En \rightarrow \text{Achieve goal}$

Proof. Assume that an agent is going to do its task, which is possible if its surrounding environment is favorable to complete its task. On the other hand, because this agent has the ability to complete its task, it can complete it successfully. In the case of an Unable agent, we can introduce the following theorem:

Theorem 2. An Unable agent cannot finish its task even if its environment (*En*) is favorable, which can be expressed:

$Unable_{ag}\ Favourable\ En \rightarrow \neg\text{Achieve goal}$

In regard to cooperation, a set of able agents will complete their task.

Theorem 3. A set of able agents finish its tasks if and only if the environment (*En*) is favorable, which can be formalized as:

$Able\ ag_i\ Favourable\ En \rightarrow\ \text{Achieve goal}$

Theorem 4. A set of able agents cannot finish their tasks although the environment (*En*) is favorable can formalized as:

$Unable\ ag_i\ Favourable\ En \rightarrow \neg\text{Achieve goal}$

Therefore, it has been identified that agents are able and unable to have the potential for cooperative work. Then, it needs to go to the next stage of the cooperation process.

Team Formation Stage

After an agent identifies the potential for cooperative action with respect to one of its goal, what will the rational agent do? Wooldridge and Jennings (1999) proposed that an agent will attempt to *solicit assistance* from a group of agents that it believes can achieve the goal. If the agents are successful, then each member has a nominal commitment to collective action to achieve the goal. The agents have not undertaken any joint action in this stage; they are only aware of being able to act together. Actually, in this stage, there is no guarantee for successful forming of the team, only an attempt to form a team. The able agents will attempt to do some action α to achieve at least some goal. Therefore, it can be formalized as:

Theorem 5. $\text{Happens}\{\text{Attempt}\ Able\ ag_i\ \alpha\} \rightarrow$ Achieve goal

The characteristics of the team building can assume that it is mutually believed that:

1. The group can jointly achieve the goal.
2. Each agent in the group is individually committed to carry out its task towards the goal or failing that, to at least cause the group to achieve the goal.
3. The individual agent has an individual goal.
4. There is a common goal which is jointly achievable.

The main assumption about team formation is that all agents attempt to form a group, and the group believes that they will have individual commitments and can jointly complete their task. If team building is successful, then it will proceed to the next step.

Plan Formation Stage

In this stage, after successfully attempting to solicit assistance, a group of agents have nominal commitment to collective action. This action will not be commenced until the group agrees on what they will actually do.

From the previous section, the authors have found that to perform collective action, it is assumed that the agents have a common belief that they can achieve their desired goal. The agents believe that there is at least one action known to the group, which will take them "closer" to the goal. Therefore, the possibility is many agents that know the actions of the group carry out the task in order to take them closer to the goal. In addition, in some cases, it is also possible in collective actions that some agents may not agree with one or more of these actions. Furthermore, in collective actions, agents will not simply perform an action because another agent wants them to (Wooldridge & Jennings, 1995). Therefore, it is necessary for the collective to make some agreement about what exactly needs to be done. This agreement is reached via *negotiation*.

Negotiation has long been recognized as a process of some multi-agent systems (Rosenschein & Zlotkin, 1994; Sycara, 1989). At the time of negotiation, the agents usually make reasoning arguments for and against particular courses of action, making proposals, counter proposals, suggesting modifications or amendments to plans. These continue until all the negotiators have agreed upon the final result. Negotiation is also an extremely complex issue. But in the case of joint negotiation, it is a bit simpler than self-interested individual agents.

In negotiating a plan, collective negotiation may also abort due to irrelevant circumstances. The minimum requirement to occur for negotiation is that *at least one* agent will propose a course of action, which is believed will take the collective closer to the goal. Therefore, negotiation may also be successful. Like team formation, we assume a group of agents also attempts to do something collectively. A group of agents g attempts to achieve a goal after performing mutual actions α which is completely or partially satisfied and can be formalized as:

$$\{\text{Attempt } g\ \alpha\} \rightarrow ?;\ \text{Achieve goal}$$

The minimum condition to occur in negotiation is that the group will try to bring about a state in which all agents agree to a common plan, and intends to act on it. The authors assume that if any agent shows its preference, then it will attempt to bring this plan about. Similarly, if the plan has any objection, then it will attempt to prevent this plan from being carried out. In this way, the agents will agree on a plan to carry out their actions. If the plan formation stage is successful, then the team will have a full commitment to the joint goal and will proceed to execution phase.

Execution Stage

When the agents have a collective plan to do something, then they are ready to move to this phase, as the group knows what to do. That is, each agent has its own target and the group has its intention to perform actions to achieve the goal. The group mutually believes that the action they intend to perform in order to achieve the goal can actually happen.

Monitoring Stage

How do we know that all the agents are performing their tasks according to the plans? What if an agent is unable to complete its task in the middle of the plan? Who will take this responsibility, or will another agent perform this task? How will it be solved? For these reasons, the authors identified that it is necessary to have a monitoring phase when the execution stage is carried out. An agent will need to monitor the execution phase; if something unusual occurs, it can be solved accordingly. For example, if an agent cannot finish its task, then the monitoring agent will request another agent to complete this task and the agent who could not finish its task can be defined as a partially able agent.

Evaluation Stage

This research identified some additional questions:

1. Which agent completed its task?
2. Which agent did not complete its task?
3. Which agent partially completed its task?
4. Which agents did extra tasks?
5. How do we know which agent performed what action?

Therefore, the authors recognized that it is also necessary to evaluate the execution stage by using an agent to evaluate and allocate reward benefits. From this evaluation, processes can be improved or updated according to necessity. After this stage, the agent can go back to the first stage to begin a new cooperative work. Therefore, we can consider it as *enhanced and effective cooperative stages*, as depicted in Figure 3.

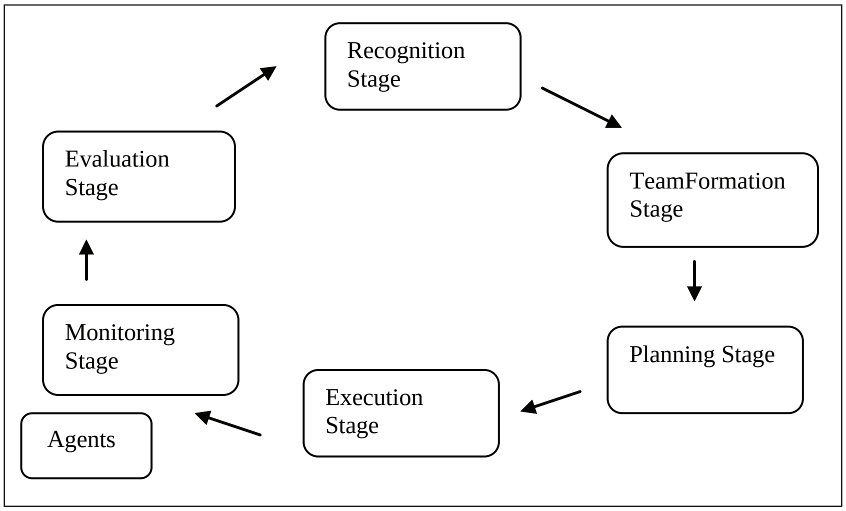
In summary, the model developed by Wooldridge and Jennings (1999) has been extended by this research to include two more stages, the monitoring stage and the evaluation stage. The new model, shown in Figure 3, is applied to the TAC SCM game as a case study to investigate its potential performance.

TAC SCM Game Overview

The TAC SCM is an international competition where six software agents are the manufacturers of personal computers (PC) in a simulated common market economy linked with two markets: the *component market* and the *product market*. The full specification can found at http://www.sics.se/tac/tac06scmspec_v16.pdf. TAC SCM is designed as a traditional supply chain model where supplier and end users (customers) are directly involved in an electronic market. Each manufacturing agent can manufacture 16 different types of computers, characterized by different *stock keeping units* (SKUs). SKUs consist of different combinations of components in 10 types.

During each TAC day of the game, customers send a set of request for quotes (RFQs) to the agents. Each RFQ contains a SKU, a quantity, due date, a penalty rate, and reserve price (the highest price that customers are willing to pay). Each agent responds to the RFQ by sending an offer that states a price less than the reserve price. The agent that sends the lowest price wins the bid.

Figure 3. Enhanced and effective cooperative processing stages



The winning agent delivers the entire order by the due date and is paid in full if it is delivered within five days of due date. If the order is not delivered by the due date, a penalty is incurred based on the number of late days. Consequently, if the agent cannot deliver the entire order within five days of its due date, then this order is canceled and the maximum penalty is incurred.

On the other hand, agents can send a RFQ to the suppliers for the required components and the expected delivery date. The suppliers can respond to the RFQ the next day with offers specifying the price per unit. Offers either have a delivery date on the day requested or a delivery date later than the requested day. The agent can accept or reject these offers according to their requirements and enter into an agreement with the supplier. The agent will be charged for the components on delivery. This simple negotiation mechanism must follow when agents purchase their components from suppliers. This mechanism only focuses on the accept or reject method.

Each agent must solve daily problems:

- Bidding problems for a customer's order of PCs.
- Negotiating a supply contract when the procurement problem deals with components that need to be purchased from the supplier.
- Production problems concerned with everyday scheduling.
- Allocation problems that deal with matching SKUs in the inventory to orders.

At the end of the game, the agents receive awards based on profits.

Product Market Performance

As we know, a pure competitor or monopolist can simply choose its price or output policy and directly calculate the resulting gain or loss. In an oligopoly market setting, the choice of a price, output, or other marketing policy does not uniquely determine profit, because the outcome for each firm depends on what its opponents decide to do. The Cournot and Chamberlin descriptions of oligopoly suggest the kind of interdependence that arises explicitly here, but do not take into account uncertainty about opponents' decisions (Meyer, 1976) .

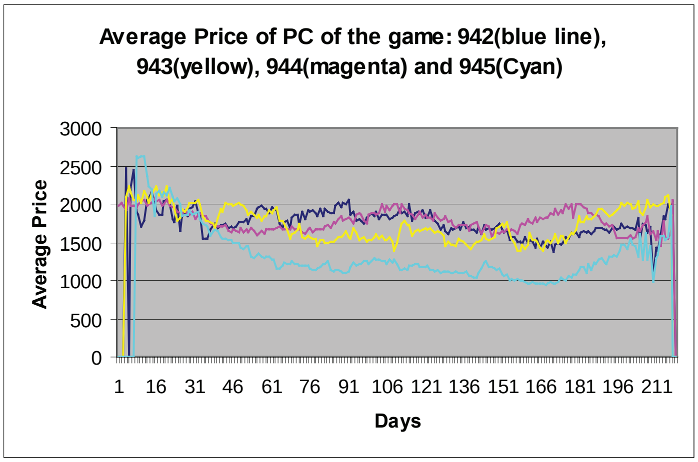
The market price of PCs for all the agents depend on the quantity they produce. This means that the profit for each agent is linked directly to the profit of the other. Consequently, different agents have their own cost functions, which imply different payments for inputs. Therefore, each agent has its own policy to bid for a customer order, which it will enhance to win the bid.

The PC market is another vital part of TAC SCM in which agents are directly involved in winning. In the competition, the authors recognize the following critical questions to resolve or improve the agents' performance as price competition:

- How does the agent bid for a customer's reserve price for a PC?
- What strategies need to be adopted for this?
- How much does the agent need to reduce the price to win the bid?

To improve the performance of the agent, it is necessary to learn from the history of the game. For example, Figure 4 presents the average price of PC of the competition. The agents can learn from the chart when the market price of PCs are high, medium, and low. Equilibrium prices arise when supply equals demand: $Q^s_i = Q^d_i$ for product *i*. If $Q^s_i \geq Q^d_i$, agents will bid price P_i lower ; if $Q^s_i \leq Q^d_i$, agents will bid price P_i higher. Usually the price of the product increases at the beginning of game due to lack of supplies. Therefore, the agents who supply the product at the time of low market supply can get a higher price and, as a result, can earn more market share with more profit. Consequently, the agent who can adopt this

Figure 4. Market price of PC of the game 942–945



strategy of increased productivity, and bids according to the market situation will have a better opportunity to maximize profit.

Huq (2006) analyzed the product market of the TAC/SCM 2004 game and observes the lack of cooperation among agents involved in component purchasing and product selling. The average market demand for PCs in the semifinal and final round game can be depicted in Tables 1 and 2, where the second column is the average PCs delivered by the agents; the third column is the total average market demand. The authors subsequently find that the free agent bids on an average with a higher average price and a higher percentage of orders.

In summary, the TAC SCM has a distinct lack of cooperation among the agents involved in component purchasing and product selling, and this led the authors to conclude that the game was a likely case study to investigate modeling coordination and cooperation.

MODELING COORDINATION AND COOPERATION IN TAC/SCM

According to the TAC/SCM, all manufacturer agents are rational or self-interested and their main focus is to maximize profit. If we assume that the agents cannot achieve their goal in isolation or that they would prefer to work with each other, then this has the potential for cooperation. In this context, all the manufacturer agents can work together towards their goal. On the one hand, manufacturer agents will be able to increase their production capacity and sell the final products to

Table 1. Average total PCs delivered in semifinal of Gr-1 (TAC3 and TAC4)

Agents	Average Delivery	Total Average Price	% of Order	Average
FreeAgent	46882	291505	16	1656
SouthamptionSCM	61759		21	1508
Mr. UMBC	51587		18	1527

Mr. UMBC	44665		22	1481
ScrAgent	13765		7	1434
KrokodilAgent	24487		12	1869
Socrates	31186		15	1764

customers, and on the other hand, suppliers will benefit by supplying more components to the manufacturers, which will result in more profit. The following discussion proposes a theoretical model, which will be able to solve the coordination and cooperation problem of the TAC/SCM game.

The authors have found in the TAC/SCM competition that three or four agents always dominant the market of buying components or selling the products. Therefore, this research characterized these agents as big agents and the other agents as small/medium agents (SMAs). Again, it was also found that SMAs could not purchase enough share of the components to produce a final product to sell. This is a technical/strategic or financial problem for the SMAs. Consequently, if the SMAs purchase components from big agents and sell to customers, then it is possible to survive. Otherwise, the SMAs cannot compete with the big agents. In the real world, usually the intention of large organizations is to extend their business and make more profit. This increases production which ultimately leads to increased profit. Using this strategy, we assume that big agents want to extend their business, and at the same time, the SMAs would like to work with big agents. This way, big agents and SMAs can work together to achieve their common goals. As a result, every agent will be benefited by participating in shared activities. Therefore, to work together the agents need to follow the stages defined in the previous section, Cooperative Problem Solving Process. In this regard, the following characteristics can be defined (see the agent types in Definition 1 of the Recognition Stage of the Cooperative Problem Solving Process section):

Theorem 6.

a. There exist some group of agents *g* such that the individual agent *i* believes that the *g* can jointly achieve goal.
b. either:
c. An agent *i* cannot achieve goal individually.
d. an agent *i* believes for every action that could be performed to achieve the task, it has a goal of not performing the goal.

Theorem 7. The outcomes ensure their profit if and only if the *cooperative agents* complete their task successfully.

If the *cooperative agents* complete their task successfully, then all the participating agents will share the profit, otherwise it will be considered an incomplete task.

Theorem 8. The *cooperative agents* are those if and only if they agree to work together.

In the Cooperative Processing Stage, only those *able agents* that are determined to complete their tasks towards a common goal are considered *cooperative agents.*

Definition 2. A *decommitted agent* is an agent that started its task but did not complete that task, and therefore needs to be penalized.

Definition 3. Let a set of *able agents* that share their work to achieve a common goal be called *cooperative agents,* which is:

$$ag_i \in A = \{ ag_1, ag_2, \ldots\ldots ag_n \} = \phi \quad (1)$$

Definition 4. The accumulated task of the *cooperative agents A*, the utility *u* of that task can be considered as unique, and can be expressed as:

$$u(A) = \Sigma \; A_i = \; n1 \qquad (2)$$
$$i = 1$$

Definition 5. Profit allocation to the agents: The percentage of the utility of each agent can be worked out according to the contribution of each agent, which can be expressed as:

$$u(ag_i) = \frac{u(ag_i) \times 100}{u(A)} \qquad (3)$$

Definition 6. Cooperative action takeover: If any agent fails to complete its task, then other agents will need to complete that task to achieve the goal.

If any agent is unable to finish its allocated tasks due to unavoidable circumstances, then the other agents will take over that unfinished task enthusiastically to achieve the goal.

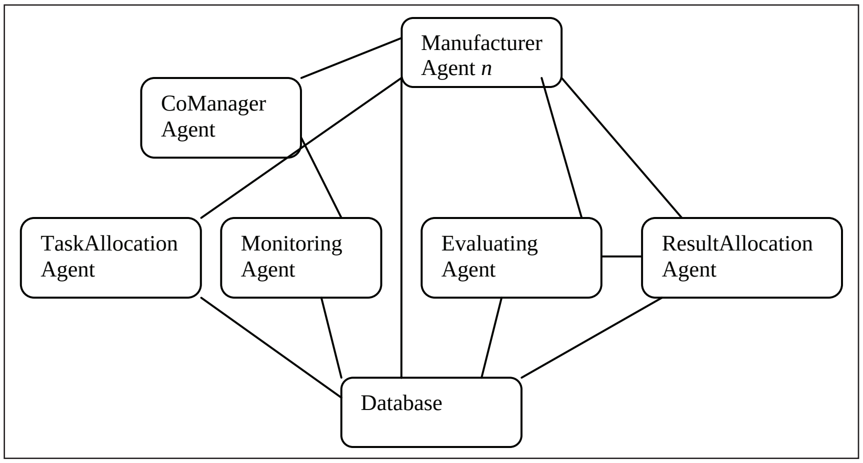
Definition 7. The set of *cooperative agents A* are a finite set and said to be bounded.

The *cooperative agents* must be limited in number for efficiency in task allocation, as it is not possible to have an unlimited number of agents working together. The *cooperative agents* are bounded, for instance: (a) the agent who invests or sells the greatest is called the upper bounded; and (b) the agent who invests or sells the lowest is called the lower bounded.

Architecture of the Cooperative Processing Agents

Let us consider that a number of companies in different locations have agreed to sell some products to customers within a limited time frame. Assume that the agents are going to work together according to the Cooperative Processing Stages. A proposition for architecture of effective cooperative processing is shown in Figure 5. In this figure, there is a collection of manufacturer agents *n* in the domain. When these agents have agreed to perform tasks to achieve a specific goal, to complete the cooperative processing, other agents are needed. This research argues that these agents are Task Allocation Agent, Monitoring Agent,

Figure 5. Architecture of effective cooperation model



Evaluating Agent, Result Allocation Agent, and Coordination Manager Agent (CoManager).

When a problem is decomposed into smaller subproblems, the *Task Allocation Agent* is responsible for allocating tasks to the a*ble agents* in order to achieve the goal. The *Monitoring Agent* is responsible for monitoring the performance of the agents' tasks, that is, which agent is doing its task and which is not. Finally, this agent will produce a report to the *CoManager Agent*. According to this report, the *CoManager Agent* will reallocate the unfinished task to the agent that is willing to undertake that task.

The *Evaluating Agent* will evaluate all tasks from the *Monitoring Agent*. The *Evaluating Agent* will provide analytical and objective feedback on efficiency and effectiveness of the performance of agents. Finally, it will produce an overall final report including benefits of each agent to the *Result Allocation Agent*. Eventually, this final report allows the agents to learn lessons. The *Result Allocation Agent* then processes the benefits deserved by each agent, and finally produces a benefit report to the agents.

The contribution made by this research is the addition of the monitoring and evaluation stages for the Cooperative Problem Solving Process, and the results described in this section. The TAC/SCM was used as a case study to illustrate the concepts outlined in the theorems and definitions.

FUTURE TRENDS

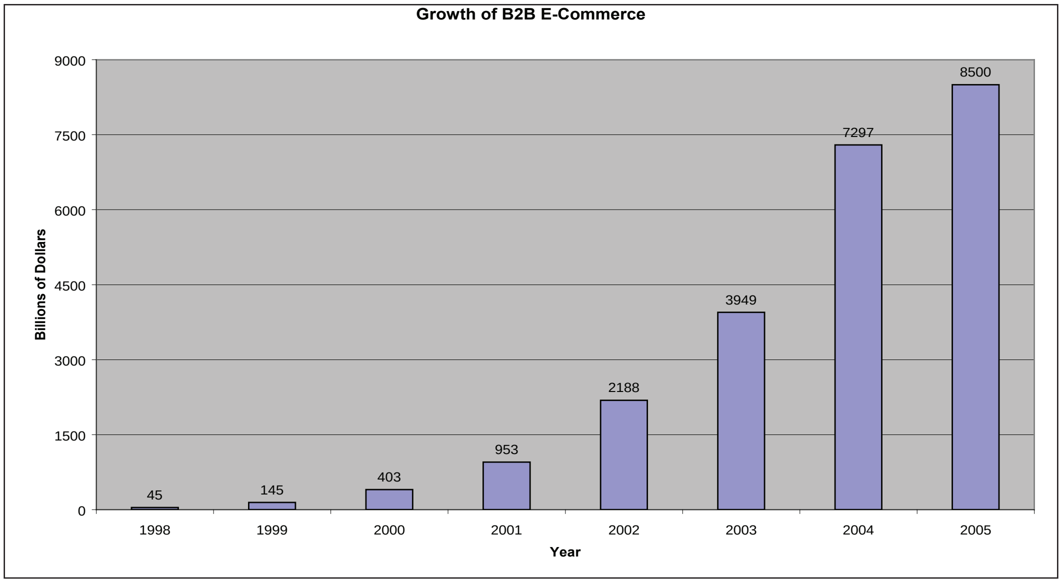
The potential for B2B e-commerce is now projected to be much larger than that for consumer oriented e-commerce (Chan, Lee, Dillon, & Chang, 2001). Conducting electronic B2B transactions is an emerging and potentially lucrative issue. For example, in the supply chain, manufacturer organizations or retailers are dependent on supplier organizations. There are many processes in selling and purchasing that can be conducted electronically. Particularly, at the time of purchasing, many processes are complex and involve negotiation, cooperation, and coordination. In the real world, these processes are very time consuming and complicated. Therefore, if we can utilize these processes electronically, we can avoid complexity and will be able to reduce costs and time taken. Figure 6 shows how B2B e-commerce has grown from 1998 to 2005.

As a result, we can predict that this trend in e-business utilization will increase into the future. As described in the previous sections, both large organizations and SMEs will be able to work together to conduct e-business on a global basis. In regards to implementing cooperative work utilizing multi-agent systems, the agents need to follow the stages defined in this chapter. As a result, all the participant organizations will benefit in overall performance outcomes. In conclusion, the authors argue that team effort, rather than individual effort, will give more robust and sustainable results. The cooperation and coordination protocol, and information sharing among various agents can be future research areas, which will facilitate in building the software that enables coordination and cooperation activities.

CONCLUSION

This chapter identified problems in conducting e-business and managing the supply chain. It also identified expected benefits for supply chains with agents working together in coordinated and cooperative processes. The utilization of a multi-agent system in supply chain management and the *cooperative problem solving stages* have been presented and discussed. To apply these stages, the proposition for architecture of effective cooperative processing for agents and some characteristics in modeling coordination and cooperation for TAC/SCM have been outlined. The ultimate goal is to develop the capability of organizations to work effectively together in online e-business transactions. In addition to this,

Figure 6. Projection growth of B2B e-commerce drawn from a report by Gartner Group



large organizations can expand their businesses and SMEs can work with large organizations. Finally, it can reduce time for selling and buying activities and increase the total profits of the supply chain. In addition, it will facilitate the ability to cooperate and coordinate among multi-agents in e-commerce. Further, it will enhance customer satisfaction and streamline B2B transactions by reducing transaction costs of tasks at every stage of the supply chain. Therefore, it will increase trust and confidence in the component market and product market.

Chapter 3.4

Supporting Executive Intelligence Activities with Agent-Based Executive Information Systems

ABSTRACT

This chapter examines the theoretical underpinning for supporting executive intelligence activities and reviews conventional studies of executive information systems (EIS) over the last two decades in responding to the current executives' information processing needs and the current Internet era. The reviews suggest the need for designing advanced EIS that are capable of responding and adapting to executive information. This chapter recognizes the necessity of revitalizing EIS with advances in intelligent technologies and Web-based technologies. Empirical studies were conducted to elucidate executives' desires and perceptions of the prospect of agent-based technologies for supporting executive intelligence activities in the more integrated and distributed environment of the Internet. Based on the insights gained from empirical studies, this chapter concludes by presenting a three-level agent-based EIS design model that comprises a "usability-adaptability-intelligence" trichotomy for supporting executive intelligence activities.

INTRODUCTION

It is widely recognized that there is an increasing complexity and dynamism of operational and strategic information in electronic and distributed environments. Executives are now seeking assistance for continuous, self-reactive and self-adaptive approaches to acquiring, synthesizing, and interpreting information for intelligence with a view to determining the course of action that is executive intelligence activities. Executive information systems (EIS) originally emerged as computer-based tools to provide executives with easy access to strategic information and to support and enhance their information processing activities. EIS were popularized in the 1990s but EIS study has not advanced to a great extent in either research or practice in recent years. Conventional EIS studies have established a range of views and guidelines for EIS design and development, but the guidelines underpinned by extant research have failed to develop robust and intelligent EIS.

The most common deficiency of conventional EIS is their inflexibility, relying on processes designed for static performance monitoring and control and predetermined information needs. The emergence of the intelligent software agent, as a concept and a technology, provides the prospect of advanced solutions for supporting executive's information processing activities in the more integrated and distributed environment of the Internet. Nevertheless, executives' desires and perceptions of agent-based support must be elucidated in order to develop systems that are likely to be considered valuable in practice and stand the test of time when implemented.

The objectives of this chapter are threefold. First, the chapter examines the theoretical underpinning for supporting executive intelligence activities and the need for designing advanced EIS that are capable of responding and adapting to executive information. Second, the chapter reviews conventional studies of EIS and confirms the need for revitalizing EIS with emerging technologies. Third, the chapter proposes a model for designing an advanced EIS with agent-based support. This chapter starts with a review of theories and debates on understanding the need for supporting executive intelligence activities. It then provides a review of the emergence of executive information systems (EIS) in responding to the executives' information processing needs over the last two decades and identifies the problems with conventional EIS in the current Internet era. It recognizses the necessity of revitalizing EIS with advances in intelligent technologies and Web-based technologies. This chapter also discusses the current development and applications of intelligent technologies and the potential contributions of intelligent software agents could make to revitalize conventional EIS.

Based on the insights gained from empirical studies, this chapter concludes by presenting a three-level agent-based EIS design model that comprises a "usability-adaptability-intelligence" trichotomy for supporting executive intelligence activities. The emphasis of this agent-based EIS design model is an intelligent and executive-centered system that focuses on these three dimensions.

THEORETICAL UNDERPINNING OF EIS DEVELOPMENT

As the business environment becomes more volatile and competitive the appropriate handling of information and knowledge has become a distinct core competence. The capability to know itself, know its "enemies," and know its business environment significantly affects a company's success or failure. The challenge is that organizations and their environments are systems that continually present a variety of disturbances through signals and messages that senior executives should attend to (Auster & Choo, 1994; Daft, Sormunen, & Parks, 1988). As a result, senior executives are facing increasing complexity and variety in operational and strategic issues.

From the notion of cybernetics, Ashby (1956) formulated the law of requisite variety that has contributed significantly in management and organizational studies. The variety of a system is defined as the number of possible states it is capable of exhibiting. It is a measure of complexity but a subjective concept depending on the observer. Ashby's law of requisite theory states that in order to control a system the control measures must have as much variety available as the system itself exhibits. In other words, only variety can counteract variety.

The law of requisite variety applies to the situation where executives have to learn to live with probabilistic systems as they are continually confronted by new and unexpected events. Executives have to exhibit enough variety in order to counteract the variety of disturbances. The challenge is that executives are facing ever-increasing amounts and complexity of operational and strategic variety. The capacity of the channels of communication to be used for perceiving the disturbances and for transmitting the control measures suggests the concept of intelligent support in this study. Senior executives are seeking assistance in the search of variety that can cope with the organizational environment that continually creates disturbances. The search of variety allows executives to have a better understanding of how to manage in a complex and dynamic organizational context. In this case, the better an executive is capable of perceiving disturbances and exhibiting control or action, the better their capability in reducing or removing the impact of the disturbances.

With the increasing availability of electronically distributed information, senior executives suffer from information overload, especially an over abundance of irrelevant information (Maes, 1994; Shapira, Shoval, & Hanani, 1999). Senior executives simply cannot relate simultaneously to all information available to them. They have to select and then make sense of what is selected. Ackoff (1967) foresaw this dilemma with the introduction of management information systems (MIS). He strongly believes that the emphasis of an executive support system should shift from supplying relevant information to eliminating irrelevant information. He argues, "Unless the information overload to which managers are subjected is reduced, any additional information made available by an MIS cannot be expected to be used effectively" (Ackoff, 1967, p. 148).

Based on the implications of Ashby's law of requisite variety, Beer (1979) introduced the viable system model (VSM). The VSM provides a theoretical basis for supporting executive intelligence activities because it is concerned with planning the way ahead in the light of external environmental changes and internal organizational capabilities. One of the subsystems in VSM model is concerned with Intelligence, called System Four. System Four emphasizes the scanning of the organizational environment and the filtering process. System Four can, therefore, act as a "scanner" that scans all unidentified relevant information from the overall environment. The scanning process allows the organization to adapt its internal environment to meet its external environment. As senior executives can easily be overloaded with irrelevant information, System Four can also act as a "filter" that captures only strategic information for senior executives. The information scanning and filtering process puts senior executives in a better position to react to threats and/or opportunities, as well as to anticipate future changes despite the turbulent environment. Using the VSM, Carvalho (1998) describes the role of computer-based support systems in organizations and suggests that EIS should aim to provide intelligence support as required in System Four.

Simon's (1965) intelligence-design-choice model states that executives spend a large fraction of their time surveying the organizational environment to identify new varieties that call for new actions in the "intelligence" phase. In the "design" phase, executives probably spend an even larger fraction of their time, individually or with their subordinates, to design and develop possible courses of action for handling situations where a decision is needed. They then spend a small fraction of their time in the "choice" phase, selecting from those available courses of actions to meet and solve an identified problem. According to Simon (1965), the three phases sum up what executives do in most of their time.

Here, the support for "intelligence" activity is of particular importance, because intelligence activity precedes design, and design activity precedes choice. The intelligence activity phase is the first principal phase, which emphasizes the search for variety, occasions, or conditions that call for decision. In the intelligence activity phase, the environment is examined and problem areas as well as opportunities are identified. Often, this phase is triggered by dissatisfaction with problems and organizational objectives. Besides the recognition of problems or opportunities, the intelligence activity phase also involves classification of the opportunity or problem from the business environment. Simon's (1965) model implies that intelligence activity support is critical for intelligence processing activities. Any advanced information systems that can provide intelligence activity support will assist executives in the recognition and classification of environmental conditions and so will reduce the fraction of time expended on this activity.

The above review provides a theoretical foundation to underpin the design of advanced EIS that are capable of responding and adapting to environmental changes.

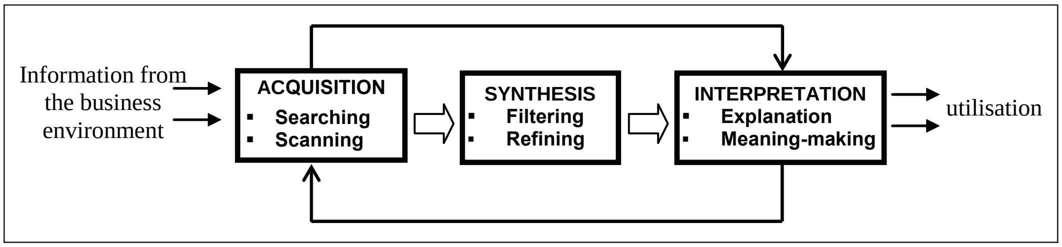
EXECUTIVE INTELLIGENCE PROCESS AND ACTIVITIES

As senior executives need to respond to their changing and unpredictable environment continuously that can help or support executives in the following three aspects of intelligence processing. First, advanced EIS are needed to reduce the amount of information from the environment and capture only relevant information, secondly, to capture and process information according to individual executives' specific needs and interests, and thirdly, to learn and adapt to information changes and to anticipate future changes.

Support for executive intelligence activities (see Figure 1) is essential for senior executives to better cope with the increasingly dynamic and complex executive information through value-added information seeking, information gathering and information manipulating activities. The theory of information retrieval (IR) suggests that efficient information search and processing can be achieved through a closed-loop process that involves evaluation and modification either through the user's explicit relevance feedback or the system's implicit relevance feedback (Belkin & Croft, 1992). Hence, there is a need to support executive intelligence activities through a closed-loop process, whereby actions could be suggested and/or taken continually in order to process information on behalf of senior executives.

The study of environmental scanning suggests that scanning is the key means for obtaining intelligence about the past, the present and the future (Aguilar, 1967; Hambrick, 1982; Lozada

Figure 1. Executive intelligence activities



& Calantone, 1996; Stoffels, 1994). The concept of environmental scanning underlies the understanding and the need for information acquisition in executive intelligence activities (see Figure 1). In order for executives to understand their internal business environment and to attend to signals and messages generated from the external business environment, they need a system that is capable of providing a broad range of information. The information is typically spread across several computer systems within the organization as well as the external information on markets, customers, suppliers, and competitors, influenced by political, economic, social, and technological issues. It is more than just providing historical data through basic query and reporting mechanisms. It involves sophisticated information scanning and searching activities through macroscopic viewing (radar) and microscopic search (search) of potentially relevant information. Scanning activities provide early signals from potential threats and opportunities and help executives understand the external forces of change. Search activities provide specific information on newly arising issues and help executives understand the details of those issues. Although companies have little control over external events, this acquisition activity can reduce remoteness and increase the predictability of future possibilities.

The concept of information filtering (IF), originating from the theory of information retrieval (Belkin & Croft, 1992), provides the basis for information synthesis in executive intelligence activities (see Figure 1). The goal of IF is to screen through a massive amount of dynamically generated information through user profiling and relevance feedback (explicit and implicit) and to present users with information likely to satisfy their information interests. Similar to the goal of IF, information synthesis acts as a "variety reducer" by screening out irrelevant information and refining information through relevance feedback for their relevancy. Irrelevant information will be eliminated and relevant and useful information will be extracted through filtering activities. One key activity in information filtering is user profiling. User profiling enables elimination of irrelevant information and personalization of information delivery according to user preferences (Balabanovic & Shoham, 1997; Shapira, Shoval, & Hanani, 1997). Information refining activities involve both explicit and implicit relevance feedback by the user or the system itself (Belkin et al., 1996; Kelly & Teevan, 2003; Morita & Shinoda, 1994; Salton & Buckley, 1990; White, Jose, & Ruthven, in press). User relevance feedback is used to create and refine user profiles. A continuous creation and modification of user profiles through user relevance feedback (both explicit and implicit) will gradually improve the results of information processing activities.

Finally, information interpretation is pertinent to executive intelligence activities (see Figure 1). Information interpretation involves making sense of the incoming information (Thomas, Clark, & Gioia, 1993). It entails the process of translating the viewed and searched events, the process of developing models for understanding, the process of generating meaning, and the process of assembling conceptual schemes (Daft & Weick, 1984; Gioia, 1986; Liu, 1998a; Taylor & Crocker, 1981). Synthesized information is further processed to resolve the equivocality of information and to give meaning and understanding about the organization's events. Explanations are key functions in information interpretation activities, in which explanations help provide adequate justification on information such as the meaning of data, the reasons for advising a particular course of action, and the justification for a particular piece of information (Gregor, 2001; Gregor & Benbasat, 1999). However, these activities pose challenges because executives are cognitively complex individuals who tend to use their innate mental models to perceive and understand the searched and viewed events (Agor, 1984; Isenberg, 1984; Kuo, 1998; Liu, 1998a).

CRITICAL REVIEW OF EIS IN THE CONTEXT OF INTELLIGENCE SUPPORT

Many information systems have been developed to support executives' information processing activities, such as management information systems (MIS), decision support systems (DSS), executive information systems (EIS) and executive support systems (ESS). EIS, in particular, emerged as computer-based tools to provide executives with easy access to strategic information and to support and enhance executives' information processing activities (Millet & Mawhinney, 1992; Rockart & Treacy, 1982; Watson, Houdeshel, & Rainer, 1997; Watson, Rainer, & Koh, 1991). Since the early 1990s, many studies have been conducted on EIS as companies and researchers foresaw the great potential (Belcher & Watson, 1993; Edwards & Peppard, 1993; Jordan, 1993; Millet & Mawhinney, 1992; Wetherbe, 1991; Watson & Frolick, 1993; Watson et al., 1991; Warmouth & Yen, 1992). However, only a few papers on EIS have been published since 2000 (notably Averweg, Erwin, & Petkov, 2005; Salmeron, 2002). Conventional EIS studies have established some consensus on guidelines for EIS design and development. However, the guidelines underpinned by preceding research have failed to develop robust and intelligent EIS. What is often reported is EIS failure (Bussen & Myers, 1997; Lehaney, Clarke, Spencer-Matthews, & Kimberlee, 1999; Rainer & Watson, 1995; Xu, Kaye, & Duan, 2003).

The design of EIS typically focuses on office support applications, planning and control process, and improved analytic and modeling capabilities (Rockart & De Long, 1988). Key functions of earlier EIS design are mainly standard office automation packages and management reporting facilities on key performance indicators (KPIs) and critical success factors (CSFs) (Millet & Mawhinney, 1992; Rockart & Treacy, 1982). The improved analytic and modeling capabilities are mainly developed to provide status and trends of internal and historical information (Millet & Mawhinney, 1992). Hence, it is rather a management control and planning system with performance measures based on critical success factors. This has failed to meet the primary purpose of EIS, which is to provide executives with easy access to both internal and external information that is relevant to their critical success factors (Watson et al., 1991; Watson et al., 1997). Conventional EIS are also inflexible in adapting and meeting changing information needs due to the predefined rules for exception, manipulation, reporting, and control. (Bajwa, Rai, & Brennan, 1998; Young & Watson, 1995; Salmeron, 2002).

Conventional EIS studies indicate that most EIS were used predominantly for communication, performance monitoring, and control (Edwards & Peppard, 1993; Nord & Nord, 1995; Vandenbosch & Huff, 1997). This implies the inability of conventional EIS in managing strategic information due to their internal focus. However, EIS can increase executives' confidence in decision-making (Nord & Nord, 1995), and improve executives' efficiency through successful information acquisition (Rainer & Watson, 1995; Vandenbosch & Huff, 1997; Watson, Watson, Singh, & Holmes, 1995). This suggests the need for supporting information scanning and searching in EIS.

It has been emphasized by many researchers that value added presentation of data via user-friendly interface such as graphical, tabular, and/or textual information presentation is essential in EIS design (Nord & Nord, 1995; Watson et al., 1995). Data should be processed (i.e., summarized, aggregated, analyzed), prepared and reported to executives using a friendly and colourful interface. Ease of use is considered relatively important in EIS design and development (Nord & Nord, 1995; Rainer & Watson, 1995; Watson et al., 1995). These guidelines suggest some basic ideas for EIS design and development, yet they are unable to develop robust and intelligent EIS.

Other EIS studies also attempt to explore factors contributing to the success of EIS adoption and implementation. Most of the studies imply that there are relationships between EIS success and support from top management, IS or vendor (Bajwa et al., 1998; Rai & Bajwa, 1997) and between EIS adoption and environmental uncertainty (Rai & Bajwa, 1997). However, these studies provide not many useful guidelines for successful EIS design and development.

Despite the integration of data manipulation and decision support tools into EIS, the key deficiency is that they do not efficiently support intelligence processing activities (Liu, 1998a, b; Montgomery & Weinberg, 1998). In particular, current EIS do little in the way of actively and continuously scanning the business environment, automatically filtering out irrelevant data and information, and constantly providing signals or warning of potential opportunities and threats. The advent of artificial intelligence (AI) (sometimes called soft computing) techniques, such as fuzzy logic, neural networks, and genetic algorithms gives the possibility of developing intelligent support systems, such as expert systems (ES) and knowledge-based systems (KBS). However, ES and KBS are mainly adopted to support operational and tactical decisions, rather than strategic decision (Eom, 1996; Wong, Chong, & Park, 1994). In practice few ES are successfully adopted and implemented due to the limited functions, high cost of development and organizational resistance (Grove, 2000; Watson et al., 1997; Wong & Monaco, 1995). Grove (2000) raises several problems and limitations associated with current ES/KBS applications: (1) Experts are often unable to express explicitly their reasoning process; (2) ES tend to perform poorly due to the limitations in its coded expertise, which relates to a narrow domain; and (3) the stand-alone mainframe, AI workstations or PC platforms causes limited use of ES and difficulty in information sharing, as well as difficulty in software installation and upgrades.

Nevertheless, one of the subfields of artificial intelligence (AI)—distributed artificial intelligence (DAI)—has led to the advent of the intelligent software agents (or software agents). The emergence of this concept and technology provides the opportunity for intelligence support in information processing activities. The intelligent software agents offer potential because these agents are integrated in the distributed environment of the Internet. With the overwhelming flow of distributed information produced for the senior executives from an increasing number of sources, intelligent agent-based support systems have the potential to fulfil the following three key functions in intelligence processing, first, the screening and filtering of data and information, second, the personalization of information gathering and processing according to individual users, and third, the learning and adaptation of system to information changes.

The Internet, or Web-based technologies, can overcome some of the drawbacks of conventional EIS, especially with regard to cost, geographically distributed location, ease of use, development cycle, architecture and additional advanced features such as intelligent software agents (Basu, Poindexter, Drosen, & Addo, 2000; Gopal & Tung, 1999). White (2000) suggests that executives are becoming more comfortable and confident using the Internet. Web-based technologies have also led to the emergence of portal solutions through the intranet, extranet, and enterprise information portal (EIP). The enterprise information portal (EIP) is a single point of access, where it gives users a unified view of all corporate knowledge assets using the new universal interface, the Web browser. An executive, for example, can do a single search to access competitors' information that may reside in corporate databases, business libraries, file archive, or on the Web. With the advent of intelligent software agents and the proliferation of Web-based technologies EIS design, development and implementation will be revitalized in the near future.

THE POTENTIAL OF INTELLIGENT TECHNOLOGY FOR INTELLIGENCE PROCESSING

Many intelligent software agents have been developed or are currently under development in academic and commercial research laboratories, but they are yet to be deployed in the commercial world (Nwana, 1996; Wooldridge & Ciancarini, 2001; Wooldridge & Dunne 2005; Wooldridge & Jennings, 1995). Software agents, like remembrance agents (Rhodes & Starner, 1996), Letizia (Liebermann, 1995, 1997; Liebermann, Fry, & Weitzman, 2001) and Let's Browse (Lieberman, Van Dyke, & Vivacqua, 1999) adopt a strategy that is mid-way between the conventional perspectives of information retrieval and information filtering. In this instance the user achieves efficient information searching and processing through a closed-loop process that involves evaluation and modification either through the explicit relevance feedback or implicit relevance feedback from the system itself. Automatically and unobtrusively collecting user profiles and monitoring the user's processing behavior is one mechanism for software agents to gather relevance feedback from the user or the system. Therefore, software agents offer the potential to automatically scan the distributed heterogeneous environment and proactively search information that best matches a user profile learned through relevance feedback. Information acquisition can become more intelligent as software agents are capable of looking ahead in the user's information processing activities and act as an advance scout to recommend the best paths to follow and save the user needless searching.

Adaptive software agents, like Amalthaea (Moukas & Maes, 1997) learn the user's interests and habits using machine learning techniques and maintains its competence by adapting to the user's interests (which may change over time) while at the same time scanning new domains that may be of interest to the user. A software agent can learn by itself, as well as learning from multiple agents. Learning among multiple agents may be collective, which means that the agents adapt themselves in order to improve the benefits of the system (Klusch, 2001). Here, software agents offer the potential to personalize information acquisition through intelligent information filtering and to deal with uncertain, incomplete, and ambiguous information through intelligent information refining. Hence, information synthesis that consists of information filtering and information refining can be intelligently supported and enhanced by software agents. In this case, software agents perform the information filtering process according to specific user's interests identified and learned over a period of time. Software agents also perform the information refining process through learning from multiple agents.

Proactive software agents, like Watson (Budzik, Bradshaw, Fu, & Hammond, 2002) and I2I (Budzik et al., 2002) proactively and automatically retrieve potentially useful information from online repositories to recommend to users based on their ongoing information processing activities. The goal of proactive software agents is to foster an awareness of relevant information resources available to users. In this case, software agents must be able to reason about the contents of a document, in the right context, in order to provide helpful recommendation, the meaning of the information, the reasons for advising a particular course of action, and the justification for a particular piece of information for example. Using knowledge engineering, software agents offer the potential to make the implicit control knowledge more explicit. In this case, information interpretation could possibly be achieved through intelligent explanation and reasoning services, natural language processing, and knowledge representation. However, the software agent has to be highly user-specific, as well as domain-specific with relatively fixed representation of knowledge because it requires substantial efforts from knowledge engineers to encode implicit control knowledge using complex algorithms (Klusch, 2001).

Many software agent applications are yet to be deployed in real applications due to the following challenges (Nwana, 1996; Wooldridge & Ciancarini, 2001; Wooldridge & Dunne, 2005; Wooldridge & Jennings, 1995):

- **The identification of appropriate techniques for the development of useful software agents:** Software agents are still very much limited by the current state of the art in machine intelligence.
- **The development of software agents is too diverse:** Researchers tend to suggest agent-based solutions based on what they see fit, in accordance with their own respective definitions and approaches.
- **The ability to demonstrate that the knowledge learned with software agents can truly be applied to help users and reduce users' workload in a specific context and domain:** Most of the conceptual architectures of agents are generic solutions that are designed for a wide range of applications.
- **The infancy of development of software agents suggests that users do not actually have a clear vision of how agents can be deployed to assist them:** This also leads to a potential lack of acceptance by users in terms of using and trusting software agents to perform the tasks on their behalf.
- **The ability of software agents to negotiate with other peer agents:** Software agents tend to be distributed by their very nature, working and collaborating with other agents under a multiagent environment.

Although software agents and their applications are still in the early stage of development, they will advance increasingly as research and development in software agents have been mushrooming across different fields, such as intelligent information gathering and processing, personalized information acquisition and knowledge sharing.

EMPIRICAL STUDIES

Software agents offer the potential to support information processing intelligently but executive criteria for agent-based EIS support must be made known in order to develop a system that is considered useful by executives. Executive criteria refer to critical requirements for an agent-based support systems based on executive's desires and perceptions in judging the usefulness of the agent's functions or attributes. The authors conducted empirical studies in order to identify executive criteria for an agent-based EIS to support executive intelligence activities. First, four focus groups were conducted to explore and reveal the current state of executive's information environment and information processing behaviour in the light of Internet era, from which to examine the validity of the conventional views of EIS purpose, functions, and design guidelines. Initial executive criteria for agent-based EIS design were also identified in the focus group study. Second, 25 senior executives were interviewed for deeper insights on value-added attributes and processes of executive criteria for building agent-based EIS. Value-added attributes are functional requirements needed for an agent-based system to assist the executive in information processing activities. Value-added processes are specific activities performed by agent-based system that add value (i.e., enhance) to the executive intelligence activities.

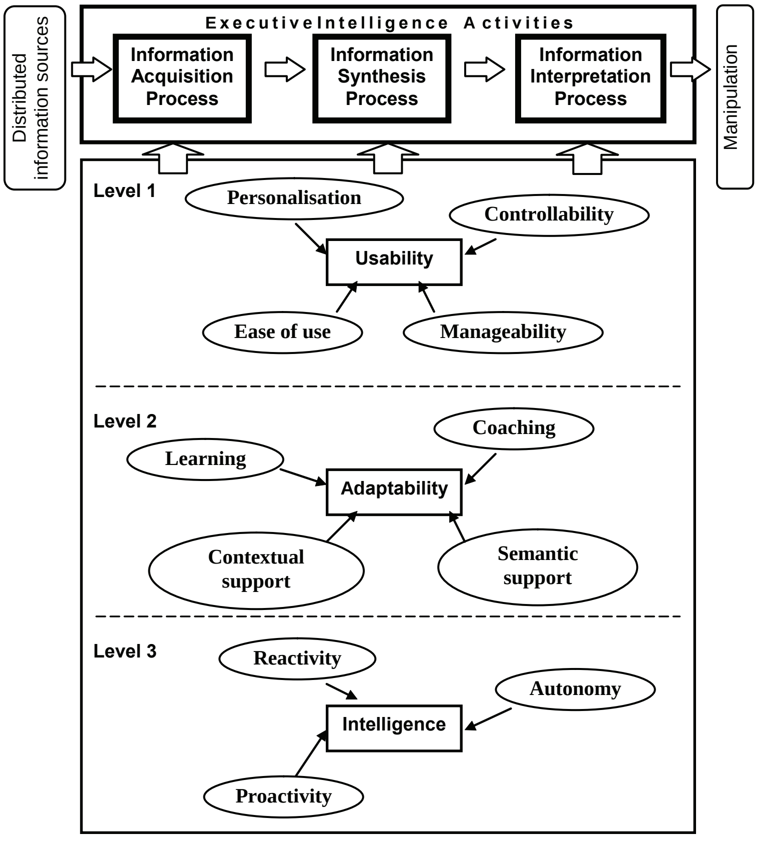
All the discussions were recorded and transcribed verbatim for later analysis. The categorization of meaning approach was adopted for qualitative analysis, in which raw data were organized into structured, meaningful themes according to predefined or newly emerging themes and categories (Dey, 1993). With the high volume of raw data obtained from all the transcripts, qualitative analysis software, NVivo was selected and employed for efficient handling, managing, searching, display, and analysis of findings. Each transcript was analyzed and coded into either the predefined code scheme (nodes) or newly emerging nodes. For a more detailed interpretive conceptual analysis, meanings were sought from the quotes to identify consensus, dilemmas, and contradictions through reading and re-reading of transcripts (Nicholas & Anderson, 2003).

AGENT-BASED EIS DESIGN MODEL: "USABILITY-ADAPTABILITY-INTELLIGENCE" TRICHOTOMY

The findings from empirical studies suggest a "usability-adaptability-intelligence" trichotomy for agent-based EIS design models that comprises executive criteria of value-added attributes and processes for building a usable, adaptable and intelligent EIS. Usability refers to the extent to which a system can be used by specific users to achieve specific goals of information processing in a specific domain of work and information. Adaptability refers to the extent to which the system fits the specified and right context of work and information, with the ability to strengthen the responsiveness of system in coping with the executive information. Intelligence refers to the extent to which the system exhibits self-determined activities that performs a specific task on behalf of an executive, with no or very little executive interaction. The agent-based EIS design model is illustrated in Figure 2.

Under the criterion of usability design, the empirical findings suggest implications for value-added processes on the following value-added attributes: personalization, controllability,

Figure 2. An agent-based EIS design model



manageability, and ease of use. First, the personalization attribute in an agent-based EIS should involve the process of designing and building a comprehensive and specific user profile for individual executives. The executive profiles would comprise individual executive's information domains, roles and preferences. The goal of personalization according to senior executives is to customize according to application-dependent information, application-independent information and user-agent interaction information, thus, reducing the generic information.

Second, the design of controllability attribute in an agent-based EIS allows the flexibility for executive to take control and make changes of information process criteria. Executives should have explicit control over their respective user profiles via explicit user action and user control. Explicit user action allows executives to determine their specific requirements of information process, thus facilitating executive learning in intelligence processing. User control allows executives to make changes on the information process criteria as their information needs and interests change over time, thus making the system more acceptable to the executives.

Third, the manageability attribute in an agent-based EIS suggests the provision of appropriate information density and the reduction of information overload without losing potentially critical information. The provision of appropriate information density can be achieved through paragraphing, summarizing and highlighting imperative messages that are useful. Dissecting information into appropriate units with options for further explanation and understanding can also increase the level of manageability.

Fourth, the key elements for ease of use attribute in an agent-based EIS are simplicity, accessibility and browseability. Simplicity can be achieved through easy functionalities and user-friendly interface. The reduction of steps needed for information access can increase the level of accessibility. Browseability can be achieved through uncluttered information presentation and organization.

In terms of adaptability design, the following value-added processes are identified on the following value-added attributes: coaching, learning, contextual support, and semantic support. First, coaching attributes in an agent-based EIS suggests that executives can assess the information via user's explicit feedback. The system can also seek confirmation and clarification from executives. This interactive process can gradually update and refine executive profiles. As a result, an agent-based EIS would adapt to changes of information needs and requirements.

Second, the design of learning attributes in an agent-based EIS suggests intuitive learning of executive's interests and behaviors based on implicit observation, monitoring and assessment of the system with the intention of understanding executive's interests and mimicking executive's information processing behavior. The implicit relevance feedback must be personalized to executive profiles. The purpose here is to learn and understand executive's information processing behavior and thus conduct continuous, self-reactive and self-adaptive activities of information processing.

Third, the design of contextual support attributes in an agent-based EIS involves the ability to increase information richness through the collection and provision of associative information and context-aware information. The system should be able to monitor and update the collection and provision of associative information and context-aware information in the executive profiles.

Fourth, the design of semantic support attributes in an agent-based EIS includes the ability to increase information relevancy through the collection and provision of associative meanings of information and semantic-aware information. The process includes complex knowledge-based natural language processing activities and the development of ontological domains.

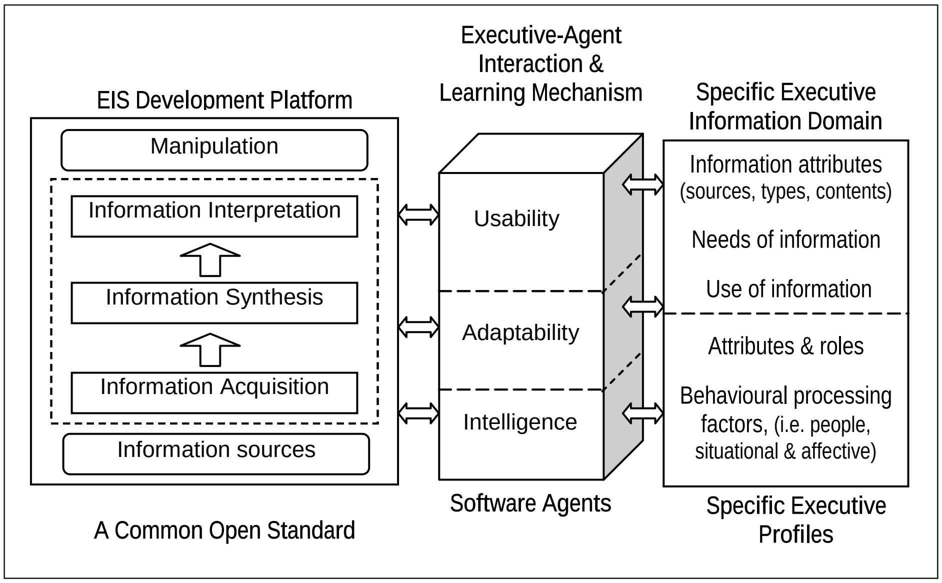
Under the criterion of intelligence design, the findings and discussion suggest preliminary implications for value-added processes on the autonomy, proactivity, and reactivity attributes. First, the design of autonomy attributes in an agent-based EIS should be a semi-autonomous function that involves executive's occasional interaction or input. The system is expected to perform information search autonomously on static information but not dynamic information. Executive's input or feedback is expected for dynamic information. Second, the proactivity attributes in an agent-based EIS should be a proactive interface agent that is capable of performing information manipulation, such as alert notification, ranking and recommendation, with some kind of proactive assistance via user interfaces. The goal is to increase executive's awareness of information. Third, the design of reactivity attribute in an agent-based EIS should be a semi-reactive function that performs self-determined tasks with executive's knowledge. The system should be able to trigger executive of any changes in the information process.

GUIDANCE FOR BUILDING AN AGENT-BASED EIS ARCHITECTURE

The empirical findings suggest guidance for building an agent-based EIS architecture for supporting executive intelligence activities. The architecture will consist of a common EIS development platform, a specific executive profile and information domain, and an executive-agent interaction and learning mechanism. Figure 3 illustrates this architecture.

The EIS development platform will facilitate and enhance executive intelligence activities. This platform will progressively enable the key functional features to be developed, such as searching tools, decision support tools and user interface tools. It is an open standard platform in the sense that the functional features are essential to any EIS and are common to all EIS users. Distributed information sources are widely scanned, filtered and interpreted for manipulation. With the support of software agents, information can be autonomously and proactively scanned or searched, at the same time filtered and/or refined according to executive's information needs and interests. Data manipulation tools such as categorizing, ranking,

Figure 3. An agent-based EIS architecture



and alerting tools can be incorporated in the standard EIS development platform. Data manipulation tools are important because executives with severe time constraints would want to have the needed information processed beforehand. This can save their time and quicken their subsequent information processes if necessary.

All functional features in the EIS development platform would have to be highly dynamic and would probably have to operate in real time as executive's concerns and strategic issues change over time. Web-based technologies and intelligent technologies are potential and appropriate for building the intelligent functions with usability-adaptability-intelligence criteria. The representation and processing of ontological knowledge and semantic metadata, user profiles and natural language input, coupled with the application of machine learning techniques enable the intelligent EIS to acquire and maintain knowledge on itself and its environment.

Executive's information needs and behavior in acquiring and processing information is dynamic and heterogeneous. Hence, it is impossible to establish a common executive information domain. The executive information domain represents an executive's information needs, preferences of information attributes (i.e., sources, types, and contents), and use of information. It is also unlikely that common profiles of executives and processing behaviour in acquiring and using information can be formulated. Executive profiles represent an executive's attributes and roles, as well as the factors that influence or shape executive's information processing behavior. Therefore, the executive information domain and executive profiles must be specific to individual executive, company, and industry sector. A comprehensive and specific executive information domain and executive profile should be incorporated into the EIS architecture so that a personalized rather a general system is built for individual executive.

The key to make the common EIS platform work in conjunction to specific executive information domain and executive profiles is the executive-agent interaction (EAI) and executive-agent learning (EAL) mechanism. The EAI and EAL mechanism are agent-based applications supported by multiple software agents. User programming, knowledge engineering, and machine learning are potential approaches to adopt to build appropriate agents for interaction and learning. The building of EAI and EAL mechanisms will be based on the usability-adaptability-intelligence trichotomy of agent-based EIS design model. Research shows that user profile bases, knowledge bases, and case bases are useful to teach the software agents what to scan, what to filter, and what to process according to individual users. However, these static rules will not reflect executives' dynamic information needs and changing behavior. The agents must also be able to learn continuously in order to make the EIS more adaptable. The EAI mechanism comprises agents that react on explicit feedback, a coaching approach in which executive explicitly and interactively updates and refines his profile so that the system can adapt to changes of his information needs and requirements. The EAL mechanism involves no executive's intervention, but the agents learn through implicit feedback. The agents learn about executive's interests and behaviours based on implicit observation, monitoring and assessment with the intention to understand executive's interests and mimicking executive's behaviours. Over time, the EAI and EAL mechanism will become more and more autonomous, proactive and reactive in assisting executive intelligence activities.

THE CHALLENGES FOR DEVELOPING AN AGENT-BASED EIS

The real challenge lies not on the decision support capability of the EIS, but on the ability to process intelligence. The dilemma which requires due considerations when designing EIS concerns the ability to scan for information to the maximum capability of the system whilst providing manageable, relevant data and information to executives in a systematic way. The technical challenge related to intelligence processing is the software agents' capability to understand an executive as an individual user with specific domain of work and information, and to fit the intelligence processing into the right context and content of work and information.

The application of software agents in executive intelligence activities could potentially change executives' information processing behaviour. This is a two-way impact between the executives and the EIS. It can be envisaged that an executive's information role will not be weakened or replaced by software agents, because the agent is coached by the executive, and is a part of the executive's information processing process. On the other hand, executives may fear that software agents would take over some of their intelligence roles and limit their development, thus resist substantial reliance on software agents.

CONCLUSION

This chapter has argued that there is a need for revitalizing EIS with emerging intelligent technologies. An intelligent agent-based EIS will support and enhance executive intelligence activities through identifying, collecting, and processing potentially strategic information in a turbulent environment. The results of the empirical studies suggest an agent-based EIS design model for system developers, managers and researchers in the field of EIS. The agent-based EIS design model provides guidance for developing and utilizing software agents for continuous, self-reactive and self-adaptive activities or approaches of acquiring, synthesizing and interpreting information for executives to obtain strategic intelligence with a view to determining the course of action.

With advances in the development of software agents and Internet technology, an agent-based EIS platform for supporting executive intelligence activities is likely to be one of the future trends in EIS development and implementations in organizations. Future research can look into the development and implementation of an agent-based EIS architecture based on the proposed "usability-adaptability-intelligence" trichotomy of agent-based EIS design model. The architecture can consist of a common EIS development platform, a comprehensive and specific executive information domain and profiles, and an executive-agent interaction and learning mechanism. The development of specific domain and profiles and executive-agent interaction and learning mechanism involve the design and development of software agents using the appropriate techniques. The development and implementation process will involve close collaborations between system designers and executives for continuous improvement and success.

Chapter 3.5

Beyond Intelligent Agents:
E-Sensors for Supporting Supply Chain Collaboration and Preventing the Bullwhip Effect

Walter Rodriguez
Florida Gulf Coast University, USA

Janusz Zalewski

Elias Kirche
Florida Gulf Coast University, USA

ABSTRACT

This article presents a new concept for supporting electronic collaboration, operations, and relationships among trading partners in the value chain without hindering human autonomy. Although autonomous intelligent agents, or electronic robots (e-bots), can be used to inform this endeavor, the article advocates the development of e-sensors, i.e., software based units with capabilities beyond intelligent agent's functionality. E-sensors are hardware-software capable of perceiving, reacting and learning from its interactive experience through the supply chain, rather than just searching for data and information through the network and reacting to it. E-sensors can help avoid the "bullwhip" effect. The article briefly reviews the related intelligent agent and supply chain literature and the technological gap between fields. It articulates a demand-driven, sense-and-response system for sustaining e-collaboration and e-business operations as well as monitoring products and processes. As a proof of concept, this research aimed a test solution at a single supply chain partner within one stage of the process.

INTRODUCTION: FROM E-BOTS TO E-SENSORS

As e-business and e-commerce has grown, so has the need to focus attention on the: (1) Electronic communications between e-partners; (2) operational transactions (e.g., sales, purchasing, communications, inventory, customer service, ordering, submitting, checking-status, and sourcing, among others); and (3) monitoring improvements in the supply (supply, demand, value) chain of products, systems, and services (Gaither & Fraizer, 2002).

Integrating continuous communication protocols and operational and supply chain management (SCM) considerations, early on in the enterprise design process, would greatly improve the successful implementation of the e-collaboration technologies in the enterprise. It is particularly important to examine the resources and systems that support the electronic communications, and relationships among partners, in the supply chain.

In addition, there is a need for obtaining (sensing) real time data for managing (anticipating, responding) throughout the supply chain. Typically companies need to synchronize orders considering type, quantity, location, and timing of the delivery in order to reduce waste in the production and delivery process. The data collection and availability provided by the e-sensing infrastructure/architecture discussed later in this article will allow for a collaborative environment, improve forecast accuracy, and increase cross-enterprise integration among partners in the supply chain.

Current supply chain information technologies (IT) allow managers to track and gather intelligence about the customers purchasing habits. In addition to point-of-sale Universal Product Code (UPC) barcode devices, the current IT infrastructure may include retail radio frequency identification (RFID) devices and electronic tagging to identify and track product flow. These technologies aid mainly in the marketing and resupply efforts. But, how about tracking partners' behaviors throughout the chain in real time?

Artificial intelligent agents (or e-bots) can be deployed throughout the supply chain to seek data and information about competitive pricing, for instance, e-bots can search for the cheapest supplier for a given product and even compare characteristics and functionality. For this reason, the concept of an *agent* is important in both the Artificial Intelligence (AI) and the e-operations fields.

The term "intelligent agent" or "e-bot" denotes a software system that enjoys at least one of the following properties: (1) Autonomy; (2) "Social" ability; and (3) Reactivity (Wooldridge & Jennings, 1995). Normally, agents are thought to be autonomous because they are capable to operate without direct intervention of people and have some level of control over their own actions (Castelfranchi, 1995). In addition, agents may have the functionality to interact with other agents and automated systems via an agent-communication language (Genesereth & Ketchpel, 1994). This agent attribute is termed here *e-sociability* for its ability to interact with either people, or systems (software).

The next evolution of the intelligent agent concept is the development of integrated hardware/software systems that may be specifically designed to sense (perceive) and respond (act) within certain pre-defined operational constrains and factors, and respond in a real time fashion to changes (not a just-in-time fashion) occurring throughout the supply chain. These integrated hardware-software systems are termed *e-sensors*, in this article. Indeed, there is a real opportunity for process innovation and most likely organizations will need to create new business applications to put e-sensors at the centre of a process if they want to be competitive in this new supply chain environment. Aside from asset tracking, each industry will have specialized applications of e-sensors that cannot be generalized. Before getting into the e-sensors details, let us review some key supply chain management (SCM) issues relevant to this discussion.

SUPPLY CHAIN MANAGEMENT IN THE E-COLLABORATION CONTEXT

SCM is the art and science of creating and accentuating synergistic relationships among the trading partners in supply and distribution channels with the common shared objective of delivering products and services to the 'right customer' at the 'right time.' (Vakharia, 2002)

In the e-collaboration/e-business context, supply chain management (SCM) is the operations management discipline concerned with these synergistic communications, relationships, activities and operations in the competitive Internet enterprise. SCM involves studying the movement of physical materials and electronic information and communications—including transportation, logistics and information-flow management to improve operational efficiencies, effectiveness and profitability. SCM consists in the strategies and technologies for developing and integrating the operations, communications and relationships among the e-trading partners (producers, manufacturers, services providers, suppliers, sellers, wholesalers, distributors, purchasing agents, logisticians, consultants, shipping agents, deliverers, retailers, traders and customers) as well as improving their operations throughout the products' or services' chain.

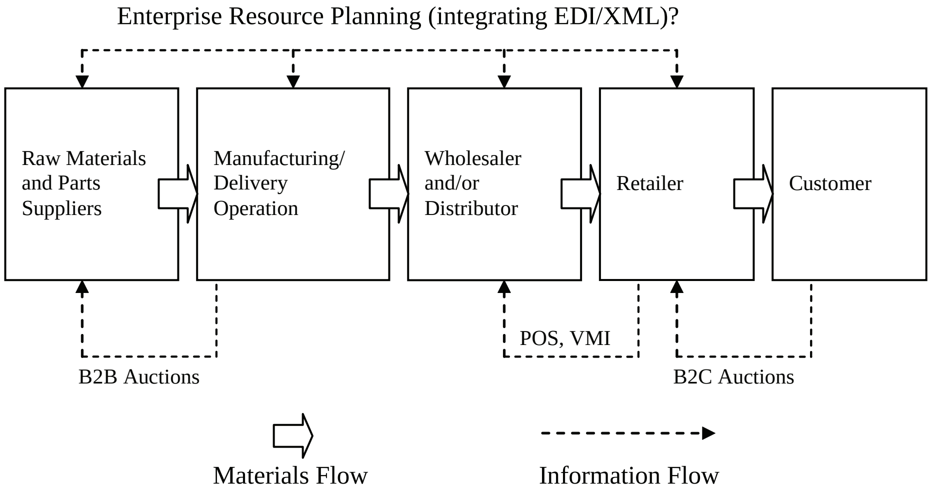
Integrated e-business SCM can enhance decision making by collecting real time information as well as assessing and analyzing data and information that facilitate collaboration among trading partners in the supply chain.

To achieve joint optimization of key SCM decisions, it is preferable that there be a free flow of all relevant information across the entire chain leading to a comprehensive analysis. (Vakharia, 2002)

As shown in Figure 1, IT systems, such as, enterprise resource planning (ERP), point of sale (POS), and vendor managed inventory (VMI) systems permit and, to some extend, automate information sharing.

The advent of reliable communication technologies has forced business partners throughout the supply chain to rethink their strategies as well as change the nature of the relationships with suppliers and customers. Companies that have made the shift have benefited from: "Re-

Figure 1. Information flow using electronic information technologies in the supply chain (after Burke & Vakharia, 2002; Vakharia, 2002)



duced operating expenses, increased revenue growth, and improved customer levels," according to IBM ERP/Supply Management Division (Cross, 2000). According to the same source, the companies that have implemented supply chain improvement projects have been able to increase forecast accuracy and inventory reduction (up to 50% in overall improvement!). Some of the newer activities being implemented include: Supply-and-demand auctions, integrated collaborative product design (CAD/CAM), cross-enterprise workflow processes, demand management collaboration. In addition, some companies are even deploying SCM as an offensive tactic to gain a competitive edge (Cross, 2000).

Meixell's "Collaborative Manufacturing for Mass Customization" (2006)site, at http://www.som.gmu.edu/faculty/profiles/mmeixell/collaborative%20Planning%20&%20Mass%20Customization.pdf, provides extensive information about the use of collaborative technologies in the supply chain. The same author recently compiled a literature review; particularly, on decision support models used for the design of global supply chains (Meixell & Gargeya, 2005). This, however, does not mean that there are no strategic and technological gaps in the supply chain.

PARADIGM SHIFT: FROM 'PUSH' (SCM) TO 'PULL' (SRS)

We are not smart enough to predict the future, so we have to get better at reacting to it more quickly. (GE saying quoted by Haeckel, 1999)

E-business forces have shifted both the enterprise landscape and the competitive power from the providers of goods and information (makers, suppliers, distributors and retailers) to the purchasers of goods and information (customers). For this reason, e-businesses must collaborate electronically and sense-and-respond very quickly to the individual customer's needs and wants. So, rather than considering SCM analysis from the "supply" perspective, some researchers and practitioners advocate analyzing the market operations from the "demand" perspective: Sensing-and-responding to the consumer changing needs and wants by quickly collaborating and communicating in real-time throughout the chain. Researchers argue that e-businesses should measure and track customers' demands for products and services, rather than relying solely on demand forecasting models.

Fisher (1997) studied the root cause of poor performance in supply chain management and the need to understand the demand for products in designing a supply chain. Functional products with stable, predictable demand and long life-cycle require a supply chain with a focus almost exclusively on minimizing physical costs—a crucial goal given the price sensitivity of most functional products. In this environment, firms employ enterprise resource planning systems (ERP) to coordinate production, scheduling, and delivery of products to enable the entire supply chain to minimize costs and maximize production efficiency. The crucial flow of information is internal within the supply chain. However, the uncertain market reaction to innovation increases the risk of shortages or excess supplies for innovative products. Furthermore, high profit margins and the importance of early sales in establishing market share for new products, the short product lifecycles increasing the risk of obsolescence, and the cost of excess supplies require that innovative products have a responsive supply chain that focuses on flexibility and speed of response of the supplier. The critical decision to be made about inventory and capacity is not about minimizing costs, but where in the chain to position inventory and available production capacity in order to hedge against uncertain demand. The crucial flow of information occurs not only within the chain, but also from the market place to the chain.

While Selen and Soliman (2002) advocate a demand-driven model, Vakharia (2002) argues that push (supply) and pull (demand) concepts apply in different settings. That is, since businesses offering mature products have developed accurate demand forecasts for products with predictable lifecycles, they may rely more heavily on forecasting models. While businesses offering new products, with unpredictable short cycles, are better off operating their chains as a pull (demand) system, because it's harder to develop accurate demand forecasts for these new (or fluctuating demand) products.

The difficulty in synchronizing a supply chain to deliver the right product at the right time is caused by the distortion of information traveling upstream the supply chain. One of the most discussed phenomena in the e-operations field is called the Forrester (1958) or "bullwhip" effect which portrays the supply chain's tendency to amplify or delay product demand information throughout the chain (Sahin & Robinson, 2002). For instance, a particular supplier may receive a large order for their product and then decide to replenish the products sold. This action provides the quantity to restock the depleted products, plus some additional inventory to compensate for potential variability in demand. The overstated order and adjustments are passed throughout the supply chain causing demand amplification. At some point, the supply chain partners loose track of the actual customer demand.

Lee et al., (1997) proved that demand variability can be amplified in the supply chain as orders are passed from retailers to distributors and producers. Because most retailers do not know their demand with certainty, they have to make their decisions based on demand forecast. When it is not very accurate, the errors in the retailers forecast are passed to the supplier in the form of distorted order. They found that sharing information alone would provide cost savings and inventory reduction. Other factors that contribute to the distortion of information is over reliance on price promotion, use of outdated inventory models, lack of sharing information with partners, and inadequate forecasting methods.

An important question in supply chain research is whether the bullwhip effect can be preventable. Chen et al., (2000) quantified the bullwhip effect for a multi-stage system and found that the bullwhip effect could be reduced but not completely eliminated, by sharing demand among all parties in the supply chain. Zhao et al., (2002) also studied the impact of the bullwhip effect and concluded that sharing information increases the economical efficiency of the supply chain. In a later study, Chen (2005) found that through forecast sharing the bullwhip effect can be further reduced by eliminating the need for the supplier to guess the retailer's underlying ordering policy.

The causes of uncertainty and variability of information leading to inefficiency and waste in the supply chain can be traced to demand forecasting methods, lead-time, batch ordering processes, price fluctuation, and inflated orders. One of the most common ways to increase synchronization among partners is to provide at each stage of the supply chain with complete information on the actual customer demand. Although this sharing of information will reduce the bullwhip effect, it will not completely eliminate it (Simchi-Levy et al., 2003). Lee et al., (1997a, 2004) suggests a framework for supply chain coordination initiatives which included using electronic data interchange (EDI), internet, computer assisted ordering (CAO), and sharing capacity and inventory data among other initiatives. Another important way to achieve this objective is to automate collection of Point of Sale data (POS) in a central database and share with all partners in a real time e-business environment. Therefore, efficient information acquisition and sharing is the key to creating value and reducing waste in many operations. A specially designed adaptive or sense-and-response system may help provide the correct information throughout the supply chain. The proposed system would have two important system functions—maintaining timely information sharing across the supply chain and facilitating the synchronization of the entire chain.

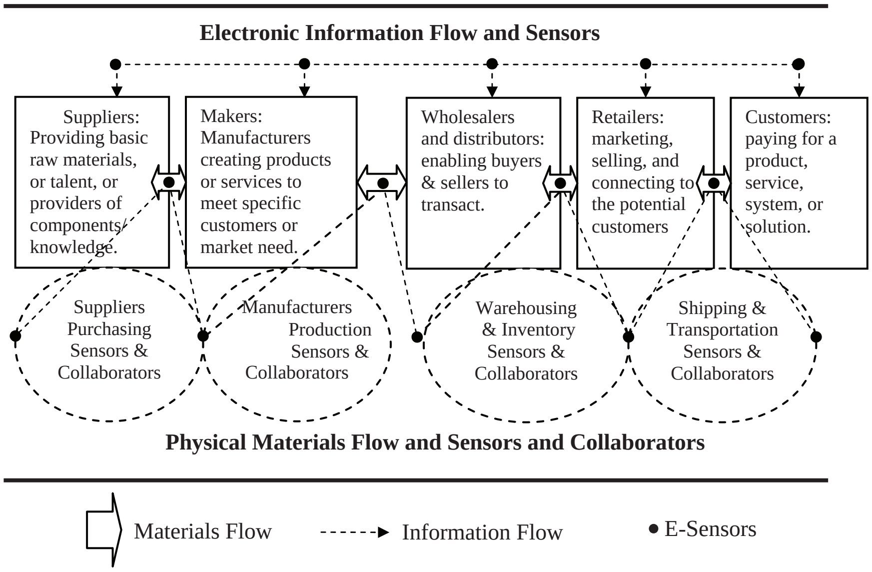
Haeckel (1999) indicates that “unpredictable, discontinuous change is an unavoidable consequence of doing business in the information age.” And, since this “intense turbulence demands fast—even instantaneous—response,” businesses must manage their operations as adaptive systems. Adaptive (sense-and-response) models may help companies systematically deal with the unexpected circumtances, particularly, e-businesses need to be able to anticipate and preempt sensed problems.

SENSE-AND-RESPONSE SYSTEM (SRS) MODEL AND FRAMEWORK

Figure 2 shows the proposed SRS model and framework for integrating real-time electronic communications, information sharing, and materials flow updating as well as monitoring the e-supply/demand/value chain—towards a new e-collaboration paradigm.

The “e-sensors” in the diagram are computer programs (software code) and its associated data and information collection devices (hardware), and communication interfaces. These sensors are designed for e-collaboration, data capturing (sensing), and information sharing, monitoring and evaluating data (input) throughout the value chain. Ultimately, this approach would result in semi-automated analysis and action (response) when a set of inputs are determined (sensed) without hindering human autonomy. That is, the sensors will gather the data, monitor, and evaluate the exchange in information between designated servers in the e-partners (suppliers and distribution channel) networks. Sensors will adjust plans and re-allocate resources and distribution routes when changes within established parameters are indicated. In addition, sensors will signal human monitors (operations or supply chain managers) when changes are outside the established parameters. The main advantage of this approach is that sensors will be capable of assessing huge amounts of data and information quickly to respond to changes in the chain environment (supply and demand) without hindering human autonomy. Particularly, e-sensors can provide

Figure 2. SRS framework for integrating communication, information and materials flow and monitoring the e-business supply/demand chain



the real-time information needed to prevent the bullwhip effect.

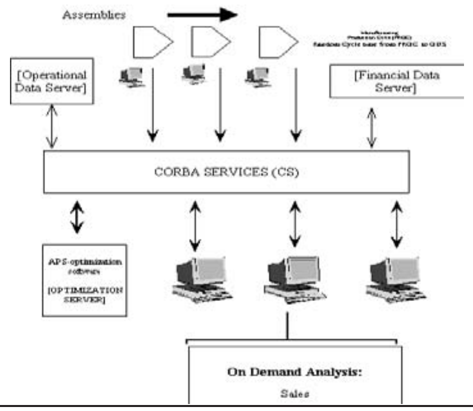
Companies like Cisco, Dell, IBM and Wal-Mart have led the development of responsive global supply chains. These companies and a few others have discovered the advantages of monitoring changes in near real-time. By doing so, they have been able to maintain low inventories, implement lean production and manufacturing operations, and even defer building and assembly resulting in lower costs and increase responsiveness to variable customer demands. This practice can be extended to incorporate e-sensors and human collaborators throughout the value chain and perceive and react to the demands.

SYSTEM ARCHITECTURE AND IMPLEMENTATION

To develop the implementation of the entire framework outlined in Figure 2 one faces involvement of multiple supply chain partners and months, if not years, of work just to develop a reliable communication infrastructure. In order to provide an immediate viable solution to test the concepts, in this research, the authors aimed at a single supply chain partner/company at only one stage illustrated in Figure 2, to provide interfaces to the immediate preceding and the immediate succeeding stage (Kirche et al., 2005). Choosing a wholesaler/distributor (the middle box in Figure 2) as the company to automate its information flows and material flows with e-sensors and e-controls interfacing to the manufacturers and retailers, as well as to internal storage and distribution centers, we developed the overall design architecture as illustrated in Figure 3.

The selected communication architecture is based on CORBA (Common Object Request Broker Architecture), a standard solution available from multiple vendors (Bolton, 2002). CORBA is an open system middleware with high scalability and potentially can serve an unlimited number of players and virtually any number of business processes and partners in the supply chain environment. As a communication infrastructure, it enables an integrated view of the production and distribution processes for an efficient demand management. Other benefits include continuous availability, business integration, resources availability on demand, and worldwide accessibility. The architecture presented in Figure 3 gives the wholesaler/distributor direct access to the assembly lines of the manufacturers and their shipping/transportation data via the operational

Figure 3. Architecture of distributed services for the wholesaler or distributor (after Kirche et al, 2005)



data server. Full communication with the retailers is available. The wholesaler/distributor company does have itself full control over their financial data server and optimization server. The detailed functions of this architecture are described in (Kirche et al., 2005).

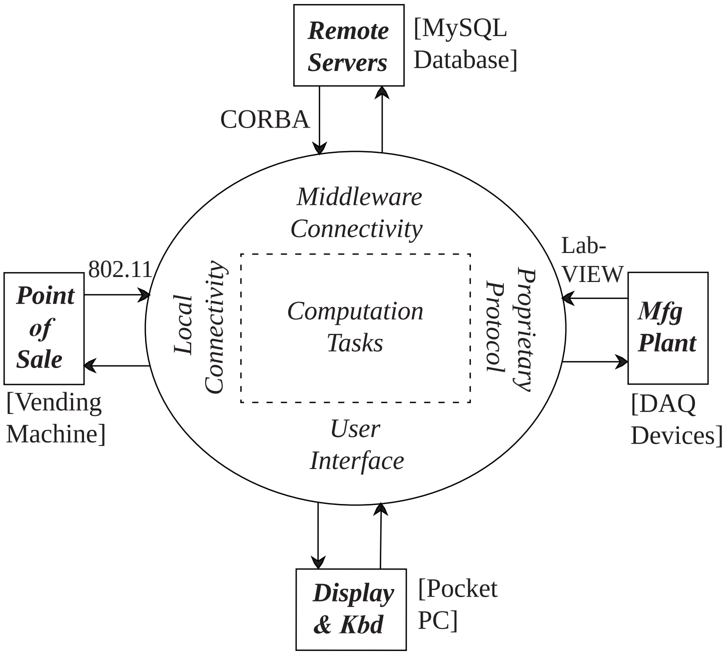
The goal of the real time system based on this architecture is to dynamically integrate end-to-end processes across the organization (key partners, manufacturers and retailers) to respond with speed to customer changes and market requirements. The real time CORBA framework enables employees to view current process capability and load on the system and provide immediate information to customers, by enabling tuning of resources and balancing workloads to maximize production efficiency and adapt to dynamically changing environment.

A sample implementation of the system architecture from Figure 3 is presented in the form of a context diagram in Figure 4. To achieve the project's objective, that is, remote data access to enterprise networks with e-sensors/e-controls, we provide the capability of accessing enterprise-wide systems from a remote location or a vehicle, for both customers and employees.

The overall view of the system is as follows:

- When access to manufacturers from Figure 2 is considered, the focus can be on *plant access* for immediate availability of data and functions of the system; in that case, a remote *e-sensor/e-control* application using LabVIEW data acquisition software (Sokoloff, 2004) comes into play, with graphical user interface capable of interacting with remote users connected via the Internet.
- When access to warehousing from Figure 2 is considered, the focus can be on *business integration* via a multi-purpose enterprise-wide network; in that case, a CORBA based framework is employed for a remote access

Figure 4. Context diagram of the system being implemented (DAQ stands for data acquisition and control, 802.11 stands for an IEEE Std 802.11 for wireless networks, SQL stands for standard query language)



to data objects identified as *e-sensors*, that can be stored on typical SQL database servers (Kirche et al., 2005).

From the network operation and connectivity perspective, e-sensors and e-controls provide business services, so they play the role of servers. Access to servers in this system is implemented via two general kinds of clients:

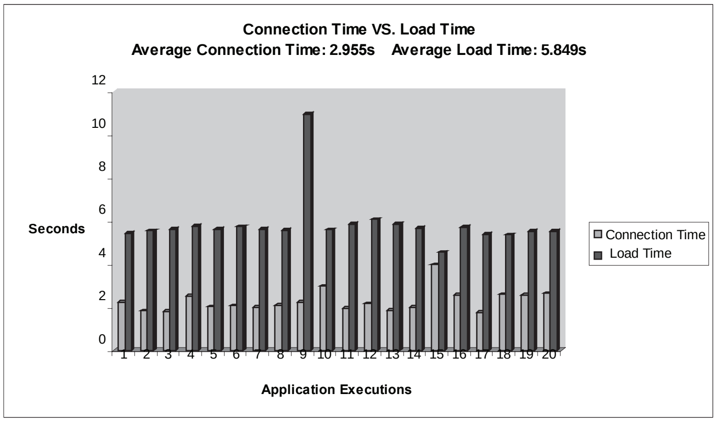
- When focus is on the *customer access* to obtain services, a cell phone location-aware application for business transactions has been developed, using order services as an example
- When focus is on the *employee access* to obtain services, such as conducting business on the road, a wireless PDA application for remote vending machine access has been developed, using the IEEE Std 802.11 wireless network protocol.

Several tests have been conducted to check behavior and performance of all four applications listed above and presented in Figure 4. For concision, it shows only a sample behavior of a PDA client via connectivity/performance test, in Figure 5. The graph shows how long it takes for the server to receive the connection request from the client application after the application was started. It is marked "Connection time." Another bar on the same chart shows how long the program itself took to load completely after being started (marked "Load time"). The connection graph was created to give an indication of how long, on average, one can expect for requests to be acknowledged and accepted by the server. Since all requests are handled the same way as the initial connection, this average connection time reflects sending and receiving of data to and from the client application. The load time is just a measure of performance for the application on the PDA itself. The data collected that way show the feasibility of all applications built within the SRS framework, as presented in Figure 2, for the architecture outlined in Figure 3.

CONCLUSION

This article briefly reviewed the current intelligent agent and supply chain paradigm and presented a conceptual framework for integrating e-collaboration tools in the operation and monitoring of products and services across value chain networks without hindering human autonomy. The demand-driven, sense-and-response framework model incorporates e-sensors and e-collaborators (humans using communication tools, computer software

Figure 5. PDA client connectivity/performance test



programs and its associated data-capturing hardware devices) throughout the supply chain. In practice, these e-sensors would be designed for data-capturing (sensing), monitoring and evaluating data (input) throughout the value chain, while humans collaborate and communicate in real-time, as tested in the above solution.

The implications of this new framework are that it contributes to the enhancement of the current SCM/DCM systems (such as Manugistics' demand planning system) that analyzes manufacturing, distribution and sales data against forecasted data. The addition of SRS sensors would signal human monitors (operations or supply chain managers) when changes are outside the established parameters. The main advantage of this approach is that sensors would be capable of assessing huge amounts of data and information quickly to respond to changes in the chain environment (supply and demand) without hindering human autonomy.

Ultimately, this approach would result in the semi-automated analysis and action (response) when a set of inputs are determined (sensed) without hindering human autonomy. That is, the e-sensors would gather the data and monitor and evaluate the exchange in information between designated servers in the e-partners (suppliers and distribution channel) networks. E-sensors would adjust plans and re-allocate resources and distribution routes when changes within established parameters are indicated. Particularly, the new approach will aid managers in the prevention of the bullwhip effect.

Having real time data is critical in managing supply chain efficiently. Typically companies need to synchronize orders considering type, quantity, location and timing of the delivery in order to reduce waste in the production and delivery process. The data collection and availability provided by the e-sensing infrastructure/architecture will allow for a collaborative environment, improve forecast accuracy and increase cross-enterprise integration among partners in the supply chain. E-sensors will also offer a more proactive solution to current ERP systems by giving them the ability to process in real time relevant constraints and simultaneously order the necessary material type and quantities from multiple sources.

This e-sensor concept opens additional research opportunities within the boundaries of the operations management and information technology fields, particularly in the development of new software-hardware interfaces, real-time data capturing devices and other associated technologies. Finally, it leads to future 'automated decision-making' where IT/operations managers can "embed decision-making capabilities in the normal flow of work" (Davenport and Harris, 2005).

Chapter 3.6

An Ontology-Based Intelligent System Model for Semantic Information Processing

Mark Xu
University of Porstmouth, UK

Yanqing Duan
University of Bedfordshire, UK

ABSTRACT

In the context of increasing usage of intelligent agent and ontology technologies in business, this study explores the ways of adopting these technologies to revitalize current executive information systems (EIS) with a focus on semantic information scanning, filtering, and reporting/alerting. Executives' perceptions on an agent-based EIS are investigated through a focus group study in the UK, and the results are used to inform the design of such a system. A visualization prototype has been developed to demonstrate the main features of the system. This study presents a specific business domain for which ontology and intelligent agent technology could be applied to advance information processing for executives.

INTRODUCTION

Many executive information systems (EIS) failed to provide strategic significant and meaningful information to executives (Bussen & Myres, 1997; Rainer & Watson, 1995; Xu, Kaye, & Duan, 2003) despite enormous efforts to make EIS easy to use for executives. This is due to the nature of strategic information for executives and technological weakness in semantically scanning and processing information. On the one hand, information needed by executives is primarily about the external environmental changes, which is often diverse, dynamic, and usually scattered in locations and not readily available (Xu & Kaye, 1995); in addition, making sense of emerging events and signals from the environment relies on executive's interpretation and knowledge, which is subtle and tacit in nature (Choo, 1998). Moreover, an individual manager has limited capacity to notice and process all the information needed from the external environments, which results in limiting the scope of input coverage and the stretch of the output delivery (Martinsons, 1994; Xu & Kaye, 2002). On the other hand, semantic information processing technology, for example semantic indexing, ontology have the potential to advance future EIS design, however, they have not been applied to the domain of EIS. As suggested by Fensel, Harmelen, Klein, and Akkermans (2002), the main burden in information access, extraction, and interpretation, still rests with the human users. Current document management system on market exhibits the main weaknesses: (a) existing key-words-based search for information cannot avoid retrieving irrelevant information if a word has different meanings, or missing retrieving relevant information if different words have the same meaning; (b) current automatic agents do not possess the commonsense knowledge required to extract information from textual representations. Human browsing and reading are required to extract relevant information from various sources.

There are specific challenges to the domain of executive information processing. Data extraction from current EIS is usually based on key performance indicators (KPIs), which are drawn from existing databases or data warehouse. Information provided to executives is often internal and historical orientated (Xu et al., 2003a). Besides, information provided from EIS is often already existed in other forms (Koh & Watson, 1998). Moreover, information provision is reactive not proactive, that is executives need to initiate their information search. Automatic, systematic and proactive information scanning and provision for executives has yet been realized in practice. As a result, information can easily become stale in most current EIS due to static presentation of data and incapability of handling soft information semantically (Watson et al., 1997). Despite the over emphasis on easy of use, friendly interface and wireless access features, the usefulness of the information contents of EIS is often neglected (Xu et al., 2003). Although EIS has been enhanced with data manipulation and decision support tools, the key deficiency still remains, that is the lack of intelligent functionality (Liu, 1998a, b; Montgomery & Weinberg, 1998). For instance, very few EIS can systematically scan business environment, automatically and semantically filter information, and proactively report/alert significant information to executives.

With the emerging semantic Web and domain specific ontology, it is imperative to explore the possibilities and the potential of applying latest technologies in the domain of executive information systems. Within this context, a project was initiated to examine how intelligent agent and ontology-based semantic information processing could be applied to revitalize information processing for executives. This study reports the perceptions of executives towards an agent-based EIS, based on which an ontology driven EIS visualization prototype has been developed. The following sections will present a review of the intelligent and ontology technology, a brief introduction to the methodology, the main findings of executives' perception on agent-based EIS and the main features of an ontology driven intelligent EIS through the visualisation prototype.

LITERATURE REVIEW

Intelligent Agent Technology

Agent technology has contributed to intelligent systems development (Klusch, 2001). Intelligent agents are "*software entities that carry out some set of operations on behalf of a user or another program with some degree of independence or autonomy, and in doing so, employ some knowledge or representation of the user's goals or desires*"

(Maes, 1994). Demazeau and Muller (1990) elaborate that the word "agent" is used in a broad sense to describe an intelligent entity, acting rationally and intentionally with respect to its own goals. By "autonomous" agent, it means that each agent has its own existence, which is not justified by the existence of other agents. Several autonomous intelligent agents can coexist and can collaborate with other agents in a common world. Each agent may accomplish its own tasks, or cooperate with other agents to perform a personal or a global task. Research in artificial intelligence (AI) suggests that to design an agent which has full capability to control its environment appears a difficult task. Because the agent has to deal with multiple, uncertain, contradictory sources of information, and to deal with multiple, contextual, conflicting goals. Therefore, multi-agents are necessary. This requires cooperation between agents. Each agent is assigned a particular task, it accomplishes its own task and submits a solution to other agents, for example, a data collecting agent forwards collected data to an interpreting agent who interprets and transfers the information to the decision makers. If the problem can be decomposed into several subproblems, several agents may synchronously perform its own functions and submit a solution synchronously with other agents to an electronic co-ordinator. Each agent has an associated work pattern; this can be either:

- Agents are controlled by time events, executing at time intervals.
- Agents are triggered by system events (e.g., system start up, system close sown).
- Agents are triggered by other agents (e.g., information arrival).
- Agents are triggered by a combination of certain times dependent on certain conditions.

An agent is empowered to act on behalf of a user. It works according to encapsulated knowledge of rules, assumptions, and samples which either are predefined by systems developers, users, or learnt by the agent themselves. Maes (1994) describes how an agent learns from three different sources:

- By continuously "looking over the shoulder" of the user as the user is performing actions
- From direct and indirect user feedback, coaching
- From examples given explicitly by the user

Information Agent

Research on software agents are looking into ways to improve current information acquisition and processing activities from distributed information sources. Information agents are emerged as a major domain in intelligent software agent technology. The goal of an information agent is to perform the role of managing, manipulating, or collating information from one or many different information sources through advanced information acquisition and retrieval (Klusch 2001; Nwana 1996). Klusch (2001) defines an information agent as one that can satisfy one or more of the following requirements:

- **Information acquisition and management:** The agent is capable of providing transparent access to one or many heterogeneous information sources. It extracts, monitors, filters, analyzes and updates relevant information on behalf of its users or other agents. The acquisition of information includes advanced information retrieval from both internal and external distributed information.
- **Information synthesis and presentation:** The agent is able to filter and refine heterogeneous data and to provide unified, multidimensional views on relevant information to the user.

- **Intelligent user assistance:** The agent can dynamically adapt to changes in user preferences, the information and network environment.

It is envisaged that information agents can assist users in information scanning and monitoring, extracting and filtering, manipulating and interpreting, recommendation and notification. However, not many information agents have been developed and deployed to support executive information processing (Nwana, 1996; Wooldridge & Jennings, 1995; Wooldridge & Ciancarini, 2001). Most of information agents are currently under development in research labs (Liebermann, 1995, 1997; Liebermann, Fry & Weitzman, 2001; Moukas & Maes, 1998), or remain as conceptual models (Liu, 1998a, b). One exception is Comshare—an intelligent agent software for information detecting and alerting, which is named as Comshare Detect and Alert. The core component of the agent is a robot that is trained to watch targeted databases for changes, trends, and other patterns that are known to be of potential interest to a user. Like an electronic personal assistant, the robot continually watches the data sources, and re-evaluates the rules every time the data changes. The system comprises of a set of products, these include:

- **Robot for Dow Jones:** Monitors NewsFeeds and stock quotes from Dow Jones News/Retrieval
- **Robot for Reuters:** Monitors news and stock quotes provided by Reuters Business Alert server.
- **Robot for Lotus Notes:** Monitors Lotus Notes databases for keywords and phrases.
- **Robot for OLAP:** Monitors Commander OLAP Server data sets for complex numerical patterns or trends.
- **Comshare's News Alert:** Works as a personalized electronic newspaper as shown in Figure 1.

The agent sends out alert to the desktops of interested users. The alert is displayed in a personalized electronic newspaper, along with the background information and tools needed for detailed analysis. Many alerts are created, each with a different set of recipients. E-mail system provides a capable backbone for the delivery of alerts. Alerts can be deposited into the e-mail system by the software robot. A software agent, running on the desktop of each user, can be programmed to look for incoming alerts, pull them out of the e-mail system, and insert them into the electronic newspapers. Each edition of

We are in final negotiations with Games Unlimited to become our largest European Distributor. They will carry the entire JAC line of products. The JAC 1100 however sold the deal. Please ensure that Production and Marketing are prepared for a new launch. We have guaranteed them 2week delivery of the JAC 1100 and they are committed to 5000 units over the first 6 months of the deal. They also plan a full advertising campaign and we will have to support

Information can be textual & is presented in an easy to view Newspaper style format, with headlines for fast access the newspaper is personalised for the individual reader and consists of a front page for the most important news stories followed by a series of individual news sections. Each user determines which sections appear in their personal newspaper and which types of alerts will appear. NewsAlert can also be used to broadcast news, where every user sees the same news, regardless of their individual interests. With the NewsAlert, there is a ClipPad which is a standard application serves as the electronic equivalent of a pair of scissors and a file box, which the newspaper reader uses to snip, save, and add commentary to articles or segments of articles from the news paper. The ClipPad also provides ready access to e-mail and Fax. Exploratory tools are available, so that readers can investigate any story and drill-down to the source data.

Although most information agents have been conceptualized to support automatic information scanning, processing, and reporting, a bottleneck for realizing their full potential is the lack of semantic data processing capability, which make current agent-based EIS attempts less appearing to executives.

The Challenge: Semantic Data Processing and Ontology

Heterogeneous sources and types of external information pose challenges to effective information scanning and processing, mainly because most of the information is textual and disseminated in various formats. Human knowledge is needed to browse and identify the most relevant information contained in the text file. Most of the current text retrieval systems are keywords matching based application programs that discover word or phrases encountered in the text. Keywords-based scanning could lead to information irrelevant, as indicated earlier, one word could have several different meanings in different context, or several terms may designate to the same concept. As a result, keywords based information retrieval system can hardly determine the correct meaning of the word encountered in different context, which can significantly degrade a query's precision and recall (Lu, Dong, & Fotouhi, 2003).

Another approach to retrieve text data is syntactic analysis. Syntactic based text retrieval system attempts to overcome the problem of keywords based scanning (Silverster, Genuardi, & Klingbiel, 1994). This system uses a recognition dictionary to assign syntax to each word encountered in the text, and to use Machine Phrase Selection program to string words together according to specified grammar rules. However, such a system requires large rules to handle different meanings of context sensitive words, and also needs enormous amount of information to disambiguate words. This makes the system's use impracticable. Problem also exists in understanding the meaning of the text, as the attention of the syntactic system is to form rather than content (Dorr, 1988). Only limited semantics can be derived from syntactic content of the Web pages (Lu, Dong, & Fotouhi, 2003).

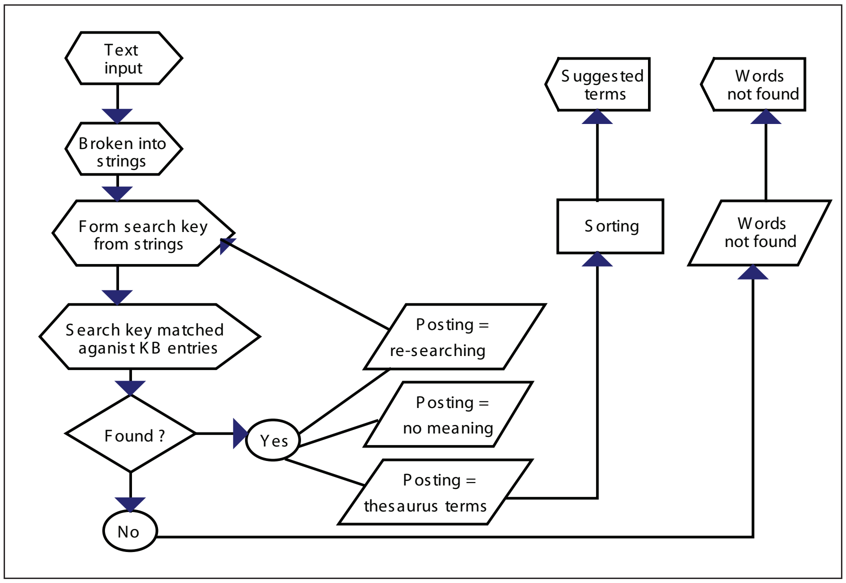
The above approaches pose challenge to transform distributed information into a semantically enriched information. Semantic data processing may offer a better solution to assign meaning to information and thus retrieve potentially relevant information. Several systems have been built to overcome the problems based on the idea of annotating Web pages with special HTML tags to represent semantics, including simple HTML ontology extensions system (SHOE) (Luke, Spector, Rager, & Hendler, 1997). The limitation is that they can only process Web pages that are annotated with these HTML tags, and there is no agreement upon a universally acceptable set of HTML tags. XML is another mark-up language that provides a text-based means to describe many different kinds of data. XML is a much more adequate means for knowledge representation, however, it can represent only some semantic properties through its syntactic structure.

Semantic-based text retrieval system has advantages over keywords based, and syntactic-based text scanning system. Silvester et al. (1994) introduced a machine aided indexing (MAI) system used by National Aeronautics and Space Administration (NASA) Centre for AeroSpace Information, which is a semantic-based indexing system. The MAI system is based on the use of "domain-specific terminology" as suggested by Melby (1990). This refers to words and phrases that are not broad in their meanings but that have domain-specific, semantically unambiguous, indexable concepts. These text words and phrases are matched against a list of text words and phrases that are generally synonymous to NASA's thesaurus terms. This system automatically suggests a set of candidate terms from NASA's controlled vocabulary for any designated natural language text input. Figure 2 depicts the procedure of the system.

The system consists of: (a) a text processor, the main function of this program is to identify the source of the text to be processed, to break the text into word strings, to delineate word strings found in natural language text; (b) a knowledge base (KB) which contains the Key field (Phrase Matching File) with more than 115,000 entries, and the Posting term field (NASA's thesaurus terms)—this is the dataset that provides the translations from natural language to NASA's thesaurus terms; (c) modular programs, this is to construct the search key in the string, look up the search key in the knowledge base, and return the output of the search to the index viewer or to the text processor. Although the system is mainly used for text indexing purpose, it allows limited semantics to be described by the controlled thesaurus terms. Using domain specific terminologies to automate machine indexing is akin to the ontology approach.

Ontology is key technology used to describe the semantics of information exchange. Berners-Lee (2001) suggests that an ontology is a document that describes a vocabulary of terms for communication between humans and automated agents. The most often cited definition for ontology is an explicit specification of a conceptualisation (Gruber, 1993). Nelson and Nelson (2005) suggest that an ontology can be thought of as a vocabulary (a set of words), a grammar (the set of rules or combining words into larger structures), and semantics (the meanings of the words and the large structure) all

Figure 2. Overview of NASA's online machine aided indexing system (MAI)



defined within a specific domain. Ontologies are useful because they encourage the standardization of the terms used to represent knowledge about a domain. In the context of business information, it is possible to have an executive ontology by which standard terms and specific meaning are defined to guide machine scanning and filtering. In addition, source documents provided to executives can be annotated by using ontology-annotation tools. In this way, machines are able to understand the meanings—semantics of the documents. Various ontology tools have been developed for building semantic data on the Web (Barros, Goncalves & Santos, 1998; Erdmann & Studer, 2001), and for digital library (Shum, Motta, & Domingue, 2000), but ontology specific to the domain of executive information processing have yet been developed, except a recent proposal (Camponovo, Ondrus & Pigneur, 2005) of an ontology for environment scanning that sheds some lights on this yet exploited area.

In summary, it appears that intelligent agents and ontology have the potential to advance executive information processing through automatic, semantic information scanning, refining, and sense making of data. The methodological setting described in the Methodology section aims to empirically examine executives' perception towards an agent-based executive support system. The findings will inform the development of an agent-based ontology driven EIS system or prototype.

METHODOLOGY

The methodological design consists two phases: the first phase is to examine executives' perceptions on using agent based EIS through a focus group study. The second phase is to develop an agent-base EIS visualization prototype on the Web in order to demonstrate the main features of such a system. The first phase involves a focus group study with 41 middle towards top-level managers in the U.K. The size of the focus group is about 10 persons per group. Each session begins with a brief statement on the purpose of the focus group, the confidentiality and ground rules for the discussion, that is, one participant talks at a time. The discussion questions, the related concepts and the use of software agents are also introduced prior to the discussion. Each focus group session took between 45 minutes to 1 hour to complete. Data is initially organized into meaningful themes according to predefined or newly emerging themes and categories. Thematic qualitative analysis (TQA) (Nicholas & Anderson, 2003) is used to conduct a detailed interpretive conceptual analysis and mapping. Meanings were sought from the transcripts to identify consensus, dilemmas, and contradictions. Selected quotes are directly presented as evidence.

In the second phase, an ontology driven intelligent system model and a visualisation prototype is designed to demonstrate the main features of the system for semantic information processing. The visualization prototype serves as a demonstration tool, rather than a tool for technological testing or implementation.

Findings

1. **Agent-based EIS scenarios:** Managers seem well perceived the importance of agent based EIS, and expect such a system to work for them by giving the following scenarios:

   Scenario 1: *"… you set up to run (the agent-based EIS) overnight, or whatever, and when I come in the morning, there will be something to look at …" "If the agent hasn't searched for a while, it could actually suggest to the user."*

   Scenario 2: *"You want to actually have the agent to be aware of that daily change. Today, priority for me is one thing. Tomor-*

row, it's something completely different. Now if I define within the agent, this is what I need now, tomorrow could be something completely different."

Scenario 3: "*… you could say to the system, 'get me half of page of view', it will then search all sources and present them in half a page.*"

Some issues emerged from the focus group discussions that may shape the development of an agent based EIS. These issues are described below:

2. **Semantic information processing:** Participants recognize the importance of obtaining semantically enriched information due to the different meanings that can be applied to the same word. As a result, they are concerned with the incomplete information processing caused by the lack of semantic information. Participants also express their frustration over the limitation of current search engine in natural language processing. Some managers perceive semantic information can be improved through better processing of natural language, in which the system is capable of categorizing natural language texts into predefined content categories. For example:

   "*If I am looking for something in my business, they might be in my head ten or eleven different words, which mean the same thing. But in various filter to get them, I have to put all those in. And then I might be missing something, because somebody else might call it something else.*"

   "*… is the frustration with natural language, like searching through the Internet. Conventional searching is giving you too much information, not the right information or whatever.*"

   "I think the challenge is to make sure that it conveys your meaning that (the EIS) provides needed information, and the way to improve is to understand the natural language."

3. **An executive controlled, personalized, adaptable learning system:** Participants raise the importance of adaptability and the learning capability of the agents, that is, the system should be flexible to adapt to changing situation and individual executive's managerial behavior through some kind of learning and user feedback. One manager suggests that the system *must* have a sort of flexibility within itself to retain (some of your interests and thoughts) as well as to develop. They further argue that the big mistake made is one usually driven by the software developer to drive what the rules are, for example, what we want to search, how you want to search, how you use it, and this has to be tailored into the context of the organization. The key to ensure EIS flexibility and adaptability is that the agent knows very clearly what the executive is looking for and what structure or format the executive would like to receive. Most managers suggest that great efforts are needed in order to coach the agent in order to enhance its learning capability, for example:

   "*I think the fact is that both systems would have learning curve. One is actually the programme itself, you wouldn't actually know what it's working on. And the people who are using it would actually go and say, 'oh, I did that last week and get the information or whatsoever'. From there, the system learns and how to turn and change.*" "*…it's the effort of coaching your agent*"; "*… more effort needed to train the agent.*"

   The finding suggests that the agent should understand the relevant characteristics of end-users. Hence, the setting of user profile and preferences, and domain specific ontology need to be established.

4. **Functionalities: Semantic scanning-filtering; categorizing-ranking-alerting, and analytical support:** Most managers tend to agree that data overload is a problem facing executives, thus filtering function is needed. One manager suggests that there is an immediate need for a filtering mechanism because of the volume of workload. For example:

   "*Conventional searching gives you too much information, but not the right information.*"

   "*I agree with the information overload, the quantity of information pouring into my consciousness*"; "*There's plenty of super fluid material that is going to me that there is no filter in between ...*"

In addition to semantic scanning and filtering function that enables systematically scan and retain relevant information, participants suggest a number of additional features of an agent based EIS. These features include information categorizing, ranking, alerting function, which will enable executives to manipulate information and to be informed proactively with new information. Managers comment that the system should have:

"*... the ability to filter and rank the importance of information … categorise the search results according to meaningful topics*"; "*…it should have different ways of organising information, for example, information of the day before, information of the day after.*"

"*Once the information comes in, the executive can get a rule of thumb, so the agent probably can give a flash, for example, about new information.*" "*… it will actually suggest things to you on what you are trying to look for.*"

Some managers expect an agent-based EIS to support decision analysis and decision-making in addition to strategic information provision. The key functions will include analytical tools such as data analysis, modeling, forecasting, comparison, drilling down, strategic mapping, and so forth. As generated from the group discussion, managers want the EIS:

"*to predict and forecast as well, but that will be the next level*"; " *to provide recommendation based on the information provided*";

However, not all executives agree on the filtering function of an EIS. The main concerns are the risk of filtering out potentially useful and important information, as expressed by a manager as follows:

"*There's a great possibility, very high risk, you are actually filtering out fringe of information that could be probably more beneficial to you than the initial information that you are looking for in the first place.*"

Although one participant expressed that "*… the raw data needs to be processed in a meaningful way*", most executives are sceptical to the interpreting function of the EIS. Most executives tend to agree that interpretation should be done by the manager.

"*I have extreme concern about that interpretation function*"; "*I believe interpretation should be done by executive … I think it has to be a low level interpretation first*"; "*…certainly for me, I interpret the data myself.*"

5. **Executives need a small amount of information that is manageable:** Participants were very concerned with the time needed

in processing information. Managers express that the key issue is to have the right balance of the amount of information. It is evident from the following statements:

"*It's about time constraints. We are talking about using executive time effectively and efficiently*"; "*Due to the lack of time, it should be manageable, with a small amount of information*"; "*The key driver is time, because the time you need to spend on the system. You only spend that time if it's key information that you need firstly according to your role*."

It suggests that the amount of information provided must be manageable and the time spent on processing the information must be kept to a minimum.

6. **Executives are concerned with the impact of using an agent based system:** Executives are concerned with the possible impact of the agent-based EIS on their information processing behavior. Some participants feared that their managerial roles could be changed or replaced by the system. The concerns are "*the system could actually force me to look at thing I don't want to look at …*"; "*Would it replace executive when it learns too much?*" and "*could it lead to the redundancy of managers?*"

    The main impact perceived by executives is over-dependent on the system, which will limit executives' personal development, as well as creativity as a senior manager. They express that:

    "*this system would actually limit the development of senior executives.*"; "*…the concern is this limiting development kept coming back to me.*"; "*…becoming more and more dependent on the software and not thinking for themselves, reducing creativity.*"; "*My another concern is probably people would completely start depending on the system rather than using their own brain.*";"*…sitting in front of computer, limit the creativity, losing the skills …*"

    An agent-based EIS may play limited role in directly support managerial decision making. Executives treated EIS as a complimentary tool that supports executive information processing activities rather than in any way to replace it. The main reason explained by the participants is intuitive nature of management decisions that require human intelligent instinct. However, the system has been perceived useful in the way that "*senior executives would use it more as gaining background knowledge and keeping up-to-date*", and "*It could be a useful source to back up some of your tacit knowledge*."

7. **Other Issues:**
    Ease of Use: It is believed that executive information system (EIS) should be easy to use, incorporate standards for good user interfaces, and allow quick access to vast amount of data by combining graphic, tabular and textual information on a single screen. Participants in this study suggest that the intelligent agent based EIS should be accessible, manageable and simple for users to use. A manager states, "*I think it should be simple for recipient to utilise the information*."

    Security: Information and system security have been highlighted as another concern for developing an agent-based EIS, particularly the confidentiality in the process of analyzing and interpreting information. As expressed by the manager that the software agent needs to have the real confidence in analyzing information, and be confidential if we ask software agents to interpret.

Cost Saving and Culture Change: One manager comments that his concern is the cost, and it has to be a cost-effective way particularly for information filtering. Change is inevitable for implementing agent based EIS, this may include not only the system itself, but also the vision, process, and culture. A manager comments that it might be more of a cultural challenge to get the system to work for them.

In summary, the criteria for an agent-based EIS from executive's perspective is self evident as disclosed above. Although some of the concerns are not subject to technological solutions, for example the concerns of the impact, the cost, and culture issues, their views on how an agent-based EIS will work for them shed light on how such a system shall be developed. The section titled "An Ontology Driven Intelligent EIS Model and Prototype" presents our initial efforts to turn executives' views into a system model and a visible prototype, which demonstrates the key features of the functionality of an ontology driven intelligent system for semantic information processing.

AN ONTOLOGY DRIVEN INTELLIGENT EIS MODEL AND PROTOTYPE

The key features of an ontology driven intelligent EIS can be summarised as below:

- Systematic scanning of information from multiple internal and external sources. The scanning engine incorporates executive ontology, and/or semantic indexing to ensure relevant information being widely scanned.
- Semantically filtering information to the level that the executives like to receive. The filter shall be driven by learning agents that filter out irrelevant information according to user profile, criteria defined by the user, user feedback, case based reasoning, and knowledge base.
- Automatic categorizing, ranking, prioritizing items according to its significance, and alerting significant news/unsolicited/unexpected information to the executives. Limited interpretation and recommendation can be offered as an advanced function. Intelligent agents perform these tasks according to user profile, user feedback and coaching, and agents learn from cases and examples.
- The system will integrate tools that support intelligence disseminating and sharing, allowing executives to manipulate information—drill down, track original information sources, and to support decision analysis.

The main agents and the bases underpinning agents' activity are depicted in Figure 3.

A visualization prototype of this model has been developed on the Web using Active Server Pages (ASP) and MySQL database. It is beyond the scope of this study to use the prototype in an online setting with live data stream. Hence, the prototype is not built for technological testing or as a technological solution. Figure 4 shows one of the interface windows of an ontology driven intelligent system for executives.

The left-hand window is an environment for executives to browse or search for both internal and external information. This window also serves as a personalized electronic newspaper and has a function to alert executives when unexpected (unsolicited) information has been detected. This is a workspace that integrates, aggregates, and presents strategic significant information from multiple sources, including the Internet, newsfeeds (press, subordinate, employee, customers, etc.), internal systems (ERP, CRM), internal reports, data warehouses, images, and file server. This is different from an enterprise information portal (EIP) in that the process behind the window

is driven by intelligent agent and ontology that is specific to the individual executive. Hence, the information reported/alerted here has been semantically processed for relevancy and significance, and has been personalized for individual executive's managerial role and preferences.

The agent set-up window is shown in Figure 5. The agents could comprise past information search activities and predefined information needs in "*user profiles*", which is generated by a learning agent, or defined by the user. The user profile can consist of executive's personal profile, executive's information needs and interests, executive roles, and organizational environment profile, which enable software agents to perform domain-specific acquisition and filtering of information. As a result, information processing becomes more personalized to the executive.

The "agent setup" function allows executives to coach the agents by using natural language to define information needs and changes. In order for the agents to understand semantic meaning

of executives' requests and enquiry, executive ontology shall be configured to the search engines for semantic scanning and refining. Different ontologies may be needed, for example, an environmental scanning ontology, and an information refining ontology. For example, the term "*Business*", "*Travel news*", "*Leisure News*" displayed on the right-hand window shall be the concepts defined with agreed meaning for a specific industry or an individual executive. The semantic meaning and coverage of word "business" in travel industry will be different from that of chemical industry. Thus, even using the same word, different ontologies will result in different information being scanned and processed. The ontology will define its domain specific concepts and a scheme showing relationship with other related concepts. The ontology-driven configuration will ensure only relevant information is scanned and filtered. Semantic indexing system using domain specific thesaurus may be an alternative solution. For example, synonymous terms related to "business" that is specific to the industry are defined in a controlled thesaurus. It is expected that executives can also use ontology-annotation tools to annotate items/signals to assist agent's learning and knowledge sharing.

In addition to the information provided by the alert agents, an interpretation agent may analyze the information using AI techniques, such as case base reasoning, production rules, and machine learning. Figure 6 shows a sample of agent interpretation.

It is essential that executives give explicit feedback to the information agents through a rating system or using ontology annotation tools. Whenever the executive finds that the agents fail to provide relevant and less significant information, the executive can always give comments to the agents in order to improve his user profiles. Figure 7 shows an example of user giving feedback to agents.

IMPLICATION

The applications of software agents and ontology for semantic information processing are still in its infantry, particularly in the domain of executive information processing. The implications of this study are: firstly, the domain specific issues concerning executive information processing are revealed, which shed light on future development of agent-based EIS and other systems related to

executives' information acquisition and processing. Secondly, this study takes an innovative step to explore the possibility of applying ontologies to agent-based EIS for the purpose of semantic information scanning and processing. Although such an executive ontology has not yet been developed within this study, the novelty of this exploration is expected to generate more interests and efforts in developing and applying ontology in the domain of executive support system. Thirdly, the Web-based interface prototype sets an example that could stimulate ontology and intelligent system developers to develop system solutions related to the work of executive information processing. Lastly, developing and implementing an agent-based EIS and executive ontology need executives' participation and support, for example executives annotate information received and give feedback. Considerations also need to be given to nontechnical issues such as cost, impact on managerial work, culture changes, and security of information.

CONCLUSION

Our study explored the opportunities of applying agent and ontology technologies in the domain of executive information processing, and revealed executives' perceptions towards developing an ontology-driven intelligent executive information system. Many executives perceive such a system useful by particularly using the system for semantic information scanning, filtering, and alerting as well as advanced executive decision analysis and support. However, the capability of this type of system shall not be exaggerated, as executives see it as only a useful supplementary tool. Executives tend to make sense of data (interpretation) and make intuitive decisions themselves. Executives also need a manageable amount of significant information from EIS. This implies that an agent-based EIS shall be able to selectively and semantically scan and filter information and report only significant information to executives.

The technological challenges rest on machine learning for semantic information scanning and processing. A range of tools for semantic information processing are available, but these tools are not yet used for executive information processing. In particular, executive ontology has not yet been considered as a potential tool to advance EIS design. The integration of intelligent and ontology offers great potential to revitalize EIS. Its realization however, relies on the development of functionality of the information agents, the executive ontology, and an environment that can facilitate agent learning.

Future studies can be carried out to address some of the limitations of this study in three directions, firstly, to develop executive ontology that is specific to industry sector and individual executive. Secondly, to continue developing a fully functional Web-based prototype/system that incorporates intelligent information agent and executive ontology with an emphasis on semantic strategic information scanning, filtering, and alerting and thirdly, to explore suitable ways of the interaction between executives and the agents through coaching and learning. It is hoped that this study will attract more research into this yet being exploited, but significant arena.

ABSTRACT

The rapid development of computing technology has facilitated its use in engineering design and manufacturing at an increasing rate. To deliver high quality, low cost products with reduced lead times, companies are focusing their efforts on leveraging this technology through the development of knowledge-based systems such as an IDA. An IDA, which can also be referred to as a design information system, is a part of the overall enterprise information system framework, and plays an important role in improving competitiveness in product development oriented companies. Not only must such a system utilize human expertise and address CE issues in decision making, it must also lead to the preservation and transfer of technical knowledge to minimize the knowledge loss from organizational moves such as personnel retirements and company relocation. The emphasis in CE is to consider downstream aspects of different phases in the product life cycle as early as possible in the design stage. These aspects include production process planning and realization, manufacturing and assembly resources, maintainability, costing and other factors. Both human expertise and downstream aspects predominantly consist of information that is descriptive. This paper discusses the structure and development of a knowledge-based design information system that can convert this descriptive information into forms that are suitable for embedding within decision-making algorithms. Information in such a system is sorted in terms of its nature into three groups: input data infor-

mation, constraint information, and objective information, all having different representations. Information is also mapped to the relevant design objectives and ranked in importance to facilitate the trade-off analysis.

INTRODUCTION

Concurrent Engineering (CE) has become a very attractive and enthusiastically discussed product development approach in recent times. To realize the concurrent design process, a key demand is to find an appropriate way to present life cycle information to the design stage. On the other hand, designs are normally required to achieve a set of objectives. Generally, these objectives are correlated to each other with either positive or negative dependencies. Therefore, solving a design problem always involves numerous trade-off decisions. It is a big challenge even for an expert to find an optimal compromising point and almost an impossible task for a less experienced designer. Thus, designers need a computer system to support the design course by providing them with the right advice at the right time (Reidsema, 2001). The rapid development in computer science and information technology has given birth to many new software tools for product development. Computer-Aided Design (CAD), Computer-Aided Manufacturing (CAM), Computer-Aided Engineering (CAE), Computer-Aided Process Planning (CAPP), Design for Manufacturing (DFM), and Design for Assembly (DFA) are quite commonly-used tools in today's product development practice. To a large or less extent, these tools adopt some aspects of the concurrent approach through the inclusion of product data management and collaborative work tool functionalities. Quality Function Deployment (QFD) is another successful product development technique which is also compatible with the idea of CE as it provides a systematic methodology for ensuring that constraints and objectives identified in the client specification phase are maintained through the entire development phase. Although these systems may provide the designer with very good support at specific points, they lack the ability to observe the design problem from an overall point of view.

Knowledge Based Engineering (KBE) represents potentially the most significant product development technique to date. It provides a new strategic approach for realizing the concurrent product development process to improve effectiveness in design and manufacturing. It also facilitates the preservation and transfer of knowledge in companies that operate in a physically-distributed environment. Not only does it utilize traditional elements in the design process such as geometric models, it also captures other underlying attributes of design such as experience and expertise. In our research, an Intelligent Design Advisor (IDA) is proposed based on this approach in an integrated, concurrent engineering environment. On the one hand, it addresses the "life cycle" design challenges by incorporating multi-disciplinary knowledge resources into the system to achieve design and manufacturing intent, and other subsequent requirements generated through the product's distribution, use, and disposal. On the other hand, it utilizes an expert's knowledge in the course of product development to guide less experienced designers. The system can also suggest design alternatives in terms of cost, time, equipment availability, or other critical requirements to enable the creation of a fully-engineered design by acquiring, representing, planning, reasoning and then communicating the intent of the design process. Thus, it can provide the necessary degree of intelligent interaction that enhances the designers own inherent skills and creativity (Cooper, Fan, & Li, 2001).

To implement the IDA, all related product information, including raw numerical input data, physical design and manufacturing constraints, design objectives and various other life cycle requirements, as well as human expertise, must be stored in a design information system. The information must be attained and saved in a structured and reusable manner to emulate expert-like problem-solving styles (Yang & Reidsema, 2004), which can improve overall efficiency and solution accuracy, and reduce development costs. With such an information system, the generation and evaluation of new design alternatives can occur quickly and easily by changing and analyzing only the relevant parts of the system within the IDA. This frees the engineer from time-intensive, detailed engineering tasks such as repetitive and unnecessary calculations and allows more time for creative design work. An IDA also provides a proprietary intellectual base to avoid the loss of knowledge within a company, and can guide new designers towards a solution which represents "best practice" according to company requirements.

As a part of the whole Enterprise Information System (EIS), an IDA plays an important role in a product-development-oriented company. Unlike other earlier information systems such as Material Requirement Planning (MRP) and Manufacturing Resource Planning (MRPII), which focus on manufacturing aspects, an IDA is concerned with the product development and the design function of an organization. It may also interact with other information systems, such as Computer-Aided Design (CAD) and Computer-Aided Manufacturing (CAM), to increase functional integration within a company and to perform information verification, characterization, development and distribution in the overall perspective of the company.

In this paper, a brief literature review is first carried out, and the basic requirements for a KBE system are summarized. Then, a matrix-based approach to represent design information within a concurrent product development environment is explained including its configuration, working principle and failure recovery mechanism.

LITERATURE REVIEW

KBE has found a large number of applications in product and process design. Chau and Albermani (2002) have developed a system prototype to assist in the preliminary design of liquid retaining structures by providing expert advice to the designer in selection of design criteria, design parameters and optimum structural section based on the minimum cost. Kwong, Smith, and Lau (1997) presented a blackboard-based system for concurrent process design of injection molding to obtain process solutions quickly and easily. Both systems are focused on the particular products. They are difficult to extend to the other applications because they do not have a general implementation frame. Reidsema and Szczerbicki (2001) discussed the development of a general knowledge-based system for the design planning process in concurrent engineering by utilizing the Blackboard Database Architecture (BBDA). However, this system is mainly concerned with process planning rather than specific design parameter selection. There are also some commercial KBE systems; among them, ICAD is one of the first developed and most commercially successful system. It consists of two interfaces: the CAD interface handles the geometric model and the knowledge interface deals with the programming of rules (KTI, ICAD). Although ICAD provides a connection between the actual geometry and the associated knowledge, the design process is still a repetitive loop, and thus efficiency is compromised. Moreover, knowledge preservation in ICAD is not emphasized. Studer, Benjamins, and Fensel (1998) pointed out that reuse of knowledge is advantageous in reducing development costs of knowledge-based systems because such a system can be constructed from ready-made modules instead of being developed from scratch. Recent research on KBE has concentrated on the knowledge preservation and utilization within companies and institutions. A useful approach is the case-based reasoning approach (Pokojski, Okapiec, & Witkowski, 2002; Pokojski, Strzelecki, & Sledziona, 2002) which involves solving new design problems on the basis of similar solutions from previous problems. The stored cases are previously solved problems that include not only the final solutions but also the project evolution history. Gardan and Gardan (2003) proposed to record knowledge from experts that can be invoked within CAD software in the form of scripts. The purpose of using such design scripts is to separate the knowledge from the implementation, and then to bridge the gap between design and knowledge management. Though knowledge storage is achieved more or less in these methods, it is not easy to maintain, structure, and re-process the preserved knowledge.

In summary, a KBE system must be easy to access, maintain and be documented, and most importantly, is able to solve a design problem correctly and efficiently. Some basic requirements include:

- Correctness and efficiency: It must ensure that a design problem can be solved efficiently and accurately.
- Maintainability: The model must be flexible so that it is easy to add/remove or modify knowledge.
- Compatibility: The model must be easily associated with other commercial software tools to improve its accuracy and efficiency, and broaden its use.
- Communicability: It should be easy for a designer to access and communicate with the model, and monitor and intervene in its progress.
- Reusability: It must be structured in a reusable manner so that it can be retained as generic design knowledge.

Our proposed IDA can be referred to as a matrix-based design information system since information in this system is presented as a matrix pattern and involves activities of acquisition, structuring, and processing. It has the ability to take comprehensive consideration of all design objectives and also utilizes an objective-oriented approach by mapping design parameters to the relevant design objectives. The IDA can also be used as a product development frame. It can generate, or at least suggest, a new design automatically based on a previous example and new design objectives through structuring and characterizing the design information

The matrix-based design information system meets most of these requirements. Organizing all information in a matrix promotes maintainability as any information can be included in the matrix, and it is easy to add/remove and modify information. Matrices are a simple, straightforward yet powerful representation pattern. It is easy for people to accept, understand and handle, and therefore improves communicability. The matrix is also able to record a large amount of knowledge and leads to the preservation of technical knowledge to minimize the loss from organizational moves such as personnel retirements and company relocation. Once a design project is finished, the information matrices, including characterized sub-matrices and the detailed problem-solving process, can be saved in design history storage for future use. In this system, information processing is finished before making decisions in the selection of design parameters. The information processing results can also be stored for future re-use. Thus, solving a new design problem becomes relatively easy, and the time and cost can be saved because of reduced and simplified computations.

CONFIGURATION OF THE INTELLIGENT DESIGN ADVISOR

The configuration of our proposed matrix-based IDA can be shown in Figure 1. Within such a system, we assume that a project library has been established in a company. The library contains all existing products that a company has developed, and is saved in an information model that contains such attributes as geometry, decomposition scheme, information matrices, characterization results, and decision tables. For a new design, a new information matrix can be established based on previous similar design examples and new design inputs, then after a series of processing stages, a decision-making algorithm will provide solutions or present suggestions to the new design objectives.

The configuration of the IDA also indicates that such an information system can be summarized into four typical stages from the sequential point of view. As described in Figure 2, after the first step of information acquisition, the information is prepared for introduction to the processing stage. Then, processed information is integrated to facilitate the decision-making process.

Information Acquisition

In the information acquisition stage, all information that is relevant to the design problem, such as attributes, requirements, constraints, and objectives, is collected. This is a particularly difficult stage as it requires manual inputs from designers. This stage also involves searching for previous similar examples from the design project library in order to develop a new or adapted design based on the previous product. The design project library can be thought as part of the information system used as long-term memory (Yang & Reidsema, 2004). It should be well-organized and indexed to enable efficient searching.

When a finished design is saved into the project library, it will be allocated to an appropriate family domain from a list of existing domains under which it can be saved. Alternatively, a new family domain can be created. Once a new family domain is created, it will then appear in

Figure 1. Configuration of the IDA

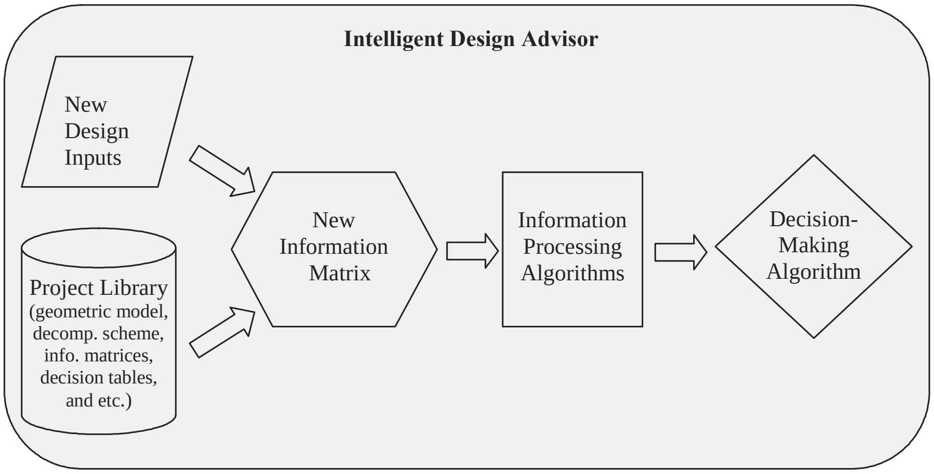

Figure 2. Information handling in IDA

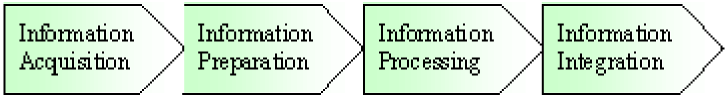
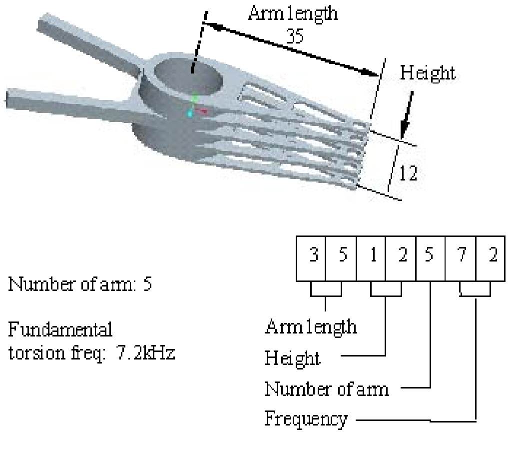


the option list in future saving and searching processes. The name of the family domain must be meaningful and descriptive to describe the nature of the model clearly. After choosing the appropriate family domain, critical factors must be selected from a list, and their relevant values entered to be saved together. Newly identified critical factors, which are associated with this family domain, can be added to the list. In general, the designer will be given information such as key design specifications and design targets at the beginning of the design process. Therefore, to facilitate the searching process, these key design specifications and targets are normally chosen as the critical factors. For example, in the design of an actuator arm for a hard disk drive as shown in Figure 3, the height, arm length, and the number of arms can be thought as the critical factors, as well as the fundamental torsion frequency which is a key design target for actuator arms in general. These critical factors can serve as a searching index. During searching, the process is quite similar to that describe earlier. First, the designer is asked to choose a family domain, and then must provide preferred target critical factors and their desired values. Based on these values, it would be relatively easy to obtain one (or even more) close design example upon which the new design can be developed.

Figure 3. An actuator arm and its name code

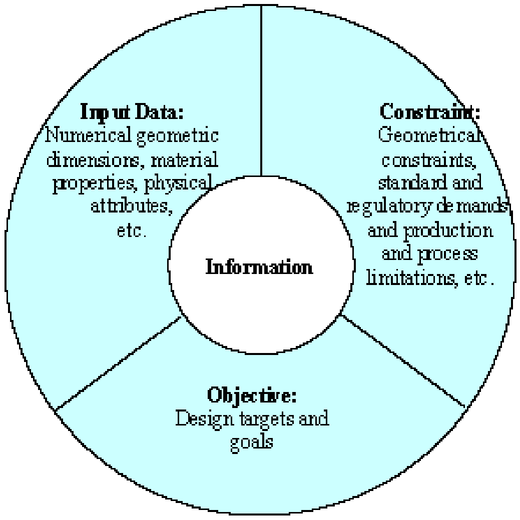


Alternatively, instead of setting critical factors, we may develop a name code system to label the critical parameters and their respective values (or value ranges) for a particular product. As shown in the actuator arm, its name can be coded as 3112572 in which the first two digits indicate the length, the third and fourth indicates the height, the fifth suggests how many arms it has, and the last two indicate the fundamental frequency. However, this method may not be as flexible as the first method since it prevents the designer from freely adding new codes.

Information Preparation

The second phase of information preparation includes elimination of duplicated or unnecessary items and the sorting of these items. This must be done manually by the designer. The aim of doing this is to cross-check the gathered information so that it is suitable to be introduced into the next processing stage. Normally, the gathered initial information is unstructured and needs to be cleared up. The designer can answer questions regarding the redundancy or necessity of the information in order to discard all unnecessary information. This sorting is also very important

Figure 4. Information wheel



in order to classify the information in terms of its nature. All information items can be sorted in terms of their nature into three groups: input data information, constraint information and objective information, as shown in the information wheel in Figure 4. Input data are in numerical form and include geometric dimensions, material properties, physical attributes and characteristics, as well as production and process data. Constraint information includes geometrical constraints, standard and regulatory demands, and production and process limitations. There are two types of geometrical constraints: numerical constraints such as distance and angle, and symbolic constraints such as coincidence and parallel (Wang, 2003). For instance, in the design of a slot, it is required that its width should not be less than a certain value, and its two edges must be parallel. Hence, the width requirement is a numerical constraint while the parallel condition is a symbolic constraint. Constraints are normally expressed either in declarative forms, "if-then" rules, or as mathematical equations. Constraint information is extremely important in a knowledge-based system as constitutes a critical component of the knowledge and can allow for constraint relaxation methods to be employed when possible solutions become overly constrained. Objective information includes certain targets and goals that the design is expected to achieve. These should be clearly stated and uncomplicated. An ambiguous or ill-defined design objective can easily result in either a failure to arrive at a solution or an excellent but incorrect recommendation. Some objectives may be uncertain, such as minimum cost and mass for a design. In such a case, certain levels can be set for them based on the previous example.

It should be pointed out that it may not draw a clear line to distinguish the objective and the constraint information. Constraints are something that must be followed in the design process and are used to guide parameter selection. The objectives can be thought of as indications that a design has been finished successfully. Objectives can also be used to evaluate the performance of a design. In the previous example of an actuator arm, an engineer may be asked to design an arm for which the fundamental torsion frequency is not lower than 7 kHz and the length of the arm is between 33 mm and 37 mm. The first requirement is a design objective and the latter is a constraint.

The preparation stage may also involve the preliminary analysis of information. First, the previous similar design example(s) need to be modified based on the new design requirements, in order to remove any conflicting elements. For instance, the overall length of the selected design case may be a little less than required. Thus, it can be identified as a parameter that must be modified to form the new design. In other cases, analyses such as FEA might be carried out on the initial model to obtain preliminary physical and structural characteristics. These preliminary analytical results are introduced into the information processing model as well to give a measure of the initial performance of the design based on the new design objectives.

Information Processing and Integration

The third phase of information processing is a core part in an IDA. The main processing activities in a matrix-based IDA system involve the following steps:

- Identification of relationships between information items,
- Problem decomposition by grouping input information items into families towards objectives,
- Quantification of relationship strength, and
- Measurement of factor priorities.

The design problem may be decomposed into smaller more tractable sub-problems in the information processing stage. However, each sub-problem may involve only specific points, and therefore, all sub-problems need to be integrated again after the information processing phase in order to solve the overall design problem. Based on the integrated information processing results and the constraint information, a decision table can be established, and the decision-making algorithm in the IDA can then provide design solutions in terms of new design requirements.

Suitability of the IDA System

In solving a design problem, the four main phases involved are (Dixon & Poli, 1995):

- Engineering conceptual design,
- Configuration design,
- Parametric design, and
- Detail design.

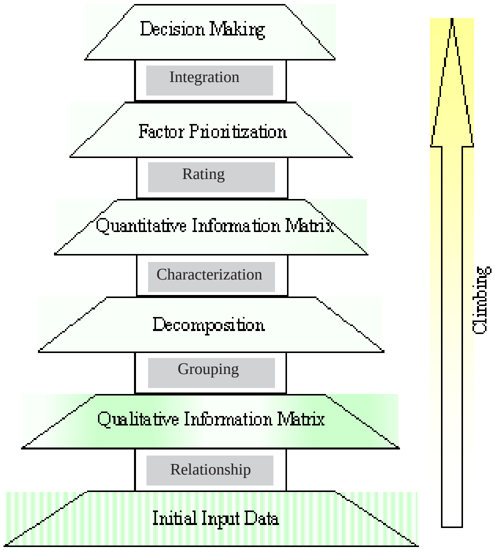
The first two phases of this process are to establish the function structures and define the geometric features. This requires a significant amount of creative work for the designer and is very difficult to enable through the use of a computer-based system. The parametric and detail design phases mainly focus on identifying and classifying the specific design parameters. A computer system may provide help in the selection of suitable parameters to meet certain design goals. The IDA will focus on these two phases, aiming to guide the less-experienced designers to achieve multiple-design goals that satisfy both company objectives and general design requirements such as performance and manufacturability.

The computer-based generation of original or unique design concepts is a problem that has yet to be solved. The approach that is taken in this research is a case-based approach where the inputs to an information matrix are based on previous design cases. In industry, about 75% of design work is of either the adaptive or variant type (Singh, 1996). In adaptive or variant design, a new design is derived from an existing design case that has a high degree of similarity. Hence, the implementation of an IDA in this research will be based on proposing solutions based on variants to a designer.

WORKING PRINCIPLE OF MATRIX-BASED IDA INFORMATION SYSTEM

The working principle of this system can be described by the information processing tower in Figure 5. Climbing up to the top of the tower, the information processing is completed. All information items are listed in a matrix through which the information relationships can be identified, and then the problem can be decomposed by grouping interrelated information into families. Following that the characterization is carried out for each sub-problem to obtain the quantitative information matrix, and all input data information items are rated to show their effectiveness towards the objective information. Finally, all the sub-problems are integrated again to arrive at an overall solution.

Figure 5. Information processing tower



Problem Decomposition

In the first matrix, all collected initial information items are listed both across the top and down the left of the matrix. Their interdependencies are then qualitatively identified. This may be performed automatically by the system and then reviewed by the human designers. To illustrate this, consider a hypothetical design scenario involving eight input data information items, four constraint items and three objectives. The information matrix for this situation is shown in Figure 6. A star indicates that the two information items are interrelated to each other.

For a large and complex design problem, the divide-and-conquer strategy is often used. The problem is decomposed into smaller tractable sub-problems which can be solved separately and in parallel. A matrix-based method called a Design Structure Matrix (DSM) has been used to determine the process sequence of interrelated known subtasks of product development and manufacturing (Chen & Lin, 2003; Yassine, 2004). However, instead of focusing on the process sequence, the decomposition we discuss here aims to divide the design problem into subtasks by grouping the information to form sub-systems based on the qualitative matrix. It results in another matrix as shown in Figure 7. Different algorithms, such as the Similarity Coefficient Method (Kusiak & Cho, 1992), Branch and Bound algorithm (Kusiak & Wang, 1993), and Genetic Algorithm grouping technology (Falkenauer, 1998) may be employed in order to obtain appropriate decomposition schemes depending on the type of problem under consideration, The decomposition shown in Figure 7 is an ideal case in which all sub-systems are independent of each other (that is there is zero interaction density). Practically this may not be achieved. However, as it is pointed out by Yang and Reidsema (2004), independence can be achieved by allowing an information item to appear in different sub-problems if a link is introduced to maintain the equality. Figure 8 shows a decomposed matrix with shared items in which item 3 is included in both Sub-system 1 and 3, indicating they are related to each other.

An expected decomposition is that each sub-system has no more than one objective. Thus, all the information can be mapped to respective objectives after decomposition. In the case where a sub-system doesn't have objective information, it is still acceptable if it has shared items with other sub-systems which include objective information. In such a case a shared item can be treated as an objective. Otherwise, such an independent sub-

system without an objective can be deleted since it does not affect any objectives.

Relationship Characterization

After decomposition, problem solving can then be carried out on each sub-system separately. A particular concern is to determine the strength of relationships. That is, how much it affects the others, especially the objective information, when one information item is varied. For a hypothetical case with continuous linear relationships, a rearranged quantitative information matrix of Sub-system 1 can be shown in Figure 9. It must be noted that two rows, (Constraint Information item 9 and Objective Information item 13) are deleted, as these two items are defined as fixed parameters during the earlier stage of character-

Figure 9. Rearranged qualitative information matrix for Sub-system 1

6	-0.8	0.6	-0.67	1	*	-1.2

ization. It can be seen that constraint information item 9 is related to input data information items 5 and 6, meaning it defines the physical relationship between these two items.

In order to compare the effect among different items, a normalized number is used in the matrix. The sign indicates a positive or negative effect. For example, if the value of item 1 is increased by 10%, this results in the value of item 5 increasing 3%, item 6 decreasing 4.5%, and objective information item 13 decreasing 9%. Therefore, the information matrix can be represented by $I_{1-5} = 3/10 = 0.3$, $I_{1-6} = -4.5/10 = -0.45$, and $I_{1-13} = -9/10 = -0.9$ (in which I denotes the information matrix). In this case, the row suggests the influence *on* the other items while the column indicates the influence *from* the other items. It is worth noting that the alterable range of an item can also be identified in the characterization.

Characterization also provides a chance to cross-check the information matrix. If two items have both the same row and column characterization results, they can be regarded as two identical items, and either one can be deleted from the matrix. On the other hand, extra attention must be payed to any two items with opposite results, such as item 5 and 6 in Figure 9. This may result from two different situations. First, there may be two conflicting items that have negative correlations. Normally, this conflict is of concern as it represents the condition in which trade-offs might occur. Second, there may be two complementary elements and one of them can be deleted. For example, in the design of a part such as a rod with varied diameter but fixed overall length, as shown in Figure 10, the length of two segments, *a* and *b*, are two complementary items since the increase of one means the decrease of another. From the characterization results, it can also be determined whether two items with negative correlations are complementary. As shown in this example, a 1% increase of item 5 will cause a 1.5% decrease of item 6. Moreover, in both row and column, all results of item 5 are -1.5 times of item 6. Thus, they are two complementary items, and either one can be deleted.

The earlier discussion is focused on the case with continuous linear relationships. However, for non-linear cases the characterization becomes much more complicated. For relatively simple cases, the characterization can be implemented by focusing on a smaller range. The correlations of items within the range can then be treated as approximately linear. This can be illustratively shown in Figure 11. For further complex problems, two methods can be used to measure the interdependencies of relationships. First, using the order notation (Big O) method can be used to characterize the algorithm efficiency of a program, where an order family can be established to indicate the strength of relationships. Second, the dependencies of relationships can be more accurately expressed by approximate polynomials.

The coefficients and the order of power suggest the strength of influence. This is compatible with the concept of Principal Component Analysis (Matthews, Blessing, & Wallace, 2002).

In an IDA, the characterization may be associated with other software tools such as FEM packages. Characterization is a stage with heavy computations. It is necessary to select the most suitable algorithm for a certain sub-system. This selection is mainly based on the type of objective information within the sub-system, because the objective information is normally related to the domain concerned, such as engineering functional objectives and financial objectives. The motivation of characterization is to reduce repetitive computations to increase the computational efficiency. Since the strength of a relationship is characterized in advance, any subsequent changes of an event are very easy to compute by utilizing the quantitative relationships.

Factor Prioritization

The characterized information system provides a basis for calculating subsequent variations of an event. However, we may often need to select a parameter to work on among a number of candidates so that there is a greater probability of achieving an objective with the least compromise on other design requirements. It is, therefore, necessary to refine the matrix by prioritizing the input data information. All information items are first ranked in terms of their importance, and weight numbers are assigned to them; the priority index P_i can then be calculated for each input data information item using the formula:

$$P_i = \sum W_o \left| I_o \right| - \sum_{j \neq i} W_j \left| I_j \right|$$

in which W_o and W_i are the weight numbers, I_o and I_j are the normalized values of objective and input data information respectively. For instance, for the sub-system shown in Figure 9 (where item 6 is deleted because it is a complement element of item 5), P_i of item 5 can be computed by 4*1.8-3*0.9-2*1.2 = 2.1, as shown in Figure 12. The formula is established based on the criterion of “most contributions and least side-effects” because its first term represents the contributions toward the objective information, and the second term suggests its side effects on other input data information. The priority index offers another quantitative measure to the input data information to facilitate the trade-off analysis.

Problem Integration and Decision Making

After characterization, the design problem can then be solved. In order to achieve the overall solution, all of the sub-problems must be considered as a whole since they are normally related to each other. Thus, they need to be integrated again. An initial plan must be first generated based on the analysis of the directional relationship among all sub-problems. The analysis should focus on the

Figure 12. Prioritization of input data information

shared items to distinguish the input and output parameters of sub-problems to establish a sequential order. Sub-problems that are independent of each other can be implemented concurrently, while sub-problems with unidirectional dependency have to be executed sequentially. For those interdependent sub-problems, an iteration plan needs to be developed. This plan would consist of determining the sub-problems to start the iteration process based on an initial guess or estimate of a missing piece of information and then revise the estimation after iteration (Yassine, 2004). The decision-making process will be performed by the IDA based on an appropriate framework, such as the Blackboard Database Architecture (BBDA) or Expert System (ES) (Corkill, 1991; Nii, 1986; Reidsema, 2001). A decision table can be established to facilitate this process. Constraint information plays a key role here as it controls and guides the decision making. The factor priority index offers a reasonable quantitative sense in the selection of appropriate design features and parameters to avoid a blind "trial and error" process. A more in-depth discussion of this aspect of decision making however is beyond the scope of this paper.

FAILURE RECOVERY

In cases where the desired solutions cannot be achieved, or where conflicts occur in the process preventing the problem-solving from continuing, the system is considered to have failed in its efforts to solve the problem. This necessitates consideration of a failure recovery strategy. Failure recovery can concentrate on the following four aspects in accordance with the information processing flow:

- Check where the failure occurs and then examine whether the corresponding sub-problems are correctly characterized.
- Verify the decomposition scheme to see if it is suitable. If necessary, try to decompose the problem using other algorithms.
- Inspect the initial information matrix to see if any relationships are not included. For those relationships which are unsure or unessential, they must be included in the matrix. Although this may complicate the decomposition and characterization stages, it can avoid failure occurring. In fact, the characterization can cross-check whether a pre-defined relationship exists or not. For example, a zero value may indicate no relationship exists between two pieces of information.
- Review the information gathering and preparation processes to see if any information is overlooked and whether constraint and objective information is adequately defined.

DISCUSSION AND CONCLUSION

In this research, we propose a matrix-based IDA system. As a part of the overall enterprise information system framework, an IDA is a knowledge-based design information system. It can utilise human expertise and address CE issues in decision making. It also leads to the preservation and transfer of technical knowledge to minimize the knowledge loss from organizational moves. It is easy to access, maintain, able to solve a design problem correctly and efficiently, and has the ability to take comprehensive consideration of all design objectives. This paper has discussed its configuration and working principle in detail based on the information handling process in such a system. The information is sorted in terms of its nature into three groups: input data, constraint and objective information, all having different representation strategies. After decomposing the problem into sub-problems, information is then mapped to the relevant design objectives and processed separately and in parallel to quantitatively characterize the strength of relationships. Following that, all information items are rated, according to their importance, with weight numbers assigned in order to measure their priorities towards the design objectives. Finally, all sub-systems are integrated again to achieve the final solutions through trade-offs between interdependent sub-systems.

At the problem level, our proposed IDA information system can be summarized as Generation, Decomposition, Distribution and Integration (GDDI) (Reidsema, 2001) where:

- Generation refers to defining the problem including collecting and classifying information to present to the information system.
- Decomposition entails applying the "divide and conquer" method to split the overall problem into smaller, more tractable sub-problems in terms of the interrelationships between gathered information pieces.
- Distribution involves handling sub-problems separately through characterizing them according to the nature or objective of the sub-problems.
- Integration requires all characterized sub-problems to be brought together and then solved in an integrated and collaborated environment.

The success of an IDA is determined by the accuracy of the identification of dependent relationships, and the characterization of relationship strength. In our proposed matrix-based information system, relationships are stressed because all the relationships are important elements of knowledge. This has been pointed out by Compton and Jansen (1990), where they state that knowledge only has meaning in relation to other knowledge and can be explored in terms of relationships. This system is also an objective-oriented model. By sorting all information, the design objectives are clarified. By decomposing the problem, related information is mapped to respective objectives. By characterizing the strength relationships, the priorities of input data information toward the objectives are quantitatively measured.

ABSTRACT

Product lifecycle management (PLM) processes can be greatly improved and extended if more information on the product and its use is available during the various lifecycle phases. The PROMISE project aims to close the information loop by employing product embedded information devices (PEIDs) in products. In this chapter, we present the goals and application scenarios of the project with special focus on the middleware that enables the communication between PEIDs and enterprise applications. Furthermore, we give details of the design and implementation of the middleware as well as the role of Universal Plug and Play (UPnP) as device-level protocol.

INTRODUCTION

The PROMISE project (PROMISE Consortium, 2006) aims at improving business processes of product lifecycle management (PLM) by using the information loop across the various stages in a product's lifecycle, from beginning-of-life (design, production) to middle-of-life (use, maintenance) and end-of-life (recycling, disposal). The technological approach of the project is to use smart networked devices that are embedded into products to gather data on the product's status, properties, and working environment. The data is then made available to back-end systems to perform data analysis for decision support. Moreover, the information acquired is exchanged between the various interested parties, for example, manufacturer, customers, service and recycling companies.

The vision of closing the information loop for PLM has attracted the interest of a number of large companies, like *Infineon* (Germany), *Bombardier Transportation* (France), *Fiat/Iveco* (Italy), and *Caterpillar* (France/USA), in addition to SAP, to take part in the project. This emphasizes the relevance of the idea and also the commitment of industry in realizing it. In particular, *Infineon* is developing the hardware for PEIDs (product embedded information devices) to be installed in physical products.

PROJECT GOALS

The goals of PROMISE fall into the categories of technical, business, and research goals:

Technical Goals

- **Product Embedded Information Devices (PEIDs):** Suitable PEIDs have to be developed which turn products into smart items. PEIDs will provide data about the product to external applications. Using PEIDs will enable automatic data acquisition of high accuracy, which is less error-prone and more efficient than manual collection and entry of the data.
- **Integration of PEIDs with Backend Systems:** To enable the communication between PEIDs and backend applications, a middleware providing abstraction from device-level protocols and data transformation is required.
- **Product Data and Knowledge Management (PDKM):** Product-related data from PEIDs, field databases, and other sources have to be integrated to allow for sophisticated data analysis.
- **Decision Support:** Data from the PDKM has to be analyzed to transform the data into actionable knowledge for PLM decision support.
- **Cross-Company Information Flows**: A major hurdle for today's PLM applications is the inaccessibility of product-related data in other organizations. To overcome this, methods and software that allow sharing of data, information and knowledge among certified actors of the system have to be developed.

Business Goals

- **Enable New Business Models:** Using technology developed in PROMISE, new business models, for example in the areas of product service and recycling, will be developed to increase the economic impact of results from applied research.
- **Improve Existing Business Processes:** Business processes related to PLM will be improved and extended, for example, by achieving lower operational cost, better quality and safety, reduction of errors, and better informed decisions.

Research Goals

- **Generic PLM Models:** The consolidated requirements of many PLM application scenarios are to be integrated into domain-specific and generic models of PLM information flow and PLM workflow.
- **Information and Knowledge Management Methodologies:** To turn the collected product data into useful knowledge for decision support, methods and concepts for information enrichment and transformation of information into knowledge have to be developed.

INNOVATIONS IN PLM BUSINESS PROCESSES

In the following, three application scenarios are presented to show how PROMISE technology can be applied to a PLM business process in beginning-of-life (BOL), middle-of-life (MOL), and end-of-life (EOL).

Improved Product Design: Bombardier (BOL)

Bombardier is a provider of rail equipment and servicing. Based on a component platform, Bombardier designs and produces a large number (over 400) of different locomotives. Applying the PROMISE idea, Bombardier aims at closing the information loop between the experience in service (field data) and the knowledge needed in order to develop improved locomotives for specific criteria, such as design for reliability, availability & maintainability/life cycle costs, product safety, environment, and so forth. For these purposes, field data is recorded on the locomotives and transferred to a field database using GSM (Global System for Mobile Communication). The data is then analyzed for information on the performance of components compared to their expected behavior. Based on that, the engineers can evaluate the suitability of their designs and improve them accordingly.

Flexible Maintenance Planning: Fiat (MOL)

Fiat focuses on predictive maintenance of trucks. To improve the effectiveness of fleet management, FIAT seeks new ways to better understand the product usage and the mission profile of Iveco commercial vehicles. The objective is to provide customers with flexible maintenance planning, which is based on the actual degradation of vehicle components instead of fixed intervals. With this approach, costly breakdowns are avoided, while preventing the replacement of parts that are still in good condition. The correct timing for maintenance is determined by measuring the wear-out of selected critical components with sensors that are integrated into the vehicle. Furthermore, the mission profiles of trucks are determined in order to predict the wear-out for components depending on the respective mission profile. For each truck, the output of the decision support system is a calendar containing the time and the type of planned interventions. The maintenance crew is provided with a consolidated view on all interventions of the fleet.

Effective Recycling: Caterpillar (EOL)

Caterpillar is a manufacturer of construction and mining equipment. Using PROMISE technology, Caterpillar aims to support decommissioning of heavy-load machinery at the end of its life. More specifically, the value of the vehicle’s components has to be evaluated to identify those that can be reused. Previously, end of life decision-making was based on inspection in order to determine whether a component could be remanufactured. Now, a PEID monitors the product’s status and systematically collects data during the machine’s operation. Using a smart item middleware, this data can be accessed from the PEID and stored in a database. When the machine is decommissioned, the data associated with the built-in parts is retrieved from the databases and serves as input to a decision support system (DSS), where it is combined with data on economic demand. Thus, the appropriate handling of the various components is determined, for example, deciding whether to dispose of, recycle, reuse or remanufacture components in order to increase the re-use of components.

TECHNICAL SOLUTION OVERVIEW

Overall PROMISE Architecture

The technical solution of PROMISE consists of different layers, which are consolidated into the overall PROMISE architecture (see Figure 1).

Business processes from various application areas are supported by applications for decision support and product data and knowledge management (PDKM). These applications access PEID data through a middleware, which provides functionality for reading and writing of PEID data, as well as notifications on data updates, and PEID management. On the PEID level, mechanisms for detection of devices and invocation of services are offered.

Brief Overview of the PROMISE Middleware

A key part of the PROMISE architecture is the middleware, which was co-developed by SAP. Its purpose is to connect PEIDs with backend applications to facilitate data exchange between them (see Figure 2). One of the main challenges in the design of the middleware was to support mobility of products. As products can be mobile (e.g., trucks, locomotives), they might not be permanently connected to the network. To handle this, the communication between backend applications has to be asynchronous. Furthermore, the presence of devices has to be detected automatically in order to trigger the execution of pending requests.

The middleware is divided into three logical layers, which are described here briefly:

- **Device Handling Layer:** The DHL provides mechanisms for device discovery and invocation of services on the PEID to access data. In the PROMISE middleware, this was achieved by using Universal Plug and Play (UPnP Forum, 2006). All PEIDs implement a unified UPnP interface called

Figure 1. PROMISE architecture

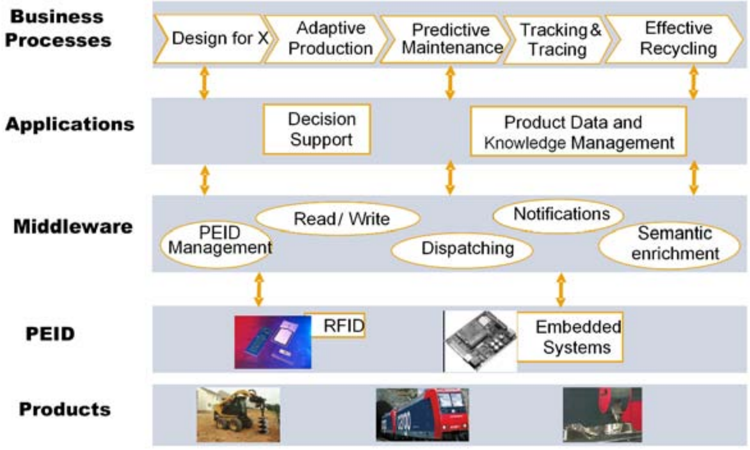

Figure 2. Logical components of the PROMISE middleware

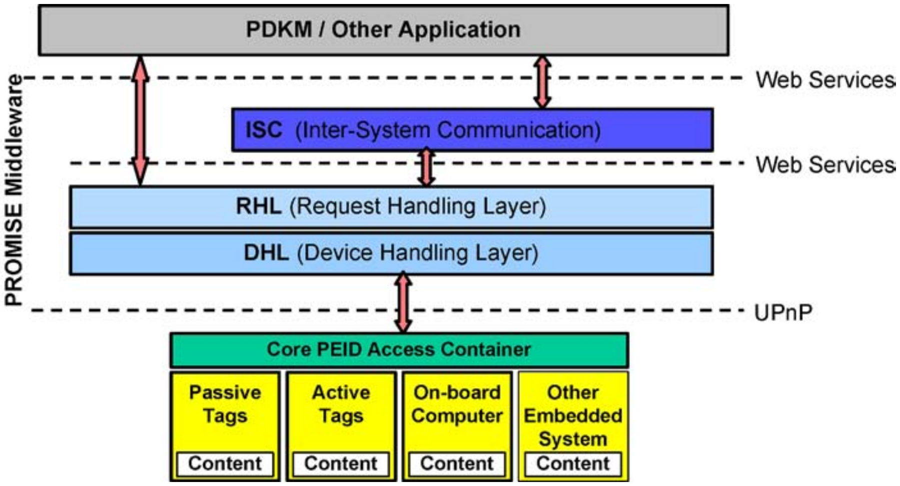


"Core PAC" (Core PEID Access Container). When a PEID is detected, the DHL connects to it and sends a notification to upper layers of the middleware. Additionally, it translates incoming requests into UPnP services invocations to read or write PEID data.

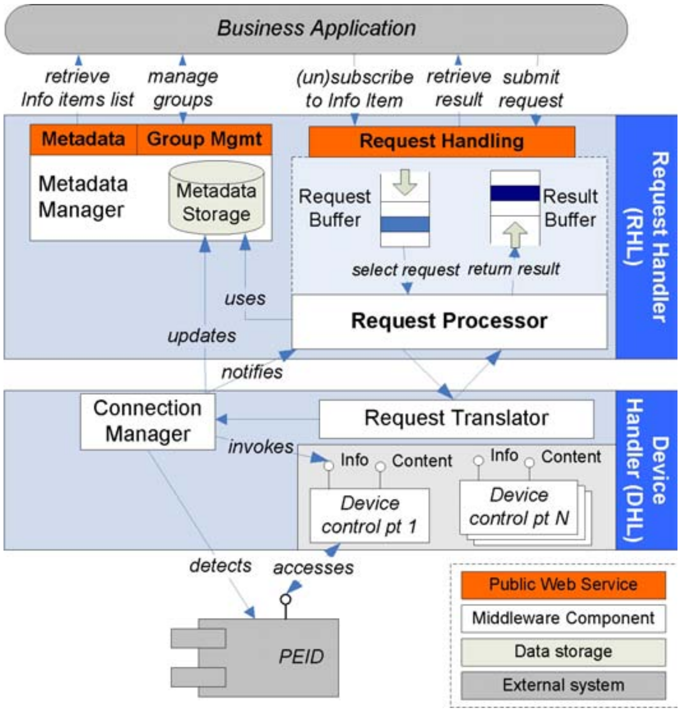
- **Request Handling Layer:** The RHL provides Web services to interface with back-end applications, which can place requests for PEID data at the RHL. If the required PEID is currently connected, the request is directly forwarded to the DHL. Otherwise, it is buffered until a connection notification is received from the DHL, which triggers the forwarding of the request. In a large-scale deployment, a RHL node can be connected to multiple DHL nodes, which can be installed in different physical locations to provide PEID connectivity.
- **Inter-System Communication:** To provide cross-organizational communication, the ISC was developed. It is an optional part of the middleware stack for scenarios where external parties are to access PEID data. In these scenarios, each organization has at least one Inter-System Communication (ISC) node installed, which then connects to other ISC nodes in a peer-to-peer fashion. Back-end applications place their request at an ISC node, which then forwards the request to the correct RHL, PDKM or third-party system. Companies can thus gather product-related information from other organizations.

IMPLEMENTATION

We have implemented the lower layers (RHL and DHL) of the middleware, which was introduced in the previous section. Figure 3 shows the detailed design of these two layers. Here we give some details of the chosen technologies and elaborate on some of the notification mechanisms developed.

The connection manager in the DHL implements an UPnP control point (Institute of Information Science and Technologies, 2006; Konno, 2006) that can read and write information on PEIDs once they have been discovered in the network. The DHL is realized as an application consisting of a set of bundles running on an OSGi (OSGi Alliance, 2007) service platform, in our case the open source distribution Oscar (Hall, 2006).

Figure 3. Detailed design of RHL and DHL layers



The RHL is implemented as a Java 2 Enterprise Edition (J2EE) application, with its functional components being Enterprise Java Beans (EJB) (SUN, 2006). For deployment, a J2EE 1.3 (SUN, 2002) compliant application server (SAP Help, 2007) was used. Container-managed entity beans are implemented to represent the business objects such as targetIds and infoItemIds. They are mapped to tables, which are then automatically deployed on the server. Web services to be invoked from back-end applications are also automatically generated from the beans. A timing service was required for the management of subscriptions to RHL requests. To compensate for the lack of an EJB Timer service in J2EE 1.3, the Open Symphony Quartz (Open Symphony, 2006) was used as a powerful library for scheduling.

Communication between RHL and DHL is established using Java Messaging Service (JMS), which provides reliable asynchronous messaging. The JMS Provider manages three queues to exchange messages between the two layers. A request queue and a response queue are dedicated to receiving requests from the back-end applications via the RHL and the corresponding responses from the DHL respectively. A third queue is used for the delivery of notification messages for PEIDs discovered as well as metadata about those PEIDs.

For the processing of messages on the DHL, a JMS MessageListener is implemented to listen on the request queue for incoming requests. To enable the DHL to retrieve the factories required for JMS communication, a J2EE client library (Opgenorth, 2005) has been included as an application bundle. On the RHL, the request processor contains message-driven beans (MDB), listening on the response queue and notification queue to process the messages, which are received on it.

When a device is discovered by the connection manager and permitted to connect by the device manager, a JMS notification message with the PEID and respective metadata is sent to the notification queue. The dedicated MDB within the request processor then performs the necessary processing to check for pending requests for that PEID. If there are requests buffered, they are sent via the request queue to the DHL as JMS messages. After performing the required operation (read/write), the result for each request is then sent back via the response queue to the RHL. The result messages are handled by the above-mentioned MDB, which places the results in a buffer to be retrieved by the back-end applications through a Web service interface. Incoming requests are forwarded to the request queue until the RHL is notified of the disconnection of the PEID.

When a back-end application has placed a subscription on the request handler, a trigger is created with a subscription interval and the subscription is then scheduled as a Quartz job. Whenever the RHL is notified of the disconnection of a PEID, all the subscriptions on that PEID are paused. When the PEID connects again, all the subscriptions placed on it are resumed. Whenever it is activated, the scheduled job sends a request according to the given interval, which is then handled as described above.

BENEFITS AND LIMITATIONS

The system presented allows back-end systems to acquire data from product embedded information systems, which can then be used to support business decisions. Using UPnP as standard technology for detection and invocation of services as well as a common data access scheme (“InfoItems” and their IDs), an abstraction from concrete products can be achieved. Thus, the middleware enables reading and writing of PEID data for a large number of heterogeneous products.

One of the major drawbacks is that all products not only have to be UPnP compatible, but also implement the UPnP interface which was defined in the PROMISE project. It remains to be seen to what extent this interface is used in real-world applications. However, our middleware architecture is designed with abstraction as a major goal. Therefore it is also possible to support other protocols and interfaces by implementing a designated DHL instance for it. Such an extension would not affect back-end applications and the RHL. Additionally, we have not yet conducted a thorough analysis of performance and scalability for the middleware.

SUMMARY

The PROMISE project shows how smart embedded systems can be employed for future generations of product lifecycle management applications. Real-world application scenarios not only give a proof-of-concept, but also show the variety of different business problems that can be addressed with the help of PROMISE technology. Transparency about product data and its exchange across company boundaries are the main drivers for these new capabilities. However, it also highlights the importance of standards for product identification, detection and data exchange. These standards have not only to be suitable for a technical problem, but also accepted in the industry to enable interoperability.

Chapter 3.9

Mobile Batch Tracking:

A Breakthrough in Supply Chain Management

Walter Hürster
T-Systems International, Germany

Hartmut Feuchtmüller
T-Systems International, Germany

Thomas Fischer
T-Systems International, Germany

INTRODUCTION AND BACKGROUND

Traditional problems of managing resources and the flow of material appear to have been solved by enterprise resource planning (ERP) systems as well supply chain management (SCM). This is true of the stationary case of an isolated factory and of the goods that form part of its inventory. However, with the increasing movement of goods, a new dimension of problems has arisen that makes it inevitable to consider transport status itself—particularly to improve the supply chain planning and the execution process. This chapter is an attempt to cope with the new challenges that result from a higher degree of mobility, a higher percentage of the mobility phase with respect to the total lifecycle, and a higher flexibility with respect to transport media and changes of the transport mode within one single transaction, such as conveying a pallet from A to B (where A and B may be located anywhere on the surface of the earth, thus indicating that also increasing distances have to be bridged).

Goods, spare parts, and assembly components are no longer kept in storage for long periods of time, but are fed in when needed. This is the effect of the popular just-in-time (JIT) approach to inventory management. Thus, managing the supply chain effectively means managing more and more of the transportation chain.

Successful attempts have been made to manage the internal transport at a factory site by means of new technologies, such as radio frequency identification (RFID) tagging or other auto ID technologies (ten Hompel & Lange, 2005). Within this context, a new class of middleware is emerging, acting as a platform for managing the data and routing them between tag readers and enterprise systems (Leaver, 2004). However, a huge gap of information exists for the increasing time of external transportation—either between two factory sites for a semi-product or between factory site and end user location for a final product.

THE CORE CHALLENGE IN SUPPLY CHAIN MANAGEMENT

In order to obtain an exact overview at any time, it is essential to track the flow of goods on batch level at least, if not on item level (for larger items). This requires acquiring knowledge about the geographical position whenever needed plus detailed information about the goods—that is, batch identification and batch description, including information about origin and destination, plus all intermediate agents involved in the process. Regulation (EC) No. 178/2002 of the European Parliament and of the Council of January 28, 2002, as an example, is laying down the general principles and requirements of food law and at the same time the procedures in matters of food safety. This includes strong implications with respect to downstream trackability (from origin to destination), as well as upstream traceability (from end user back to the production site). In the case of non-preservative food, it is of essential importance to monitor and to record the environmental data of the transport—for example, to ensure that the refrigerating chain has not been interrupted (or only for a very short period of time and within a certain temperature range). The big challenge therefore consists of getting all the required information while the goods are on their way on a transport medium in motion.

THE SOLUTION TO THE CHALLENGE

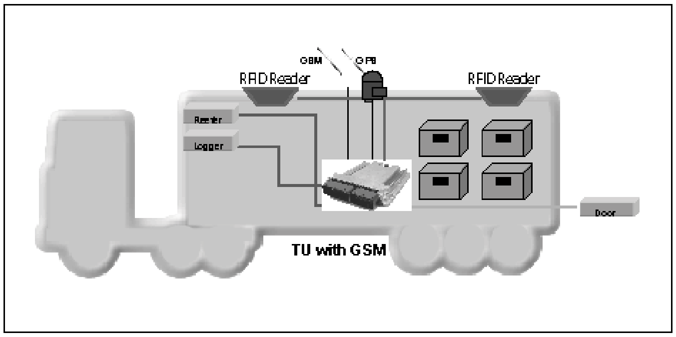
The requirements mentioned above directly lead to the way of finding an appropriate solution by a decomposition of the system into its two basic components:

a. Subsystem to determine the geographical position of the transport medium (container, lorry, trailer, wagon, ship, aircraft, etc.).
b. Subsystem to gain information about the goods transported by that medium—that is, batch identification and batch description (plus additional environmental parameters).

The first subsystem (a) preferably consists of a GPS antenna and a GPS receiver to obtain the geographical position. For the second subsystem (b), an advanced approach would be to use RFID technology—that is, RFID tags affixed to the packaging units and RFID readers installed on the transport medium to read the tags. An example is shown in Figure 1 (for the case of a trailer/lorry configuration).

The trailer contains the GPS equipment plus RFID reader(s) to identify and to read the tags which are fixed at the package units. A great advantage of RFID vs. other auto ID technologies is due to the fact that no direct geometrical line-of-sight between tag and reader is required—that is, the packages may be oriented in any arbitrary way and do not have to be aligned or rotated in a specific manner. Additional environmental parameters, such as temperature, acceleration (shock), door status, and so on (including intrusion alarm) are polled from adequate sensors by a so-called reefer and are stored locally on a data logger. All data are collected online by a telematic unit (TU) and are transmitted instantaneously or at given time intervals to a Transport Tracking Center (TTC), preferably by means of GSM or by using satellite communication (depending on the coverage and

Figure 1. Trailer equipment



the location of the transport medium on its route). This Transport Tracking Center, thus defining the third subsystem (c), collects the batch data from all connected transport units and makes them available to all subscribers and stakeholders being entitled to use them. The TTC itself will consist of a computer cluster with distributed tasks for I/O handling, central data storage, archiving, and data retrieval. Figure 2 shows an example for this network of information, again for the lorry/trailer configuration mentioned above:

Whenever a batch is leaving Factory A, a stationary tag reader identifies the batch, and the batch data are transmitted by an appropriate middleware to the ERP system of Factory A. The same procedure will take place when the batch arrives at Factory B (or at the site of final destination). The full information is available at any time by connecting the stationary ERP system to the Transport Tracking Center by means of a proprietary telecommunication link or via Internet. By those means, it is possible to obtain a more reliable estimate of the time of arrival for a specific good—thus allowing for a rearrangement of the production line at the destination site within due time (if necessary).

The eminent advantages of such a system become increasingly obvious if the transport is not a single point-to-point connection, but if a number of intermediate waypoints have to be covered, including unloading of some batches and loading of new batches, as illustrated in Figure 3, and whenever the transport medium is changed (e.g., from lorry to train) and a new batch configuration has to be assembled.

The system described here allows the user to gain an exact overview at any time and to track the flow of goods from the origin to the destination online and in real time. On the other hand, by means of archiving and retrieval, it allows for backward (upstream) traceability at batch level (or item level). In other words, by closing the mobility

Figure 2. Network of information

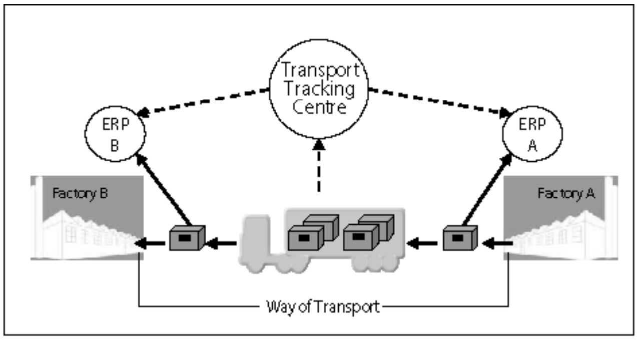


Figure 3. Intermediate waypoints

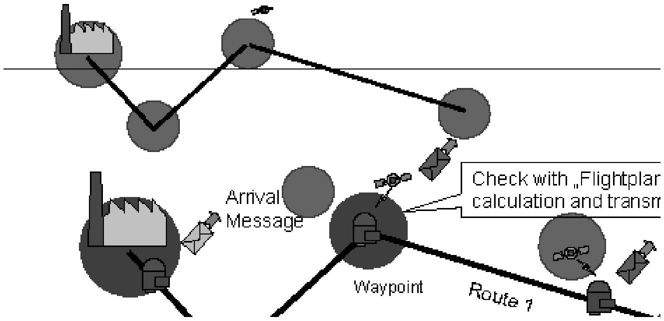


gap, this system is covering the full supply chain without any interruptions.

T-Systems has implemented such a system (called "eCargo") for RAILION, Europe's largest international logistics enterprise for railway-based transports, as described by Epple and Feuchtmüller (2005). More than 100,000 individual RAILION transports per day are crossing all over the continent, carrying a huge variety of goods. About 13,000 wagons are equipped with GPS and GSM devices at least, plus environmental sensors, reefers, and data loggers.

For a pilot installation and for operational use, a similar system (called "iTM"®—intelligent Tracking Management) has been developed by T-Systems for Schmitz CargoBull, one of Europe's leading trailer manufacturers. Reliability, safety, and security are top priority requirements for both systems.

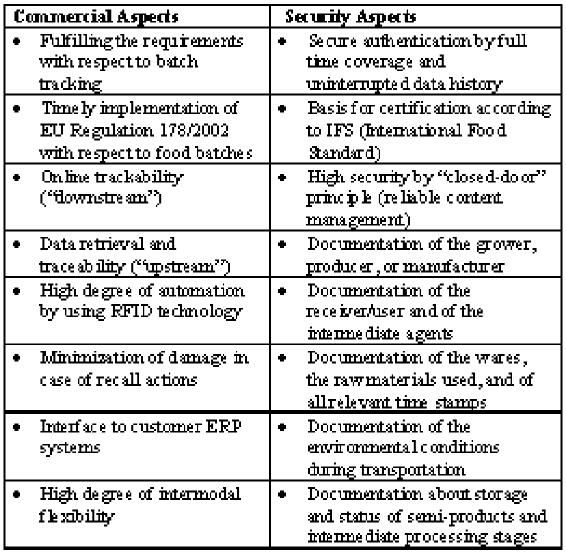
Table 1 provides a summary of the benefits and advantages of the described system solution.

LIMITATIONS AND CHALLENGES TO THE SOLUTION

Basically, there are no other limitations to a worldwide use of the system than those imposed by physics. Perturbations of the radio frequency (RF) may have to be faced if RFID is used in a ferro-metallic environment, or Faraday screening may prevent readers from identifying tags if they are "hidden" by a metallic foil. A further electromagnetic threat is encountered if the system is operated in environments with spark discharges or in cases of other events causing high-voltage electromagnetic pulses (EMPs). In those cases, the transponder chip may be completely damaged.

Besides these physical challenges and threats, a global use is rather endangered by incompatible or even competing systems with respect to the performance of readers and transponders, and with respect to the RF used. While in the U.S. the UHF

Table 1. Benefits and advantages of mobile batch tracking systems



Commercial Aspects	**Security Aspects**
Fulfilling the requirements with respect to batch tracking	Secure authentication by full time coverage and uninterrupted data history
Timely implementation of EU Regulation 178/2002 with respect to food batches	Basis for certification according to IFS (International Food Standard)
Online trackability ("downstream")	High security by "closed-door" principle (reliable content management)
Data retrieval and traceability ("upstream")	Documentation of the grower, producer, or manufacturer
High degree of automation by using RFID technology	Documentation of the receiver/user and of the intermediate agents
Minimization of damage in case of recall actions	Documentation of the wares, the raw materials used, and of all relevant time stamps
Interface to customer ERP systems	Documentation of the environmental conditions during transportation
High degree of intermodal flexibility	Documentation about storage and status of semi-products and intermediate processing stages

range between 868 and 915 MHz is favored, many developments in Germany prefer a frequency of 13.56 MHz (ten Hompel & Lange, 2005).

A different limitation to an increasing use of RFID-based systems may be given by a more commercial point of view. As for all new technologies in the beginning, the unit prices are relatively high (approximately 0.60 USD per transponder tag, depending on the storage capacity, ranging from a few bytes to several Kbytes). Drastic price reductions can be expected for the time to come when large numbers of tags will be produced.

Finally, like in many other cases, it has to be considered that the system is subject to some security risks and to the possibility of criminal attacks. Removing or destroying tags by brute force is the simplest way, followed by more sophisticated acts such as unauthorized reading of the tags, cloning of tags by means of electronic devices, and emulation of tags with any desired content (Oertel et al., 2005).

Here again, further development of the technology and international security standards will help to reduce the inherent risks.

CONCLUSION AND FUTURE DIRECTION

This chapter has shown that a system solution for mobile batch tracking is feasible that allows for online batch tracking during downstream transportation, as well as for upstream traceability. The system presented here bridges the information gap between the automated systems at the factory sites and the storage control systems at the destination sites. By using finest technology according to the state of the art, this mobility system can be considered to represent a breakthrough in supply chain management—especially when taking into account that an increasing number of goods will be “on the road” (on rails, on ship, in the air) for an appreciable percentage of the lifecycle, thus resulting in an urgent need to cover this mobility phase.

Nevertheless, a number of problems and difficulties still persist. Due to the international nature of the system, it is quite obvious that full functionality across borders will require international agreements, legal regulations, and standards. Technological standards will have to deal with reserved frequency ranges for the RFID equipment, the transmission speed, coding, protocols, and anti-collision procedures. Data standards will have to take care of a scheme for unique numbering (e.g., according to ISO/IEC Standard 15963), and application standards will have to consider new coding standards, such as the Electronic Product Code (EPC) replacing the UPC Barcode Standard (ten Hompel & Lange, 2005). Unique identification will require a well-elaborated coding standard based on a worldwide agreement, especially when thinking in terms of progressing from unit- and pallet-tagging down to item-tagging.

In parallel, sophisticated security measures will have to be developed in order to overcome the criminal risks inherent to each new technology.

Provided that these prerequisites are given, there is no doubt that mobile batch tracking systems based on RFID technology—like the one presented here—will result in a tremendous improvement of supply chain management.

ABSTRACT

RFID-enabled business models are proposed in this chapter to innovate supply chain management. The models demonstrated benefits from automatically captured real-time information in supply chain operations. The resulting visibility creates chances to operate businesses in more responsive, dynamic, and efficient scenarios. The actual initiative of such novel RFID enabled applications is therefore to encourage intelligent supply chain management to dynamically respond changes and events in real-time. As the RFID implementation costs are continuously decreasing, it is expected that more novel business models would be inspired by the technological advancement to foster more intelligent supply chains in the near future.

INTRODUCTION

Enterprises have been experiencing significant changes in the realms of technology, organization and management, due to increasing demands on the agility, flexibility, customization, and collaboration in supply chains. There is a pressing need to improve the process visibility and to facilitate supply chain wide decision-making through strategic business intelligence to sustain enterprise competitiveness (Krishnamurthy, 2002; Srinivasa & Swarup, 2002). One of the important enabling technologies to build up business intelligence is the identification and tracking technology, with which the product-centric information resources and associated decision-making systems can be established within and beyond enterprises (Davie, 2002). The information about product movements is crucial to the supply chain efficiency, agility, and product safety (Jakobs, Pils, & Wallbaum, 2001). Product identification and tracking technologies have been developed over time—from paper based manual recording systems to the "semi-automatic" barcode technology associated with optical-digital data processing systems. In recent years, a wireless identification technology, radio frequency identification (RFID), has attracted increasing attentions in supply chain management. Many trials have been implemented with recognized benefits including improved traceability, reduced labor costs, increased speed, greater responsiveness, and better product quality.

A networked RFID system integrates local identification and tracking data with a networked supply chain system through Internet. Unlike barcode systems, the RFID technology can remotely identify physical objects instead of visual alignment of each product with a scanner. It can communicate with multiple products simultaneously and dynamically update the data on RFID tags. The technology provides opportunities in automation of the data capture, item-level product visibility, and particularly in the business process transparency, integration and collaboratively decision making. Therefore, integrated RFID systems are of greater potential to enhance the intelligence of supply chain management than traditional identification technologies.

This chapter will focus on the RFID-enabled intelligence for innovation of the enterprise operations and supply chain management. The barcode and RFID based identification technologies are reviewed in the second section. The models which gain benefits from RFID applications are described in the third section. The conclusion is given at the end of this chapter.

IDENTIFICATION TECHNOLOGIES AND ASSOCIATED SYSTEMS

The RFID technology is one of the efficient identification technologies. Other technologies include one-dimension barcodes, two-dimension barcodes, DNA based bio-barcodes, and global positioning systems (GPS). Although advantages of the RFID technology have been broadly recognized in the past few years, the (one dimension or linear) barcode system has been a dominant identification technology for the last two decades. In this section, we will review technical details of the RFID and linear barcode systems.

The Barcode Technology and Associated Systems

A barcode is a data carrier which stores data as a series of stripes with different widths and with different spaces between them as seen in Figure 1. The data can be captured by a scanner or reader which requires positioning closely in line with the printed stripes. The scanner uses a laser beam that is sensitive to the reflections from the image pattern on a barcode label. The scanner

(01)04012365478912(10)8765101234

translates the light signal into digital data that is transferred to an associated computer system (Mallah, 2005). The barcode technology has been applied to industries for a variety of purposes, including consumer product identification at various packaging levels, tracking operational processes, traceability for safety and quality assurance, and so forth. (Osman & Furness, 2000).

There are several different barcode standards or symbology for various applications and used in different regions in the world. The widely accepted standards include Universal Product Code (UPC) from the Uniform Code Council in the U.S., and the European Article Numbering system (EAN) which is a UPS compatible system created by EAN International. The standard allows for a pair of extra digits along with the unique identification of a physical object to support customized coding for various internal uses in industrial operations (EAN International, 2003). On a barcode label, the relevant information can be printed for both scanning and human reading purposes. The human readable interpretations of a barcode provide flexibilities in the operations management when a human intervention is necessary.

The major contribution of the barcode technology is facilitating automatic or semiautomatic, fast and accurate acquisition of data. It dramatically improves the efficiency of information processing and avoids the error-prone manual data input into information systems. "*Previous studies have demonstrated that, while human data entry has an error rate around 1 in 300, the use of barcodes can reduce this to less than one in 2,000,000*" (Osman & Furness, 2000). The standardized coding and machine-reading technology facilitates information processing across industry and company boundaries in supply chains.

The limitations of the barcode technology are mainly in its data acquisition method and data carrier capacity. Firstly, to capture data on a barcode label, a reader must be closely positioned to the label. The reading has to be made for labels on each product or facility one by one. This procedure will apparently slow down operational processes with a large volume of product flows (Kärkkäinen & Holmström 2002). Data may also be missed due to human errors or misread due to unclean barcode labels. The second limitation of the barcode is its low data density which only allows a data capacity about 20 characters (Osman & Furness, 2000). The small data volume carried on the barcode label limits the flexibility of data transfers through supply chains, that is, a product or a logistic unit itself cannot provide enough details of themselves in many cases, and the information has to be accessed through centralized databases. Furthermore, data on a barcode label are static and cannot be changed. Therefore, the barcode cannot identify dynamic changes associated with a product and logistic unit.

The RFID Technology and the Associated Systems

Applications of the RFID technology in industries started more than two decades ago. However, the technology has not been widely adopted until late 1990s due to significantly decreased costs of the RFID hardware and software, although the development of barcode systems has significantly improved the efficiency and accuracy of data capture in supply chain operations against manual data recoding systems in 1980s. Researchers and practitioners in supply chain management are currently investigating the role of the RFID technology in another possible wave of revolutions in supply chain management technologies (Schwartz, 1997). In this section, we introduce the RFID technology, and compare it with the traditional barcode technology.

The Infrastructure of RFID Systems

A RFID system identifies products/assets or other objects via radio transmissions between data carrying devices (tags) and devices (readers) that are capable of receiving the radio transmission. It consists of three basic components, tags, readers, and the middleware which transfers the captured data into enterprise data sources with appropriate formats.

A RFID tag consists of a microchip as the memory-based data carrier and antenna to transmit encoded information through wireless interrogation with different radio frequencies. The encoded data is used to uniquely identify items (e.g., pallets, cases, or individual products) to which the tags are attached. The capacity of a tag can be 512 bytes for passive tags and up to 32Kb for active tags (Furness, 2005).

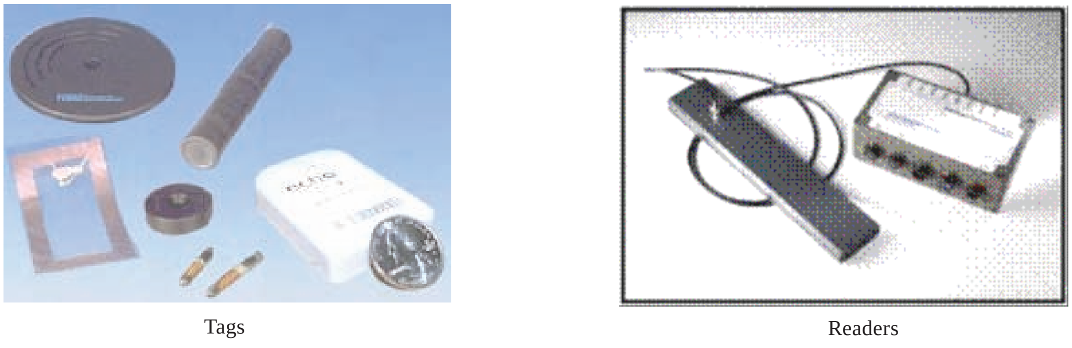
The reader as an interrogator of a RFID system automatically communicates with the tags when they enter a reader's reading field. The reader converts the radio wave into digital data and transmits the data to RFID middleware, which is a bridge of the communication between RFID systems and enterprise applications. Communications between RFID readers and tags may cause interference or collision when multiple readers or tags send signals simultaneously. Anticollision methods have been designed in RFID communication standards or protocols to solve such problems (Sarma Weis, & Engels, 2003). When a RFID tag receives overlapped signals from multiple readers, the problem is known as reader collision. On the other hand, when multiple tags send signals to a RFID reader at the same time, the problem of tag collisions will arise (de Jonge, 2004). While RFID communication protocols offer different solutions to these problems, additional software functions may also be required in associated applications to enable unique identifications and support relevant business operations.

According to communication powering features, RFID tags can be classified as active tags and passive tags. An active tag is powered by an internal battery. The power is continuous available within the battery lifetime. Active tags transmit the stored data at regular intervals. Active tags have a greater communication range than passive tags; better noise immunity and higher data transmission transfer rates as they have the greater response strength then passive tags (Furness, 2005). A passive tag is powered by an electromagnetic field generated by a reader signal and is without the internal battery. It therefore has virtually unlimited operational lifetime. However, passive tags have weaker response and shorter communication ranges compared with active tags. Passive tags cost less and may have smaller sizes (Furness, 2005).

According to the data adaptability, the tags can also be classified as read-only or read/write types. The data carried on read-write tags can be adapted through the air interface commands from readers as seen in Figure 3. On the other hand, the data on read-only tags cannot be changed (Furness, 2005).

According to the frequencies used for the communication between RFID tags and readers, RFID tags can be classified as low frequency (LF),

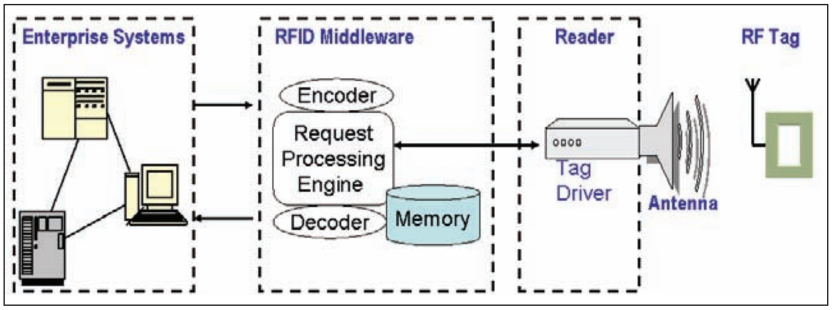
Figure 2. RFID plastic tag, paper tags, and reader systems (Source: Microlise, 2003)



Tags

Readers

Figure 3. Structure of a RFID system (Adapted from Chartier, 2005)



high frequency (HF), ultra high frequency tags (UHF). In Table 1, the communication features with different frequencies are described.

The middleware of a RFID system associates the unique identifier stored on a specific tag with the information about the product. After the middleware processes the information received from readers, it filters the data to the company's supply chain execution software, which updates its inventory data accordingly.

Networked RFID Systems and Supply Chains

Figure 4 shows a networked RFID system which includes a local RFID system and the service to integrate the local product identification information with the networked supply chain system through Internet.

To globally share the product identification information, the output from the RFID middleware is described in a subset of XML language, physical mark-up language (PML) which enables standard data communication with Web services. The data about a product in a standard format, electronic product code (EPC), can be captured through the particularly designed on-line directory, object name services (ONS), on the Internet. This Internet-enabled object name registration and discovery service facilitates the real-time location of individual products or logistic units with their relevant information throughout supply chains.

The EPC, as a RFID coding standard which is not based on the existing ISO standard, was originally developed by the AutoID Centre at MIT (de Jonge, 2004). It has been further developed towards a worldwide standard by EPCglobal which is a nonprofit organization and was set up by the Uniform Code Council and EAN International (UCC.EAN) (EAN International, 2003). The EPC stored in a RFID tag is a number with a header and three sets of data as depicted in Figure 5. The header of the code represents the version number. The three sets of data represent the manufacturer of the product (the EPC manager), the type of the product (object class), and the item unique serial number respectively.

Table 1. Communication features of RFID systems with different frequencies (Source: de Jonge, 2004)

Frequency	Shot Description	Read range (meter)	Data speed (tag/sec)
125-134 kHz	LF	0.45	1-10
13.56 MHz	HF	<1	10-40
868-870 902-928 MHz	UHF	2-5	10-50

Figure 4. Internet-enabled RFID systems

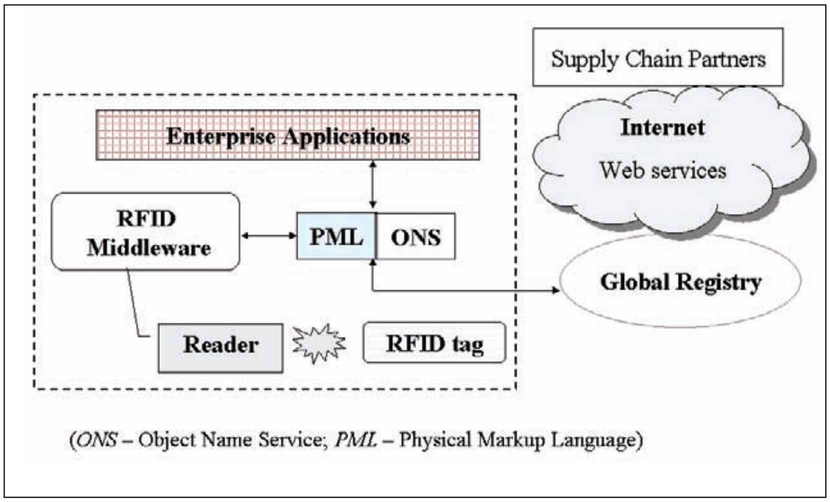


Figure 5. The electronic product code (Source: RFID Gazette, 2005)

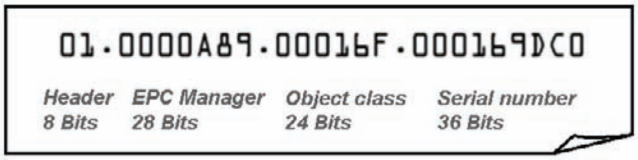


With the networked RFID systems and the standard product code, all relevant supply chain members can share the information of physical product movements and associated status (quality, processing stage, and contamination risk, etc.) in real time. This enables automatic tracking and tracing of products without human intervention.

Limitations of RFID Systems

The current limitations of the RFID technology are mainly in several aspects—high costs, barriers in standardization, concerns in data security and privacy, immaturity of necessary technologies, and technical shortcomings of the RFID technology (de Jonge, 2004; Microlise, 2003; Sarma et al., 2003; Smart Manufacturing Forum, 2003).

The investment of a RFID application depends on the scale of an application and the nature of a business. A RFID application is usually much more expensive than a barcode application due to the technical complexity of electronic tags and readers. Although RFID applications may bring significant benefits to businesses, in general the investment cannot be covered by potential profit increases in a very short term (Chadbourne, 2005). Relevant case studies for cost benefit analysis will be reviewed in the next section.

Different standards for the RFID technology have been developed such as EPC and ISO, and so forth. (de Jonge, 2004; Microlise, 2003). To apply the technology in supply chain operations, it is important to employ open standards in all business processes so that the RFID tags can communicate with all systems in the supply chain. The RFID systems with different standards are difficult to share the critical information in real time. This poor interoperability would also lead to high costs in manufacturing and operations of the incompatible RFID equipments. As the technology becomes more mature, it is expected that the RFID technology would be more standardized.

As a RFID system does not need contact or line-of-sight reading for data capture, it is difficult to prevent unauthorized users from accessing the data on a RFID tag. This exposes security and privacy threats (Sarma, et al., 2003). For instance, unauthorised RFID readers may read RFID tags on a container. As the information on a RFID tag may store valuable information for products or users, it is important to protect the data on RFID tags. For this purpose, various approaches are under development such as encryptions, data locks, and authentication keys, and so forth. (Sarma et al., 2003). However, such solutions may increase the costs of RFID technologies.

A RFID reader communicates with RFID tags through different radio frequencies as seen in Table 1. The communication will be significantly affected when the tags are placed with metal and liquid. Radio signals in high frequencies are easily absorbed by liquid and low frequency signals are strongly affected by metal (de Jonge, 2004). Therefore, in RFID applications with such environment, solutions need to be particularly designed to reduce impacts on the RFID system performance from the environment.

Benefits of RFID Over Barcode Systems

As a summary, advantages of the RFID technology over the barcode technology mainly include:

- **Automatic data capture without visual alignment with a scanner:** This reduces labor costs, improves accuracy and speed of data acquisition. More importantly, the real time information can be captured to support in-depth management functions, for example agile logistic operations control. Such information is too costly to be obtained through manual scans (Microlise, 2003).
- **Greater data storage capacity:** The enriched information from RFID tags facilitate agile and flexible supply chain operations due to reduced reliance on centralised data sources. This portable data source is particularly beneficial to distributed operations, for example construction projects and distributed manufacturing, when centralized databases are not easy to access (Marsh & Finch, 1999).
- **Durable tags which can work in harsh environments:** Barcode labels are easy to be contaminated and damaged in harsh environments (e.g., dust and high temperature). The RFID tags are much more durable to such conditions (de Jonge, 2004)
- **Rewritable tags for dynamic data modification:** This capability facilitates dynamic operational control based on the variance of product or environmental attributes, for example, temperature, pressure, and so forth. With integration of various sensing technologies with the RFID systems, product safety, and quality can be improved (Li, Tang & O'Brien, 2005).
- **Simultaneous communication with multiple tags and data reading with longer distance:** Together with the first feature, the data capture power enables efficient monitoring a large volume of physical objects in a large area without human intervention.

With these advantages, the RFID technology is generally more efficient than traditional barcode systems for supply chain management. Benefits of the RFID technology has been extensively reported from industrial trials. However, costs in the implementation of RFID projects have been a major concern and barrier in adoption of the technology. In this section, we review some cases of RFID trials which reveal major cost/benefit features of RFID applications.

Reported case studies have shown that investment returns on appropriately implemented

RFID applications would cover the costs in a limited period (Chadbourne, 2005; de Jonge, 2004). A RFID solution provider, Intellident, reported the RFID application case of Marks and Spenser (M&S Foods) with a cost benefit analysis (Chadbourne, 2005). M&S Foods uses 300 million labels per year. Cost of the barcode system, including labels, scanners, labor, and data management, is estimated at €3 million per annum. Comparing the barcode system solution, the RFID system at the company had an initial investment of £50,000. The cost of reusable tags (on crates, boxes, pallets) is €1 each and at the total of €3 million. With the estimated RFID life as ten years, the depreciation cost of RFID tags will be one-tenth of the barcode label cost per annum. With the supply chain of 200 suppliers, six distribution centers and 350 stores, the payback period of the initial investment (£50,000) on the RFID system is estimated less than 12 months based on savings (estimated as £600,000 per annum) from reduced goods intake speed (from 22 minutes to 3.6 minutes), savings (estimated as £22 million per annum) from improved delivery accuracy, improved shelf availability, and reduced store administration, and savings (£3 million labels to £300,0000 tag depreciation per annum) from removing tray labels.

In a RFID benchmark study reported by LogicaCMG (de Jonge, 2004), a detailed cost/benefit calculation framework was proposed. A RFID tag is estimated at €0.50. Its life is estimated as 7 years. The system installation cost is € 30,000 per reader. The investigated supply chain has 15 stores, 25 dock doors with one reader each door, 10,000 returnable transport items (RTI) per day. The payback period for the investments in RFID technology is between two and three years in the case. In year one, the net cost is €3.71 million. Then, from year two to year five, the net benefits will be €3.56 million, €2.91 million, €2.91 million, and €2.91 million respectively. The benefits are derived from savings mainly in the RTI handling cost reduction (€0.52 each), efficiency increase (8.5%), and stock level decrease (10%).

The evidence reported above shows that RFID-enabled supply chain systems are more efficient than those with the barcode technology. More cost benefit analyses of RFID applications can be found in various technical reports (BT Auto-ID Services, 2005; Fitzek, 2003;). While industrial RFID applications are exploring the potential of the technology as a new identification technology to improve existing operations performance, we focus on the investigation on the value adding potential of the RFID technology to innovate supply chain operations with new business scenarios. In the following sections, we will present some inspiring thinking on the supply chain innovation based on RFID enabled systems. It should be noticed that technical and economic details of the RFID system implementation are beyond the scope of this chapter.

RFID ENABLED INTELLIGENT BUSINESS MODELS

With the recognised benefits and decreasing hardware costs of the RFID enabled automatic tracking technology, numerous industrial trials and technical developments on the RFID systems have been reported such as cases at WalMart, Sainsbury, Marks and Spencer, Finnair, Ford Motor Co., BT and many others. The applications have mainly focused on improvement of the business efficiency by replacing barcode or manual tracking systems with the RFID technology.

Although promising outcomes have been obtained as evidence, using the enriched automatic tracking information as a source of strategic intelligence for business innovation still remains a challenge. Some research has reported in the literature for investigating such opportunities in different industries (Karkkainen Holmstrom, Framling, & Artto, 2003; Li, Kehoe, & Drake, 2006; Liu, Zhang, Ni, & Tseng, 2004; McFarlane, Sarmab, Chirna, Wonga, & Ashton, 2003). The RFID related research has proposed novel concepts, business processes, and information systems, which improve the efficiency, agility and flexibility of business processes through restructured business scenarios. McFarlane et al. (2003) proposed an intelligent product concept which integrates the product information content permanently with its material content. With intelligent products, the RFID technology are integrated with agent based systems to enable individual products to participate in decision making processes intelligently according to the information embedded with themselves. Karkkainen et al. (2003) developed a prototype system which controls a large number of individualized deliveries in international projects to arrive at destinations just in time. They proposed a product-centric, so called "inside-out," delivery control approach with which products themselves provide delivery requirements to the control systems through RFID tags attached to the products. The planning and control of the deliveries are relatively independent from the centralized information storage, and are flexible to uncertain supply routes and partners. The supply chain network is highly responsive to dynamic changes in the delivery processes. Liu, et al. (2004) proposed a decentralized production control system with the RFID technology applied to a manufacturing shop floor context. Intelligent agents are integrated with the system to communicate with the products that carry the information about their own destiny on RFID tags. Through a simulation of different control rules, the research concluded that, with the real-time information linked to products the agent-based model outperforms traditional control rules. Such efforts on the opportunities from the technology driven innovation of the operations management are still at the concept-proving stage (McCartney, 2006; Sullivan, 2006).

The following sections of this chapter will introduce three research cases on intelligent operations and supply chain management through utilising the RFID enabled automatic tracking technology for innovative business models.

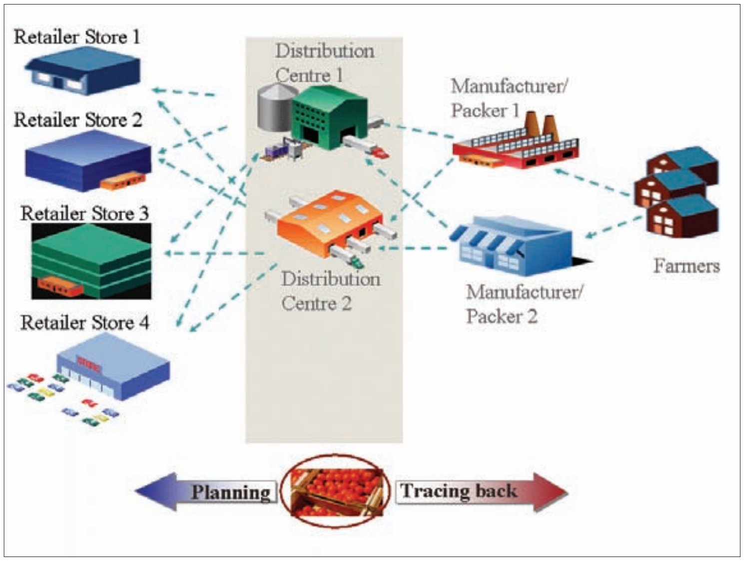
Dynamic Product Quality Tracing of Perishable Foods

It is important to maintain suitable environment to protect the quality of perishable foods. Therefore, the accuracy of the dynamic product tracking information and the technology to capture such information in food manufacturing and supply processes are crucial to the food quality control. In the industry, the RFID-sensor technology is now under investigations for the accurate estimation of product quality characteristics thorough continuously detecting changes of key environment parameters (Sullivan, 2006). In this section, a dynamic product quality tracing model which utilizes the automatically captured product data through RFID sensor systems is proposed. The quality in this model is represented by the "product value" which intends to indicate the consumers' perception of the product quality in the form of "usefulness" (in this case, edibleness). The concept of product value is derived from the research of Blackburn and Scudder (2003) in which the concept is used to abstract the consumer perceived product quality and its impact of the product value on demands. The model in this section is based on a perishable food retail supply chain context as shown in Figure 6. With the integrated RFID sensor network, the product movements and the environment changes in a supply chain can be continuously monitored or tracked with a greater accuracy comparing with traditional manual or barcode enabled control systems (Sullivan, 2006). This provides the possibility of qualitatively modelling the continuous food value or shelf life variations.

The Value: Tracing Model for Perishable Foods

To quantitatively measure the food quality deterioration, we adopt the model in Blackburn and Scudder's research (2003) which evaluates the fresh food value by an exponential function of the

Figure 6. A case of dynamic product value tracing in a food supply chain (Adapted from Li et al., 2005)



time period T and an environment parameter λ (see equation (1)). The exponential function indicates the fact that the consumer perceived product value decrease quickly over time in a nonlinear form given the environment condition. The parameter λ in our research represents the influence of the temperature on the product quality. The maximum value of a product is 100 (%) at the time of delivering from a farmer.

Present product value = *Original Value* •*EXP*(-λ•*T*) (1)

To describe the product quality (value) tracking process with the RFID sensor networks, a value tracking model is developed in equations (2).

$$V_{m,k*g} = b_{k*g} \cdot V_{f-m,g} \cdot e^{-(\lambda_{f-m,k*g} \cdot t_{f-m,k*g})}$$
$$V_{m-d,k} = b_{k*g} \cdot V_{m,k*g} \cdot e^{-(\lambda_{m,k} \cdot t_{m,k})}$$
$$V_{d,j*k} = b_{j*k} \cdot V_{m-d,k} \cdot e^{-(\lambda_{m-d,j*k} \cdot t_{m-d,j*k})}$$
$$V_{d-r,j} = b_{j*k} \cdot V_{d,j*k} \cdot e^{-(\lambda_{d,j} \cdot t_{d,j})}$$
$$V_{r,i*j} = b_{i*j} \cdot V_{d-r,j} \cdot e^{-(\lambda_{d-r,i*j} \cdot t_{d-r,i*j})}$$
$$i = 1,2,3,4; \quad j = 1,2; \quad k = 1,2; \quad g = 1,2.$$
$$b_{k*g},\ b_{j*k},\ b_{i*j}$$
$$= \begin{cases} 1, & \textit{Delivery was paased throug the route} \\ 0, & \textit{Otherwise} \end{cases} \tag{2}$$

The model is derived from the concept of product value (Blackburn & Scudder, 2003). The concept is based on the assumption that a value function can be properly structured with the key parameter λ, through quantitative approaches such as experiments and statistical analyses to represent the impacts of the production and delivery processes on the product deterioration feature and the consumers' perception of the product quality. However, such research is beyond the scope of this chapter.

In equation (2), the value deterioration parameter λ reflects the magnitude of the environmental impacts on the product quality/value per unit time. An exponential value deterioration rule (Blackburn & Scudder, 2003) is adopted, that is, with a given impact from the environment, the product quality deteriorate exponentially over time. In equation (2), *i*, *j*, *k* and *g* denote the supply chain tiers, that is, the retailer (*r*), distributor (*d*), manufacturer (*m*) and grower (*f*) respectively as seen in figure 6. *i*j*, *j*k* and *k*g* denote the immediate preceding transit routes of a supply chain node at a tier. V_r, V_d, and V_m are the product value at a supply chain node at the time of entering tiers of the retailers, distributors, and growers respectively. $V_{f\text{-}m}$, $V_{m\text{-}d}$, and $V_{d\text{-}r}$ are the initial product value in a transit process between tiers. With this model, given the initial product quality/value, the status of the product quality at any place and at any time can be quantitatively identified dynamically through RFID sensor network.

To trace the product quality changes, data dynamically stored in the RFID system would include product identifications, the manufacturer, packaging codes of the processes (manufacturing, packaging, delivery, storing, etc.), codes for preceding and succeeding processes, dates and the time of entering and leaving a process, the temperature (and other necessary quality parameters) in a time period. Readers of a RFID system is installed at key control points of each supply chain process to capture both the product and process details. The sensors in an integrated RFID sensor network should be connected to the readers to synchronize the product data reading and the environment parameter reading. This will enable the system to capture the accurate impact of the environment on the product quality while the products are moving through a supply chain. The EPC service and object naming service of a RFID system enable the supply chain partners to access the accurate information of an individual product unit (e.g., palette, case, box, etc.) or even an individual product (e.g., a bottle of milk) in a supply chain through Internet. Without the automatic product identification technology and the integration of the sensor systems with RFID systems, the accurate quality status of an individual product/product unit in bulky and fast product flows would be very difficult to capture through current Internet based information sharing applications (Li, Kehoe, & Drake, 2006).

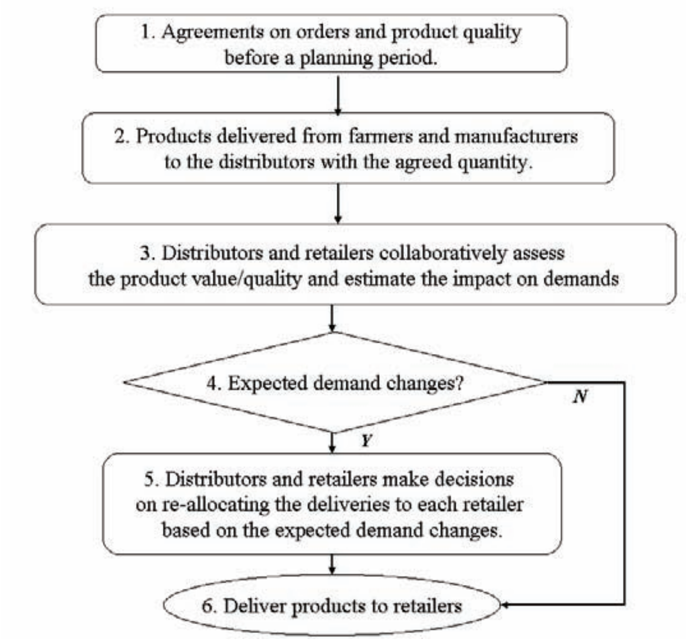
Applications of the Dynamic Product Tracking

One potential application of the above product tracking approach is dynamic planning and pricing in perishable food supply chain operations. With the context given in last section, we assume that distribution centres in the retail supply chain dynamically plan their perishable food deliveries to retail stores according to the decision on differentiated food pricing policies and estimated demands at the retailers. These dynamic planning and pricing decisions require the accurate product quality information which enables effective estimation on product demands and consequently pricing based on the potential demands. A centralized pricing decision structure is proposed in Figure 7.

Before a planning period, retailers place orders based on estimated demands and the agreed product quality. The actual demand delivered to each retail store is determined dynamically based on the product tracing information during the selling period. Variations of the actual delivery against the orders placed in agreements will incur supply rearrangements and excess stocks. It therefore leads to penalties. The objective of such an application would be maximizing the aggregated profits of the retail stores in the supply chain.

The relationship between a product sales price and demands can be represented by widely adopted price-dependent demand descriptions in the economic research literature. The form of the demand description can be either determinative in a linear or nonlinear form, or with a stochastic function. As the perishable foods deteriorate over time, given accurately captured data for the product value variations through the RFID sensor network, a dynamic pricing decision can be made against potential consumer responses to the value variation. A price marking down policy can be consequently developed to dynamically match demand changes with proper price levels.

Figure 7. Procedure of the dynamic pricing approach



The benefits identified from the product tracing approach are likely to vary with the consumer buying behavior. The more important the product quality or value that is perceived by consumers, the more benefits the dynamic product value tracing approach would generate.

Dynamic pricing models have been intensively studied in the literature. Many RFID applications have been reported. The above RFID enabled application has proposed an innovative product value tracing and dynamic pricing scenario by utilising real-time product quality information from RFID enabled sensor networks. The RFID technology underlies the implementation of such a dynamic pricing approach, because the real-time and traceable product information is a prerequisite for accurately evaluating the product value or quality. With the large volume and variety of product flows, this is very difficult, if not impossible, to be achieved by traditional product identification technologies. When consumers are able to dynamically perceive the quantitative product quality evaluation, it is particularly crucial to dynamically plan the deliveries and price the perishable food, so that better services to consumers and good profits can be achieved.

The proposed product tracing application in this section has only focused on the optimisation of retailer's profits. A supply chain wide dynamic planning and pricing scenario based on such a technology driven approach may be analysed for a wider view of the benefits. More insights into the relationships between the perceived product value and the demand in the demand function would be also beneficial to improve the applicability of the model.

Product Centric Manufacturing Scheduling

Based on the RFID and agent technologies, the concept of the Intelligent Product (IP) has been proposed (McFarlane et al., 2003). The products, with RFID tags and presented by intelligent agents, have unique identities and are capable of communicating effectively with its environment. An intelligent product can describe itself with self-retained data, and can make decisions for its own activities (McFarlane et al., 2003).

With the IP approach, the information system becomes product centric and the decision-making tends to be driven by the products themselves. This approach enables the manufacturing to be more flexible and agile when dealing with a large number of product varieties, and more efficient with given manufacturing constraints. An IP-driven agile manufacturing approach is proposed in this section to demonstrate the benefits of the IP approach in the manufacturing operations with a mass customisation context.

The Concept of Intelligent Product

The Intelligent Product has been defined as a commercial product that works with a RFID system and has part or all of the following five characteristics (Zaharudin et al., 2002):

- Possesses a unique identity
- Is capable of communicating effectively with its environment
- Can retain or store data about itself
- Deploys a language to display its features, production requirements, and so forth.
- Is capable of participating in or making decisions relevant to its own destiny.

Every IP has two components—a physical entity and informational presentation. The physical entity is the physical product which is equipped with RFID technology. The informational presentation of an IP can be an individual software agent that owns some product-related data (e.g., unique ID) and acts (e.g., negotiate with other agents, make decisions) on behalf of the product's interest (e.g., short lead-time and low costs, etc.). An IP retains data about itself. The informational part of the IP retrieves the data through the RFID technology. The IP may also keep dynamic data regarding product's movements and processing requirements, and so forth. The IP system can access networked data sources (local databases or ONS registered network sources) that stores product data such as production requirements, historical records, and so forth. The local manufacturing unit, IP systems and enterprise systems, can be integrated with such networked sources so that the data are visible and updatable by different cooperative parties. This allows manufacturing activities to be responsive to the dynamic environment.

The Intelligent Product Driven Control Approach

The use of autonomous product agent to represent the informational part of products has been reported in some recent research (Kim, Song, & Wang, 1997; Krothapalli & Deshmukh, 1999; Lim & Zhang, 2004; Reaidy, Massotte, & Diep, 2006). The research has proposed approaches with product agents to provide product information, negotiate for production control, and communicate ERP systems. The research articles did not provide details of the linkage between physical items and agents. The proposed system in this section will describe the architecture which links the physical product with the agent systems. The proposed system aims to copes with a large number of product varieties and late changes of production requirements more efficiently in manufacturing processes through the IP enabled intelligent scheduling system.

In the mass customization context, with an extreme case, every production order may be one batch itself. The traditional centralized decision-making approaches are not so scalable when dealing with such complexity in scheduling. With the IP approach, a product can make decisions about its destiny with less or without centralized management. Since each product has a duty of making decisions about itself, and the RFID technology is applied to enable agents to quickly respond to physical products, the system is potentially more scalable to the number of product varieties. In other words, the manufacturing performance becomes less affected by the complexity originating from the product variety issues.

In addition to the product variety issues, customers may request to change the requirements of an ordered product before it is produced. The requests lead to changes of a production process. Consequently, manufacturers need increased visibility to the latest updates in order to conform to the customer needs. To cope with this, the IP approach may be adopted to track individual product items in real time and responsively make decisions for updating a manufacturing process.

The IP Enabled Scheduling System

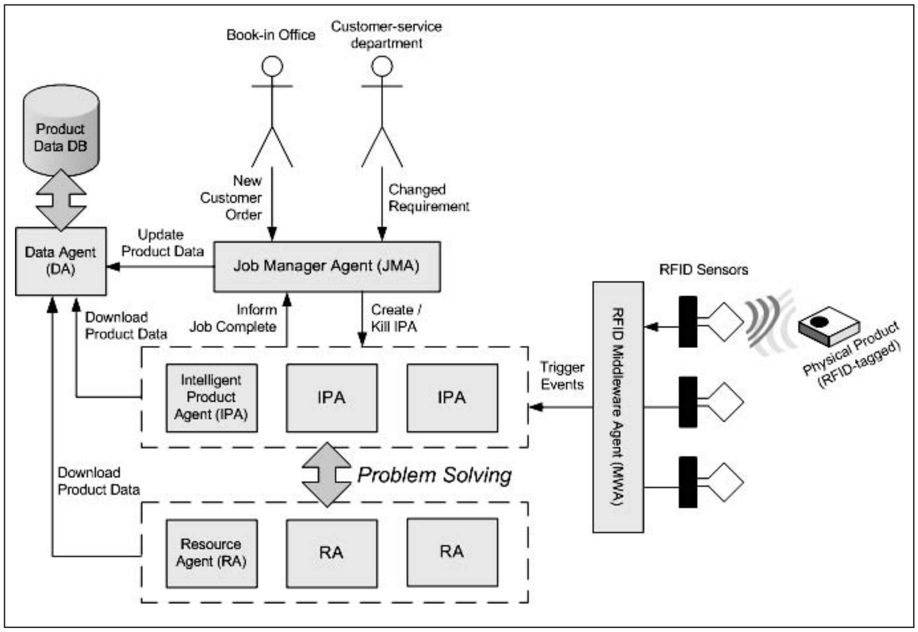
We firstly introduce a proposed MAS architecture which enables the communications between physical products and the production systems as seen in Figure 8.

The architecture includes a job manager agent (JMA), a data agent (DA), intelligent product agents (IPA), resource agents (RA), and an RFID middleware agent (MWA). The DA is in charge of receiving data transaction requests from other agents and fulfilling the data transactions to a database before giving feedback to agents about their requests. An *IPA* is the information presentation of the intelligent product. It actively drives the scheduling process and makes decisions within a negotiation process. A *JMA* receives new production orders and requests for changing production orders from other parties. It creates and removes *IPA* from MAS when a job is created and completed respectively. A *RA* is the informational presentation of resources. Based on the generalized case in the last section, a *RA* can represent a workstation. The *MWA* manages the sensor devices, receives raw data from sensors, filters and interprets the data, and finally informs the corresponding *IPA* about the status of the physical part. In other words, *MWA* and sensors are the communicational link between the physical part and informational part of an IP.

Detailed workflows of the approach can be described by the life cycle of jobs and negotiation protocols. A job life cycle is described below:

- Production orders are received randomly. After a new production order is received by the *JMA*, it will create a new *IPA* and submit

Figure 8. Proposed IP-driven scheduling system architecture (Adapted from Liu, Li, & Kehoe, 2006)



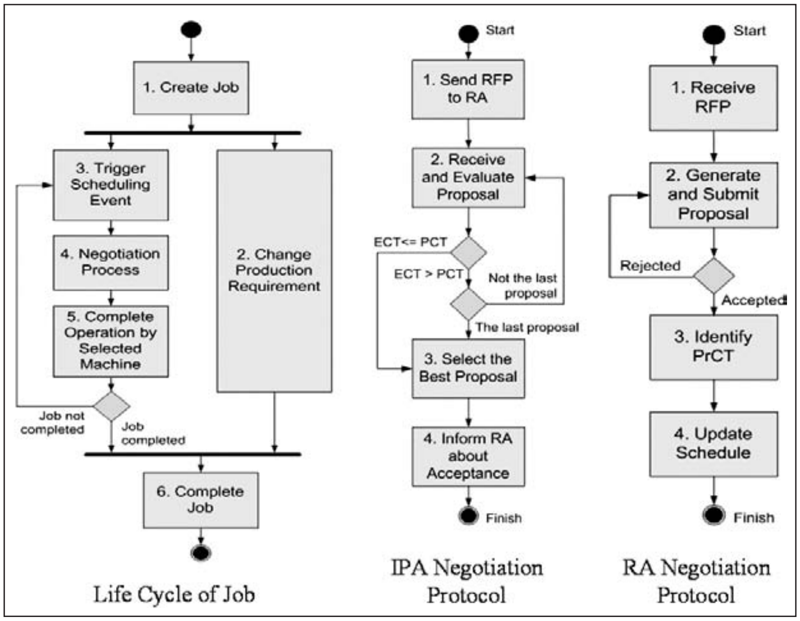
the product data to a *DA* which stores the data in a database. The physical product equipped with a RFID tag carries unique ID and necessary static data.

- When production requirements need to be altered during a manufacturing process, the changes are received by the *JMA* which checks if the process needs update.
- At checkpoints, the products with RFID tags are physically allocated to the routes of processing stations. When a process is completed and the product is leaving the station, the *MWA* retrieves the unique product ID and other relevant data from the RFID tag and informs of the *IPA* that the product has completed. Then the *IPA* will trigger the negotiation process with the *RA* for a scheduling decision of the next route.
- The *RA* will consequently add the new jobs to its schedule according to the agreement. It downloads the production requirements from centralized database through the *DA*. Finally, the workstation finishes the whole process.

The negotiation process takes the interests of both the *IPA* and *RA* into account. The *IPA* and the *RA* work cooperatively to address the production lead-time and workstation resource optimization issues respectively. Figure 9 explains the negotiation protocols. With the negotiation protocols, *IPA* initializes the negotiation process, and has the power to evaluate, accept and reject *RA*'s proposals.

Through the proposed approach, the problem of the product variety and dynamic requirement changes would be dealt in a more scalable and responsive manner. A MAS architecture is proposed to support the IP enabled scheduling approach. The architecture integrates the IP's physical and informational attributes, as well as the links between them. In order to illustrate the idea, prototype negotiation protocols are developed to implement the architecture. Further research is being performed to simulate the approach with some manufacturing cases.

Figure 9. The workflows of the proposed IP-driven scheduling system (Adapted from Liu et al., 2006)



Intelligent Traceability Systems

The traceability of product data, globalized data sharing, and risk analysis within and beyond business networks is a key capability to maintain food quality and safety. The research on traceability systems has been reported in the literature, including RFID tagging and DNA profile auditing solutions Caja (2002). A number of traceability systems and approaches (Bertolini, Bevilacqua, & Massini, 2006; EU FoodTrace 2004; Mouseavi, Bevilacqua & Massini, 2002; Sasazaki et al., 2004; Wilson & Clarke, 1998) have been developed to deliver the supply chain traceability and internal traceability for achieving different business objectives. These systems vary in complexity from simple paper recording systems, complex computer-based information technology methods, to the most sophisticated systems including biological technologies.

The traceability is defined as: "the possibility to find and follow the trace, throughout all the stages of production, processing and distribution of a foodstuff, feedstuff, and an animal destined for food production or a substance destined to be incorporated in foodstuff or feedstuff or with a probability of being used as such" (The European Parliament and the Council, 2002). According to TRACE-I Guideline (EAN International, 2003), both tracking and tracing must be in place for the effective traceability. The tracking and tracing capability of a traceability system has been used as tools for achieving a number of different objectives. Golan, Krissoff, Kuchler, Calvin, Nelson, & Price (2004) indicated that firms have three primary objectives in using traceability systems: facilitate trace-back for food safety and quality; differentiate and market foods with subtle or undetectable quality attributes; and improve supply chain management.

Although, food traceability becomes an essential issue for the food industry, companies are reluctant to invest on these systems as many food organizations acknowledge their main motivation of adopting traceability is complying with the regulations. For many businesses, implementations of traceability are still seen as a daunting task without any obvious benefits to a business in financial terms. Traceability is frequently mentally separated from other supply chain activities (EU FoodTrace, 2004). Therefore, enhancing and understanding the value of the food traceability becomes increasingly crucial for the food industry. In this section, we particularly demonstrate the potential benefits of the RFID technology for the integrated traceability-supply chain management—not only for tracing product origins, but also support the strategic and operational supply chain decision-making.

RFID Based Traceability System

A traceability system requires capabilities of identifying any items deemed necessary for traceability, and facilitating data capture, storage, management, and communication. RFID based traceability systems have the potential to improve such capabilities. Although paper based and barcode based traceability systems can deliver both internal and chain traceability with basic traceability functions, the RFID traceability system changes the way in which data are recorded, processed and transmitted across a supply chain, to manage the traceability processes innovatively and more efficiently. Wilson and Clarke (1998) indicated that the data structure used in traceability system must meet two conflicting criteria: firstly, it should be as small as possible to enhance speed and efficiency; secondly, it must be of sufficient capacity to meet the needs of large data volumes. RFID technology itself offers the speed, automation, and data capacity with a distributed data management scenario (every individual product attends the data storage and processing),which limits the complexity of the centralized traceability data management. Table 2 shows the advantages of RFID enabled traceability systems over barcode based traceability systems.

Table 2. Advantages of RFID based traceability system over barcode system

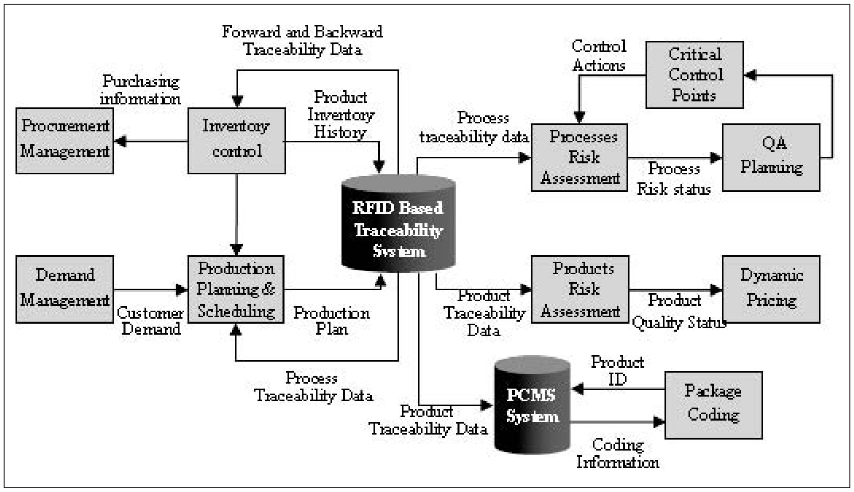
	Advantages of RFID Based Traceability System Over Barcode System
Data Feature	Capacity: More data (6bit~64kbit) can be stored in tags.
	Unique identifier: A serial number or unique identity can be assigned to specific item
Data Capture	Efficiency: Many tags can be read simultaneously
	Convenience: Data can be captured within certain range
	Location: Readers can provide location information when products being scanned
Automation	Up-to-date data: Data can be obtained continuously
	Accuracy and cost-effectiveness: Without human involvement in data scanning

Traceability System Integration

With RFID based traceability systems, a product can be tracked and traced in a more efficient way to provide accurate real time data of food and ingredients as they move through supply chains. To maximize the benefits from such systems, traceability systems need to be integrated with enterprise systems and supply chain management processes so that the traceability systems can contribute to the operations and supply chain management with the benefits beyond the contingency management. A framework of integrating the traceability system with operations management processes is proposed as seen in Figure 10 in a food manufacturing context. The investigated case is based on a British meat manufacturer. The current paper based traceability system records batch numbers and time of processing for all products. The business is experiencing problems such as low production efficiency due to long production lead time, high inventory and large batch size, high quality maintenance costs due to long storage time; and lack of real time tracking/tracing capability for production and quality control, and so forth.

With the proposed traceability-operations integration, the RFID enabled system is expected to provide the real time traceability data of production process and raw materials, such as production

Figure 10. A framework of the integrated traceability-operations management solution. (PCMS: package coding management system)



facility, processing history, supplier information of raw materials, and its storage period and quality status for production planning and inventory control processes. On one hand, the integrated solution provides the real time information that enables to optimize production plan and a better quality control for lower costs and better product quality. On the other hand, the optimised production decision as an input of the traceability system would improve both tracking and tracing capabilities through reduced unnecessary batch mix and reduced numbers of products that may be potentially recalled.

With a RFID enabled solution, enriched traceability data can be retrieved such as process environmental parameters, real time positions, product composition, packaging, and storage conditions. The information would improve customer satisfaction and more accurate and responsive risk assessment. The dynamic evaluation results in food safety risk consequently support dynamic planning for production and supply chain operations (e.g., dynamic pricing and supplier selection) and critical control points (e.g., control actions at required points according to risk alert level). With an extension to the supply chain management, Table 3 summarizes potential benefits of the integration in different domains within and beyond a food manufacturing enterprise.

To achieve these benefits, the RFID enabled traceability system must be properly designed to ensure that the right data is collected and managed effectively. The business process needs to be re-engineered to integrate the RFID based traceability system with enterprise systems.

The above research concludes that, when a traceability system is integrated with operations and supply chain management, more competitive advantages can be potentially obtained. The RFID enabled traceability system is promising in facilitating such integration. A key issue to achieve the maximum potential value of integrated traceability systems is how to utilize the traceability data for business innovation. Future research would be beneficial to such applications by identifying the benefits of the integrated traceability solution through quantitative analyses.

CONCLUDING REMARKS

The proposed business models in the third section, utilize the RFID technology to improve the visibility of products and their relevant attributes in logistic or manufacturing operations. The visibility consequently creates chances to operate the businesses in more responsive, dynamic, and efficient scenarios. In such proposed RFID

Table 3. Potential benefits of integrating traceability system with operations and supply chain management

Processes	Impact of integrated RFID based traceability systems
Production Planning & Scheduling	Optimal production planning; avoid uneconomic raw material mixture, reduce the production lead time.
Inventory Control	Inventory visibility; efficient and accurate picking and packing operations.
Quality Control	Better quality and process control; efficient and accurate risk assessment, dynamic product quality and safety evaluation.
Package Coding Management	Coding automation; accurate and efficient coding process; additional traceability data on the package.
Shelf Management	Improve on-shelf availability; effective shelf replenishment; dynamic pricing.
Reverse Supply Chain management	Quick response; efficient product recalls and returns.
Supply and Logistic/Distribution Management	Efficient and effective information flow; instantaneous decision-making responses to supply chain variations.

applications, the technology is not only used as a replacement for barcode systems. The actual initiative is to encourage the “sense and respond” management strategy which enables more agile and intelligent supply chains to respond changes and events dynamically (Ferrari, 2006). The development of advanced identification and tracking technologies, including RFID, GPS and other sensing technologies (e.g., for temperature, pressure, humidity, shock, and weight, etc.) are key enablers of the intelligent supply chains as they provide the “sense” to management systems throughout a supply chain. Therefore, integrations of the identification and tracking technologies into a business intelligence platform are required, so that the real time information at different levels (e.g., product attributes, product items, stock units, containers, vehicles, etc.) can be available for various decision-making purposes.

To achieve the potentials of the technology driven innovation, supply chain partners must be cooperative in investments of the technologies, information sharing, risk and profit sharing, and standardisation of the technologies, and so forth. Without the cooperation, the sensing information would be restrained within organization boundaries, and would not add values to supply chain operations. Lack of cooperation may simply stop supply chain partners to join in RFID applications projects (e.g., manufacturers may refuse to pay for RFID tags, when increased profits are only related to retailers). Furthermore, associated technologies also need to be mature so that the sensing data can be processed into valuable information for decision support. For instance, the software which integrates RFID systems with various enterprise applications is still under development. This has limited the potential benefits of RFID applications, and also affected the technology adoption (Microlise, 2003). Therefore, both organizational and technical supports are essential for the success of RFID technology applications.

In summary, the RFID-enabled business intelligence which improves the process visibility and facilitates decision making are increasingly important to sustain competitiveness. As the implementation costs of the RFID technology are continuously decreasing, the technology is expected to play more important roles in the innovation of supply chain management. Although this chapter focuses on the RFID enabled intelligence for innovative enterprise operations and supply chain management, it is apparently that the RFID technology is not the only player in the technology driven business innovation. Applications of the grid computing technology, agent based systems, global positioning system, wireless mobile networks, personal data assistant, and many others in the industry have generated promising outcomes in providing strategically important information sources. Such information sources would be increasingly used as business intelligence to improve business performance. We are expecting that novel business models would be inspired by such technological advancement to foster more intelligent supply chains in the near future. This, we believe, would demonstrate both the benefits and challenges of the “visibility,” not only in the industry, but also in everyone’s daily life.

Chapter 3.11

RFID and Wireless Personal Area Networks for Supply Chain Management

David Wright
University of Ottawa, Canada

INTRODUCTION

Efficient supply chain management relies on knowing where products in the supply chain are located. The ability to track items from manufacturing plant to warehouse to distribution center to wholesaler to retailer is currently provided by RFID, radio frequency identification (Weinstein, 2005). Case examples of commercial applications of RFID in supply chain management are evaluated by Jones et al. (2004). A recent development, low power wireless personal area networking, WPAN, can offer advantages over RFID in certain circumstances. It is the purpose of this article to evaluate RFID and wireless personal area networks with respect to each other and to identify the features that give one an advantage over the other. We first describe the two technologies.

RADIO FREQUENCY IDENTIFICATION (RFID)

RFID tags are of two types: passive and active. A passive RFID tag is a chip incorporating memory and a microwave transmitter that is embedded in a product or in the product's packaging. The memory contains the identification number of the tag and may also contain physical specifications of the product using PML, Physical Markup Language (York, 2003). In order to read the tag an RFID reader sends out a burst of microwave energy, which is picked up by the tag and is sufficient to allow the tag to transmit the contents of its memory, which is received by the reader. Since the tag receives power from the reader, it does not need to have its own battery, and is called a passive RFID tag for that reason. Passive tags cost about US$0.20 in large volumes, and are used much more widely than active tags.

Active RFID tags incorporate a battery, cost more than passive tags and can be used to track more expensive products. The price of tags is continuously dropping and increasing usage of active tags can be expected over time.

Some tags are read-only in which case the ID is burnt into the tag at time of manufacture. Others are read/write in which case the memory contains not only the fixed identification number of the tag, but may also contain other information such as a physical description of the product (color, size, etc., in PML format), which is added when the product is manufactured.

Standardization of the identification number, so that it can be read by the many different readers used by organizations in different parts of the supply chain, started at the Auto-ID Center at MIT, and is now being pursued by EPCglobal Inc, an industry consortium that aims to standardize the format of the EPC, electronic product code for use in RFID tags. The current proposal is illustrated in Figure 1 and consists of three parts:

- A 28-bit EPC manager allowing 268 million manufacturers,
- A 24-bit object class allowing 16.8 million products for each manufacturer
- A 36-bit serial number allowing 68.7 billion copies of each product

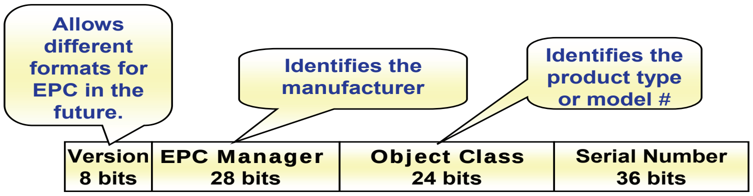
The specification of the air interface is given by the International Standards Organization (2004). Taken together, the EPC and the air interface are the main standards for RFID.

Automated input of RFID information into a supply chain management system requires RFID readers to be located on shelves in warehouses, distributions centers, and possibly also in retail stores and in delivery trucks. Readers have a range of about one meter so that multiple readers are required. Readers can input information to the supply chain management database via wired connections, for example, using Ethernet, or using a wireless technology such as WiFi or WiMAX (Wright, 2007a, 2007b). The total cost of the system consists of the cost of the tags on each item flowing through the supply chain plus the cost of the readers. Although passive tags cost only US$0.20, readers cost approximately US$250.00.

WIRELESS PERSONAL AREA NETWORKS (WPANs)

An alternative to RFID for supply chain management is a wireless personal area network or WPAN, consisting of devices that communicate with each other instead of with a reader. The word "personal" in the title does not mean that there is always a human user, instead it refers to the limited range of the wireless communications: approximately 1 meter from one device to another. WPANs are of various types and here we focus on the low power version that is standardized by IEEE (2003), and is being commercialized by the industry consortium, the Zigbee Alliance, which has developed a specification for wireless personal area network applications (Zigbee, 2006). WPANs require each device to be powered, typically with a battery, but they transmit low data rates at low power so that battery life can exceed a year. Methods for

Figure 1. 96 bit Standard Electronic Product Code, EPC



reducing power requirements are described by Liang (2003) and Rajendran et al.(2006); and the system's performance is analyzed by Chin et al. (2003). Initially applications of low power wireless personal area networks include interactive toys and industrial control, in which sensors measure temperature, humidity and position of items in a production facility and use the WPAN to communicate this information to a production control system (Egan, 2005). Supply chain applications include embedding WPAN devices with EPCs in products or their packaging and could also include sensors for measuring temperature and humidity, which are important for perishable items such as produce. WPAN devices can be designed as small as a coin, so as to be easily embedded in products and packaging (Choi, 2003).

The network architecture of a WPAN is illustrated in Figure 2, and is built up of clusters of devices. Each cluster has one device designated as a "cluster head," and one of these cluster heads is the WPAN coordinator. Although the communications range between one device and another is limited to about one meter, networks of clusters can communicate over a much longer distance. Each device uses wireless communications to communicate with its neighbors, and one device can communicate with a supply chain management system using Ethernet, WiFi or WiMAX. This "upload device" is more costly than the others, however only one is required per WPAN. Actual $ costs are not available at the time of writing (1Q06) since WPAN devices are at an early stage of commercialization. Practical methods for designing WPAN networks are described by Minami (2004).

In supply chain management, WPAN devices can be embedded in products or in packaging and can communicate with each other in warehouses and delivery vehicles. As items are added to or removed from a stack of shelves in a warehouse, the clusters reconfigure dynamically, and information about the new products is distributed to the upload device. Each stack of shelves in a warehouse needs an upload device connected to the supply chain management system to forward information it receives from all the other devices on the products stored on those shelves.

COMPARATIVE EVALUATION

A comparative evaluation of RFID and WPANs for supply chain management is summarized in Table 1.

Both RFID and WPANs have a limited communications range of about 1 meter, however the extent of a WPAN can be much greater end to

Figure 2. Wireless personal area network

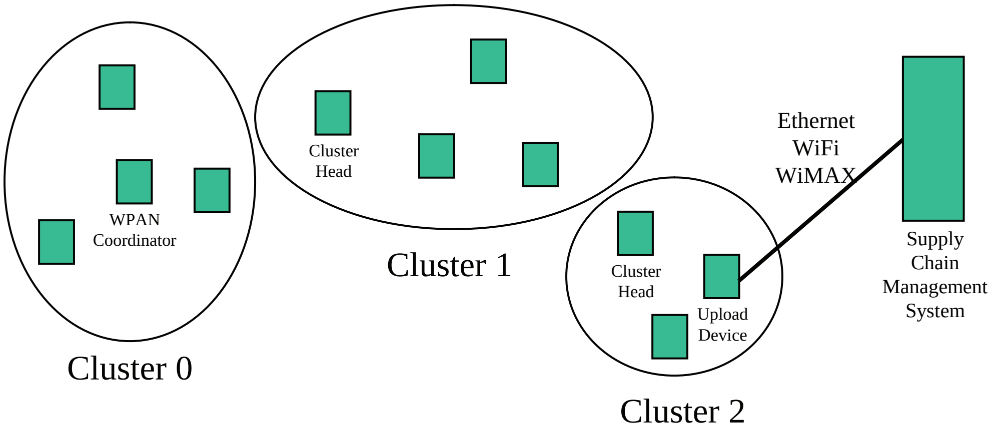


Table 1. Comparative evaluation of RFID and WPANs for supply chain management

	RFID	**WPAN**
Communications range	~ 1 meter: tag to reader.	~ 1 meter: device to device.
Networking	N/A	A network can consist of hundreds of devices.
Number of devices needed	One tag per product or package. One reader within a meter of each product or package connected to the SCM system.	One device per product or package. One upload device per WPAN, connected to the SCM system.
Cost	Very low cost per tag. Higher cost per reader.	Low cost per device. Higher cost per upload device.
Environmental monitoring	No standard integration with sensor technology.	WPAN sensors commercially available.
Reliability	< 100% reading ratio.	Error control protocol enhances reliability.
Stage of development	Established technology.	New technology at early stage of commercialization.
Power	Tags derive power from reader.	Devices need batteries or mains power.

end. In warehousing applications, this allows a WPAN to span an entire stack of shelves, using only a single upload device, whereas multiple RFID readers are required, each having an upload capability. Upload devices and RFID readers cost more than regular WPAN devices and RFID tags, so that using less of them gives a potential cost advantage to WPAN over RFID. Another advantage of WPAN is that additional sensor devices can be added to monitor temperature and humidity, which is important in the case of perishable products. This can be done in a standardized way with WPAN sensors; however sensors interfaced to RFID tags require a proprietary interface (Philipose et al., 2005). The final advantage of WPAN is improved reliability, due to the use of an error control protocol. Any low power wireless communication can be unreliable in the presence of metal, for example, in warehouse shelving and in the products themselves, and read ratios on RFID readers are often <100%. The downside to WPANs is the additional cost of the devices, first due to the fact that it is a relatively new technology, and second due to the requirement for each device to have a battery or mains power supply.

CONCLUSION

RFID is a mature technology that is currently seeing widespread deployment to provide information for supply chain management. WPAN is a more recent development which could provide similar and, in the case of perishable products, improved functionality. As WPAN technology is commercialized and unit prices drop, we can expect cost advantages compared to RFID, since the cost of multiple upload devices can be eliminated in the case of WPANs. In addition WPAN is a more reliable technology than RFID since it incorporates error control.

KEY TERMS

Electronic Product Code (EPC): A code that can uniquely identify each item in the supply chain, by specifying the manufacturer, the product code and the serial number of each item.

Physical Markup Language (PML): A language for describing the physical characteristics of items, including the dimensions, weight and operating specifications of products in the supply chain.

Radio Frequency Identification (RFID): A system consisting of tags containing identification numbers, which can be transmitted to readers over a distance of about 1 meter.

WiFi: A commercial implementation of the IEEE 802.11 standard for wireless communications up to about 100 meters, in which the equipment has been certified by the WiFi Alliance, an industry consortium.

WiMAX: A commercial implementation of the IEEE 802.16 standard for wireless communications with a range of 2-5 Km, in which the equipment has been certified by the WiMAX Forum, an industry consortium.

Wireless Personal Area Network (WPAN): A network consisting of multiple devices communicating using wireless, each within about 1 meter of its neighbor, following standards developed by IEEE 802.15.

Zigbee Alliance: An alliance of companies commercializing WPAN technology by developing specifications for its efficient application in a number of areas of business, home and industry.

ABSTRACT

This chapter investigates opportunities to integrate mobile technologies within an organization's enterprise architecture (EA), with an emphasis on supply chain management (SCM) systems. These SCM systems exist within the overall EA of the business. SCM systems are further influenced by the increasing modern-day need for information and communications technologies (ICTs) within a business, to bring together all of its disparate applications. The resultant enterprise application integration (EAI) also stands to benefit immensely from the incorporation of mobile technologies within it. Traditionally, supply chain management systems have involved management of the flows of material, information, and finances in a complex web of networks that include suppliers, manufacturers, distributors, retailers, and customers. Thus, these traditional supply chain management systems have a great need for integration under the umbrella of EAI. Mobile technologies can provide time and location independence to these EAIs in terms of information in the supply chain systems,

creating the possibility of multiple business processes that traverse diverse geographical regions. This chapter, based on the research conducted by the authors at the University of Western Sydney, discusses the opportunities that arise in supply chain management systems due to the time and location independence offered by mobility, and the resultant advantages and limitations of such integration to the business.

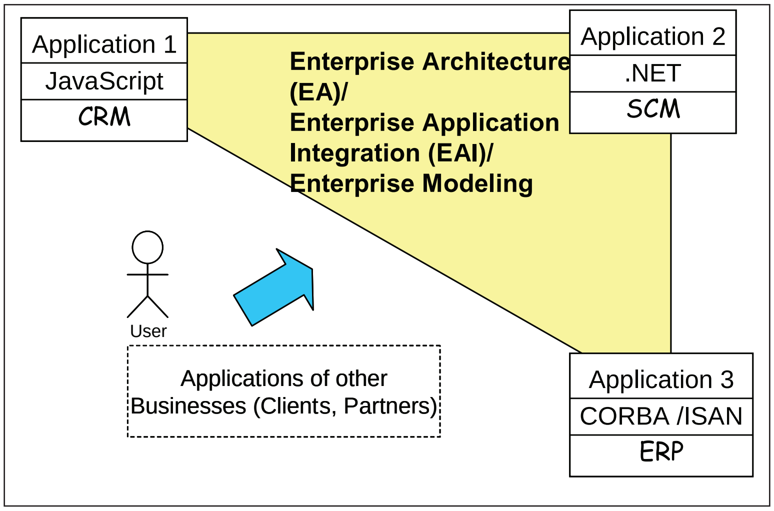
INTRODUCTION

A business enterprise uses a suite of different software applications to fulfill its various activities. These systems include supply chain management (SCM) systems, customer relationship management (CRM) systems, enterprise resource planning (ERP) systems, business intelligence (BI) systems, and other supporting financial and business systems. These enterprise systems do not operate in isolation. In fact, each of these systems depends on other systems, as well as large amounts of data in the background, to fulfill their own requirements. Specifically, supply chain management systems involve management of the flows of materials, information, and finance in a complex web of networks that include suppliers, manufacturers, distributors, retailers, and customers. The complexity of an SCM system requires it, as per Poirier (1999), to offer the right combination of data, products, and services to customers at the right time, right place, and right price. With rapidly increasing Internet access and business-to-business (B2B) connectivity, users of SCM are able to get their information needs easily—leading to what can be called electronic supply chain management (E-SCM) systems. E-SCM (Internet-based) systems are integrated together with all other enterprise applications, resulting in a comprehensive enterprise architecture (EA). Such an EA delivers the company a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer satisfaction, and enable thorough strategic planning (Unhelkar & Lan, 2006). In today's modern business environment, it is important to further extend the advantages by incorporating wireless technologies and handheld devices in the organization's overall enterprise architecture. As Barnes (2002) mentions, the impact of wireless telecommunication on the Internet has taken a new turn. We use the mobile technology application for communications, working, banking, and shopping. The "time and location" independence provided by mobile technologies leads us into the era of mobile supply chain management (M-SCM) systems. It is important to understand these M-SCM systems within the context of the overall enterprise architecture. This chapter starts with a brief review of enterprise architecture and the issues related to enterprise application integration (EAI). This is followed by an understanding of the traditional SCM systems, together with the study of mobile technologies and applications. The chapter then describes the details of E-SCM and M-SCM. Finally, an outline of a model for integration of mobile technologies with SCM processes is then presented, together with its advantages and limitations.

ENTERPRISE ARCHITECTURE

An enterprise architecture represents the enterprise's key business, information, application, and technology strategies, and their impact on business functions and processes. EA consists of four key components: enterprise business architecture (EBA), enterprise information architecture (EIA), enterprise solution architecture (ESA), and enterprise technology architecture (ETA). The overall EA comprises software systems that may have been created using different programming languages and databases, and may be operating on different technology platforms. Figure 1 presents how EA is composed of different enterprise systems. However, Figure 1 also shows that users of the system want to see a unified view of the EA. This

Figure 1. Enterprise application integration composed of different enterprise systems



need for a unified view requires the enterprise to bring these various applications together, in an integrated fashion, resulting in enterprise application integration.

An enterprise business architecture that defines the enterprise business model and process cycles and timing also shows what functions should be integrated into the system. The enterprise information architecture focuses on which data and the corresponding data model should be integrated into the system. The enterprise solution architecture, also referred to as an application portfolio, is the collection of information systems supporting the EBA, which helps the user to easily understand and use the interface and components. Enterprise technology architecture is a consistent set of ICT standards which use infrastructures to support the EBA, EIA, and ESA. The infrastructures span across various different technical domain architectures, and include databases, applications, devices, middleware, networks, platforms, security, enterprise service buses, hosting, WLAN, LAN, Internet connection, operation system, servers, systems management, and so on (Pulkkinen, 2006).

Enterprise application integration maintains data integration and process integration across multiple systems, and provides real-time information access among systems. EAI not only links applications together, but also provides more effective and efficient business processes to the enterprise. There are numerous technologies that can be used for enterprise application integration, such as bus/hub, application connectivity, data format and transformation, integration modules, support for transactions, enterprise portal, Web service, and also service-oriented architecture (Finkelstein, 2006). Most importantly, however, the technologies of Web services build on extensible markup language (XML), Web services description language (WSDL), and universal description, discovery and integration (UDDI), which provide an excellent basis for integrating the applications of the enterprise—particularly when they are on separate platforms.

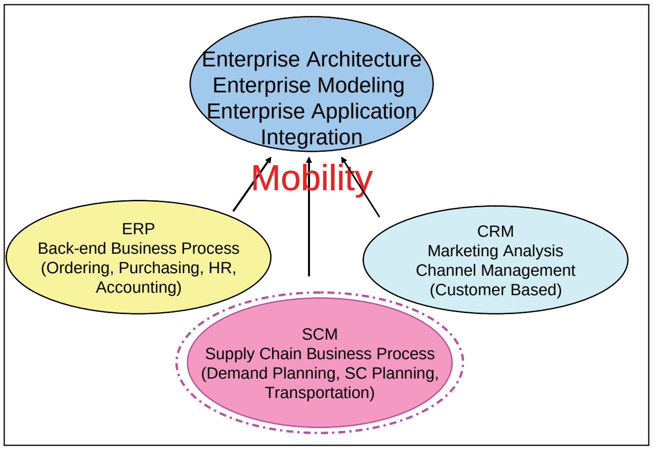
Linthicum (2000) declared that EAI enables the original chaotic enterprise processes to reach a semblance of order after the integration is achieved, resulting in increased efficiency on process flows, data integration, and data transportation. Furthermore, EAI also makes a more effective extension of enterprise processes. Irani, Themistocleous, and Love (2002) divided application integration into three categories: intra-organization, hybrid, and inter-organization. Intra-organizational application integrates packaged systems, custom applications, and EPR systems, and there are no transactions between external users or partners. Hybrid application integrates business-to–consumer (B2C) applications with IT infrastructure. Interorganizational application integrates all processes between extended enterprises, such as the supply chain, and also can be a transaction between virtual enterprises, for example, e-procurement.

Further to the above discussion, in order to bring about a successful EAI, it is also important to create a model of such integration—called an enterprise model (EM). An EM would describe the objectives pursued by an enterprise and, as per Brathaug and Evjen (1996), focus on four aspects: process, product, organization, and systems. Doumeingts, Ducq, and Kleinhans (2000) defined enterprise modeling as the representation of enterprise activities at a global and a detailed level, using functions and processes in understanding its running. A good EM would take into account not only the technical aspects but also business, social, and human aspects of the enterprise. Such a comprehensive EM will also make it easier for the incorporation of mobility.

Kamogawa and Okada (2004) pointed out that integration of enterprise systems focuses on integrating collaboration agreements, collaboration profiles, business scenario integration, business process integration, and messaging technology. The three major applications—CRM, SCM, and ERP—are all shown in Figure 2. Figure 2 also shows how these applications are integrated through the enterprise model. Our aim is to further apply mobility to the enterprise model. However, in this chapter the discussion on the application of mobility to EM will be restricted to its application to SCM systems.

EA/EM/EAI all integrate enterprise applications. Such integration cannot only enable the enterprise to present a unified view of the system to its suppliers and clients, but also reduces errors and improves quality by reducing or even eliminating duplication of data entry. Enterprise application integration brings about not only internal integration, but through extension also offers much more efficiency to its external suppliers, customers, and other trading partners over the Internet. Thus, providing mobility to EAI, and especially the SCM system, will connect existing and new systems to enable collaborative operation within the entire organization in real time—providing new and improved services without location and time limitations.

Figure 2. Enterprise model (based on Kamogawa & Okada, 2004)



EXISTING MODEL OF SUPPLY CHAIN MANAGEMENT

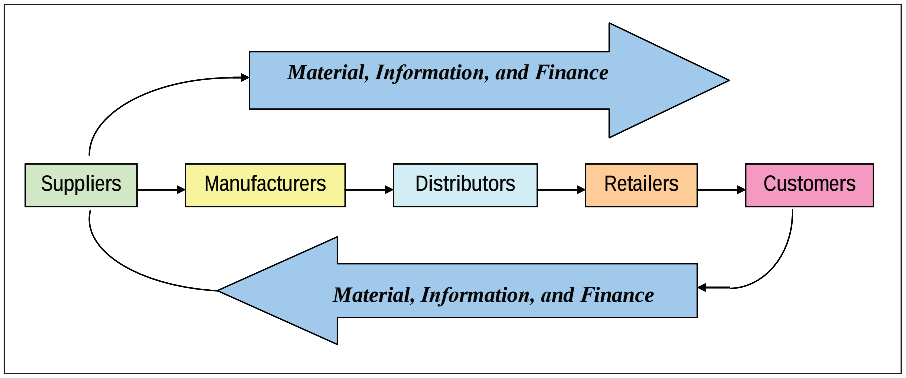
In order to successfully apply mobility to SCM, we consider SCM within the overall context of EM. Traditional supply chain management involves the flows of material, information, and finance in a network, including suppliers, manufacturers, distributors, retailers, and customers. This is shown in Figure 3, where the various parties are connected to each other through the ability to supply goods, provide information about the goods, and deal with the financial aspects of those supplies.

The traditional supply chain is a push model. As outlined by Lee (2000), material flow includes both physical products flowing from the suppliers to customers through the chain and reverse flows via product returns, servicing, recycling, and disposal. Information flows involve order transmission and delivery status. Financial flows include credit terms, payment schedules, consignment, and title ownership arrangements. These flows cut across multiple functions and areas within a company and across companies (and sometimes industries); this leads to big challenges in terms of both technologies and business. Organization and integration of these flows within and across companies are important for effective supply chain management.

Supply chains can exist in both manufacturing and service organizations. In manufacturing organizations, they are mostly concerned with the flow of products and information between supply chain member organizations—procurement of materials, transformation of materials into finished products, and distribution of those products to end customers. However, in service organizations, supply chains can focus on "values added" to the services being offered. Overall, the current information-driven, integrated supply chains enable organizations to reduce inventory and costs, to add product value, to extend resources, to increase speed time to market, and to retain customers (Burt, Dobler, & Starling, 2003).

There are complex relationships in supply chains, such as multiple suppliers serving multiple customers, or a supplier who may be a customer or even a competitor in different parts of the chain. This complexity is the reason why we refer to supply chains as "supply networks" or "supply webs." Because of the network complexity, correct quality and time transfer of information can be extremely difficult. In particular, the multiple layers in a supply chain have the potential to misrepresent order information. This misrepresentation can lead to numerous confusion and errors, such as excessive inventory, inactive capacity, high manufacturing and transportation costs, and increasingly dissatisfied customers. Achieving supply chain efficiency requires exact and timely information. And the longer and more complex the supply chain is, the greater the requirement is, according to Dong (2001), for the supply chain to have precision in

Figure 3. The supply chain flows (based on Lee, 2000)



terms of the quality and timing of information.

SCM systems primarily include the requirement for integration architecture; the varied objectives of all the participants in a supply chain; mutual collaborative functioning of interfacing systems; and the varied levels of functionalities required for customers, retailers, suppliers, and manufacturers. A comprehensive supply chain management system can be an integration of a customer relationship management system, supplier relationship management system, order/purchasing system, delivery products management (logistics management) system, as well as time management systems.

The goal of supply chain management is to reduce inventories by optimizing material and information flow without sacrificing service level. SCMs have a responsibility to maintain sufficient inventory levels to satisfy the demands. Furthermore, increasingly, industries with short inventory and product cycles, such as high-tech and customer electronics, are highly reliant on SCM to provide them with the ability to interact with their numerous suppliers and retailers. SCM also allows high-quality customer service by delivering the right products to the right place at the right time.

MOBILE (EMERGING) TECHNOLOGIES

Mobile technologies can be considered as one set of the significant emerging technologies (as per Unhelkar, 2005) that have the potential to influence supply chains. Wireless technologies encompass any aspect of communication that is achieved without land-based or wired mechanisms. Thus, mobility, in a strict sense, is a subset of wireless technologies. This is because there can be some wireless communications that need not be mobile (for example, transmissions from a wireless radio tower or between two stationary servers). We consider a range of wireless technologies in this section that are likely to influence the various business processes of an organization. Later, we will discuss the specific mobile technologies (such as RFID) from the point of view of their usage in M-SCM.

Wireless Technologies

Wireless technology refers to technology without wires and phone lines that uses a multiplicity of devices for communications (IBM, n.d.). The term "wireless technology" can also be used to describe modern wireless connections such as those in cellular networks and wireless broadband Internet. In modern usage, wireless is a method of communication that uses low-powered radio waves to transmit data between the mobile terminals (Elliott & Phillips, 2003). The terminals, such as mobile phones, iPods, personal digital assistants (PDAs), global positioning systems (GPSs), watches, email-only devices, handheld computers, and "wearable" technology, are carried by individuals and are far more "personal" than mere desktop PCs. The latest and important wireless technologies that require a brief discussion in this section are:

- "3G" mobile network
- Mobile satellite network
- Infrared
- Bluetooth
- Wireless
- Local area network
- WiMAX
- Radio frequency identification

Third-Generation Mobile Network

The development of 3G-related technologies has overcome the limitation of the previous generation of mobile technologies by allowing higher transmission rates and more complex e-commerce interactions (Barnes, 2002). Kuo and Yu (2005) and Huber (2002) list three 3G standards, including wideband code division multiple access (WCDMA), code division multiple access 2000 (CDMA2000), and time division–synchronized code division multiple access (TD-SCDMA), approved by the International Telecommunication Union (ITU).

W-CDMA is the most popular 3G mobile network which is capable of transferring multimedia between terminals; it is the technology behind the 3G universal mobile telecommunications system (UMTS) standard, combined with the 2G global system for mobile communications (GSM) standard, which is mainly dominated by European and Japanese firms.

Due to the promotion of the GSM organization and the 60% popularity usage of the 2G system in the global market, CDMA2000 gained the attention of many companies, especially U.S. and Korean firms that mainly support it. One of the advantages of the CDMA2000 system is the upgradeability of the narrowband CDMA system, so the user does not need to change his or her mobile device—just upgrade his or her user plan.

The TD-SCDMA includes three main key technologies: (1) TDMA/TDD principle, (2) smart transmitter and receiver, and (3) joint detection/terminal synchronization. It is mainly supported by China's Datang Telecom, which advocates its low-cost infrastructure.

Mobile Satellite Networks

Mobile satellite networks represent the convergence of the latest mobile technologies with space technologies. Satellites are operated at microwave radio frequencies in various bands, which are allocated by the ITU (2001). Olla (2005) declared that integrating space technology into mobile communications offers two main advantages. The first advantage is in providing access to voice and data service anywhere in the world—of which the current popular application is Internet phone (Voice over IP–VoIP). The second advantage is the exact positioning of useful location-sensitive information used for direction-finding-based and map-reading-based services, the current popular application of which is a car GPS. These applications are becoming commonplace, with Fitch (2004) pointing out that the technique for interfacing satellite links to global networks is well developed, including methods to overcome timing problems.

Infrared

Infrared (IR) technology provides directional electromagnetic radiation for "point-to-point" communication within short range. The radiation wavelength of IR communication is approximately between 750 nm and 1 millimeter. IR data transmission is a mobile application for short-range communication between a computer terminal and mobile device, such as a PDA or a mobile phone. Infrared communications are useful for indoor use in areas of high population density. IR does not transmit through physical barriers such as a wall, and so it does not interfere with other devices in the vicinity. Infrared transmission is, therefore, the most common way for remote controllers to control physical machines. Furthermore, infrared lasers are used to provide the light for optical fiber communications systems; they are the best choice for standard silica fibers, as using infrared lasers can be a cheaper way to install a communications link in an urban area (Okuhata, Uno, Kumatani, Shirakawa, & Chiba, 1997).

Bluetooth

Bluetooth is a short-range radio technology developed to connect devices without wires. It is an effective technology for a new generation of Internet-capable mobile terminals. It enables numerous innovative services and applications, which function regardless of the mobile operator. The most important solution enabled by Bluetooth technology is synchronization between a PC server and one or more other mobile terminals. Synchronization has been particularly successful in cooperative applications, providing access to SCM systems (Paavilainen, 2001). Buttery and Sago (2004) describe the Bluetooth application as being built into more and more mobile telephones, allowing some very interesting m-commerce opportunities to be created. As people currently carry mobile phones with Bluetooth technology, these technologies can be used for making payments and related service concepts through simple downloads on their mobile devices. Retailers might also be able to provide samples of products to download via a Bluetooth link located close to the actual item, potentially resulting in better customer service and an enriched shopping experience. Bluetooth can operate up to 10 meters (eventually up to 100 meters in future versions). Since Bluetooth technology is a radio transmission, it does not need line-of-sight with another Bluetooth-enabled device to communicate (Scheniderman, 2002). Once Bluetooth technology is in place, one can envisage consumers walking around and giving out messages wirelessly via Bluetooth in order to buy items from vending machines, or buying low-value tickets, or even making small-value "cashless" purchases, such as newspapers.

Wireless Local Area Network (WLAN)

WLAN technology is closer to the fundamental principle of the Internet, wherein anybody can establish an individual network as long as it follows the general intranet guidelines. The wireless links would provide a network connection to all users in the surrounding area, ranging from a single room to an entire campus. The backbone of such a WLAN network may still use cables, with one or more wireless access points connecting the wireless users to the wired network. Currently, laptop computers and some PDA devices can be attached to a WLAN network using a compact flash (CF) or a Personal Computer Memory Card International Association (PCMCIA) card. In the future, PDAs and mobile phones might support multiple network technologies. WLAN is expected to continue to be an important form of connection in many business areas. The market is expected to grow as the benefits of WLAN are recognized (Paavilainen, 2001; Burness, Higgins, Sago, & Thorpe, 2004).

WiMAX

WiMAX is defined as Worldwide Interoperability for Microwave Access by the WiMAX Forum. The forum describes WiMAX as "a standards-based technology enabling the delivery of last mile wireless broadband access as an alternative to cable and DSL." The forum also states that it "will be incorporated in notebook computers and PDAs by 2007, allowing for urban areas and cities to become 'metro zones' for portable outdoor broadband wireless access" (WiMAX Forum, 2006). WiMAX delivers 72 Mbps over 30 miles point-to-point and four miles non-line-of-sight (NLOS) (Ohrtman, 2005). Its purpose is to ensure that broadband wireless radios manufactured for customer use interoperate from retailer to retailer. The main advantages of the WiMAX standard are to enable the implementation of advanced radio features in a standardized approach, and provide people in a city with online access via their mobile devices.

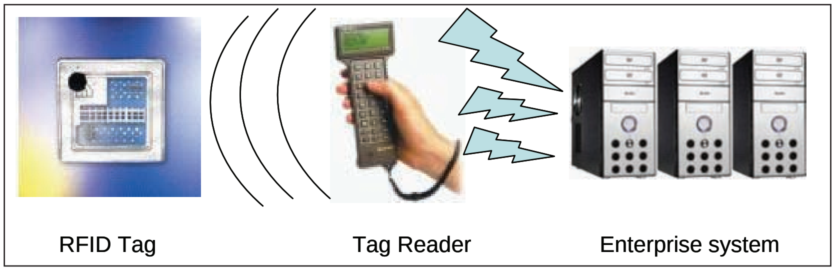
Radio Frequency Identification

RFID is an emerging technology that has been increasingly used in logistics and supply chain management in recent years. RFID technology can identify, sort, and control the product and information flow, all through a supply chain. Today, RFID is a standard technology that uses radio waves to automatically identify people or objects. There are several methods of identification, the most common of which use RFID tags and readers.

Ngai, Cheng, Au, and Lai (2005) proposed that RFID is made up of two components: the transponder, which is located on the object to be identified; and the reader, which, depending upon the design and the technology used, may be a read or write/read device.

Roberts (2006) states that an RFID system will typically comprise the following three components, as shown in Figure 4:

Figure 4. Important parts of an RFID system (based on Roberts, 2006)



- An RFID device (tag), which is a unique identifier for an object or person.
- A tag reader with an antenna and transceiver.
- A host system or connection to an enterprise system.

As Figure 4 shows, firstly we incorporate data inside an RFID tag. When the tag goes through a tag reader, the information inside the tag will automatically transfer to the host system. The host system is stored in a data center. After the data center analyzes and organizes the RFID tag information in the host system, specific useful tag information will be sent to a different enterprise SCM system.

Using an RFID system in the supply chain has been demonstrated by Asif and Mandviwalla (2005). Firstly, the SCM system constructs the item "where and when" during processing. When the items leave the manufactory and arrive at the place where they are to be read by the readers, the same information will be transferred directly to the distributor. The items are quickly sent to the correct trucks. As these items arrive at the retail outlet, they are read by the receiving RFID readers, and the retail outlet's inventories are updated automatically. Since the shelves at this outlet also have their own readers, they can directly increase replacement orders. However, using RFID technology in the SCM system, the items' quality can be automatically updated by the RFID reader sending into the SCM system. This provides highly location-based tracking, reduces the cost and human-error risks, and also improves the effectiveness and efficiency.

EPCglobal, a development of the earlier Auto-ID Center, is one of the two primary RFID standards

Table 1. Mobile technology application comparison table

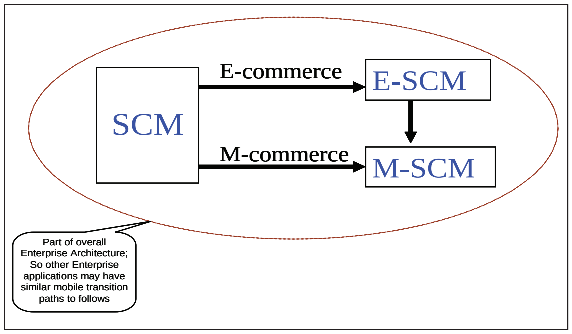
Mobile Technology	Functions and Applications
3G Mobile Network	• Application: mobile phone device • Higher transmission rate • Popular used and high marketing acceptance
Mobile Satellite	• Application: GPS device and Internet phone (Voice over IP–VoIP) • Space technology • Direction finding and map reading
Infrared	• Application: remote controller • Communication in short distance • Low cost
Bluetooth	• Application: Bluetooth device • Synchronization • Transfers data between a PC server and one or more other mobile device(s)
WiMAX	• Wireless online in urban areas by using mobile device or any computer
WLAN (Wireless Local Area Network)	• Wireless link PC or mobile device network connection in particular surrounding area
RFID (Radio Frequency Identification)	• Application: RFID tag and reader • Product tracking and controlling by automatically updating the RFID tag location through RFID reader

setting groups. It proposed an Internet-based supply chain model that is aimed at improving supply chain end-to-end efficiency. A key component of the EPCglobal model is the Electronic Product Code or EPC. The manufacturer adds an RFID tag to every item of its product line. Each tag contains a unique EPC, which is a 96-bit code that uniquely identifies objects (items, cases, pallets, locations) in the supply chain (EPCglobal, 2005).

APPLICATION OF MOBILE TECHNOLOGY IN SUPPLY CHAIN MANAGEMENT

Based on the literature surveyed so far, there appears to be a gap between what is considered traditional SCM, electronic SCM, and the potential offered by mobile SCM. The major gap in the current literature in the SCM domain appears to be a lack of discussion between the two types of commerce and, in particular, the value derived from the ability of mobility to provide time and location independence. As shown in Figure 5, SCM can be extended to the e-commerce environment and at the same time it can also be extended to M-SCM. However, there is also a potential, as again shown in Figure 5, for E-SCM to be extended to M-SCM. These are some of the important aspects of SCM systems studied in this chapter.

Figure 5. SCM to E-SCM and M-SCM



E-Supply Chain Management

E-commerce deals with a combination of hardware technologies, software applications, and changes to business processes and appropriate customer strategies. E-SCM can enable customers to use electronic connections to obtain the information and associated services from the organization's supply chain system. The objective of E-SCM is to understand customer demographics, purchasing patterns, inventories, orders, and order fulfillments, in order to enable customer satisfaction and creation of new business opportunities (Arunatileka & Unhelkar, 2003). E-commerce provides the basis for much more efficient supply chains that can benefit both customers and manufacturers. This is because e-commerce, through connectivity, brings together various parties involved in commercial transactions. In today's environment, customers are less forgiving of poor customer service and more demanding of customized products or services. As the competition continues to introduce new offerings modified to the special needs of different market sectors, companies have to respond by offering similar custom-made and highly personalized offerings. The ensuing production of various goods and services for multiple countries, customer sections, and distribution exits creates major challenges in forecast, inventory management, production planning, and after-sales service support. Internet-based E-SCM systems bring the companies a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer satisfaction, and make possible thorough planning abilities (Unhelkar & Lan, 2006).

The supply-chain e-business model creates a virtual value chain, and information flows across the supply chain. All members of the supply chain have strong electronic systems, and the information sharing to the customer is very effective in the ordering process, product delivery, and other SCM issues (Arunatileka & Arunatileka, 2003).

The e-supply chain is a pull model; in a pull-based supply chain, production and distribution are demand driven so that they are coordinated with true customer demand rather than forecasted demand. This is enabled by fast information flow mechanisms to transfer customer demands to the various supply chain participants. This leads to a significant reduction in inventory costs and enhanced ability to control materials when comparing this to the equivalent push-based system (Levi, Kaminsky, & Levi, 2003).

M-Supply Chain Management

In the 21st century, we are in the era of wireless and handheld technologies, and the impact of the Internet and wireless telecommunication has taken a new turn (Barnes, 2002). Mobile technologies are at the core of the communication revolution. They have increased commercial efforts from the removal of physical connectivity for people, processes, and businesses, resulting in a significant impact on communication. Therefore, mobile devices can also be used to optimize the flow of information and materials. An increased number of mobile workers and time sensitivity drive companies towards advanced mobile solutions.

Paavilainen (2001) highlights that the solutions of supply chain management systems are highly time sensitive. The requirement of the time sensitiveness is that SCM systems must have the ability to transact products as close to real time as possible—opening up opportunities for the application of mobile technologies. By incorporating mobility in the SCM system processes, monitoring and receiving of immediate messages from the market can be improved. M-supply chain management focuses on the shortened cycle time from making an order to the fulfillment of that order—which, in most cases, would be delivery of the product to the customer. With mobility, response and confirmation time are much quicker than with the use of the standard Internet connections. Automatic data-reading and updating can be accessed from any mobile devices without the restriction of time and place. Traffic control systems (GPRSs) can be used to deliver products in the supply chain, and also automatically detect the products and report cars' and trucks' locations.

Eng (2005) declares that three main concerns of M-SCM are:

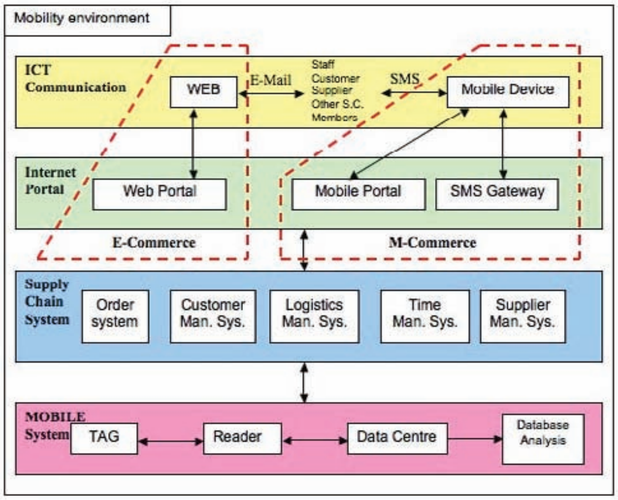
1. a place for efficient distribution of products and services,
2. timing for meeting customer demand and managing logistics, and
3. service quality for responsiveness and customer satisfaction.

In Figure 6, the M-SCM architecture is divided into four parts—the RFID system, SCM system, e-commerce, and m-commerce—and as proposed by us is an extension to the original ideas of Ngai et al. (2005). They state that RFID technology can be integrated with wireless networks to send information to a supply chain management system through a portal to staff, customers, and partners. We define that M-SCM refers to integrating the RFID system, e-commerce, and m-commerce through the Internet portal and ICT communication into a supply chain management system in a mobile environment. Moreover, we declare the RFID system's contents and supply chain management system's contents, and how e-commerce and m-commerce will integrate the SCM through the portal.

The RFID system typically integrates RFID tags, readers, and the host system that will store the received tag information in the data center. After the database analysis process inside the data center, information will be transferred from the RFID tag of each product to each company's enterprise SCM system.

The comprehensive supply chain management system can be an integration of a customer relationship management system, supplier relationship management system, order/purchasing (financial) system, delivery products (logistics) management system, and time management system.

Figure 6. Architecture of M-SCM systems (this model is proposed by these researchers as an extension to the original ideas of Ngai et al., 2005)



The e-commerce and m-commerce parts show how the communication can occur among customers, staff of enterprises, suppliers, and other supply chain management members to the SCM system. People can use e-mail via the Web to an Internet Web portal to access the SCM system to get information or conduct e-commerce. In addition, they also can use SMS via a mobile device to a mobile portal or SMS gateway to access the SCM system to get information or carry out m-commerce.

The aforementioned model can also be used to understand how existing supply chain processes transfer to incorporate mobility in them. These can be called "m-transformation of SCM" processes. When a company already has the supply chain management system in its enterprise architecture, we can help it add a mobile system and set up the Internet portal with ICT communication devices to upgrade the SCM to M-SCM. In M-SCM, the cooperation of real-time processes by using mobile technology applications provides a stable workflow of up-to-date information from both inside and outside the company. Mobile supply chain applications can also allow users to request information and conduct "ubiquity"—whatever they want, whenever they want it, wherever they want it, and how they want it.

INVESTIGATION INTO ADVANTAGE AND LIMITATION OF MOBILITY IN SCM

The traditional supply chain is a push model. However, the E-SCM and the M-SCM models that we are discussing in this chapter can be considered as pull models. Table 2 depicts the comparison of characteristics between the push and pull models of the supply chain, based on various factors.

From Table 2, Levi et al. (2003) are quite clear in stating that traditional SCM focuses on reducing the cost and recording the location of products into the system. The information flow is based on a push model. As such, the traditional SCM process undergoes a long cycle, and the process time cannot be easily estimated. E-SCM focuses on customer service, and the process is totally based on responding to customers' orders and requirements. Every member of the supply chain can access the information flow from the E-SCM system at any time if they want to track it. Thus, E-SCM can be said to follow the "pull model" of information; it shortens the product cycle and lowers complexity compared with the traditional SCM (push model). The M-SCM can also be said to follow the "pull

Table 2. Push and pull model of SCM (Levi et al., 2003, p. 127)

Portion	Push	Pull
Objective	Minimize cost	Maximize service level
Complexity	High	Low
Focus	Resource allocation	Responsiveness
Lead Time	Long	Short
Processes	Supply chain planning	Order fulfillment

model," wherein information is extracted from the system when desired by the user.

Both E-SCM and M-SCM provide 24-hour information access, accurate and fast billing, less paperwork/fewer duplicated processes, on-site technical support, and trouble-shooting databases. However, in E-SCM, the users of the supply chain can only access the information of SCM when they connect to the Internet. It is limited by the location, in that members still need to sit inside the office to plug in their computers. M-SCM members can access the system at any time and anywhere by using mobile tools with a satellite connection. This brings huge benefits to people with a more convenient and comfortable environment to increase efficiency in their part of the value chain.

Following, we would like to list the advantages and limitations of mobility in SCM.

Advantages

The M-SCM system provides real-time data that can be accessed after logging into the system (Eng, 2005). Batten and Savage (2006) highlight that M-SCM will eliminate considerable duplication of data entry through simplified automated order placement, order status inquiries, delivery shipment, and invoicing. Mobility goes through data entry when it is created to reduce paperwork, document tracking, and human error. It also brings security control. The M-SCM system shortens the organization planning and production cycles, establishes one central data repository for the entire organization, and facilitates enhanced communications through all supply chain members communicating with each other by mobility (Paavilainen, 2001). Moreover, the M-SCM allows all users to request information, place orders for whatever they want, whenever they want it, wherever they want it, and how they want it.

The investigation of mobile technology application into the supply chain systems will bring benefits to all members of the supply chain, which includes suppliers, manufacturers, distributors, retailers, and customers.

Suppliers: The M-SCM system reduces paperwork, the number of administrative employees, and inventory costs, so the company reduces the cost of the products and brings in more customers as well as retaining its present customers. It also brings increased financial incomes to the suppliers (Unhelkar & Lan, 2006).

The RFID system stores the product contents when these have been acquired. When the product is about to expire, all details are contained in each RFID tag for each item. This can help suppliers to quickly obtain the information they need, simply by scanning the RFID tag once only. Also, this can help the suppliers to forecast the schedule arrangements to process the materials and prevent materials from expiring.

Manufacturers: The M-SCM systems can provide the organization with shorter planning and production cycles, and establish one central data repository for the entire organization. Then manufacturers will know the amounts they need to produce, and save money on the products that nobody buys.

RFID has been used in manufacturing to identify items or groups of items, express production procedures, and ensure the correct product quality. It helps that the right materials arrive at the right place, and nothing will be lost (Duckworth, 2004).

Distributors: The M-SCM system ensures quicker time-to-market for the firm's products, provides the retailer with enough stock, and also reduces excessive stocks in the distribution center. A traffic control system can be used as a GPRS to deliver goods to customers/retailers, and also automatically detect control and report locations of cars and trucks.

RFID identifies the distributed items stored inside the containers or trucks, and helps the delivery process to be 100% correct to deliver the right items to the right place at the right time. It has been reported that the RFID program can estimate the need for physical cycle counting, saving companies hundreds of employee hours and days of down time (Mullen & Moore, 2006).

Retailers: No data need to be re-entered into the M-SCM system through the simplified automatic order placement, order status inquiries, delivery shipment, and invoicing. The RFID system processes automatic data-reading and reporting to the supply chain system of the products' location (Wyld, 2006).

The RFID system is also very useful in maintaining enough stock levels in retailers (Carayannis, 2004). It has the ability to automatically record sales, check inventories, and refill or order additional stock in order to reduce the amount of inventory. Some food or items with limited time span can be notified by the system to guarantee retailers having fresh products on the shelves all the time. In addition, it has been proven to reduce theft from the retailers' shelves during the product delivery process in the supply chain. Loss avoidance directly benefits the retailers by minimizing costs and improving selections (Mullen & Moore, 2006).

Customers: The M-SCM system improves customer service substantially by efficient distribution of products and service, timing for meeting customer demands and logistics managing, and service quality for responsiveness and customer satisfaction. It improves the firm's ability to attract new customers and also retain its original customers (Unhelkar & Lan, 2006).

Customers can access information about products via mobile gadgets, and also place/check their orders and pay their bills in the M-SCM system by mobility (Mei, 2004). The M-SCM also allows customers to enquire for information and purchase any products at any time, anywhere, by any method.

Limitations

Supply Chain Integration and strategic partnering: The limitation that has existed in traditional supply chain integration is "reliance and trust" among the partners (other supply chain members) in this mechanism. This is because when the supply chain system integrates all companies in the supply chain, the members need to consider how much information they should announce to other members. Moreover, the more information a company can share, the greater the efficiency and effectiveness of the system. Nevertheless, the company members of the supply chain depend on other members' reliance and trust to share the information. So, this is the critical limitation of the original supply chain integration.

Cost of M-SCM system and facilities implementation: When the companies in the supply chain want to install M-SCM systems in their companies, the cost of systems and facilities during the establishment period is an essential consideration. They need to prepare the project fee at the beginning, but this is not a small amount, and it is the reason why the companies in the supply chain always find it difficult to make decisions to implement the M-SCM system.

Different countries develop mobility at different levels—the Internet speed, WLAN population: As we mentioned earlier, the companies of a supply chain may not be only in one country. Different countries may develop mobile technology at different levels. Some countries are not able to provide wireless local area networks, and can only provide dial-up Internet speeds. In other words, there are many limitations for those companies that want to use the M-SCM systems in the whole supply chain.

Security and privacy issues: Sheng (2006) points out that the issue of security and privacy is indeed a great concern, especially when the members of a supply chain make payments by the m-payment system. The qualifications of any system to provide secure data transfer are regarded as an important standard for both existing and potential users of m-payment systems. The personal privacy of customer information is a major concern to the customer who is deciding whether to use the system or not.

Companies need to change their business process: When the members of a supply chain decide to install the M-SCM systems in their supply chain management system, the current business processes may not be available or suitable to use all the time. The system development team needs to go through the original business processes to modify the new business processes suitable for the M-SCM system users. Therefore, after the system implementation in the companies, the system team needs to prepare a training class for employees regarding the business processes change and the new system utilization in the future.

BENEFITS OF MOBILITY TO THE ENTERPRISE ARCHITECTURE

Enterprise architecture represents a technology-business philosophy that provides the basis for cooperation between various systems of the organization that could be inside or outside the organizational boundary. EA also facilitates the ability to share data and information with business partners by enabling their applications to "talk" with each other. Linthicum (2000) pointed out that many organizations would like to build their entire systems by using the emerging technologies of today, of which mobile technology is a crucial part. Using mobile devices in enterprise modeling can help real-time information access among systems, in production planning and control, inbound and outbound logistics, material flows, monitoring functions, and performance measurements (Rolstadas & Andersen, 2000).

According to Ghanbary (2006), by correct application of mobile technologies into the business processes, the business enterprises are likely to gain advantages such as increased profits, satisfied customers, and greater customer loyalty. These customer-related advantages will accrue only when the organization investigates its customer behavior in the context of the mobile environment.

It is very important to identify that not many organizations have existing mobile solutions. Umar (2005) states that next-generation enterprises (NGEs) rely on automation, mobility, real-time business activity monitoring, agility, and self-service over widely distributed operations to conduct business. Mobility is one of the most invigorating features, having an enormous impact on how communication is evolving into the future.

Enterprise application integration is a relevant approach to integrating core business processes and data processing in the organization. Lee, Siau, and Hong (2003) state that EAI automates the integration process with less effort. EAI is a business computing term for plans, methods, and tools aimed at modernizing, consolidating, and coordinating the overall computer functionality in an enterprise. With new achievements in information technologies, companies are vulnerable if they do not respond to technologies such as mobile technology in a fast and appropriate manner.

BENEFITS OF MOBILITY TO THE GLOBAL ENTERPRISE

In this globalization era, many enterprises in a supply chain are located in different countries. Enterprises in some countries can provide low labor costs, and some in different countries may have low material costs, or others in different countries may provide professional skills or ideas about product design. However, all enterprises want to sell their product globally. The resultant ability of businesses and customers to connect to each other ubiquitously—independent of time and location—is the core driver of this change (Unhelkar, 2005). It leads the supply chain management to global supply chain management. Mobile technologies are thus a key influence in any efforts towards the globalization of business (Unhelkar, 2004). The processes of such m-transformation can lead an existing business into the mobile business via the adoption of suitable processes and technologies that enable mobility and pervasiveness (Marmaridis & Unhelkar, 2005).

M-SCM can further enhance the global SCM by reducing timing and cost, increasing correct delivery and customer satisfaction, and allowing global enterprises to conduct their business at any time and anywhere. Long (2003) pointed out that international logistics management focuses on international ship delivery schedule management, time, place, and product quality management.

An M-SCM system covers from planning, purchase, and production, to delivery to the customer. Mobile technology raises global enterprises to a much higher level of efficiency and effectiveness. Global enterprises can conduct their business at any time and anywhere, and provide high-quality products at low cost, and also support customer service 24 hours a day, seven days a week, by using an M-SCM system.

COLLABORATIVE SUPPLY CHAIN MANAGEMENT IN AN ENTERPRISE ARCHITECTURE

Electronic collaboration has been studied and experimented on by many studies. In electronic collaboration, there has been ample focus on the effects of dynamic environment and the rapidly evolving technology on organizations. Undoubtedly, these changes cause organizations to restructure and introduce a new suite of business processes to enable them to collaborate with the business processes of other organizations.

There are some critical technological issues that could cause drawbacks in collaboration across multiple SCM organizations. These issues could be classified as collaborations between different platforms, managing technology and maintenance (hardware/software). Web services technology is the solution for the collaboration of applications on different platforms, also independent of their different environments.

The electronic collaboration of the business processes of different SCM organizations is causing many practical issues. These issues are as follows:

- The excess inventory and inefficiencies in the supply chain while different organizations are involved.
- Requesting information by understanding the specific organization's capability to handle the request.
- Collaboration can reduce waste in the supply chain, but can also increase market sensitivity and increase customer expectation.
- Customer satisfaction, which is directly related to the previous issue, as customers expect more.
- Competition among all members of the partnership.

As such, the SCM must also address the following problems:

- **Distribution network configuration:** Number and location of suppliers, production facilities, distribution centers, warehouses, and customers.
- **Distribution strategy:** Centralized vs. decentralized, direct shipment, cross-docking, pull or push strategies, third-party logistics.
- **Information:** Integrate systems and processes through the supply chain to share valuable information, including demand signals, forecasts, inventory, and transportation.
- **Inventory management:** Quantity and location of inventory including raw materials, work-in-process, and finished goods.

Collaboration should be taking place in order to make sure that all parties involved in the collaboration are satisfied. In the past, collaboration was inadequate, with retailers hesitant to share information with others; however, the technology is capable of providing more support for the collaboration. Based on Horvath (2001), collaboration requires individual participants to adopt simplified, standardized solutions based on common architectures and data models. The time to market is critical, and participants will have to forego the luxuries of customization and modification that characterized the proprietary infrastructures of the past.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

The chapter has introduced enterprise application integration as a part of a comprehensive enterprise model, followed by a discussion of supply chain management systems in the context of the EM. The traditional supply chain management system and investigation of the opportunities to integrate specific mobile technologies (such as 3G mobile network, mobile satellite network, Infrared, Bluetooth, WiMAX, and WLAN) with supply chain management systems have also been discussed. This chapter has further considered the advantages and limitations of such integration. The discussions in this chapter are important for understanding how and where mobile technologies fit into the overall concept of the enterprise architecture. The discussion on the collaborative nature of Web services and the ability of supply chain systems to capitalize on the connectivity of Web services is also important for globalization and appears in the global supply chain management system.

The aim of this discussion is to provide a solid theoretical basis for future research direction by the authors in the area of mobility and its incorporation in an organization's systems and architecture. Therefore, this chapter is a door opening to further research in the areas of mobile technologies in "enterprise architecture" and "SCM systems." The authors have provided more details of mobility SCM systems—actually enterprise architecture based on contributing the integration of all the enterprise information systems. Our research is opening opportunities to future research in the area of investigating how mobile technologies influence integrating other systems of enterprise architecture such as enterprise resource planning, customer relationship management, customer order control and planning, material requirement planning, financial accounting, and so on. The team members of our group (MIRAG of AeIMS of UWS) are also investigating mobility influences on business process reengineering, Web services, and project planning. In addition, we still investigate our research into how and what should be included on contributing the comprehensive mobility enterprise architecture (M-EA) model.

Chapter 3.13

Enabling the Glass Pipeline: The Infusion of Mobile Technology Applications in Supply Chain Management

Umar Ruhi
Wilfrid Laurier University, Canada

Ofir Turel
McMaster University, Canada

ABSTRACT

In recent years, the prospect of information exchange independent of time and place has been a compelling driver for organizations worldwide to adopt mobile technology applications in their various business practices. In particular, the application of mobile technology in Supply Chain Management has drawn widespread attention from researchers and practitioners who endorse adaptive and agile supply chain processes. This chapter discusses the applications of mobile technologies in various areas of supply chain management and the potential benefits of those technologies along the dimensions of reduced replenishment time and transactions and billing cycles. Among other discussions, the role of mobile procurement, inventory management, product identification, package tracking, sales force, and field service automation technologies is highlighted. To substantiate the basis for adopting mobile technologies for supply chain management, different market drivers for mobile applications are exemplified and applied to the three macro-level processes of supplier relationship management, internal supply chain management, and customer relationship management; a resulting typology of mobile supply chain management applications is presented.

INTRODUCTION

> *The nature of competition is shifting away from the classic struggle between companies. The new competition is supply chain vs. supply chain.* (Taylor, 2003, p. 3)

In recent years, we have seen various organizations from different industries focus their competitive strategies on improving their supply networks rather than concentrating on directly contending with specific companies. Companies such as Wal-Mart, Dell, and Proctor & Gamble not only have made significant headway in optimizing their own supply chains, they also essentially have redefined the way business is done in their particular industries. Their competitors have had to follow suit in order to maintain their own competitive position in the marketplace.

A major factor that has contributed to more efficient supply networks is the increasingly unhindered and efficient flow of information within and among supply chain partners. Several researchers and practitioners have commented on the importance of information flow in effective supply chains (Chopra & Meindl, 2003; Handfield & Nichols, 2002; Kalakota, Robinson & Gundepudi, 2003). Consequently, much has been said about the role of technology in enabling effective supply chains (Holten, Dreiling, Muehlen & Becker, 2002; Knolmayer, Mertens & Zeier, 2002; Poirier & Bauer, 2000).

Mobile technologies and applications offer an advanced level of efficient and effective communications among business partners in supply chains. These applications augment the static nature of their predecessor, e-commerce, phone, and fax-based technologies, by adding flexibility and spontaneity to extant business processes. Technologies in mobile procurement, inventory management, product identification, package tracking, sales force, and field service automation are expected to change the current landscape of Supply Chain Management (SCM). It is expected that mobile technologies will bridge the functionality gap in traditional Electronic Data Interchange (EDI), Enterprise Resource Planning (ERP) and Web-based SCM technologies by providing the end-to-end transparency that can help businesses perform better through improved supply chain planning and execution (Kalakota et al., 2003).

In this chapter, we provide a value proposition for mobile SCM technologies and applications. By highlighting the benefits of the latest mobile applications, this chapter aims to explicate the role of these technologies in transforming integrated and collaborative supply chains into adaptive supply networks. We start this discussion with our working definition of SCM, which will be the gate to our analysis of various technology applications. Following that, we discuss the current state of information technologies in SCM and subsequently rationalize the business drivers for implementing mobile SCM technologies. This is followed by an elaboration of a typology of mobile SCM technology applications. Our conclusion and ensuing inferences follow after a discussion on the future outlook for mobile SCM technologies vis-à-vis other SCM information systems.

SUPPLY CHAIN MANAGEMENT: A WORKING DEFINITION

There are as many definitions of SCM as there are publications, which is quite enormous within the supply management literature. Furthermore, the terminology used to describe the concept or idea behind SCM is interchangeably used in various contexts to refer to the same thing. For example, supply chains, supply networks, and supply webs often are used to describe the same idea—coordination and collaboration across business partners. Recently, however, there is an increasing tendency to use the terms *supply networks* and *supply webs* as opposed to the notion of *supply chains.* The advantage of using the former terms over the latter, is to emphasize that the links among business partners are not linear and sequential but are, instead, dynamic, interdependent, and flexible (Bovet & Martha, 2000; Murphy, 2000; Rayner, 2004).

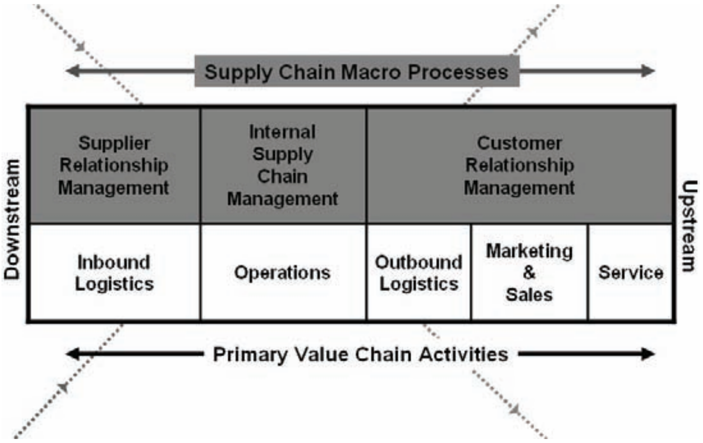
In this chapter, we use the terms *supply chains* and *supply networks* interchangeably, with the proviso that the nature of relationships among business partners is, indeed, more than just linear and sequential. As highlighted in the introduction and for the purpose of this discussion, we adopt a definition of SCM that incorporates the management of information flow as the primary functional component—material flow and financial flow both upstream and downstream the supply chain. For a descriptive and formal characterization, we adopt Handfield and Nichols' (2002) definition of SCM. The authors define SCM as:

> *The integration and management of supply chain organizations and activities through cooperative organizational relationships, effective business processes, and high levels of information sharing to create high-performing value systems that provide member organizations a sustainable competitive advantage.* (Handfield & Nichols, 2002, p. 8)

In addition to affirming the importance of high levels of information sharing, the definition prominently highlights the concept of a value system for sustainable competitive advantage.

The notion of a value system (also known as a value chain) is intertwined with that of a supply chain and needs some elaboration. Introduced by Michael Porter in his widely acclaimed book, *Competitive Advantage* (Porter, 1985), the idea of a value chain has been used to model a firm on the basis of its value-creating activities. The primary activities in the value chain include inbound logistics, operations, outbound logistics, marketing and sales, and service. Noticeably, it is several different business processes within the value-creating functions of a firm that constitute the various components in an organization's supply chain, as well. In fact, Chopra and Meindl (2003) classify all supply chain processes into three main macro processes; namely, Supplier relationship management (SRM), internal supply chain management (ISCM), and customer Relationship Management (CRM). Juxtaposing the value creating functions described by Porter (1985) with the three macro processes in a supply chain, it can be seen that inbound logistics and operations functions map diametrically to supplier relationship management and internal SCM, respectively, while the marketing, sales, and service functions map to the processes in customer relationship management. It is this inclusive framework of value-creating activities and supply chain macro processes that forms the basis of our discussion throughout the

Figure 1. Supply chain management functions and processes



rest of this chapter. Figure 1 summarizes these processes and functions in an inclusive conceptual model for SCM.

CURRENT STATE OF MOBILE SCM TECHNOLOGIES AND APPLICATIONS

As an affirmation of the prevalent adoption of wireless technologies, the Yankee Group predicts that close to 50% of large US enterprises will employ wide area wireless solutions, and that 3,000,000 mobile users will use these services (Yankee Group, 2004). In terms of technological maturity, third-generation (3G) technologies are emerging quickly, while more established technologies, such as Short Messaging Services (SMS) and the wireless Internet (e.g., Wireless Application Protocol [WAP]) are serving organizations to help fulfill their current business requirements. It is these existing and emerging technologies that act as the bearers of a large and ever increasing number of mobile SCM solutions. Furthermore, the diffusion of more advanced packet-switched data networks (e.g., GPRS, 1XRTT, etc.) is giving rise to innovative communication solutions. For example, Push-to-Talk services (P2T) that previously were available only to niche markets are now being deployed effortlessly over packet switched data networks and are being used to facilitate inexpensive interorganizational voice communications (Guy, 2003). At the same time, short-range wireless technologies, such as Radio Frequency Identification (RFID), Wireless Personal Networks (WPANs) such as Bluetooth, and Wireless Local Area Networks (WLANs) such as the 802.11, are becoming commonplace, forming the basis of wireless networking standards.

As anticipated, the previously mentioned technologies are finding their applications in various business processes in the organization’s SCM, as well. A case in point is the recent adoption of RFID solutions by Wal-Mart, exemplifying the wireless services market trends and opening doors for next-generation logistics management (Emily, 2004). Additionally, WLAN technologies already are being used widely in many industries, such as the energy sector (Yankee Group, 2001). Decreasing deployment costs as well as communication and network costs are being proclaimed as the primary drivers for the growth of this market (Rao & Parikh, 2003).

To capitalize upon the opportunities presented by mobile technologies, vendors of traditional SCM systems, such as SAP and Oracle, and new ones, such as HighJump and @Par, are vying for a piece of the pie. Most of the mobile SCM technology vendors currently offer their solutions in bundled packages as part of their m-business or m-commerce technology suites. Such an offering (under a broader umbrella of m-commerce) is in line with the treatise of mobile SCM solutions by researchers (Burchett, 2000; Cousins & Varshney, 2001). M-commerce can be succinctly defined as “a layer of applications atop the mobile Internet” (Rulke & Iyer, 2003) or explicitly as “an extension of e-commerce in a mobile environment” (Dholakia, 2002). Consequently, Mobile Supply Chain Management (MSCM) can be regarded as a specific branch of m-commerce, and it can be characterized as a layer of mobile applications that enhances existing supply chain mechanisms while enabling efficient business processes. Just like their e-commerce counterparts, the incumbent technologies in MSCM are being used increasingly to support an evolving complex transactions landscape. Researchers classify the types of transactions supported through mobile technologies under the business-to-consumer (B2C), business-to-business (B2B), employee-to-employee (E2E), business-to-employee (B2E), and machine-to-machine (M2M) domains (Alanen & Autio, 2003). With this transactions landscape in mind, let us now examine the driving factors behind the adoption of mobile technologies in SCM.

DRIVERS FOR MOBILE TECHNOLOGIES IN SUPPLY CHAIN MANAGEMENT

The use of information systems in any business context always has been driven on the basis of available technological capabilities as well as on managerial vision toward fulfilling certain business requirements via those technologies. This is why we see the proliferation of different types of information systems, depending on different eras in which they are adopted. For example, whereas data and transaction processing systems were the order of the day in the 1950s, decision support systems started emerging in the 1970s, followed by e-business systems in the 1990s. The current trend is on the collaborative aspect of information systems.

Within specific business contexts of the current era, SCM has attracted myriad information systems (e.g., Materials Requirements Planning [MRP I] systems, Manufacturing Resource Planning [MRP II] systems, Enterprise Resource Planning [ERP] systems and Advanced Planning and Scheduling [APS] systems), which all have seen their peaks during the evolution of SCM as a discipline. Whereas, these systems all have a distinct logistics-oriented flare to them, SCM also utilizes cross-functional information systems, such as decision support systems and customer relationship management systems in day-to-day activities.

There have been several drivers that have led to the adoption of different types of information systems in SCM. Perhaps the most significant driver in the adoption of such systems has been the realization of an increasing need to internally integrate within and among different business functions as well as to integrate externally with supply chain business partners (Holten et al., 2002; Poirier & Bauer, 2000). Handfield and Nichols (2002) highlight additional drivers that have led to the adoption of various types of information systems in SCM. These additional drivers include trends emerging from globalization, information management requirements, the need for new business processes, the desire to replace obsolete systems, and ensuring strategic cost management.

(Adapted from Handfield & Nichols, 2002)

Table 1 summarizes a mapping of these drivers to different types of information systems in SCM and presents our extension of this framework to assimilate the drivers for mobile technologies. An elaboration of the specific drivers for mobile technologies follows.

Internal and External Integration (Toward Pervasive Computing)

As highlighted earlier in this chapter, internal and external integrations are extremely important drivers in the adoption of information systems in today's business environment. Whereas, systems such as MRP I and MRP II lacked the functionalities that allowed effective internal integration among various supply chain functions, external integration with supply chain partners is a challenging problem for even modern-day ERP systems. It was only with the advent of the Internet and the connectivity accorded by it that the newer Web-based applications, including the likes of CRM systems, were made possible; these applications enabled more cross functional operations inside the firm and outside, to a certain extent.

The adoption of mobile technologies in SCM promises to take the integration phenomenon to the next level (i.e., pervasiveness). Gupta and Moitra (2004) characterize pervasive computing as saturating an environment with computing and communication capability, yet having those devices integrated into the environment such that they disappear. The same authors also consider mobility and wireless connectivity as an essential component in pervasive computing. Accordingly, the adoption of mobile applications in supply chains is driven partially by their capabilities to enhance internal and external integration. Internal integration at the systems level is enhanced through seamless network connectivity between the front end and back end systems through wireless local and personal area networks (WLAN and WPAN). Basic voice communication capabilities, like cellular technologies and push-to-talk (P2T), further allow employees to connect effortlessly to one another. Moreover, remote data access by employees increases the internal integration by allowing internal users to access organizational data from anywhere at anytime. Similarly, external integration is enhanced, as mobile applications enable remote access to relevant information for customers, retailers, and distributors through wireless wide area networks. This is particularly important with the increasing trend in large-scale organizations to establish supplier parks in geographic vicinities around their main manufacturing and fabrication plants (Moline, 2002). Furthermore, mobile applications also enable the organization to access external mobile data resources. For example, using a global positioning system (GPS) and wireless data services, an organization can view the location and status of a shipment arriving from one of its upstream suppliers and prepare for it accordingly. Late delivery of shipment (as well as occasional early delivery) requires careful planning, especially in case of time-sensitive goods, and mobile technologies and applications provide hitherto unknown possibilities in improving the efficiency of managing this supply chain.

Globalization

Globalization is another factor that is driving the infusion of mobile technology applications in supply chains. In remote locations, specifically where fixed landlines and other forms of communications are not available, mobile communications can provide a valuable means for voice and data transmission. Many researchers and visionaries have suggested that a wireless infrastructure can reduce the great divide between the developed and the underdeveloped countries, and it has the potential to facilitate and promote business prosperity (Parker, 2000; Rice & Katz, 2003; Wareham, Levy & Shi, 2004). For example, the wireless infrastructure in China now has surpassed the fixed-line infrastructure in terms of penetration and coverage (GSM Association, 2004). This implies that businesses and people from other countries are more likely to engage in commercial transactions with firms located in China through mobile communication networks. The ascent of this mobile penetration, especially in developing countries, also can be attributed to the fact that once a mobile infrastructure (e.g., a mobile transmission tower) is set up, it does not require any additional work, such as installation and maintenance of landlines for communication. Furthermore, mobility is now regarded as a predominant characteristic of knowledge workers, and with the widespread availability and standardization of roaming capabilities, these knowledge workers are more likely to collaborate with other businesses through mobile technologies. Whereas, 15 years ago it was unthinkable to even call someone in a different part of the world, not to mention wireless connectivity with them while on the move, today, roaming agreements have made wireless connectivity around the globe a reality by connecting over 500 GSM/GPRS (Global System for Mobile/General Packet Radio Service) networks in almost 200 countries (GSM Association, 2004).

Also, with particular reference to SCM, there is an increasing tendency to outsource non-core functions to external service providers, such as third party logistics (3PL) companies. With contemporary provisions for boundary-less commercial exchanges under global economic forums, such as the North American Free Trade Agreement (NAFTA) and the European Union (EU), there is greater potential to offshore business functions to supply chain service providers in different countries. In fact, offshoring as a global phenomenon has been fueled by organizational attempts to gain competitive advantage through concentration on their core competencies while minimizing the costs of outsourcing at the same time (Bardhan & Kroll, 2003; Nair & Prasad, 2004).

Data Information Management

Mobile applications can improve the frequency and speed of communication (Gebauer, Shaw & Zhao, 2002). With data collection at the point of activity and the elimination of paper-based desktop-centric workflows, the velocity of transactions can be increased greatly. Proof of delivery and electronic signature capture technologies are being used in various businesses to enable more efficient and more streamlined information processes within the supply chain. Moreover, these processes, enabled through mobile technologies, allow real-time data access from the source, as opposed to batches of information being transmitted through various information systems at different times. Consequently, information synchronization errors that are attributed to batch processing can be reduced greatly.

While, on the one hand, real-time data transmission helps to increase the fulfillment velocity by making information instantaneously available throughout the supply chain, on the other hand, it facilitates enhanced visibility of supply chain processes by interacting directly with concerned parties through notification and alert mechanisms. The end result is reduced order-to-delivery time and more responsive service management.

New Business Processes

Mobile applications also are driven by the need to innovate operational business processes. Companies like Wal-Mart and McDonald's are well known for acquiring favorable market positions and competitive advantage through novel business processes. In fact, it has been conferred by many authors that it is the processes and not merely the underlying IT infrastructure that enables strategic advantage (Hurst, 2003). Hence, the need to gain and sustain competitive advantage can drive companies to innovate and re-engineer their business processes using new technologies (Barney, 1995; Porter, 1980).

The well-known market leaders in SCM are just beginning to avail the opportunities afforded by mobile technologies, as well. For example, Wal-Mart's adoption of Radio Frequency Identification (RFID) and subsequent coercion of its suppliers to do the same will be indubitably accompanied by the establishment of new business processes. The workflows associated with tracking pallets and items from receiving to sales and the management of inventory status all will be affected. Among other benefits, RFID technology is being touted as an enabler for improved inventory accuracy, reduced receiving costs, lower safety stock levels, and reduced cycle count efforts. With mandates from companies such as Wal-Mart, other businesses in various industries also will be driven to explore such technologies in order to revamp their own business processes.

Replace Obsolete Systems

The adoption of mobile technology applications also is being driven by the need to replace obsolete systems and associated business processes. For example, mobile telemetry services (i.e., the use of telecommunication devices to automatically record measurements from a distance) can replace manual on-site data entry and other forms of continuous monitoring (Salz, 2003). With the proliferation of cellular networks, it makes sense to monitor remote resources and assets using wireless technologies.

The previous example is not a completely new technology phenomenon. Often, information systems from one industry find their way into other industries with a certain level of customization. Telemetry solutions have prevailed in the agricultural and military sectors for years. Feeding livestock and examining contamination levels in water are among the applications that use telemetry in an agricultural context. Similarly, remote surveillance using airborne and satellite-based cameras is an example of a telemetry application used by the military (Forrester Research, 1998).

Changing business contexts necessitate newer technology infrastructures. As illustrated in the example, wireless services and applications have the potential to steer more versatility in today's supply chains by offering features and functionalities that may have been tested in other business functions or in totally different industries. It is only a matter of time before more mobile technology applications emerge and change the current supply chain landscape.

Strategic Cost Management

As elaborated throughout this chapter, cost reduction is a major driver in adopting any new technology in SCM. Under compelling demands from various stakeholders, supply chain managers constantly are looking for ways to optimize operations with the objective of reducing operating costs. A feature that makes mobile technologies a viable contender for the supply chain applications market is their ability to account for financial information in real time. Technologies such as GPS (Global Positioning Systems), telemetry, and RFID can feed real-time data to static tethered information systems. Furthermore, by streamlining the order-to-cash process, mobile technologies can reduce the complexity in the overall supply chain execution (Kalakota et al., 2003).

Overall, it can be said that mobile technology applications are driven by a multitude of market forces, and the adoption of such applications is likely to have an impact on business functions across different industries. Mobile SCM technologies can provide processing efficiency in the form of time, cost, and quality of operations. Based on these various benefits that can be availed through the adoption of mobile SCM technology applications, organizations need a road map to implement these technologies in their various business functions and subsequently integrate these into a seamless mobile infrastructure. The next section provides a typology of mobile SCM technology applications that can facilitate an organization's efforts in this area.

A TYPOLOGY OF MOBILE TECHNOLOGY APPLICATIONS IN SUPPLY CHAIN MANAGEMENT

In presenting our system of classification for mobile technology applications in SCM, we will discuss various mobile applications vis-à-vis their associated bearer technologies. Furthermore, to help us with our analysis, we will utilize the functions and processes from the inclusive SCM framework elaborated earlier in this chapter (see Figure 1). Table 2 at the end of this section illustrates the dimensions of our typology and the incumbent technology applications that are described herein.

Mobile Technology Applications in Supplier Relationship Management (Upstream Processes)

Three things in the life of a supply chain planner are for certain: death, taxes and reconciliation. (Hammer, 1997, p. 18)

This statement by Michael Hammer (1997) epitomizes a classic problem in SCM. Traditional information systems fall short in their functionality in order to reconcile cash and inventory at various points in the supply chain. It is not surprising, then, that manifest reconciliation emerges as the most popular application in mobile SCM (see Table 2). An example in upstream supply chain processes is the enduring difficulty in reconciling purchase orders to truck manifests at check-in times and freight pickups. The solution to such problems lies in the integrated use of bearer technologies, such as RFIDs, WWANs, and WLANs. Using emerging technologies in smart bar coding, the receiver can seamlessly scan incoming shipments, note discrepancies between purchase orders and truck manifests, make relevant changes to purchase orders, and update back-office systems as well as supplier databases at the same time. Furthermore, the ability for the driver to connect instantaneously with the materials planner for the upstream supplier helps to resolve exceptions and system errors at the point of delivery. Together, these technologies allow increased transaction velocity in the supply chain and higher levels of supplier coordination versatility (Kalakota et al., 2003).

Also, mobile technologies based on GPS allow for greater inventory visibility throughout the supply chain. By pinpointing the location of delivery trucks and the status of delivery packages, upstream suppliers can coordinate shipment schedules with downstream customers, who, in turn, can communicate expectations to their own downstream business partners. Telematics, which is defined as the integration of wireless communications, vehicle monitoring systems, and location devices (GSM Association, 2004), is one such suite of applications that is known to enhance confidence in business functions, including SCM, through facilitating greater visibility and enabling greater control in the supply chain (Hanebeck & Tracey, 2003).

Mobile Technology Applications in Internal Supply Chain Management (Internal Processes)

Mobile technologies also offer significant advantages to internal business operations by facilitating express and streamlined workflows. Among others, workflow applications in business operations include document approval, expense reporting, payment, and purchase orders (Kalakota et al., 2003). According to a recent pilot study by Gebauer, Shaw, and Zhao (2002), the most significant benefits in wireless procurement services result from speeding the overall processing time of an approval request. It is estimated that close to half of the processing time of a purchasing request is due to managers being out of the office, and, from their study, the researchers conclude that wireless technologies can appreciably help manager approvers as well as finance and accounting

Table 2. A typology of mobile technology applications for SCM

Supply Chain Macro Processes & Value Chain Activities

Bearer Technologies

	Supplier Relationship Management	Internal Supply Chain Management	Customer Relationship Management		
	Inbound Logistics	Operations	Outbound Logistics	Marketing & Sales	Service
GPS	☐ Load Verification ☐ Vehicle Dispatching ☐ Package Tracking ☐ Asset Tracking ☐ Telematics		☐ Route Management ☐ Vehicle Dispatching ☐ Package Tracking ☐ Asset Tracking ☐ Telematics	☐ Location-based Information Access	☐ Telemetry
WWAN	☐ Advance Shipping Notifications ☐ Manifest Reconciliation		☐ Advance Shipping Notifications ☐ Manifest Reconciliation		
Cellular	☐ Delivery Confirmation ☐ Manifest Reconciliation ☐ Electronic Signature Capture ☐ Exception Notification ☐ Driver Contact	☐ Approval Workflows ☐ Managerial Contact ☐ Employee Contact	☐ Delivery Confirmation ☐ Manifest Reconciliation ☐ Electronic Signature Capture ☐ Exception Notification ☐ Driver Contact	☐ Sales Promotion ☐ ATP/CTP Channel ☐ Reverse Logistics ☐ Location-based Push Services ☐ Sales Contact	☐ Service Contact ☐ Telemetry
P2T	☐ Delivery Confirmation ☐ Exception Notification	☐ Employee Contact	☐ Delivery Confirmation ☐ Exception Notification		☐ Employee Contact
RFID	☐ Asset Tracking ☐ Barcode Scanning	☐ Barcode Scanning ☐ Telemetry	☐ Asset Tracking ☐ Barcode Scanning		
WLAN (Wi-Fi / Bluetooth)	☐ Back-office Updates	☐ Telemetry ☐ Manifest Reconciliation ☐ Receiving & Payment Workflows	☐ Back-office Updates		

Mobile SCM Applications

Acronyms Glossary: ATP/CTP—Available-to-Promise/Capable-to-Promise; GPS—Global Positioning System; P2T—Push-to-Talk; RFID—Radio Frequency Identification; WLAN—Wireless Local Area Network; WWAN—Wireless Wide Area Network approvers by providing support for delegation, communication, notification, and information access (Gebauer et al., 2002).

Another major category of mobile technologies that is redefining internal supply chain processes is wireless product identification. This suite of technologies is regarded as an enabler for handling efficiency, customisation, and information sharing (Karkkainen & Holmstrom, 2002). An example of wireless product identification technology is an RFID system that comprises electronic product codes stored on RFID tags. These tags can be read seamlessly through tactically placed RFID scanners, which, in turn, transmit inventory information to back-office systems through specific middleware. The advantage of such systems is that they can be used without requiring line of sight. The tag readers, hence, can be attached to forklifts, mounted in freight and shipment pathways, or built into stacking shelves. The idea in using such a technology is to eliminate the extra step in scanning pallets or items and to automate the process.

Other internal mobile applications that drive process efficiencies include direct machine-to-machine data exchanges through telemetry. As defined in the previous section, telemetry is the use of telecommunication devices (including wireless) to automatically record measurements from a distance. The automatic notification of inventory management system by an RFID reader when inventory gets depleted below a certain level would be an example of a telemetric application. Again, this type of application can facilitate efficient and streamlined process flows in warehouse and inventory management systems.

Finally, as mentioned earlier, wireless technologies usually are always strongly integrated with other SCM enterprise systems. Back-office updates resulting from real-time data capture at the source are almost never stored or used independently of these systems. The medium of transmission for updates between wireless devices and enterprise systems can be in the form of a WLAN, based on short-range Wi-Fi technology or the proximity-based Bluetooth technology.

Mobile Technology Applications in Customer Relationship Management (Downstream Processes)

Many technology applications in the outbound logistics function coincide with those in the inbound logistics function. This is because of the sophisticated omni-directional nature of supply networks of today, where the position of an organization might be that of an upstream supplier as well as a downstream customer at the same. Similar technologies can be utilized in both cases, albeit in different business contexts. For example, in the instance of delivering a package to a customer, the manifest reconciliation is still a useful application, except this time, the customer invoice will be reconciled with the bill of loading. Similarly, GPS bearer technologies can be used in conjunction with transportation management systems to determine dispatching routes and daily delivery schedules for outbound freight drivers and delivery personnel.

The marketing and sales function in customer relationship management can benefit greatly from information access provided through wireless handheld and pocket-pc-type devices. Using their handhelds, field sales employees can connect directly to back-office inventory management systems or enterprise resource planning systems in order to perform available-to-promise (ATP) checks or capable-to-promise (CTP) checks, respectively (May, 2001). They then can provide up-to-the-minute information to their customers. Not only do these types of applications result in lower costs, due to increased employee productivity and more streamlined workflows and faster decision-making, they also result in higher levels of customer satisfaction. Returns processing and reverse logistics presents yet another area where mobile technologies can help alleviate business pain spots. By allowing drivers and field service representatives to accept returns (due to product defects or a change of mind from the customer) and with the ability to dispatch pickup trucks in near vicinity, if need be, businesses can drastically increase customer satisfaction levels and operational productivity.

Lastly, with respect to mobile technology applications in the service function, telemetry applications have the potential to provide yet again an effective means of monitoring and controlling remote resources. Service levels can be monitored, and personnel can be assigned, based on the type of problem incurred. These applications can help to reduce employee time and costs associated with routine administration of assets in remote locations.

From the discussion in this section, it should be evident that the mobile supply chain applications described herein, along with their respective bearer technologies are indeed in harmony with the various drivers for mobile technologies described earlier. Table 2 presents our typology of mobile technology applications as a juxtaposition of bearer technologies and their functional scope in different supply chain activities. In the next sections, we discuss our future outlook for these mobile technology applications followed by our conclusions.

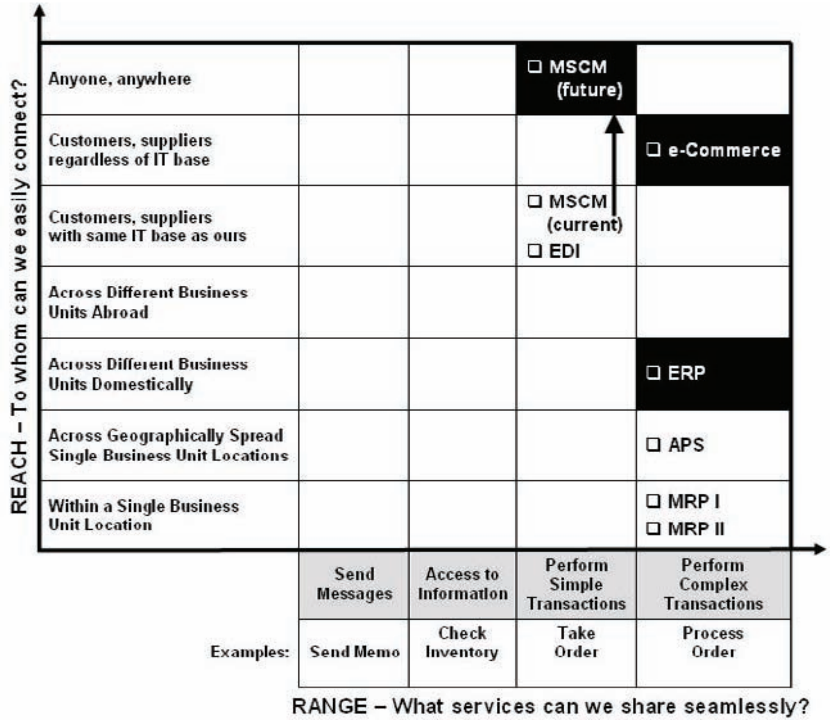
FUTURE OUTLOOK

Recent developments in new wireless technologies, more sophisticated end-user devices, and improved network coverage all have resulted in greater adoption rates for mobile applications (Alanen & Autio, 2003). However, in order to predict the future pathway of different types of mobile technology applications described in this chapter, we need to consider them vis-à-vis other technologies that have been used in SCM for some time, such as MRP I, MRP II, APS, ERP, EDI, and e-commerce systems. It is the combination of these functional and enabling technologies that constitutes the essential technology base for different supply chain environments. As elaborated throughout this chapter, mobile technology applications have the potential to assimilate in this current portfolio of technologies by improving process efficiencies and allowing streamlined access to these traditional back-end systems.

First, let us consider the technical interaction between current systems and how mobile technology applications are changing the current landscape. To reiterate our point from the previous section, mobile technologies currently are being used in conjunction with other systems, such as enterprise resource planning (ERP) systems, and it is our belief that this joint utilization will prevail at least in the short-term future. In order to explicate our position further and discuss our viewpoint for the future of mobile SCM technologies, we utilize the range/reach framework developed by Broadbent, Weill, and Clair (1999). The framework was used originally to explain the findings of an academic study that explored the functionalities of different types of information systems, and it lends well to our discussion of SCM systems. Figure 2 depicts our conceptual positioning of various SCM systems along the two dimensions.

As depicted in Figure 2, it can be seen that the current positioning of MSCM applications is such that these applications are bound to augment the reach and range of other enterprise systems (including ERP, MRP, and APS systems) that support various supply chain processes. The two types of technologies are complementary, in that although contemporary enterprise systems such as ERP are capable of performing complex transactions, they are limited to operations cross-functionally across the same organization. Wireless applications can help overcome these spatial boundaries in order to allow communication, collaboration, and coordination across different businesses. Furthermore, with the ongoing standardization of communication protocols, the introduction of new transmission mechanisms (e.g., GSM/GPRS), and

Figure 2. Positioning of various SCM systems in the range/reach framework (adapted from Broadbent et al., 1999)



improved network coverage worldwide, wireless connectivity very soon can enable the anytime/anywhere business paradigm across global supply chain partners. Figure 2 illustrates the direction of this shift upwards from the current position of MSCM applications along the dimensions of range. However, it should be noted that, although this advancement in mobile technologies may enable more complex transactions to be executed than is possible today, the level of complexity cannot catch up to that of e-commerce and ERP systems. This is because of the nature of computing resource requirements for these complex systems. Hence, in the near to medium future, mobile technology applications in SCM will complement other more complex technologies, such as ERP systems and e-commerce systems. The shaded cells in Figure 2 illustrate this unison among the three systems.

Lastly, theorists and practitioners also envisage that mobile technologies will find their way into horizontal, function-specific services, only after they have been tried and tested in vertical, industry-specific applications (Alanen & Autio, 2003; Forrester Research, 2001).

CONCLUSION

The adoption of mobile technology applications for SCM is being driven by various business and technical factors. At the end of the day, managers at the helm of decision making are interested in increasing productivity by reducing process costs and time, increasing process responsiveness, and improving product and service delivery quality. Researchers and futurists contend that MSCM technology applications can turn that vision mentioned previously into a reality by enabling new processes in order to seamlessly connect into existing supply chain planning and execution systems. Through omni-directional, real-time transmission of information, instantaneous reconciliations, and elimination of non-value-added activities from the supply chain, these new mobile applications are enabling increased fulfillment velocity, improved inventory visibility, and higher levels of supplier coordination versatility in the supply network.

In this chapter, we have discussed various categories of mobile technology applications for SCM. A typology based on these applications and associated bearer technologies was presented to highlight various applications within the three supply chain macro processes of supplier relationship management, internal SCM, and customer relationship management. The current and predicted positioning of these technologies in the near to medium time frame shows that the business process changes that will be instigated by the introduction of mobile technologies will lead to gradual, albeit fundamental, transformations in the organization's operations.

It is hoped that the discussion of technology drivers and the typology of mobile applications will prove to be a useful conceptual vehicle for understanding mobile SCM technologies and aid practitioners in making a business case for adopting these technologies. Finally, organizations that recently have undertaken MSCM initiatives can provide useful test beds for the validation of these conceptual models. Case studies investigating the undertakings of these organizations and their experiences with different technologies can provide valuable insights for revising and improving the ideas presented in this chapter.

Chapter 3.14

Bridging the Gap:

Connecting Internet-Based Spatial Decision Support Systems to the Field-Based Personnel with Real Time Wireless Mobile GIS Applications

Ming-Hsiang Tsou
San Diego State University, USA

ABSTRACT

Internet GIS provides a collaborative communication environment for sharing data, information, and knowledge. Mobile GIS can add both geospatial information and global positional systems (GPS) coordinates from remotely located field-based personnel to spatial decision support systems (SDSS). By adopting broadband wireless telecommunication technology for connecting Internet GIS and mobile GIS devices, decision makers can gather near real-time information from field personnel and, equally quickly, distribute updated information back to the field. This chapter introduces a collaborative GIS prototype that demonstrates an interoperable framework for combining Web-based GIS technologies and wireless mobile GIS applications. The integrated framework provides real-time or near real-time GIS data update functions (such as adding new spatially located map features or GPS tracking locations) between mobile GIS devices and Internet GIS servers. Although these real-time GIS functions can be very important during time-urgent emergencies, they can be equally beneficial and highly cost effective during routine field activities.

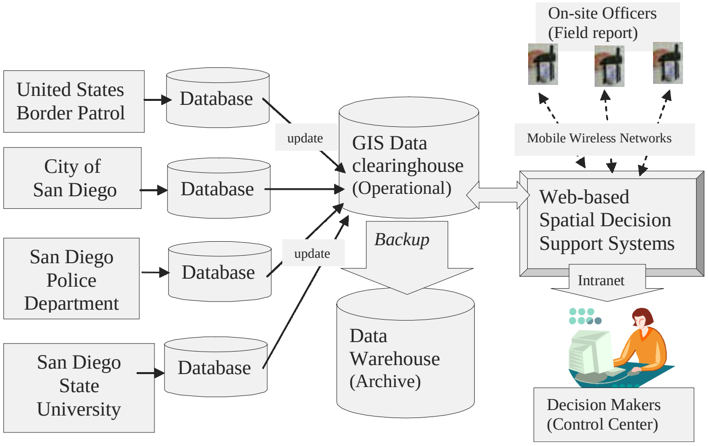
INTRODUCTION

Internet GIS (Peng & Tsou, 2003) can facilitate the implementation of collaborative GIS in the form of a Web-based spatial decision support system (SDSS) having remote communication channels. Currently, the greatest challenge for Web-based spatial decision support systems is the creation of a real-time or near real-time GIS-based communication channels between senior decision makers and multiple in-field personnel (such as first-responders). The objective of this book chapter is to introduce an integrated collaborative GIS architecture that combines Web-based GIS and wireless mobile GIS with a spatial decision support system. By adopting wireless telecommunication technology and advanced Internet GIS tools, decision makers can benefit from real-time information obtained from in-field personnel. In turn, in-field personnel benefit from more timely updated information from decision makers. The two-way communication mechanism between in-field personnel (*in situ* agents) and decision makers can facilitate a better and timelier decision-making process. Such an integrated framework combined with a client-side wireless mobile GIS application and a server-side Web-based decision support system will help optimize field-based management tasks, whether they are time urgent such as emergency dispatch, or a more mundane utility service call.

Both mobile GIS and Internet GIS technologies have been available for almost 10 years. However, very few collaborative GIS projects or spatial decision support systems have adopted both technologies for collaborative work. A principle problem has been the lack of comprehensive communication framework to combine Internet GIS and mobile GIS. Recent dramatic progress in broadband wireless technology has opened a new direction for connecting Internet GIS and mobile GIS with collaborative GIS architectures. Moreover, the GIS community is working on the establishment of interoperability standards, network-based GIS communication protocols, and XML-based geospatial data structure. These efforts from the GIS and telecommunication communities are beginning to facilitate the seamless integration of mobile GIS and Internet GIS.

Figure 1 displays an integrated spatial decision support system prototype that demonstrates an interoperable framework for combining Web-based GIS technologies and wireless mobile GIS applications. The major consideration of this prototype framework is to facilitate the interoperability between heterogeneous systems and platforms. To enhance interoperability, the integrated SDSS utilized a standardized Web-mapping interface, along with OGC Web Map Service (WMS) interfaces (provided by ESRI's ArcIMS OGC WMS connector) to provide online mapping functions and the display of remotely sensed data. By adopting XML-based metadata frameworks (ISO 19115 standard, 2003), multiple network-based geospatial information servers

Figure 1. Interoperable framework for Internet-based spatial decision support systems and wireless mobile GIS applications



work together via a centralized GIS data portal (data clearinghouse) with a duplicated backup data warehouse server. Each individual participating agency (such as police departments, university GIS centers, border patrol sectors, fire departments, etc.) can implement and update their own data systems and services while maintaining an aggregated system-wide interoperability through multiple data warehouses and Web-based decision support systems. The Web-based SDSS will be used by decision makers and spatial analysts in a control center to collect and process information via a secure intranet or encrypted mobile wireless networks in order to make better and more timely decisions, and to initiate improved responses to on-site personnel.

One unique design strategy of this Web-based spatial decision support system (Figure 1) is to combine distributed database connectivity and a centralized data archive system. The GIS data clearinghouse will automatically fetch the newest updated data from remote data servers (located in US Border Patrol, San Diego Police Department, and City of San Diego). Then the clearinghouse will maintain an archived, centralized database inside the system. The Web-based SDSS interface will only create a single database connection channel to access the operational GIS data clearinghouse, rather than establishing multiple database connections from various data resources at the same time. If any distributed data nodes (servers) are not available (due to system shutdown or networking problems) during an operational runtime, the GIS data clearinghouse will retrieve archived datasets from the backup data warehouse automatically. This unique design will improve the efficiency of database connection, and provide a more reliable Web-based SDSS framework.

This chapter also provides an overview of current Internet GIS and mobile GIS technology, and discusses implementation issues and experiences in creating this SDSS prototype. This Web-based prototype (http://geoinfo.sdsu.edu/reason) was funded by a NASA research program, REASoN (Research, Education and Applications Solution Network). The project goal is to assist in the development of a border spatial decision support system (BSDSS) for allocating and deploying resources to secure U.S. borders. A team of security agents with the U.S. Border Patrol, law enforcement, state and local resource protection agencies, researchers from San Diego State University (SDSU), and remote sensing technology companies is collaborating on this project. Case-study experiences, data security and classification, encryption for wireless communication, and two-way communication techniques are highlighted in this chapter.

ADVANCED GEOSPATIAL TECHNOLOGIES FOR COLLABORATIVE WORKS

Collaborative GIS is an integrated GIS framework that can facilitate its participants to work on geospatial related tasks with a shared understanding of geospatial information. The development of collaborative GIS is related to collaborative spatial decision making (CSDM) (Jankowski & Nyerges, 2001), computer-supported cooperative work (CSCW) (Li & Coleman, 2002), and group decision support systems (GDSS). According to Jankowski and Nyerges (2001), the term “collaborative” indicates a higher level of operation agreement among the participants comparing to other terms such as “communication,” “cooperation,” and “coordination.” Collaborative GIS, or spatial understanding (and decision) support systems can be used to “facilitate geographical problem understanding and decision making for groups, including groups embroiled in locational conflict” (Jankowski & Nyerges, 2001, p. 50).

One major research gap in collaborative GIS is the connection between system design and actual GIS applications and usage (Jankowski & Nyerges, 2001). Most collaborative GIS projects emphasize the location/relocation problem tasks, rather than the spatial dispatch coordination or emergency response plan. With the availability of the Internet, many collaborative GIS started to adopt the Web-based environment for their development frameworks (Churcher & Churcher, 1999; Dragicevic & Balram, 2004; MacEachren & Brewer, 2004). However, very few collaborative GIS extend the system framework from Web-based GIS to wireless GPS-enabled devices. This chapter will try to fulfill these gaps to combine both the application-oriented system design strategy and the integration of Web-based GIS and wireless mobile GIS devices. The following sections highlight recent developments in Internet GIS, mobile GIS, and wireless networks used to establish collaborative GIS architectures.

Internet GIS for Collaborative Works

Internet GIS is a collection of network-based geographic information services that utilize both wired and wireless Internet functionality to access geographic information, spatial analytical tools, and GIS Web services. The major goal of an Internet GIS is to develop a high-level GIS federation, that is, to be fully interoperable, where users can transparently access remote services and yet still maintain their autonomy (Bishr Yaser, 1996). The GIS community started to research online distributed GIS in the mid-1990s (Gardels, 1996; Peng & Tsou, 2003; Plewe, 1997; Tang, 1997). The development of Internet GIS was motivated by the adoption of an open and distributed architecture and the redesign of GIS metadata and distributed component frameworks. The contents of Internet GIS include not only displaying Web-based maps or sharing online geospatial information, but also providing advanced GIS analysis functions and new information services. Internet GIS are built upon a distributed computing framework, which is an example of the revolution of information systems from traditional architecturally closed and centralized information systems to more open and distributed information service architectures (Tsou & Buttenfield, 2002).

The driving force behind this GIS architecture transformation is the availability of new technology in network communications and programming. New languages such as Java, Python, and C# (C-sharp) support platform-independent applications across the Internet. Advanced network technologies such as Microsoft .NET framework, J2EE platform, and Common Object Request Broker Architecture (CORBA) provide a comprehensive scheme for distributed component technology essential to the development of Internet GIS. Distributed component technology allows clients to access heterogeneous servers dynamically, which is an essential feature of distributed geographic information services (GIServices). In the future, traditional geographic information systems (GISystems) designed as isolated islands, will become increasingly less attractive, possibly disappearing altogether. The cost efficiencies and flexibility of reusable and interoperable open and distributed-services interfaces provide much greater economies. GIServices focus on open, distributed, task-centered services that broaden geographic information uses into an increasingly wider range of online geospatial applications These include digital libraries, digital governments, online mapping, data clearinghouses, real-time spatial decision support tools, distance learning modules, and so on.

In general, Internet GIS can provide a collaborative communication environment for sharing data, information, and knowledge. The easy and ubiquitous access of Web-based interfaces can help various GIS users (decision makers, remotely located field agents, and the general public) to gain access to essential geospatial information for their individual needs. Online geospatial analytical functions can be combined and integrated to develop collaborative GIS architectures with other external systems and platforms (such as mobile GIS, hotel reservation systems, or financial management systems). The following section describes a mobile GIS, which is another important component of collaborative GIS architectures.

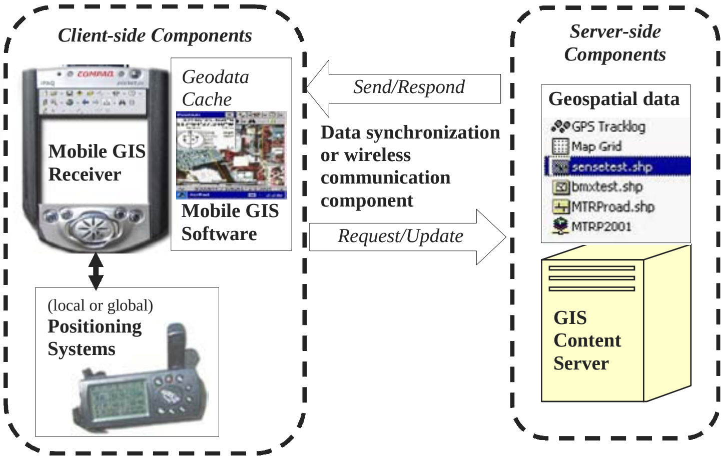
Mobile GIS for Collaborative Architectures

Mobile GIS is an integrated software/hardware framework for the access of geospatial data and services through mobile devices via wireline or wireless networks (Tsou, 2004). There are two major application areas of mobile GIS: *field-based GIS* and *location-based services (LBS).* Field-based GIS focus on the GIS data collection, validation, and update in the field, such as adding or editing map features or changing the attribute tables on an existing GIS dataset. Location-based services focus on business-oriented location management functions such as navigation, street routing, finding a specific location, tracking a vehicle, and so forth (Jagoe, 2002; OGC, 2003). The major differences between the field-based GIS and LBS are the data-editing capabilities. Most field-based GIS applications need to edit or change the original GIS data, or modify feature attributes. LBS rarely change original GIS datasets, but rather use them as background or reference maps for navigation or tracking purposes.

Most field-based GIS software packages are cross-platform and independent of hardware devices. On the other hand, LBS technologies focus on creating commercial value from locational information. Each mobile phone system has its own proprietary operating systems that are very difficult to customize. The architecture of mobile GIS is very similar to the Internet GIS. It follows the concepts of client/server architecture as in traditional Internet GIS applications. Client-side mobile GIS components are the end-user hardware devices that display maps or provide analytical results of GIS operations. Server-side components provide comprehensive geospatial data and perform GIS operations based on a request from the client-side components. Between the client and server, there are various types of communication networks (such as hard-wired cable connections or wireless communications) to facilitate the exchanges of geodata and services. Figure 2 illustrates the six basic components of mobile GIS: 1) positioning systems, 2) mobile GIS receivers, 3) mobile GIS software, 4) data synchronization and wireless communication component, 5) geospatial data, and 6) GIS content servers (Tsou, 2004).

Mobile GIS can provide geospatial information and GPS coordinates for field-based personnel conducting remote field *(in situ)* GIS tasks. For example, landscape architects may use mobile GIS to display a remotely sensed image as a background in a remote field location, and then

Figure 2. Architecture of mobile GIS (Tsou, 2004)



draw a preliminary design for a tree line based on GPS locations. Facility management workers can download a newly updated power-line map to identify the connections required at a specific power pole. To enable comprehensive mobile GIS, wireless communication is essential for connecting mobile GIS devices and GIS content servers. The next section introduces recent progress in broadband wireless technology that can bridge the gap between mobile GIS and Internet GIS.

Recent Progress in Broadband Wireless Technology

Recent progress of broadband wireless technology is the major momentum for the integration of mobile GIS and Internet GIS. The wireless service coverage and the bandwidth (speed) are the two key issues for wireless communication. There are many different wireless technologies, ranging from a walky-talky to high-speed WiMAX, to satellite phone systems. Based on the speed of data transfer, current wireless technologies can be categorized into two groups: narrowband wireless systems and broadband wireless systems. To communicate between mobile GIS and Internet GIS, broadband wireless technology is a better choice because most geospatial information and remote-sensing data are very large and complicated, which requires broadband wireless communication. Currently, there are no clear definitions about the distinction between narrowband and broadband in the telecommunication industry. This paper will define broadband communication as a communication speed (both input and output speed) greater than 1Mbps, such as Wi-Fi or EV-DO. Narrowband wireless systems have data transfer rates that are less than 1Mbps such as current GPRS and CDMA technology.

Generally, there are three different types of wireless communication systems: ad-hoc systems, cellular phone systems, and Wi-Fi/WiMAX data network systems. The ad-hoc wireless systems are custom designed for specific applications such as direct satellite phone systems, General Mobile Radio Service (GMRS) for walky-talky devices, or ham radio communication. Usually, these systems are narrowband and localized for a small group of special users, and require specialized user licenses.

Cellular phone systems are the most popular wireless systems, and are supported by several distinct telecommunication infrastructures to provide comprehensive service coverage. Originally, the focus of cellular phone systems was to provide voice communication rather than digital data transfer. The evolution of cellular phones started from the first generation (1G: analog signal mobile communication), to 2G (digital signal communication, speed range from 9.6Kbps to 14.4Kbps), to 2.5G (larger data speeds from 20 to 100Kbps), to 3G (third generation: near broadband speed ranging from 144Kbps to 2Mbps) (Janowski, 2005). Some researchers indicate the future development of 4G (fourth generation) cellular phone systems can provide ultrabroadband speed from 2Mbps to 10Mbps. 3G and 4G mobile cellular phone communication systems can provide high-speed communication and allow other wireless devices, such as PDA and Pocket PC, to receive multimedia services (such as streaming audio and video on the devices).

Wi-Fi/WiMAX data network systems are another promising category for broadband wireless mobile GIS communication. Both Wi-Fi and Wi-Max are the wireless network standards defined by the IEEE 802 LAN/MAN Standards Committee (http://grouper.ieee.org/groups/802/). The IEEE 802 committee forms multiple working groups in developing local area network (LAN) standards and metropolitan area network (MAN) standards such as 802.3 (Ethernet), 802.11 (wireless LAN), 802.15 (wireless personal area network - WPAN), and 802.16 (broadband wireless access – WiMAX). Currently, the most common wireless LAN infrastructures are the IEEE 802.11 (or Wi-Fi) technology. IEEE 802.11 specifies the physical and media access control (MAC) layers for operation of wireless local area networks (WLAN). The 802.11 standard provides for data rates from 11Mb/s to 54Mb/s (Pandya, 2000). The term Wi-Fi (wireless fidelity) is the global brand name across all markets for any 802.11-based wireless LAN product. Many computers, PDAs, printers, and so forth, have begun to adopt Wi-Fi, or IEEE 802.11, as their major communication channels. There are four extensions in the 802.11 group technology (a, b, g, and n).

WiMAX is an emerging IEEE 802.16 standard for broadband wireless wide-area network (WWAN) or metropolitan area network (MAN) applications. WiMAX can provide a larger coverage of service area than Wi-Fi. Its communication signals can cover a 4-6 miles range (up to 20 miles for the long distance setting). WiMAX can provide broadband to areas that do not have cable or DSL services. Presently, WiMAX includes two steps of the IEEE 802.16 technology. The IEEE 802.16**d** is the first step, which will be used to specify large area wireless communication via outdoor antennas in a fixed location. A fixed WiMAX service can provide up to 75 Mbps speed with Sub 11Ghz radio frequency. The IEEE 802.16**e** will be the next step (under development), used to specify portable wireless hardware for mobile WiMAX services. The new mobile WiMAX can provide roaming capability and enable more persistent connectivity within a service area (Intel, 2004a).

Table 1 illustrates the major wireless standards that are suitable for mobile GIS with collaborative GIS architectures. Note that the two major wireless systems (cellular networks and IEEE 802 groups) both focus on the development of next-generation broadband wireless communication coverage. However, the two systems are not currently compatible with each other due to the different radio frequency. From a GIS user's perspective, it is very difficult to switch seamlessly between Wi-Fi and EVDO wireless network while working in the field or traveling. Actually, the two systems may have to compete with each other in the future, because the new voice-IP technology will enable Wi-Fi or WiMAX to provide wireless phone services over a large area.

Table 1. Suitable broadband wireless standards for mobile GIS communication (table modified from Intel, 2004b, http://www.intel.com/netcomms/bbw/, and Janowski, 2005, p. 100)

INTEGRATION OF INTERNET GIS AND WIRELESS MOBILE GIS

Collaborative GIS are required to support interactive spatial query and visualization of geospatial problems from its participants. By combining Internet GIS and wireless mobile GIS, the new framework of collaborative GIS can provide more interactive GIS functions and real-time data update from distributed participants and decision makers. However, we need to establish a seamless and robust linkage between Internet GIS and mobile GIS in order to provide such high-level services. An integrated spatial decision support system will rely on three major components: Internet GIS, mobile GIS, and broadband wireless communication networks. Each component will need to be customized in order to provide real-time or near real-time GIS functions. Interoperability and upgradeability are two key issues for successful system integration and long-term operation because these GIS technologies change rapidly. The following sections will discuss the major issue in establishing the robust linkage between Internet GIS and wireless mobile GIS, and their major challenges.

The Linkage between Internet GIS and Wireless Mobile GIS

The first issue of the linkage between Internet GIS and mobile GIS is the communication type. There are two types of communication: real-time synchronized communication (via Wi-Fi or cellular phone signals) and cable-based asynchronous communication (via USB or serial ports). Both mechanisms can provide two-way communication between Internet GIS and mobile GIS. For cable-based connections, the Internet GIS servers can send geodata to the mobile GIS receivers whenever the connection is available. Then the mobile GIS receiver can upload geodata or new information back to the Internet GIS server later on. For real-time wireless communication, the mobile GIS receivers can create a continuous link to the Internet GIS server, and the server *responds* to the request in real time by sending the new map to the receiver. To facilitate two-way communications, several middleware or data synchronization software packages (such as Microsoft ActiveSync or Web Services) are required for bridging the mobile GIS applications and Internet GIS. For collaborative GIS, Internet-based protocols, such as TCP/IP and HTTP, can provide an open and standardized communication channels for the linkage between Internet GIS and mobile GIS applications.

The second issue of the linkage is the data exchange methods between Internet GIS and mobile GIS. There are two major methods: data transmission and database connection. The first method, data transmission, is to utilize network data transfer tools like FTP or HTTP to upload or download the whole data items. The second method is to create a database connection between the Internet GIS and mobile GIS that can provide more advanced database query and search functions. Most collaborative GIS will prefer the second method because the first method (data transmission) requires a higher network bandwidth when the size of GIS data becomes large. The format of data/databases is another consideration for data exchange methods. For example, mobile GIS units can send text-based GPS signals to the Internet GIS via a database connection. An alternative method is that a segment of GPS signals can be converted into a compressed binary file, then use FTP to send the file back to the Internet GIS server. Both approaches can fulfill the need of data exchanges between Internet GIS and mobile GIS.

The Challenges for the Integrated Spatial Decision Support Systems

There are several challenges in creating an interoperable SDSS framework. The first challenge is to ensure interoperability across the mobile

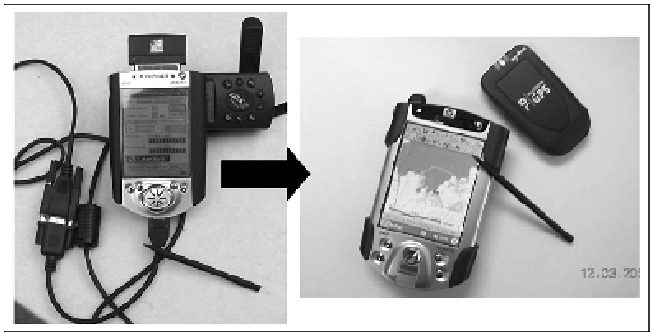
GIS and Internet GIS interface. Most mobile GIS software and devices are vendor-based and use proprietary data formats and specialized communication protocols. Proprietary data formats and protocols will create difficulty during the customization of mobile GIS software when fitting various field-based GIS tasks. Some mobile GIS platforms required a specialized combination of hardware devices, which cannot be substituted or replaced by other systems. Therefore, the ideal mobile GIS software should utilize standard data formats and protocols and be independent of hardware devices, allowing later upgrade or substitution. The same criteria should be applied to the choice of Internet GIS server and its software packages. For the development of collaborative GIS, the software and data format independence is also very important because the participants of collaborative GIS might come from different agencies that have different computing resources and hardware equipments.

Figure 3 illustrates an example of an independent hardware device upgrade used to replace a proprietary cable-based GPS. The cable-based GPS device is replaced with a wireless blue tooth GPS within the same mobile GIS unit.

The second challenge in creating an interoperable SDSS framework is the search and indexing functions for geospatial information on the Internet. Most GIS users have problems in finding online data effectively because they lack a comprehensive data search and indexing mechanism for geospatial data sets. One possible solution is to create detailed metadata information archived in an easily accessible mode, such as a GIS Web portal. The user-friendly GIS Web portal should have a powerful search engine to connect hundreds of data clearinghouses at the same time. Some researchers suggest that what is needed is a Google-like geodata search service that can rank the importance of geospatial data by their popularity and linkage numbers. For collaborative GIS, the metadata search engine will help different participants to gather the information they need effectively, and provide a better understanding of geospatial problems.

The third challenge in creating an interoperable SDSS framework is to the ability to merge the services of online data download and interactive Web-based mapping tools together. Both types of Internet GIServices are needed for creating a collaborative GIS environment. However, most current Internet GIS applications separate the functions of data downloads and Web mapping as two separate and distinct functions. From a GIS end-user perspective (or a decision maker's perspective), both raw data and online maps can fulfill the same GIS need during the decision-making process. For example, a city mayor may want to find out the location of major hotels in downtown areas. He or she can either view the locations from a Web-based map viewer, or download a

Figure 3. Independent mobile GIS hardware upgrade (from a cable-based GPS to a blue tooth GPS)



GIS hotel map into his/her GIS software package to view it off-line. Both approaches can provide the mayor with the same geospatial information he/she needs. Therefore, a comprehensive GIS Web portal should index both raw GIS data and Web-based mapping services together.

The fourth challenge is to enable real or near real-time data updates and two-way communications between clients (field agents) and their server (control and command centers) via broadband wireless networks. The availability of wireless networks will be the major technical challenge in setting up real-time mobile GIS applications. Many locations, such as national parks, or rural areas, lack wireless network coverage, making it difficult to implement broadband wireless devices or stations. Data security in wireless communications has also become another technical challenge. Currently, it remains very difficulty to create a fully automated mechanism on the server side to receive updates from remotely located field agents. Most current Web-based mapping servers still require manual conversions to update geodata received from field agents. Without automated data conversion and update mechanisms on the server-side, each Internet map server will require a full-time analyst operating the map server for real-time or near real-time data updates.

The following section introduces a success development of an integrated spatial decision support system that addresses some of the problems mentioned above while providing real-time or near real-time GIS data update and GPS tracking functionality.

The Establishment of a Real-Time Spatial Decision Support System

Based on the previous considerations, the research team developed an integrated, real-time SDSS framework that utilized state-of-the-art mobile GIS application software (ArcPad and ArcPad application builder), global positional systems (GPS), and wireless networking technologies (IEEE 802.11b, Wi-Fi standard). This SDSS architecture provides a scalable client/server wireless framework to access large volumes of geospatial information and remotely sensed data. The two-level real-time SDSS allows in-field agents access to multiple Internet map servers via their mobile devices, and the ability to submit updated field reports or messages back to a control and command center.

Figure 4 and Figure 5 illustrate the two scales of wireless architecture for real-time spatial decision support systems. The first level (level-1) is an independent, localized mobile wireless framework (Figure 4). The second level (level 2) is a wide-area, control-center-based wireless systems that directly connects decision makers to in-field

Figure 4. Level-1: Independent, mobilized wireless mobile GIS infrastructure

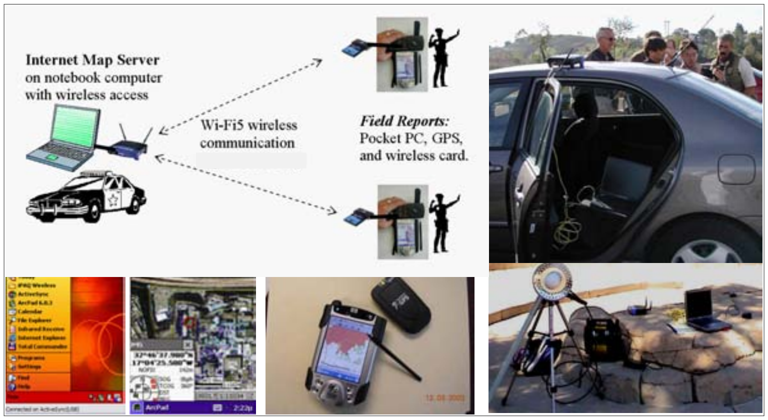


Figure 5. Level-2: Control-center-based wireless mobile GIS infrastructure (under development)

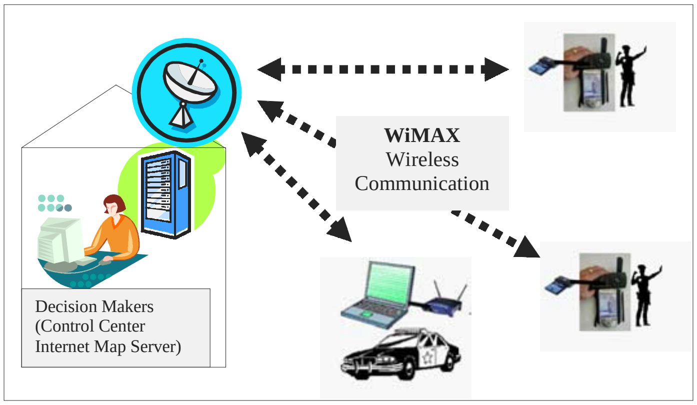

agents and to the first level mobile systems (when the vehicle drives back to the WiMAX cover areas) (Figure 5). Currently, our research team has completed the first level framework testing and implementation, and is planning to implement the second level framework once the WiMAX network is available.

The level-1 real-time SDSS framework utilizes a wireless local area network for the communications between mobile GIS receivers and portable Internet map servers. In the prototype, an Internet map server (ESRI ArcIMS) was installed on a notebook computer equipped with a wireless access port (Linksys Wireless Access Point Router). The notebook and wireless access port were placed inside a vehicle, and used the vehicle's electrical system, via the cigarette lighter socket, to power the wireless communications components. Field staff then used Pocket PC's equipped with Bluetooth GPS and Wi-Fi cards to access remotely sensed imagery and GIS data layers from a large capacity database residing on the notebook Web server via wireless communication channels (Wi-Fi) (Figure 4).

The level-2 framework will utilize WiMAX broadband wireless networks. Both in-field agents and level-1 mobile SDSS will be able to communicate to the control and command center and decision makers. Since WiMAX coverage may not reach into rural areas, updated information from level-1 systems can be uploaded to the control center map server when the mobile systems enter WiMAX coverage areas. Utilization of two levels of scalable wireless framework for real-time and near real-time SDSS will provide a more cost-effective information update and sharing mechanism between centralized decision makers and remotely located field agents.

Using the two-level wireless SDSS framework, Wi-Fi and WiMAX can provide two-way communication channels between Internet map servers and mobile GIS devices, such as Pocket PC and notebook computers. The Internet GIS software and mobile GIS packages will be customized to provide real-time display on the Web-based map viewer.

The following paragraphs and figures (from Figure 6 to Figure 9) will introduce some key examples in our prototype development for a real-time SDSS. These examples demonstrate the efforts to create an open, Internet-based communication channels between Internet GIS and mobile GIS, and the Web GIS data portal for collaborative GIS participants.

Figure 6 illustrates a prototype testing of real-time GIS data updates functionality from a mobile GIS device (left) to an Internet Map Server (right). The system was created by using ESRI's ArcPAD, MS Access databases, and ESRI ArcIMS. The figure shows that a triangle polygon, digitized on

the Pocket PC by remotely located field agents, was successfully submitted and updated at the centralized Internet map server via Wi-Fi channels with TCP/IP. One unique feature is that the system utilizes an open Internet-based protocol (TCP/IP) that can be easily applied in a different network environment. Most traditional GPS tracking devices only utilized proprietary protocol that cannot be shared or applied by other applications or different networks. This type of functionality will be very useful during emergency response or security management incidents, such as drawing a safety buffer-zone area around an accident. The original real-time update function was develop by an ESRI technical group, and then customized by our REASoN project team.

In addition to real-time GIS updates or data submissions, another important real-time SDSS function is GPS tracking of all in-field agents. Figure 7 shows a Web-based GPS-tracking map browser that illustrates a simulated security officer carrying a Pocket-PC with GPS functionality

across the campus of San Diego State University. In the Web browser, the red dot can dynamically move according to the GPS signals received from the security officer's Pocket PC. This testing was created by using ESRI's Tracking Server (beta-version) with customized ArcPAD GPS functions. Due to the lack of WiMAX wireless channels on the campus, the system relied on a GPS simulator to create the real-time GPS signals feeding to the Internet map server via TCP/IP.

The development of a GIS Web portal is another important component for spatial decision support systems. A comprehensive GIS Web portal should include download services for both raw GIS data and Web-based mapping services. Figure 8 illustrates a GIS Web portal, developed for our project, called San Diego Emergency Response GIS Data Portal. This Web portal was created by using ESRI ArcIMS Metadata Server Extension with ArcSDE and MS SQL server. Users can type keywords or select themes to query the metadata of geospatial information stored in the Web portal. The Web portal includes both downloadable data and online mapping services (Figure 9).

To summarize, this section introduced the development of a real-time or near real-time spatial decision support system prototype. By combining real-time GPS tracking, GIS Web portals, online mapping services, and real-time in-field agent data updates, it is possible to create a Web-based decision support system designed to help optimize field-based management tasks, such as emergency dispatch or utility service calls. The two-level Wi-Fi and WiMAX wireless networks can be used to create an effective collaborative GIS framework that provides the two-way communication channels for the Web-based decision support system.

There are some limitations in our prototype design. First of all, the security of wireless communication and mobile GIS devices is a major concern of the U.S. Border Patrol. Mobile GIS devices are very likely to be stolen because the device size is so small. Some critical information and criminal apprehension data are very sensitive and need to be protected within the system framework. However, the current technologies in wireless communication and mobile devices can only provide very limited protection mechanisms. The second limitation of our system is the balance between open-source packages and vendor-based GIS software. Most of our prototype system adopted vendor-based GIS software packages because the vendor-based GIS packages already have many needed GIS functions available, and can significantly save our system development time. However, vendor-based Internet GIS and mobile GIS packages might become difficult to customize or develop new GIS functions, compared to the open-source packages. In the long run, vendor-based GIS packages might need more effort to create additional new GIS functions for the future prototype development.

FUTURE TRENDS

In the future development of collaborative GIS frameworks or Web-based decision support systems, many innovative Web technologies, such as Grid computing and Semantic Web, can be adopted. These Web technologies, from a technical perspective, will enable more efficient and intelligent data search mechanisms and online mapping services.

Ideally, multiple geodata and GIS functions from heterogeneous servers or platforms should be connected and integrated dynamically to conduct a specific geospatial analysis tasks. To dynamically construct distributed GIServices, tremendous amounts of geospatial data and computational results would be requested and transferred across the network. Therefore, the GIS community needs to establish a comprehensive GIService framework in order to keep all available heterogeneous GIService components synchronized in terms of data flow and operation procedures. Such a framework needs to become dynamically adjustable in order to accommodate complicated network environments (dial-up modem, cable modem service, ISDN, T1/T3, wireless channels, etc.). The recent development of Grid technology provides a possible framework for the deployment of Internet GIService with its powerful computational and resource management capabilities. In the computer science community, the focus of Grid technology is to resolve low-level Grid computing technology issues (e.g., communication, protocols, and resource management) and to build a collaborative network architecture for Grid (e.g., Globus Toolkit). However, the deployment of collaborative GIS needs a high-level application framework rather than low-level Grid computing architecture. Grid technologies have been rapidly evolving since the mid-1990s. There are two types of Grid technologies, "data Grid" and "computational Grid." Data Grid (Chervenak, Foster, Kesselman, Salisbury, & Tuecke, 2001) can offer a basic architecture for geospatial data management with coordinated data storage, data access, metadata, and security services. Data Grids can provide various downloadable GIS data and online mapping services via the grid's metadata search engine. Computational Grid (Foster & Kesselman, 1999) will primarily be concerned with issues related to building the infrastructure to meet the requirements for high-performance computational needs. Both data Grid and computational Grid are emerging to provide effective computing resources for sharing and integration.

Semantic Web is another future trend for collaborative GIS. Semantic Web can facilitate the Web-based data sharing within a global network system. This technology can provide better definition of Web data and services, allowing large-scale data sharing and reuse (Berners-Lee, hendler, & Lassila, 2001). A working group in W3C (World Wide Web consortium) has defined related standards and languages for the applications of semantic Web technologies (http://www.w3.org). RDF (resource description framework) was designed to organize Web information into triple terms for easier data retrieval (http://www.w3.org/RDF/). To better handle terms and relations in semantic Web, Web Ontology Language (OWL) was also proposed to define terminology used for specific contexts and properties in terms of classes and relations (http://www.w3.org/TR/owl-guide/). Besides the reorganization of online content, recent breakthroughs have been made in defining Web services using mark-up language. OWL-S is a specification designed to help Web services discover and use the mark-up language. (http://www.w3.org/Submission/2004/SUBM-OWL-S-20041122/). In addition to all of the standards set by W3C and other organizations, semantic Web tools have been developed for data parsing, metadata processing, ontology management, and RDF/OWL formatting. To facilitate the integration of heterogeneous collaborative GIS frameworks, we might need to create a geospatial semantic Web that requires developing a geographic Web ontology language (G-OWL) to facilitate the geospatial data sharing and service integration.

CONCLUSION

On December 26, 2004, people from around the world began to realize the power of nature, and that natural disasters are a daily risk we must address. Following a massive 9.0 earthquake in the Indian Ocean, a horrifying tsunami destroyed the coastline areas of 11 countries, and caused a massive number of deaths (over 150,000). Many geographers and GIS professionals asked themselves a fundamental question: "Why did such a tragedy happen in these areas and could we have responded better?" What if these areas have an advanced collaborative, Web-based emergency response system?

A Web-based spatial decision support system could assist the local governments and emergency response teams in identifying potential threat areas so critical "hot zones" could be quickly and accurately identified. A Web-based GIS data portal could be used to rapidly generate the most effective evacuation routes and emergency plans during natural hazard events including wildfires, flooding, and tsunami. Real-time or near real-time GIS could also assist public policy officials, firefighters, and other first responders with identifying areas where their forces and resources are most needed. Many people agree that an integrated and comprehensive geographic information system (GIS) is an essential component for successful disaster prevention and mitigation. Clearly, collaborative GIS could become a vital technology to save lives and assist in recovery.

This paper gives a brief introduction about the capability of collaborative GIS. It is important to educate people and organizations on the utility of collaborative GIS technology, and why it is to their benefit to adopt the technology in their daily lives. As always, the cost of disaster recovery and mitigation is much more expensive than the cost of early prevention using systems such as a Web-based SDSS.

In order for collaborative GIS to be most effective for natural hazard prevention and response purposes, the system should be incorporated into the regular planning activities; training; and exercises conducted by local, regional, and federal government officials and agencies. An example of the routine use of an SDSS in improving emergency response would be the application of real-time SDSS by local governments to monitor the roadway traffic, air quality, and E-911 responses. Monitoring daily roadway traffic can quickly be transformed into monitoring evacuation routes or routing emergency relief aid. Without training, familiarity, and exercises, any emergency response tool, including a real-time SDSS, may not be effective to an official, organization, or government when an actual hazard situation occurs.

This chapter introduced a real-time Web-based spatial decision support system for use by decision makers and *in situ* agents to collect and process information via a secure intranet or encrypted mobile wireless networks to make better and timelier decisions. The goal of an integrated SDSS is to bridge the gap between traditional control-center-based spatial decision support systems and field agents through the use of real-time wireless mobile GIS applications and their benefits to decision making.

The unbelievable tragedy in December 26, 2004 taught us many valuable lessons. We should use collaborative GIS as a tool to understand and respect the power of Nature. When viewing online maps, satellite images, categorizing land-use data, or conducting spatial analysis, we are actually communicating with Nature, and trying to understand her behaviors at that moment. Therefore, the Web-based SDSS introduced in this chapter is not a tool to be used to conquer Nature or to fight back Nature, but a tool to learn the knowledge of Nature, and to collaborate with her.

ACKNOWLEDGEMENT

This paper forms a portion of the NASA REASoN-0118-0209 project at San Diego State University. Funding by the NASA REASoN program, and matching funds from San Diego State University Research Foundation are acknowledged and greatly appreciated. The author wishes to thank John Kaiser, the NASA REASoN program coordinator, and Dr. Douglas Stow, the NASA REASoN program Principle Investigator, for their coordination efforts on this project and the comments of this paper. The author also thanks Lauren Rizzo, Cristiano Giovando, and Tong Zhang (graduate students) for their help in prototype development.

ABSTRACT

Wireless, handheld devices are becoming increasingly popular in health care settings, but the full potential of their role in patient-specific decision support remains to be achieved. This article presents a multicriteria framework for choosing technologies apropos to handheld and ubiquitous decision support architecture. This framework is illustrated through architectural middleware choices made in the context of a podiatry and diabetes care network. Performance issues are found to be very important in the handheld space, and minor aspects of connectivity and other constraints drive significant changes in choices of architectural approach. The resulting architecture employs layers, including serialized objects, XML payloads, event notification, Web services, and dynamic class loading, with the mix varying among the system interfaces. The overall recommendation is that organizations wishing to fully exploit mobile technology must use a flexible policy and pursue a process of technology choice that is scenario-based and iterative to take into account discoveries from prototyping and field-test experience.

INTRODUCTION

Handheld computers acting as personal digital assistants (PDAs) are growing in popularity in health care. They are increasingly trusted (particularly as sources for reference material), used, and considered to be efficient (Cimino & Bakken, 2005). A mid 2004 survey (Grasso, Yen, & Mintz, 2005) found 52% of medical students reporting handheld computer use, with drug reference and clinical calculators the major clinical applications of the technology. Characterizing the use and capability of PDAs is an exercise in measuring the position of a moving target, but the dominant trend sees students as a key user group and reference for education as a key application area. PalmCIS (Chen, Mendonca, McKnight, Stetson, Le, & Cimino, 2004) illustrates the less common use of mobile technology as a terminal for viewing patient data. In a nursing context, Chang, Lutes, Braswell, and Nielsen (2006) found that mobile technology integrated with a hospital's mainframe system improves the communications between shifts. Lu, Xiao, Sears, and Jacko (2005) and Fischer, Stewart, Mchta, Wax, and Lapinsky (2003) also have reviewed handheld applications in health care, and Wu and Straus (2006) and Lane, Heddle, Arnold, and Walker (2006) have conducted systematic reviews. Wu and Strauss found limited, but supportive, evidence that handhelds improved documentation taken by physicians. The more functionally ambitious handheld solutions in health care are generally "home-grown" (i.e., purpose-built for a specific application context).

Handheld computing and mobile communications move us closer to a ubiquitous computing environment, where the notions of "a computer" or "the information system" become less central to the attention of the end user and where many often loosely coupled subsystems collaborate to achieve an overall goal. At the University of South Australia (UniSA), we have been following a vision of ubiquitous decision support for chronic disease management with an emphasis on diabetes and foot care that integrates the roles of clinical decision support, provider education, and patient education (Warren, Lundstrom, Osborne, Kempster, Jones, Ma, & Jasiunas, 2004). Two key elements of this vision have been a handheld data collection and decision support application for students at the UniSA Podiatry Clinic (Lundström, Warren, Jones, Chung, & Jasiunas, 2003); and an individualized Web-based consumer diabetes information service (Ma, Warren, Phillips, & Stanck, 2005).

In the context of ongoing iterative development of handheld and ubiquitous decision support, one is faced with a diversity of architectural options in an environment of rapidly changing technology. The remainder of this paper presents a framework for consideration of relevant technology choices, with particular focus on middleware architecture, which is illustrated in terms of a cycle of development in the UniSA podiatry/diabetes management environment. The outcomes highlight the sensitivity of technology appropriateness to existing constraints and the ongoing relevance of performance.

METHODS

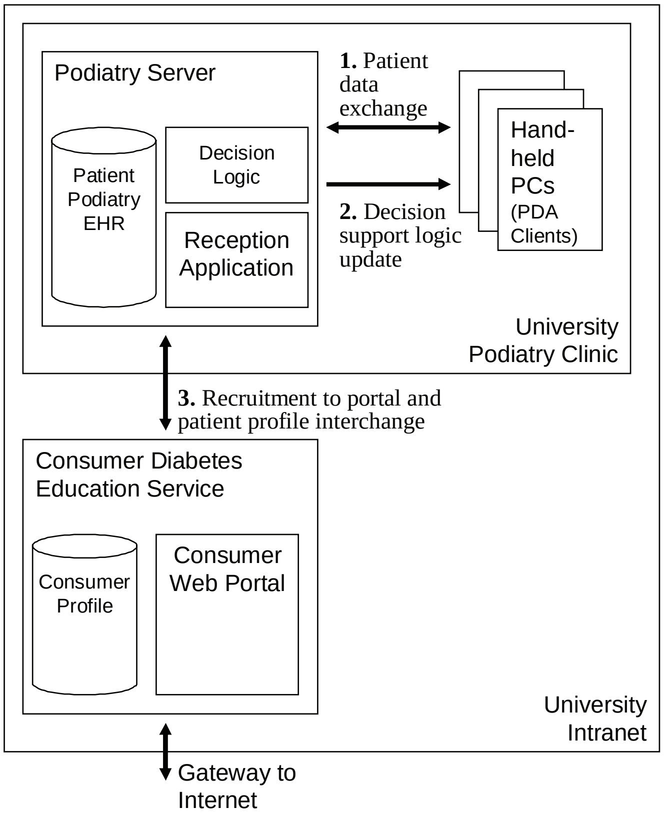
Setting

A spiral development lifecycle has been pursued with the UniSA Podiatry Clinic from mid 2002. The objectives of a cycle for calendar year 2005 entailed: (a) achieving a production client-server system in the podiatry clinic, allowing students to undertake podiatry assessments using handheld computers with results logged to a central database; (b) active decision support for the podiatry students on the handheld terminal to critique assessment and plan in terms of recorded observations; and (c) interfacing of the podiatry clinic to a diabetes consumer education service such that the clinic acts as a recruitment point for the education service, and podiatry observations lead to tailoring of educational priorities. The environment, with the major communication scenarios addressed in the 2005 cycle, is illustrated in Figure 1.

Aspects of the design were fixed at the commencement of the 2005 cycle, constituting developments, investments, and decisions that were undesirable or infeasible to back away from. These fixed aspects of the design include: (a) use of Hewlett-Packard iPAQ pocket PCs with Microsoft Windows operating system as the podiatry clinic terminals; (b) the elements recorded in the podiatry review, user interface design for data capture, and podiatry clinic server database design (encompassing some 200 specific observations, including some free-hand sketches); (c) the use of Bluetooth for communication within the podiatry clinic (due in part to administrative "turf" problems entangling development on 802.11 standards); and (d) the implementation of the Web portal for the consumer diabetes education service to be impacted minimally.

Outside of these fixed constraints, the outstanding architectural decisions concerned the approach to data interchange at the application level among the major system components, including interchange of decision support logic, a realm that can be termed "middleware architecture." All of these communication interfaces were required to support modification of content in the future, but the decision support content was seen as the most volatile, with plans for active iterative refinement of the logic in a future cycle. Experience with an earlier cycle prototype indicated that the data transmission speed performance of the podiatry server to handheld data exchange link was problematic, although a naïve analysis of Bluetooth bandwidth left the source of the problem unclear.

Figure 1. Podiatry/diabetes care network setting (technology choice scenarios numbered)



Procedure

Our procedure was informed by Serain's (2002) "criteria based table model" (p. 211) and the practice of defining scenarios that are to occur within the architecture, as demonstrated by Goedicke and Zdun (2002) and Dobrica and Niemelä (2002).

Major architectural options were identified and each assessed in terms of a number of criteria. It should be noted that the architectural options are not, in general, mutually exclusive, and assessment on criteria is qualitative. The purpose of the resulting option-×-criteria grid is to inform the synthesis of candidate designs, not to support a mechanistic choice of a single option. Each cell of the grid should be populated with an explanation of the qualitative judgement and possibly include a number of unresolved issues. This procedure is iterative. Review of the option-×-criteria grid can result in options being dismissed, merged, or split.

Criteria

The decision criteria group was separated into what classically is called "functional" and "'non-functional" requirements, although we prefer to designate the criteria groups as *case-specific* and *generic*. One case-specific criterion is identified for each major system interfacing scenario. In the current setting, these scenarios are:

1. distributing and synchronizing patient data (around the podiatry clinic);
2. ability to transfer decision support logic (from the podiatry server to handheld PCs); and
3. ability to transfer profiling information (to focus consumer diabetes education, moving data between the podiatry clinic and Web-based consumer education setting).

The generic criteria are fairly standard aspects of systems integrity, but many take on a degree of specific meaning in the health computing context:

- Security—acceptable handling of patient data (notably HIPAA compliance in the United States, although not in demonstration context);
- Performance—chiefly latency, and also reliability;
- Maintainability—outlook for the long-term feasibility of the solution in terms of a continuing user community and availability of technical staff for maintenance;
- Maturity/vailability—presence of standards (de facto or otherwise) to provide stability and practicality of acquisition;
- Flexibility—supporting explicitly expected changes and reasonable estimation of long-term change (A special bonus is if one technology is flexible enough to encompass multiple requirements of the system, making the system simpler overall.); and
- Feasibility—to further diffuse "tick-box" thinking, a summative assessment that the technology is actually practical and can fulfil the requirements in question.

RESULTS

Technology Assessment Decisions

Initial brainstorming in the development team (authors Darren Woollatt, Jim Warren, and Paul Koop) revealed seven options for further exploration from among a diverse range of health-specific initiatives, relatively modern generic solutions, and solutions of historical interest for comparison. Probably the least generally well-known option under consideration was iROS (Open Source Technology Group, 2006), which had a track record of use for enabling "interactive rooms" through a messaging service and was familiar to the authors. An abbreviated first-cut option-×-criteria grid is shown in Figure 2. The full grid, as used by the development team, occupies a color A3 sheet in 10-point type with 40 footnotes on ancillary pages.

With respect to the first scenario, remote method invocation (RMI) and iROS emerged as strong options based on transfer of serialized objects. Simple object access protocol (SOAP) (W3C, 2004) also had promise. It also had an edge in extensibility, if serialized objects were not used, but required use of XML, which seemed like it might be a performance issue, especially on the client (handheld) side, where computing power for parsing a large XML payload is quite limited. All three options are capable of having XML components to the message, which could then support Health Level Seven (HL7)(2006) or OpenEHR (n.d.) as a further layer.

Performance analysis revealed that a "typical" patient review as a serialized object was 564kB in size and required about 14 seconds to transfer over our BlueTooth connection from the client to server using iROS. However, application of a compression routine from the Sun Microsystems Java Development Kit JDK reduced this to 14.5kB and brought the transfer time (with the negligible compression time included) down to an acceptable 0.85 seconds. iROS was compared to SOAP and found to be about 2.5 times faster for the same test object. Encryption of several sensitive fields (again using a JDK routine) also was included with no observable performance impact, yielding an overall acceptable solution to scenario 1.

Figure 2. Abbreviated option—criteria grid for middleware architecture technology choices

Criterion	HL7	openEHR	iROS	SOAP	CORBA	DCOM	RMI
Scenario 1	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Scenario 2	Yes, Arden	N/A	1, 2	1, 2	1	1	1
Scenario 3	Yes	Yes	Yes	Yes	Yes	3	Yes
Security	Add on	Add on	Add on	Add on	Built in	Built in	Built in
Performance	4	4	4	4	4, well-studied	4, well-studied	4
Maintainability	5	5	OK	Good	OK	3	Good, part of JDK
Maturity/ availability	5, 6	5, 6	6	6	6	3	6
Flexibility	Suits purpose	Suitable for scenario 1 and 3	Very flexible	General	General	General	General
Feasibility	7	7	Good	Good	8	3	Good

[1] *Can transfer guideline representation for interpretation on client*
[2] *Can serialize object with decision logic for execution on client*
[3] *Operating system and language limitations of DCOM (or .NET) are a concern; current Diabetes Consumer Education Service is on Linux*
[4] *A concern for Scenario 1—must be measured in context*
[5] *Steep learning curve and technology is rapidly changing, although adherence to a standard is a plus.*
[6] *Open with freely available implementations and user communities; somewhat more restricted to members for HL7. iROS community rather small but deemed adequate*
[7] *HL7 v3 requires process using RIM to create new messages for our highly specialized application; somewhat better supported and more approachable process using openEHR archetypes*
[8] *Possible, but over-spec to needs in absence of multilanguage and legacy system integration motivators of CORBA*

Layering of HL7 or openEHR was not pursued in this scenario, due to performance concerns, availability issues that parallel scenario 2 and 3 as discussed below, and minimal perceived relevance for a system as tightly coupled as the podiatry server and handheld client. The iROS solution was chosen over an RMI solution largely due to developer familiarity.

With respect to scenario 2, SOAP emerges as particularly promising for invocation of decision support methods on the server from the handheld devices. However, a significant constraint in this scenario is that the users may wander outside of BlueTooth range at the time when decision support alert logic must be checked. (This is done interactively in the consulting rooms, whereas scenario 1— completion of the previous patient and start of the next—is done in close physical proximity to Clinic reception desk and the server.) As such, we are restricted to methods that actually transfer the decision support *logic* to the client at some time between user login and start of processing on the first patient of the user session.

One promising option for transfer of decision support logic was to use a representation scheme, such as the Arden syntax (Jenders, 2006) of HL7. However, this requires the client to interpret logic statements in a high-level specification language, raising issues around performance, as well as the question of availability of such an interpreter to run on a handheld PC. Given the difficulties of an interpreted logic solution, the technology choice taken was to write the decision logic in Java such that all decision alerts shared a common Java interface. Central update of decision logic is achieved by redirecting the handheld client's class loader to the server (see Figure 4), exploiting the compactness of a Java archive (JAR) file to move the logic as Java byte code.

In scenario 3, SOAP wins out. While the podiatry server and Diabetes Consumer Education Service currently reside on a common university intranet, the probability of the clinic and Web-education services becoming more widely distributed is high, and hence the ability of the SOAP protocol to cross organizational firewalls provides maximum maintainability of the solution.

The case is strong for layering either HL7 or openEHR onto the SOAP message that transfers the patient profile (observations collected in the podiatry clinic of relevance to diabetes education; some 40 data items in the current data sets). The application fits well with the model of either an HL7 message or an openEHR EHR extract. At the time of implementation, however, neither HL7 v3 nor openEHR were offering a convenient Java toolkit; this situation is changing rapidly (see the Future Research section). The medium-term solution implemented was to provide the profile as an XML payload, but to leave the reconciliation of that payload to the HL7 RIM or an openEHR archetype for future extension of the system. W3C standards of XML signatures (Eastlake & Reagle, 2006) and XML encryption (Reagle, 2006) are applied to meet the security requirements of scenario 3.

Resulting System

With the technology assessment decisions taken as per above, the result is a close coupling of the podiatry server to the PDA clients (handheld PCs) and a looser coupling of the podiatry clinic (through the podiatry server) to the Diabetes Consumer Education Service. The PDA clients communicate to the server over BlueTooth. A sequence of iROS messages, as illustrated in Figure 3, keeps the client up-to-date with the available patients in the waiting room (tracked via a Microsoft .NET application local to the podiatry server) and transfers patient data prereview and postreview. The PDA client implements a common user interface for decision support alerts, the decision logic, which is loaded from the podiatry server when a user logs onto the podiatry application on the PDA (as per Figure 4).

At the end of the podiatry review for patients with diabetes, the PDA client prompts the user to

Figure 3. Sequence diagram for podiatry application client/server interaction

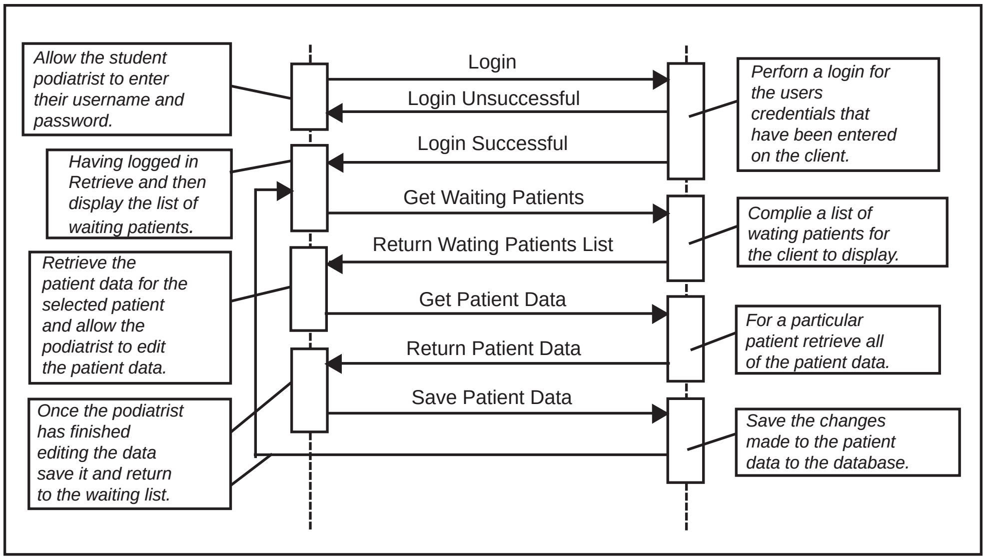


Figure 4. Architecture for updating client decision support logic

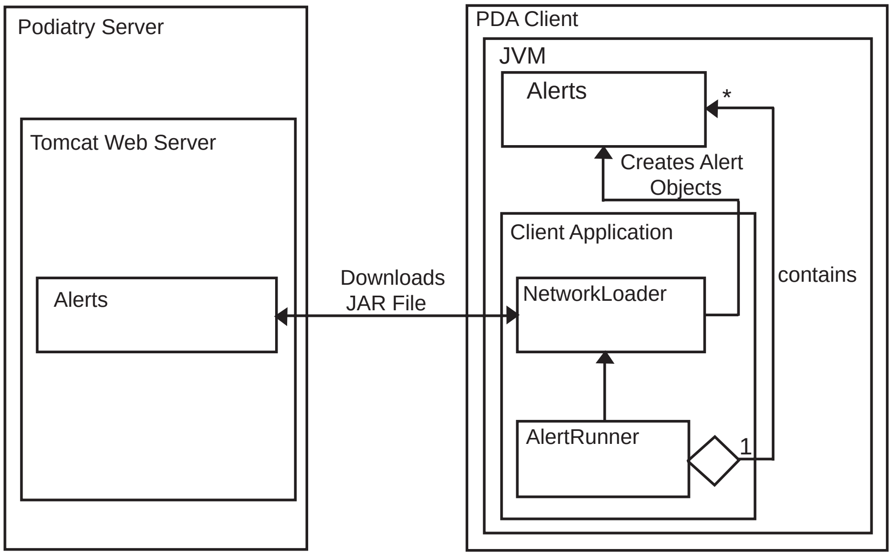

ask whether the patient would like access to the Consumer Diabetes Education Service. When the podiatry server receives the message to update the patient database and sees the request for an education service account, a SOAP request is issued for an account to be created on the consumer portal. Upon receiving the SOAP result, the server prints a hardcopy invitation letter for the patient with login information, including their specific username and password as provided by the Consumer Diabetes Education Service. Upon login to the portal, the consumer is prompted for consent for the transfer of information from the podiatry clinic, at which time a getProfile method is invoked from the education service to the podiatry server, causing clinical data to be extracted from the patient's podiatry reviews. This data is composed into an XML snippet by the podiatry server and returned to the education service for parsing into its own consumer/patient profile database.

DISCUSSION

We have reached an age that is ripe for innovation in handheld and ubiquitous information technology. It has never been easier to integrate applications across a range of platforms to achieve decentralized behavioral changes, such as improved chronic disease management. Specifically, growing acceptance of handheld computing in the health workplace, ubiquity of short-range radio communications, and the advent of Web services standards are making it feasible and inexpensive to field health data collection and decision support tools. Moreover, it is increasingly easy to "tack on" new avenues for the exploitation of existing functionality (taking an existing application and putting it on the Web, adding a mobile portal, mounting it as a Web Service for other applications, etc.). And many of these integration solutions are well packaged for programmers using common development environments, such as JDK and Microsoft .NET.

The range of available technology choices presents in itself a challenge. An open-minded, explicit and semistructured (but not overstructured) process of technology evaluation is warranted. Mandating a technology choice will cull potential opportunities by making them infeasible for the present, where a more flexible policy could allow them. The process of technology choice must be iterative to take into account discoveries from prototyping and field test experience, even if these emerge uncomfortably late in the project schedule (better late, or even cancelled, than an on-time, on-budget failure). Choices must be scenario based, not just generic criteria based, as subtly different constraints can make major differences in the feasibility or acceptability or particular technology choices.

Performance is a particularly sensitive issue in that technologies can yield surprisingly high latencies and surprising variances in performance among technologies and their implementations, latencies that can render a solution unusable under field conditions. This problem is acute with low-powered mobile devices, especially when using advanced solutions recently ported from mainstream computer systems. While performance of mobile devices will continue to improve, one can expect it to continue to lag the performance of nonmobile counterparts.

The issues of choice are well illustrated in our experiences with middleware architecture. A show stopper emerged on the issue of disconnected operation (for access to decision support alert methods), removing all choices based on remote method invocation from one of our scenarios. Latency was a strong issue in another scenario, driving a technology choice (and also requiring a well positioned use of compression). In addition, we placed a high value on programmer experience and toolkit availability to go ahead with what was known and involved a short learning curve. We found that very different middleware architecture technology choices came through as appropriate for each of our three major system interfacing scenarios.

Many (if not most) experienced developers will disagree with our specific choices. We fully admit to our own biases, idiosyncratic experience levels, and valuation of the features and limitations of certain options. The important message is not in our choices, but the process of choice and acknowledgment of the diversity of outcomes, even within the same development group, in differing scenarios with differing constraints.

An interesting feature of our solutions for the reported development cycle is that we did not use some of the obvious health-specific technology standards. However, we left room for their adoption in the near future.

FUTURE DIRECTIONS

We may be poised for a time where the easy uptake of health informatics standards begins to parallel their mainstream counterparts, such as SOAP and other XML-based methods. The HL7 Java SIG API (Hendler & Schadow, n.d.) indicates the emergence of appropriately usable mechanisms to integrate HL7 with ubiquitous computing applications, such as the one described in this article. In a case, such as integrating the podiatry clinic with a Consumer Diabetes Education Service, this API should prove an excellent fit. Similarly, recent release of the openEHR specification project release 1.0 (OpenEHR, n.d.) should promote further development of Java APIs on this paradigm. Proposal for a Java Compiler for GELLO,an object-oriented query expression language,(Index of /hl7/arden/2005-05-AMS, n.d.) is also timely. As per our decision support scenario, allowing use of the ubiquitous JVM as the decision support interpreter, rather than needing to port (and get adequate performance from) a high-level guideline expression interpreter, is an excellent solution where system capacity and performance are issues.

A question remains as to whether performance of new health informatics packages will be acceptable for use on small devices, including PDAs. We can expect that these devices will remain dependent on application-specific coupling to servers for many scenarios, where more than a few fields of patient data must be exchanged or where the devices must sometimes operate in disconnected mode.

ACKNOWLEDGMENT

The work reported in this article was partly funded by the Co-operative Research Centre (CRC) for Enterprise Distributed Systems Technology (DSTC) through the Australian federal government's CRC Programme (Department of Education, Science, and Training). All authors were employees or students of the University of South Australia at the time the work was conducted. Special thanks to Helen Banwell and all the UniSA Podiatry Clinic staff and students.

Chapter 3.16

Mobile Technologies in the New Zealand Real-Estate Industry

Eusebio Scornavacca
Victoria University of Wellington, New Zealand

Federico Herrera
Victoria University of Wellington, New Zealand

ABSTRACT

The Real Estate industry can be viewed as a prime candidate for using mobile data solutions since it possesses a dispersed workforce as well as intensive and complex information requirements. This paper investigates the perceived value of mobile technologies in the New Zealand Real-Estate industry. It was found that mobile technologies are perceived as a strategic element in the Real-Estate industry. However, the use of data services still is bounded by industry practices and voice remains the most used application among agents. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

Mobile Business-to-Employee (B2E) applications have the potential to improve business processes and transform entire industries (Scornavacca et al., 2006b, Basole, 2005, Barnes et al., 2006, Wigand et al., 2001, Scornavacca et al., 2006a). A particular industry that is well suited to gain from the potential benefits of mobile technologies is the Real-Estate industry – since it possesses intensive information requirements as well as a distributed workforce (Basole, 2005, Wigand et al., 2001, Crowston et al., 2001, Sun et al., 2006). It is important to understand and to identify the strategic role that mobile technologies can actually play in this industry (Scornavacca et al., 2006a).

The aim of this paper is to investigate the perceived strategic value of mobile technologies in the New Zealand Real-Estate industry. Through multiple qualitative case study method, six participants from distinct organizations participated in this research - four of them representing Real-Estate agencies, one representing the industry association, and one representing a telecommunication provider. New Zealand offers an excellent opportunity for study as it has a booming house market and enjoys almost total cellular coverage from two different network providers (Barnes et al., 2006, Scornavacca and McKenzie, 2007, Scornavacca et al., 2006b). In addition, the country has a very high mobile phone penetration – with a population of 4 million people, there are over 3.8 million active mobile phones in the country (Geekzone, 2007).

The remainder of the paper is structured as follows. The following section will present a brief review of relevant literature. This will be followed by an explanation of the research methodology applied—multiple case study. The results of the research are then provided, along with an analysis. The paper concludes with a discussion of the key research findings, limitations, and suggestions for further research and practice.

M-BUSINESS AND THE NZ REAL-ESTATE INDUSTRY

M-business can be understood as the use of mobile information technologies enabling organizational communication, coordination and management of the firm (Walker et al., 2006, Barnes, 2002). Analysing the value chain, Barnes (2002) identified that connectivity, interactivity, flexibility, location and ubiquity are key characteristics of m–business that define its uniqueness and potential. Furthermore, Folinas et al. (2002) as well as Siau and Shen (2003) identified some additional characteristics of m-business such as personalisation, time sensitivity and reachability.

The current literature is concerned with mobile interactions that are dominantly embedded within the Business-to-Consumer (B2C) relationships (Scornavacca et al., 2006a, Varshney and Vetter, 2000, Siau and Shen, 2003). However, there has been an increasing shift of focus onto the importance and potential of B2E applications (Basole, 2005, Berger et al., 2002, Leem et al., 2004, Oliva, 2002, Scornavacca et al., 2006a, Folinas et al., 2002).

Mobile B2E applications have the greatest value to employees that are constantly working remotely from their base of operations and need the support of information and communications technologies (ICT) in order to accomplish their specific business tasks in real-time. Employees must be able to update and retrieve information seamlessly (Basole, 2005, Barnes et al., 2006, Oliva, 2002, Walker et al., 2006).

Mobile B2E is known to provide a number of benefits to organizations (Scornavacca et al., 2006b, Basole, 2005, Barnes et al., 2006, Walker et al., 2006). Previous studies examining the impact of mobile B2E applications in New Zealand observed an overall improvement on individual and organizational performance generated by the enhancement of information accuracy and flow (Barnes et al., 2006, Walker et al., 2006). However, these authors also found that the development of mobile solutions has been limited to the improvement of existing processes, and is quite dependent on the performance of mobile networks and bandwidth availability.

The Real-Estate industry plays a significant role in a country's economy (Seiler et al., 2001). Traditionally, the industry has made its contributions through the ability of handling and transferring Estate specific knowledge and information (Crowston et al., 2001). This traditional model is being challenged by the threat of disintermediation, brought on by the emergence of new technologies, like the Internet. As a result, the focus has shifted from sole information handling to providing value adding services in coordination with information transfers (Muhanna and Wolf, 2002).

METHODOLOGY

The purpose of this study is to gain insight into the strategic value of emerging mobile technologies in the New Zealand Real-Estate industry. The study follows multiple qualitative case study method (Benbasat et al., 1987, Creswell, 2003). The selection of case research as the research method is appropriate since this study investigates an area where theories are at formative stages and little research has been completed up to date. In addition, case study is particularly useful in this instance since practice-based problems and emerging technologies are the focus of the investigation (Benbasat et al., 1987, Orlikowski and Baroudi, 1991, Yin, 1994).

Participants were selected through a convenience sampling strategy (Paré, 2004). In order to capture different perspectives within the Real-Estate industry, a total of six participants from distinct organizations were selected for this study: four of them representing Real-Estate agents and agencies, one representing the industry association, and one representing a telecommunication provider.

Participant 1 is a resource manager of the Real-Estate Institute of New Zealand. Some of her responsibilities include promoting the industry, providing expert advice and support to institute members. Due to her role at the Institute she is able to provide a valuable and broad view of industry in regards to the elements investigated in this research.

Participant 2 is a mobile solutions specialist at a leading New Zealand telecommunications provider. While representing one of the technology providers, she is also able to relate to specific issues of the Real-Este industry - she is responsible for the nationwide corporate account a major Real-Estate company in New Zealand.

Participants 3, 4, 5 and 6 split their time as Real-Estate agents and branch managers of four Real-Estate agencies located in three major NZ cities. They provide valuable insights from the front-line since they still work as agents while being responsible for running the local branch as well as managing the sales people.

A interview protocol was developed and validated (Benbasat et al., 1987, Creswell, 2003). The final protocol contained twenty-five open ended questions which aimed to:

- Gain an understanding of the background of the interviewee
- Gain an understanding of the organization that she/he represents
- Identify mobile applications currently in use in the organization and industry
- Identify key benefits and inhibitors for mobile applications at an individual and organizational levels
- Explore the perceived impact of mobile technologies in the Real-Estate industry
- Identify suitability of advanced mobile applications
- Explore the perception of the future of mobile application in the Real-Estate industry

The data collection was carried out primarily through semi-structured interviews. Each interview lasted between 40 minutes and 50 minutes. The interviews were recorded on audiotape and supplementary field notes were made during the interviews. Some supplementary data was collected through supporting documents volunteered by the interview participants. The content of the interviews were transcribed and the data analysis was carried out using a matrix (Creswell, 2003, Miles and Huberman, 1994).

RESULTS

In this section, the results are presented. Initially, the perceptions regarding the business benefits and challenges at the organizational/industry level are explored. This is followed by an analysis of the current and potential benefits of mobile technologies at the individual level (agent). Finally, the Mobile Enterprise Model (Barnes, 2003) is used in order to examine the strategic value of mobile technology in the Real-Estate industry.

Business Benefits and Challenges

The results indicate that the device of choice in the NZ Real-Estate industry is the standard mobile phone, which is mostly used for voice communications and occasionally to send and receive short-messages (SMS). The use of smart phones and internet enabled PDAs still is moderate despite its potential usefulness for a number of routine tasks accomplished the agents (e.g. scheduling and accessing information).

Despite the low use of data applications, the interviewees indicated that mobile technologies are allowing agents to better meet information requirements in the selling process as well as information demands of clients.

The core perceived business benefits generated by mobile applications that emerged in the interviews are illustrated in Table 1. Each perceived business benefit is further classified accordingly to its predominant effect at the strategic or operational level.

Overall, the main benefit being provided by the use of mobile technologies refers to the enhancement of the information flow in the organization which is a critical success factor in this type of business.

Taken as a whole, industry representatives and branch managers' perceptions are mostly similar in regards to the use of mobile applications – focusing on the ability to connect stakeholders. However, participants 1 and 2 had more positive views regarding the strategic value of mobile technologies. They (1 and 2) highlighted strategic benefits such as allowing organisations to nurture their market share and enabling new services in order to gain a competitive edge.

Table 1. Key business benefits

Benefits	Strategic/ Operational	
Expanding market share	X	
Improved customer service		X
Information flow	X	X
Streamlining business processes	X	
Efficiency		X

All participants shared similar views regarding the main challenges holding the full deployment of mobile applications within the industry. The following issues were identified:

- **Development of Value Adding Mobile Applications and Partnerships –** There is a clear need for applications that are easy to use and closely tied to business processes as well as focused on core business functions. Identifying suitable hardware, software and application areas that suit industry specific needs are currently some of the major challenges for the full deployment of mobile technologies in the Real-Estate industry. Although having a strong understanding of the capabilities of their own products and services, software developers as well as telecommunications providers seem to have a limited knowledge of the Real-Estate industry and how to leverage their offerings to that industry. Perhaps partnerships among key-players at the industry level could enable specific applications to be developed and supported throughout the value-chain. Such initiative could perhaps change the current perception of one of the branch managers interviewed:

> *Technology can prove as a great source of procrastination, it actually distracts salespeople from what they should do. You sit around playing with gadgets that don't particularly streamline your business.*

- **Costs:** The costs associated with utilising mobile technologies have high implications at the organisational level. One of the branch managers said:

Calls are huge cost to us, our telecommunications bill is huge, and you could say it's a cost of business, but unfortunately at the moment, it is a big cost to our business.

It was noticed that perceptions regarding the cost of mobile technologies can certainly hinder an organisation's desire to explore further solutions in this arena. In addition, investments in technology were commonly seen as a risk.

- **Network Connectivity:** The majority of participants interviewed expressed some concerns regarding network connectivity. One of the branch managers pointed out:

We've got a person in the office who was on the "X" network. She lives in a suburb with poor coverage from "X". As result she's just flicked to the competitors' network…". Participant 2 reinforced this notion by saying: "People seem to want coverage in every single lift there is, and wherever their car happens to be….

Individual Benefits and Challenges

Results have shown that mobile applications are adding value to the day-to-day business of agents. Improving communication, information access as well as enabling them to address time sensitive issues. Overall, the use of mobile technologies is perceived as a factor to increase individuals' productivity.

The perceived key benefits of mobile technologies to agents are listed in Table 2. It was also identified which benefits are perceived as already in place and which of them are mostly seen as "potential benefits".

The mobile nature of Real-Estate agents means that a large proportion of their time is spent away from the office. Agents can easily lose touch with the occurrences at the office, leading to a lag of communicating critical information. One of the managers highlighted:

Table 2. Key individual benefits

Benefits	Current	Potential
Reachablility	X	
Data access		X
Image	X	
Information accuracy		X
Improved communications	X	
Improved customer service	X	
Increased productivity	X	
Personalisation of services		X
Improving business processes	X	

in this game you need to be ready to run, a phone call could be worth $10000 to you.

Undoubtedly, the interviewees noted that the advent of mobile technologies has meant that agents are able to leave the office, while retaining a level of contact with the organization as well as key stakeholders (buyer and vendors). Even though the use of mobile technologies is perceived as currently enabling core benefits to the agents, it is still mostly seem as an area "full of potential" for further developments.

The participants have identified the following challenges to be overcome in order to have a wider adoption of mobile data services by individuals operating in the Real-Estate industry.

- **Perceived Cost/benefit:** For an agent, the costs are mostly associated with the purchase of hardware and network connection. The participants shared the opinion that mobile technologies are simply seen as a part of business expenses instead of a strategic factor of competitiveness. The opinions regarding costs are commonly associated to frustration and decisions to adopt a certain technology are usually made on the basis of the lowest cost instead of best cost/benefit ratio.

- **Training**: it was identified that the majority of sales consultants have not come from a technical background and many of them may require one-on-one assistance in overcoming the learning curve for utilizing the new technologies. A manager indicated:

We've got a reasonably aging population in sales consultants, so technology is something that they're trying to embrace and it's not something that is obviously natural to them.

If appropriate training was not undertaken by the agents, mobile applications were deemed to be underutilized – or not used at all.

- **Usability:** Display size and input methods were the main challenge identified by the interviewees in regarding the usability of mobile technologies.
- **Traditions of the Real-Estate industry:** There is a strong focus in the industry to foster relationships and development of social networks, and closing sales face-to-face. A participant pointed out "

real-Estate doesn't happen on the computer or on the phone. You have to get in people's faces.

Another manager said:

I've sold real Estate for a number of years and I don't sell anymore now than I did 15, 16 years ago and I didn't have all the bells and whistles then.

Although there was an agreement that mobile technologies can enhance business processes, there was still a strong belief that the 'qualities of a salesperson' cannot be changed or assisted effectively through the utilisation of mobile technologies.

The potential widespread adoption of mobile technologies in the Real-Estate industry relies mostly in the hands of the agents - as a branch manager commented:

We (agency) don't typically impose anything on our staff when it comes to technology, they'd either see that it is meaningful and useful, or they won't use it. If you impose it on them, and they don't see any value in it - they won't use it anyway.

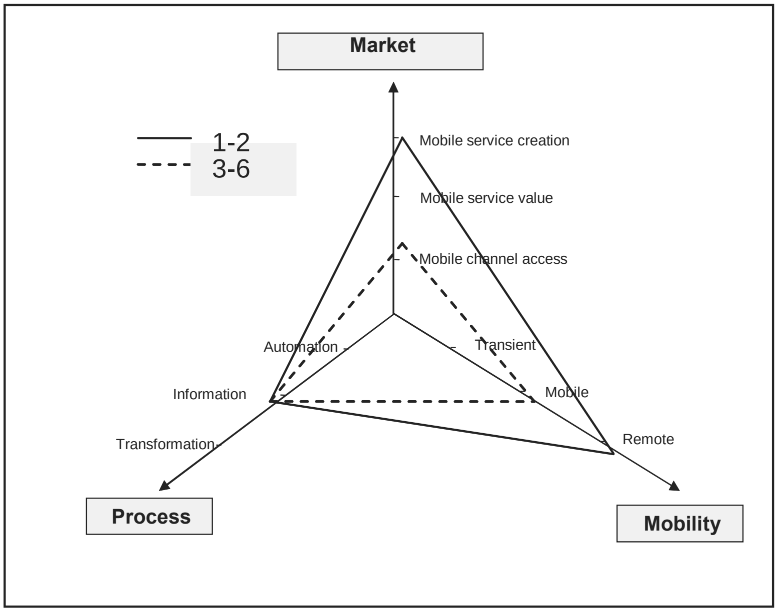
Enterprise Mobility

Based on the previous analysis of business benefits and challenges the mobile enterprise model (MEM) (Barnes, 2003) can be used to identify the strategic value of mobile applications. The MEM achieves this by mapping businesses against three axes: mobility, process, and market (Figure 1).

Mobility measures the location dependence of workers, including transient (tied to specified locations), mobile (increased independence with periodic location specific needs), and remote (almost completely independent from a specified location). From the perspectives of Participant 1 and 2, the level of geographic dependence for the agents are extremely low and salespeople have the ability to be almost completely removed and independent from the office. Mobile technologies can provide agents with remote linkages into corporate information systems allowing higher degrees of freedom from the office. From the branch manager perspective, mobile technologies are allowing salespeople to have geographic independence for prolonged periods of time - however there is still a need of "a base of operations" for a number of business processes.

Process maps the business transformation as a result of the introduction of mobile technologies. It can be classified in three levels: automation, information and transformation. The NZ Real-Estate industry appears to have barely reached the "information level". Developments such as the use of mapping systems to enable remote

Figure 1. Mobile enterprise model



agents to access and display properties images as location could certainly support the existing processes and improve service delivery.

Market maps the value propositions, starting with mobile channel access (use as a channel for information access), mobile service value (adding value to market offerings) and finishing with mobile service creation (use of entirely new offerings). Participants 1 and 2 see the potential for m-applications to allow for mobile service creation, using mobile applications to create entirely new services. However, participant 1 felt that such development may be not valued by agents. The branch managers focused on mobile channel access. However, they expressed some indication of the value that new mobile services may have to their business and to gains of competitiveness. The differences in perspectives of enterprise mobility are illustrated above in Figure 1. Participants 1 and 2 are represented by the solid line while participants 3-6 are indicated by the dashed line. It is clear from the illustrations that participants 1 and 2 have a more positive perception of the strategic value of mobile technologies.

CONCLUSION

The distributed nature of the work of Real-Estate agents as well as the intensive use of time sensitive information makes this industry a primary candidate for the deployment of mobile technologies. This study aimed to investigate the perceptions of key-industry players towards the strategic value of mobile technologies in the Real-Estate industry in New Zealand.

The participation of six organizations representing Real-Estate agencies as well as the industry association and one of the main telecommunications providers allowed us to capture different views and realities regarding the applications of mobile technologies in this industry.

This study was able to identify current and potential benefits that mobile technologies may provide to this industry. In addition it was also able to identify the current challenges that inhibit a wider uptake of these technologies.

It was found that despite the wide availability in NZ of advanced mobile technologies such as laptops with wireless capabilities, PDAs' and smart-phones, most agents are only using standard mobile phones for voice communications.

The prevailing perceived business benefits derived almost exclusively from the ability to access the mobile channel, aiming for efficiency gains and improving customer service. However, there were challenges such as cost, network coverage, the identification and development of industry specific mobile application as well as nurturing partnerships across the industry value chain.

At the individual level, perceived benefits surrounded the ability to be constantly able to reach and to be reached by other parties involved in the sales process. Cost, training and tradition of business practices appeared as barriers for the adoption of mobile data services.

The perceptions captured in this research indicate that there was a consensus among participants that mobile technologies play a vital role in the Real-Estate industry. However participants' opinions were quite divergent regarding to what extent there is room for further development.

Although there was agreement that mobile technologies can enhance business processes there was still a strong perception that the 'qualities of a salesperson' cannot be changed or assisted effectively through the utilisation of mobile technologies. Some perceptions indicate that many agents believed that relying too much on technology could be risky. In addition, there was a clear belief that the salesperson's role is about building networks and relationships with clients and associates. Therefore the perceived strategic value and enthusiasm for adopting mobile technologies could be diminished by long standing traditions and business practices of the Real-Estate industry.

Most of the technology adopted by the branches (and agents) was not guided by a strategic planning. As a manager commented they are adopted on a *"need to survive basis"*. This makes it evident that 'catching up' with technology is a common practice instead of outlining a strategy towards the adoption of new technology. Even for the more pro-active adopters there was a feeling of risk of being overwhelmed by technology.

Above all, this study provides an interesting initial point of discussion for the current literature in mobile business. Previous studies (Varshney et al., 2004, Beulen and Streng, 2002, Muhanna and Wolf, 2002, Yuan and Zhang, 2003, Barnes, 2002, Barnes, 2004, Kadyte, 2004, Tollefsen et al., 2004, Basole, 2005) suggest that an industry that has qualities such as intensive information requirements, distributed workforce as well as time sensitive processes would be a primary candidate for a successful deployment of mobile technologies. However, contrary to some of the literature, this study found that despite the fact that the New Zealand Real-Estate industry possesses the qualities abovementioned, a full deployment of mobile technologies is still bounded by its tradition of business practices.

The findings described in this research, while generalizable to its peculiar context, must be closely scrutinized in their application to other contexts. The research was conducted at a singular point in time and consisted of only one round of data collection with six participants. The results were drawn solely from the interviewees' perspectives and thoughts.

Future research should aim to widen the current scope of this research focusing on the individual level. A longitudinal study is also suggested in order to understand the sustainability of benefits and how they change over time. Research efforts could also explore the effect of mobile technologies on individuals' performance.

Chapter 3.17

Group Support Systems as Tools for HR Decision Making

James Yao
Montclair State University, USA

John Wang
Montclair State University, USA

INTRODUCTION

In the late 1960s, a new type of information system came about: model-oriented DSS or management decision systems. By the late 1970s, a number of researchers and companies had developed interactive information systems that used data and models to help managers analyze semistructured problems. These diverse systems were all called *decision support systems* (DSS). From those early days, it was recognized that DSS could be designed to support decision-makers at any level in an organization. DSS could support operations, financial management, and strategic decision making.

Group decision support systems (GDSS) which aim at increasing some of the benefits of collaboration and reducing the inherent losses are interactive information technology-based environments that support concerted and coordinated group efforts toward completion of joint tasks (Dennis, George, Jessup, Nunamaker, & Vogel, 1998). The term *group support systems* (GSS) was coined at the start of the 1990s to replace the term GDSS. The reason for this is that the role of collaborative computing was expanded to more than just supporting decision making (Patrick & Garrick, 2006). For the avoidance of any ambiguities, the latter term shall be used in the discussion throughout this article.

Human resources (HR) are rarely expected like other business functional areas to use synthesized data because HR groups have been primarily connected with transactional processing of getting data into the system and on record for reporting and historical purposes (Dudley, 2007). For them soft data do not win at the table; hard data do. Recently, many quantitative or qualitative techniques have been developed to support human resource management (HRM) activities, classified as management sciences/operations research, multiattribute utility theory, multicriteria decision making, ad hoc approaches, and human resource information systems (HRIS) (Byun, 2003). More importantly, HRIS can include the three systems of expert systems (ES), decision support systems (DSS), and executive information systems (EIS) in addition to transaction processing systems (TPS) and management information systems (MIS) which are conventionally accepted as an HRIS. As decision support systems, GSS are able to facilitate HR groups to gauge users' opinions, readiness, satisfaction, and so forth, increase their HRM activity quality, and generate better group collaborations and decision makings with current or planned HRIS services. Consequently, GSS can help HR professionals exploit and make intelligent use of soft data and act tough in their decision-making process.

BACKGROUND

In the early 1980s, academic researchers developed a new category of software to support group decision making. Execucom Systems developed Mindsight, the University of Arizona developed GroupSystems, and researchers at the University of Minnesota developed the SAMM system (Power, 2003). These are all examples of early group support systems. "A Group Support System could be any combination of hardware and software that enhances group work. GSS is a generic term that includes all forms of collaborative computing" (Turban, Aronson, & Liang, 2005, p. 374). The increased need for GSS arises from the fact that decision making is often a group phenomenon, and therefore computer support for communication and the integration of multiple inputs in decision support systems is required. The desire to use GSS therefore comes from the need of technological support for groups.

GSS are designed to remedy the dysfunctional properties of decision-making groups, such as groupthink, lack of coordination, information overload, concentration block, and so forth. These systems are becoming popular in aiding decision making in many organizational settings by combining the computer, communication, and decision technologies to improve the decision-making process. These systems use a key tool to improve the quality of decisions made by a group. This key tool is the anonymity of members of a decision-making group. The purpose of GSS is to maximize the benefits of group work while minimizing the dysfunctions of group work. This maximization and minimization can be made possible by GSS mainly by two factors: anonymity and parallelism.

MAIN FOCUS

Strengths and Weaknesses of GSS

GSS provide support for communication, deliberation, and information flow especially for group activities that may be distributed geographically and temporarily. Group work has numerous benefits and advantages. First, groups are better at understanding problems and catching errors than individuals (Korpela, Sierila, & Tuorninen, 2001; Kwok & Khalifa, 1998). Second, a group has more information than any one member which when combined can create new knowledge. Third, working in a group stimulates creativity and synergy. Finally, groups balance out the risk-tolerant and risk-averse. GSS offer many benefits. First, GSS support parallel information processing, parallel computer discussion, and generation of ideas. Second, they promote anonymity, which allows shy people to contribute and helps prevent aggressive individuals from driving the meeting. Finally, these systems help keep the group on track and show the big picture. The two keywords here are parallelism and anonymity (Turban et al., 2005).

Some of the potential dysfunctions of group work are not automatically eliminated by GSS: first, groupthink, as suggested above, where people begin to think alike and not tolerate new ideas; second, lack of coordination, excess time consumption, poor quality solutions, and non-productive time; third, duplication of efforts and high cost of meetings, including travel; and finally, information overload, concentration blocking (disturbance from inappropriate influences, free-riding discussions), and group misrepresentation (improper or badly chosen groups) can be added as the potential dysfunctions of group work. Process dysfunctions are caused by structural characteristics of the group setting that could hinder a group from reaching its full potential. Process dysfunctions hinder productivity because of unequal participation or unequal air time. This happens in a setting where only one person can take control of the floor. This sort of dysfunction can be countered by the use of computerized exchanges because people may enter their comments and thoughts simultaneously. Power (2003) utters that simultaneous expression of ideas may be beneficial to the quantity of ideas generated. This is because computers have the capacity for concurrency. Finally, process dysfunctions are usually caused by limitations in the structure and forms of meetings.

Social dysfunctions, as Power (2003) describes, can hinder group productivity through undesirable social processes that occur in the group. Social processes refer to those activities, actions, and operations that involve the interaction between people (De Millo, Lipton, & Perlis, 1979; NASA, 1996). For example, a group may limit the quality and quantity of input from any of its members by social processes such as evaluation apprehension, conformity pressures, free riding, social loafing, cognitive inertia, socializing, and domination due to status imbalance, groupthink, and incomplete analysis. These problems arise from processes present in all groups and are rooted in the ways in which group members change their behavior to adapt to the group. Finally, the prevalent analysis of group decision making is that social influences within the group lead the rational individual astray.

The view of GSS portrayed by Power (2003) is that they are text-based tools made with the purpose of remedying some problems of decision making in copresent groups. These systems claim to remove the social obstacles that prevent individuals from attaining their full potential in the group. Anonymity is central to achieving this full potential of individuals in a group. Shy people tend not to speak in a group discussion face-to-face. This hinders them from contributing to the group. GSS solve this problem by allowing these individuals to evade their shyness in the public and input their contributions through individual human computer interaction devices, thus achieving the goal of removing this social obstacle from these individuals and facilitating them to reach their full potential in the group. Meanwhile, the systems help prevent aggressive individuals in the group from driving the meeting, which is typically a potentially intimidating source to the shy people in a group.

Recent GSS Research Findings

Decision making in an organization today has become more the work of some form of group. Whether this group is a board, team, or a unit, important issues can be at stake. It is fair to ask, given the possible problems that occur in a group setting: Would the group setting have a negative effect on the quality of decisions that have to be made by the group? Current research in this area suggests that GSS, if implemented and used correctly, can improve the quality of group decision making significantly by minimizing the negative effects of group decision making and by maximizing the benefits of group collaboration and decision making. GSS have come a long way since their inception. Current and previous research efforts have made significant findings on the effects of the numerous criteria that affect the decision-making process in a group setting while using GSS. The results show that while the Internet has made it easier and less costly to use GSS than ever before, the social effects of group decision making can have a significant effect on the quality of decisions made in a group setting using GSS. By manipulating things such as visual cues, group vs. individual-based incentives, anonymity, group size, feedback, leadership role, communication mode, type of tool used, social presence (degree of personal connection in communication settings) (IJsselsteijn, 2003; Markopoulos et al., 2003; Nowak, 2001), face-to-face vs. distant, shift work or nonshift work, the fit between facilitation style and agenda structure, and finally, a relationship vs. a task focus, it is possible to significantly impact the quality of decisions made by a group using GSS.

According to Barkhi, Jacob, and Pirkul (2004), GSS are divided into two groups: distributed GDSS (DGDSS) and face-to-face GDSS (FGDSS). DGDSS groups consist of members who use GSS at the same time but at different places. On the other hand, FGDSS groups consist of members who use GSS at the same time and same place. The authors studied and compared the decision process and outcomes of groups that use FGDSS to those that use DGDSS. The results indicate communication mode and incentive structure can influence the effects of each other. Therefore, the appropriate design of incentive structures may be important to the success of virtual organizations.

The Web-based multicriteria group support system (MCGSS), according to Lu, Zhang, and Wu (2005) and Zahir and Dobing (2002), is designed so that users can enter their preferences in an easily understood and user-friendly interface through a Web browser. They state that easy-to-learn and user-friendly interfaces are essential if GSS are to become more commonly used in organizational decision-making and that MCGSS uses a new visual mode of preference entry. The relative importance of any two objects is expressed through a pair of side-by-side bars drawn in a graphical window. The ratio of the heights of two bars represents the user's relative preference for the two objects. Bar heights can be adjusted dynamically by dragging the mouse or utilizing some other device. Their article presents the design of a Web-based MCGSS that can be used by a group of geographically dispersed decision makers. This system takes advantage of Internet technology and enables a novel procedure to aggregate intensities of preferences.

In line with Kim (2006), the role of leadership facilitates group processes by adding structure to group interaction. The effects of leadership on group performance in GSS settings still remains one of the least studied areas of GSS research. An analysis of comments by group leaders show that they are more efficient when making comments on group objectives and interaction structure, but this is only true in the early stages of group interaction. In the later stages, it is of increasing importance that group leaders make comments that encourage interaction and maintain cohesion between members of the group. Dennis and Wixom (2001/2002) present a meta-analysis investigating five moderators. These moderators are as follows: tool, the type of group, task, the size of the group, and facilitation. The authors studied their effects on GSS. Results of the study draw multiple conclusions. First, process satisfaction is less for decision-making tasks than it is for the idea-generation tasks. Second, the GSS tool itself influences decision quality. Finally, the authors conclude that group size is an important moderator when it comes to measuring satisfaction with the process and decision time.

Rutkowski, Fairchild, and Rijsman (2004) demonstrate experimentally that in the context of dyadic conflict, patterns of interpersonal communication, supported by a particular group support system technology, affect the quality of decision making. The authors found that GSS are efficient tools that support intergroup communication and relations. The authors also delved further into this topic and discussed the implications of their research on the study of intercultural negotiation and conflict resolution. They observed that groups are becoming increasingly important in organizations and that intercultural negotiation and conflict resolution use electronic groupware to facilitate communication and workflow. Barkhi (2005) compared the performance and information exchange truthfulness of groups under these various experimental conditions. The author utilizes a game theory perspective to study the behavior of members in these groups. The results indicate that communication channel and incentive structure mitigate strategies that lead to decision choices and information exchange truthfulness among members in a group.

GSS can improve communication and learning as demonstrated by Bandy and Young (2002). Their study examined the impact of two collaborative technologies and a priming agent upon communication complexity and learning style in a group decision-making context. Their findings revealed that communication complexity was significantly greater in groups using GSS compared to groups using simple chat systems, suggesting that characteristics of the GSS served to structure discourse among group members. Burke (2001) examined how GSS learning environments (face-to-face vs. distant) and task difficulty level (simple vs. difficult) influenced participation levels and social presence among accounting students working collaboratively on an accounting task.

Hostager, Lester, Ready, and Bergmann (2003) examined the effects of agenda structure and facilitator style on participant satisfaction and output quality in meetings employing GSS. This study indicates that GSS facilitators should try to find a fit between their facilitation style and the agenda structure, while not forgetting to adopt either a relationship or a task focus and ensuring that they are consistent with their choice. GSS are designed as an analysis tool to support the decision processes of a group. Inherent in the design is the developer's desire to make the basic meeting process better either by increasing process gains or reducing process losses. Further, it is suggested by Martz and Sheperd (2003) that one way that GSS attack these losses is by providing immediate feedback.

GSS IN THE REAL WORLD

There are three options for setting up GSS technologies. One of them is in a special-purpose decision room, another is at a multiple-use facility, and the third is a Web-based groupware with clients running wherever the group members are.

Facilitating Meetings

One example of the use of GSS is the system developed by a group of researchers at the University of Arizona to facilitate the organization of meetings. A typical meeting room consisted of a microcomputer for each participant, as well as a large projector for the display of either individuals' work or the combined results of the group efforts. A typical meeting is composed of a three-tier process consisting of electronic brainstorming, idea generation, as well as voting. Under the electronic brainstorming phase, all group members typed at separate terminals using electronic brainstorming software, and recorded their ideas regarding questions posed for the day. Even though these sessions were anonymous, everyone could see the abundance of ideas. Additionally, an issue analyzer assisted the group in identifying and consolidating key ideas generated from the idea generation. Lastly, a voting tool provided various methods for prioritizing key terms. Here, even though voting is anonymous, the results are readily displayed for all to view. This group support system by Nunamaker, Briggs, Mittleman, Vogel, and Balthazard (1996/1997) was used at an IBM site. It was found that process structure helps focus the group on key issues and discourages irrelevant digressions and unproductive behaviors.

Web-Based GSS

A Web-based decision support system (DSS) is a DSS built with Web technologies so that the DSS users access with Web browsers through an Internet connection. In addition, Web-based DSS applications that are developed by companies may be deployed on company intranets to support internal business processes or can be integrated into public corporate Web sites to enhance services to trading partners (Power & Kaparti, 2002).

Most Web-based DSS are currently individual DSS systems (Bharati & Chaudhury, 2004). On the contrary, Web-based GSS provide a broader approach to solving complex problems that are less structured. As noted earlier, there are a few Web-based GSS and one of them, GroupSystems, is a local area network-based client-server that exists for online collaboration. Several commercially available Web-based GSS products also contain decision-making tools. These products provide support to the group decision-making process with tools that facilitate brainstorming, idea generation, organization, prioritization, and consensus development (Facilitate.com, 2006).

Distance Learning

Several courseware packages that have GSS functions facilitate distance learning. They range from such tools like Blackboard, through Microsoft NetMeeting, to PlaceWare Virtual Classroom. Distance learning, as a tool, can be an effective part of GSS. Many corporations have taken advantage of it mostly through Web-based streaming and other private company intranets. Distance learning, therefore, can act as a strong collaborative and knowledge management tool in GSS, with a distinctive feature, namely, being accessible every hour of the day.

GSS for Political Events

The multifaceted use of GSS is reflected in the dynamism inherent in organizational structures. For instance, political risk associated with corporations' decisions to expand internationally could be alleviated using GSS. This is because the key to analyzing political events is obtaining good information about these events. GSS thus provide higher reliability in accessing this needed information, through anonymity, simultaneity (may apply only to certain types of GSS), and documentation, features that are lacking in face-face interactions. Among other advantages, anonymity offers participants a greater degree of freedom in expressing their thoughts, and presents them with a greater sense of confidence to be more critical. Blanning and Reining (2005) suggest a two-characteristic framework depending on whether analysis of the event under consideration is static or dynamic, as well as whether the analysis is one-dimensional or multidimensional.

FUTURE TRENDS

GDSS is transforming into GSS and the same ideology used for enhancing group meetings is being used in other areas as well. The idea is not just to increase the effectiveness of decision making, but to incorporate the current improvements in communication technology to redefine collaboration. Anonymity is also becoming more and more widespread in this new Internet culture; its effects on collaboration are very interesting as discussed (e.g., allowing shy people to contribute and helping prevent aggressive individuals from driving the meeting). The findings presented in this article uncover the social effects that might affect group work. These findings can also be applied to other fields in which collaboration is experiencing growth as in education and social networking. By combing the Internet, emerging technologies, and the findings in social behavior as they relate to group work, with the exploding growth currently being experienced in communication, the results and the rate of introduction of new ways of collaborating will be absolutely amazing.

CONCLUSION

GSS, if implemented and used correctly, can improve the quality of group decision making significantly by minimizing the negative effects of group decision making and by maximizing the benefits of group collaboration and decision making. GSS have come a long way since their inception. Current and previous research efforts have made significant findings on the effects of the numerous criteria that affect the decision-making process in a group setting while using GSS. The results show that while the Internet has made it easier and less costly to use GSS than ever before, the social effects of group decision making can have a significant effect on the quality of decisions made in a group setting using GSS. By manipulating things such as visual cues, group vs. individual-based incentives, anonymity, group size, feedback, leadership role, communication mode, type of tools used, social presence, face-to-face vs. distant, shift work or nonshift work, the fit between facilitation style and agenda structure, and finally, a relationship vs. a task focus, it is possible to significantly improve the quality of decisions made by a HR group using GSS.

KEY TERMS

Distributed Group Decision Support Systems (DGDSS): Groups consisting of members who use a GDSS at the same time but at different places.

Face-to-Face Group Decision Support Systems (FGDSS): Groups consisting of members who use a GDSS at the same time and same place.

Group Polarization: The tendency of people to become more alike or extreme in their thinking following group discussion. It is also the phenomenon that is generally considered decision bias.

Group Support Systems (GSS): Can also be referred to as group decision support systems (GDSS). GSS is any combination of hardware and software that enhances group work. GSS is a generic term that includes all forms of collaborative computing.

Multicriteria Group Support Systems (MCGSS): GSS designed so that users can enter their preferences in an easily understood and user-friendly interface through a Web browser. Multicriteria is a linguistic term oriented fuzzy group decision making method which allows the group members to express their power, favor, and judgment in linguistic terms. See Lu et al. (2005) for reference of the model.

Social Presence: The degree to which people establish warm and personal connection with each other in a communication setting. Changes in the level of social presence can affect group communication.

Time/Place Framework: A framework for classifying IT communication support technologies. The matrix consists of four possibilities: same time/same place systems, same time/different place systems, different time/different place systems, and different time/same place systems.

ABSTRACT

This study proposes a new methodology that facilitates organizational decision support through knowledge integration across organizational units. For this purpose, this study develops a decision support loop and explains how to organize individual knowledge related to a specific business problem and formulate and test the organized knowledge using cognitive modeling techniques for decision support. This study discusses the proposed approach in the context of an application case involving a beverage company. The application case shows the validity and usefulness of the proposed approach.

INTRODUCTION

Knowledge management (KM) can be defined as the uncovering and managing of various levels of knowledge within individuals and teams and within an organization. The aim of KM is to improve organizational performance. One of the prerequisites for successful KM is an appreciation of what Nonaka (1994) described as “tacit” knowledge. Effective KM requires such “tacit” knowledge to be transformed into “explicit” knowledge and then organized accordingly (Brown & Dugid, 1998). Integrating individual knowledge from diverse areas into organizational knowledge leads not only to new knowledge but also to new understanding (Cai, 2006; Huber, 1991; Siau 2000). This in turn helps decision makers choose the appropriate action to achieve organizational goals (Brown & Dugid, 1998; King, 2006; Stein, 1995).

However, competitive advantage results from applying knowledge, rather than knowledge itself (Alavi & Leidner, 2001). However, most KM research (Davenport, De Long, & Beers, 1998; Grover & Davenport, 2001; Kankanhalli, Tan, & Wei, 2005; Lee & Kim, 2001; Sambamurthy & Subramanu, 2005; Xu, Tan, & Yang, 2006) has focused on identifying, storing and sharing knowledge for efficient and effective transaction processing. There has been little research into the application of organizational knowledge or KM in the core business management tasks of decision making and strategy development. Yet the scope of knowledge application in these top-level tasks is organization wide. Knowledge application at this level, therefore, would influence organizational performance even more than knowledge management in transactions processing, where the scope is more localized. The research gap shows the need to shift the focus away from obtaining and storing knowledge to using it appropriately for business decision making.

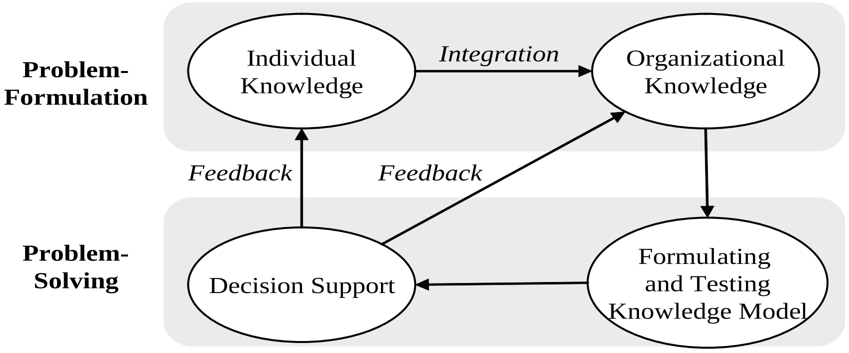
Based on the research needs outlined above, this study aims to propose a new methodology for organizational decision support through knowledge integration across organizational units. Bridging the gap between having knowledge and using it is a very valuable endeavour, both for theorists from the descriptive perspective and for practitioners from the normative perspective. For this purpose, this study develops a decision support loop. The developed decision support loop explains (1) how to organize individual knowledge related to a specific business problem using cognitive modeling, and (2) formulate and test the problem reflected in the organized knowledge using cognitive matrix and causal path identification for decision support. We apply the proposed approach to a decision support case of a beverage company. The application case shows the validity and usefulness of the proposed approach.

This paper is organized as follows. First, we propose a decision support loop formed by integrating individual knowledge as it resides in mental models into an organizational model. Next, we compare the approach of this study with other approaches. We then discuss the proposed model based on its application to a real-world managerial problem.

DECISION SUPPORT THROUGH KNOWLEDGE INTEGRATION

This study proposes a decision support loop through knowledge integration across multiple knowledge sources, as illustrated in Figure 1. Based on an identified managerial problem, individual knowledge is gathered and then integrated into organizational knowledge, which captures

Figure 1. Decision support loop



and defines the problem. This constitutes the problem formulation phase. Managerial problems commonly entail two stages in their resolution: problem formulation and problem solving (Smith, 1989). To provide a linkage between knowledge integration and decision support, the organizational knowledge model is formulated and tested, and then decision guidelines are generated based on the knowledge model. This constitutes the problem-solving phase.

To facilitate this decision support loop, we propose a cognitive modeling methodology. Table 1 illustrates an overview of the proposed methodology. We will discuss the goal, tasks, and details of each step in the following sections.

Individual Knowledge

Knowledge is useful only when it is related to a target task or problem. If the knowledge is not helpful in a given situation, it can be deemed not knowledge at all in that situation, even though it might be in another situation. Individual knowledge means individual and partial mental model knowledge related to the target problem. As a way for capturing knowledge, cognitive modeling has been used to represent relationships that are perceived to exist among the attributes and/or concepts of a given environment or problem (Eden, 1988; Fiol & Huff, 1992). The cognitive modeling method thus can be applied to capture individual (departmental) or partial knowledge (Lenz & Engledow, 1986).

As one of the tools for cognitive modeling, the cognitive map has been widely used in previous research (e.g., Axelrod, 1976; Siau & Tan, 2005, 2006; Zhang, Wang, & King, 1994). Cognitive mapping techniques are known as effective tools to elicit and represent human cognition (Siau & Tan, 2005). In this study, the cognitive map is represented in matrix as well as diagram forms. Diagram representation is used for capturing cause-effect relationships in an organization because it is relatively easy to see how each of the causal factors relates to each other. Matrix representation is used for identifying the most

Table 1. An overview of a cognitive modeling methodology for the decision support loop

Step	Objective	Task	Details
Individual knowledge	Lower-level cognitive model generation	Specify goals Identify causal factors Identify causal connections	Use brainstorming, interview, document analysis, and survey
Organizational knowledge	Higher-level cognitive model generation	Integrate lower-level cognitive models	Link maps based on common causal factors Resolve discrepancies through meetings
		Assign causal values	Use an eigenvector assignment algorithm
Formulating/testing knowledge model	Identification of significant causal paths	Identify causal impact paths and compute the causal values	Use a causal path computation algorithm
Decision support	Identification of core factors	Identify the most positive/negative impact factor for the organizational goal	Compute the most positive/negative impact value for the goal factor
	Identification of core business activities	Identify the path that makes the most positive impact factor stronger	Compute the largest path value for the most positive impact factor
		Identify the path that makes the most negative impact factor weaker	Compute the smallest path value for the most negative impact factor

effective causal path because it is convenient to apply a mathematical algorithm.

A prior cognitive model or belief structure shapes each department's interpretation of information, and affects its decision making or task processing (Huber, 1991). These cognitive models vary across organizational units, depending on their different responsibilities and viewpoints. For example, the marketing team might have knowledge regarding the way in which delays in delivery affect sales volume, but not know how such a delivery delay could be minimized. In contrast, the delivery team might know little about increasing sales but a lot about minimizing delivery delay. In this way, each team has a partial mental model or individual team knowledge about the target issue.

In this study, the cognitive model is generated through three tasks. The first task, specifying the goal, facilitates the generation of a robust cognitive map from the rest of the tasks because goals serve as guides to action (Simon, 1964). Clarifying the goal of each functional unit, therefore, helps to capture the cause-effect relationships among cognitive elements. A number of techniques can be used to generate and validate the cognitive maps of the organization: brainstorming, interview, document analysis, and survey.

Organizational Knowledge

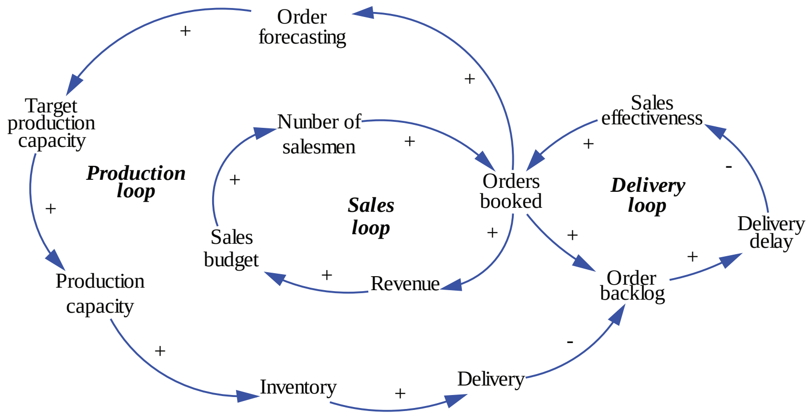
In real-world situations, not only human employees but also each functional department tends towards a silo viewpoint and understanding. Before knowledge is integrated across functional areas, each department may diagnose a business problem from its own viewpoint. Thus, each department may identify a core issue and suggest a solution without first adopting a cross-functional viewpoint. For this reason, cross-domain knowledge integration and sharing have been suggested as an important issue for KM (e.g., Hanse, 2002; Nadkarni & Nah, 2003; Nilakanta, Miller, & Zhu, 2006) and for enhancing organizational performance (e.g., Cai, 2006; Nambisan & Wilemon, 2000).

For organizational knowledge modeling, we generate an integrated global (higher-level) cognitive model by combining local (lower-level) cognitive models, which leads to a combined view for the problems. The integrated cognitive model represents the cognitive model of the group, which consists of individual departments. Local reasoning is done at each functional (operating or product) unit to form its own local cognitive model. However, global reasoning is necessary to combine local cognitive models into an integrated cognitive model. Because cognitive maps tend to impose structure on a vague situation, group members can gain a clearer understanding of problems and opportunities (Weick & Bougon, 1986).

In order to combine the local cognitive maps, we first identify the common causal factors between any two local cognitive maps, and link the maps based on these factors. Each common causal factor plays the role of a coupling device. In turn, the next local cognitive map is joined with the previous result. In this way, the combination process continues until all local cognitive maps are exhausted. While the local cognitive maps are being combined into a global cognitive map, various discrepancies between the maps might arise. In that case, these discrepancies should be detected and resolved through the meeting in which the related functional units participate in order to create a complete global cognitive map.

Integrating the different bodies of individual knowledge constitutes organizational knowledge in that a network of knowledge is produced across different areas in the organization. Organizational knowledge is a specific knowledge model related to a target concern or problem. It can also be modeled on a cognitive model. For example, for the purpose of revenue enhancement, individual knowledge from the sales, production, and delivery teams can be integrated as in Figure 2. This integrated organizational knowledge can explain many issues to the various teams. The teams can then collaborate and know how sales

Figure 2. Representation of organizational knowledge using cognitive maps



are affected by delivery delay and how they can shorten delivery delay. That is, the organizational knowledge model regarding the target issue shows all the relationships among elements across all areas, and it helps decision makers understand the problem clearly and choose appropriate actions to achieve organizational goals. As such, organizational knowledge constitutes the core competency of management.

Although teams and individuals create their respective knowledge models, work that is shared among teams calls into use separate bodies of individual knowledge and generates an organizational knowledge model as well. The organizational knowledge model becomes a basis for understanding the dynamic complexity of the target situation. It enables decision makers and subunits to understand the entire structure of the target business problem (e.g., how to increase revenue). It also helps them assess the behavioural mechanism involved, thus facilitating the choice of appropriate actions to achieve organizational goals.

Formulating and Testing Knowledge Model

For the purpose of decision support, the most important thing is to identify several decision options and validate the best option for solving the problem at hand. For this purpose, the organizational knowledge model must be translated into an analyzable form. Although cognitive maps improve communication and comprehension among their users, they may not render an organizational knowledge model adequately analyzable.

There are various ways to analyse a cognitive model. One alternative is to investigate causal paths. This aims to identify the paths leading to either causes or effects for each causal factor. For this purpose, the organizational cognitive model should be analysed in terms of the strength of the impact between causal factors. The cognitive model includes the indirect causal paths as well as the direct causal paths. Direct causal paths easily can be identified from the cognitive map, but it is difficult to do so with indirect causal paths. In addition, there are usually multiple indirect causal paths. In this context, the aim is to identify the causal paths that have the maximum causal impact among all causal paths, regardless of whether the impact is direct or indirect. To capture those causal paths, some studies have proposed methods that combine heuristic algorithms with the cognitive model (Kwahk & Kim, 1999; Zhang et al., 1994).

Table 2 illustrates how to create and analyse a knowledge model. This method is helpful in analysing the organizational knowledge model because it takes into consideration both the qualitative and quantitative aspects of the cognitive model.

Table 2. Creating and formulating a knowledge model

Objective	Task	Output	Tools
Cognitive model generation	Specify goals	Goal statement	Brainstorming Interview Document analysis Survey Eigenvector algorithm
	Identify causal factors - List all causal factors - Cluster the causal factors	Causal factor list	
	Identify causal connections - Identify the relationships between clusters - Identify the relationships between causal concepts	Cluster relationship diagram Causal factor relationship diagram	
	Assign causal values - Conduct pair-wise comparison - Compute eigenvectors	Pairwise comparison matrix Causal values	
Causal path identification	Initialize cognitive matrix	Cognitive matrix	Matrix operation Causal path computation algorithm
	Compute causal impact paths and values	Causal impact paths and values matrix	

A cognitive map is composed of three components: causal factor, causal value, and causal connection. The main difficulty lies in determining the causal value component. Specification of the causal value is the most challenging problem in generating a cognitive map because it has a qualitative property reflecting people's cognitive status, which cannot be directly measured. Besides, human perception is often inconsistent. Direct scale values have been used by most of the methods for cognitive modeling (Eden & Ackermann, 1989; Zhang et al., 1994). However, this direct assignment approach has limitations in that the procedure is not systematic and the result heavily depends on the analysts' or participants' subjective judgment.

For this method, an eigenvector approach through pairwise comparison was chosen for more systematic determination of causal values. This approach is based on the analytic hierarchy process (AHP) method developed in the 1970s (Saaty, 1980). Strength of the AHP method lies in its ability to structure a complex problem hierarchically and to evaluate the relationships between entities systematically. In the application of AHP method, the eigenvector assignment approach is conducted through pairwise comparison and eigenvector computation.

Pairwise comparison technique starts from the idea that the measurements based on experience and understanding are obtainable only from relative comparisons and not in an absolute way (Saaty, 1980). The intensity of our feelings serves as a scale adjustment device to put the measurement of some objects on a scale commensurate with that of other objects. The results of pairwise comparisons are represented in a form of matrix, called pairwise comparison matrix. A pairwise comparison matrix has cell entries as a scale indicating the relative strength with which elements in one cluster influences other elements in other clusters. This scaling process can then be translated into impact weights. The eigenvalue method is the most preferred approach for the estimation (Saaty, 1980). When a pairwise comparison matrix has a maximum eigenvalue and the corresponding eigenvector whose components are all positive, this eigenvector becomes a ratio scale that are the estimates of relative impact values of elements under comparison. Eliciting causal values in a cognitive map can be viewed as a process that transforms qualitative mental status into quantitative numerical scale. The eigenvector approach provides a way for calibrating a numerical scale, particularly in areas where measurements and quantitative comparisons do not exist.

The completed global cognitive map is analyzed in terms of the strength of the impact between causal factors. Our concern is to identify the causal paths with the maximum causal impact among all causal paths regardless of the direct or indirect impact. These causal paths take negative or positive path values, depending on their causal values. In order to identify the causal path(s) with the maximum causal impact, we adopted the algorithm proposed by Zhang et al. (1994) and extended it to find the paths and values simultaneously. The algorithm produces an n x n matrix called the causal impact path and a value matrix consisting of X_{ij}, where X_{ij} is the set of $\{+p_{ij}, -p_{ij}, +v_{ij}, -v_{ij}\}$: $+p_{ij}$; is a positive causal impact path from element i to j, $-p_{ij}$; is a negative causal path, $+v_{ij}$; is a maximum positive causal impact value corresponding to $+p_{ij}$, and $-v_{ij}$; and is a maximum negative causal impact value corresponding to $-p_{ij.}$ The algorithm is applied iteratively, while either maximum positive value ($+v_{ij}$) or maximum negative value ($-v_{ij}$) can be improved; in other words, until new dominant values cannot be identified (refer to Appendix 1 for the simplified algorithm).

Decision Support

The analyzed knowledge model should suggest guidelines for decisions on managerial problems. A decision guideline can be generated in view of the organizational goal, based on the organizational knowledge model (or cognitive model) and the causal path analysis. An organizational goal is a desired future state of affairs that the organization attempts to realize (Etzioni, 1964). A goal pertains to the future, but it influences current activities. Because organizations are goal-attainment entities, goals play a role in setting directions for its members' activities, leading their thoughts and actions to a specific result (Hamner, Ross, & Staw, 1983). Decision guidelines thus can be identified by analyzing people's thoughts and actions with respect to their organizational goals.

To facilitate decision support, we propose analyzing the organizational knowledge represented in cognitive maps in terms of the causal paths and strengths among the causal factors. The causal impact paths and values among the causal factors can be computed based on the proposed methodology, as mentioned in the previous section. The derived matrix includes the negative path and value as well as the positive path and value for each relationship among the causal factors.

Regardless of the polarity of the impact, it is first necessary to focus on the most effective causal factor in achieving the goal. This factor can be an opportunity, if it has a positive impact, but it can be a problem, if it has a negative impact. It is then necessary to identify the relevant feedback loop paths that strengthen the positive impact and weaken the negative one. For a causal factor with a positive impact, this involves making its positive loop more positive and making its negative loop less negative. For a causal factor with a negative impact, this involves making its positive loop less positive and making its negative loop more negative.

The output from such a process enables a decision to be made on a managerial problem. There are many reasons that update individual and organizational knowledge and upon which the selection of an appropriate option can be made. That is, there is a feedback process from integrated knowledge and decision support to individual knowledge and mental models. This is a kind of organizational learning process. Although decision makers cannot apply the same option and the same knowledge to similar problems in the future, they can now understand the dynamic complexity of the target problem, the structure among the elements, and the behavioural patterns. Decision making via understanding dynamic complexity, based on a cognitive model, enables the acquisition of real leverage in managerial problems (Fiol & Huff, 1992; Senge, 1990; Sterman, 2001).

COMPARISON WITH OTHER APPROACHES

The proposed approach can be compared with other KM methods. Our research focuses on enterprise wide improvement by enhancing managerial decision support by means of organizational knowledge, whereas other KM methods (Davenport, 1998; Davenport et al., 1998; Kankanhalli et al., 2005) aim to obtain better efficiency and effectiveness in task processing by knowledge attainment and knowledge repository management. Due to this difference in approach, other KM methods are more concerned with individual or departmental tasks at the operational level. They highlight declarative knowledge (which is related to each employee's cognitive model) and procedural knowledge (which is stored as document- or database-type knowledge). In contrast, the proposed method that we have presented emphasizes integrating the partial knowledge of different departments and employees into organizational knowledge. By doing so, our method facilitates effective business decision making and strategic planning.

The proposed approach can be compared with other cognitive modeling methods. Several cognitive modeling methods and tools using the cognitive map have been developed in various domains, including business policy establishment, organizational learning, and strategic option development (Eden & Ackermann, 1989; Hall, 1984; Lee, Courtney, & O'Keefe, 1992). However, most cognitive modeling methods emphasize map representation as a knowledge representation scheme rather than as a problem-solving tool (Kwahk & Kim, 1999). The proposed approach provides a representation scheme as well as some guidelines for problem solving, by further investigating the knowledge represented in the cognitive map, based on the analysis of the most effective paths.

The proposed matrix approach also can be compared with system dynamics (Sterman, 2001). System dynamics is a methodology aimed at designing better behaved system, by understanding the target system, especially with feedback loops among system components and behaviour patterns over time. System dynamics attempts to conceptualize any business problem with a causal loop diagram, and formulate and test it after transforming the causal loop diagram into a stock-flow diagram. The standard application of system dynamics includes identifying the core loop and core factors as part of policy development. However, identifying the core loop and core factors relies on either the intuition of the modeler or user, or the somewhat cumbersome simulation testing of several alternatives. While the identification of the core loop and core factors is very critical to the application of system dynamics and effective policy development, little research has been done in the area. By proposing a new method for identifying the core loop and core factors, this study has contributed to system dynamics literature.

APPLICATION CASE

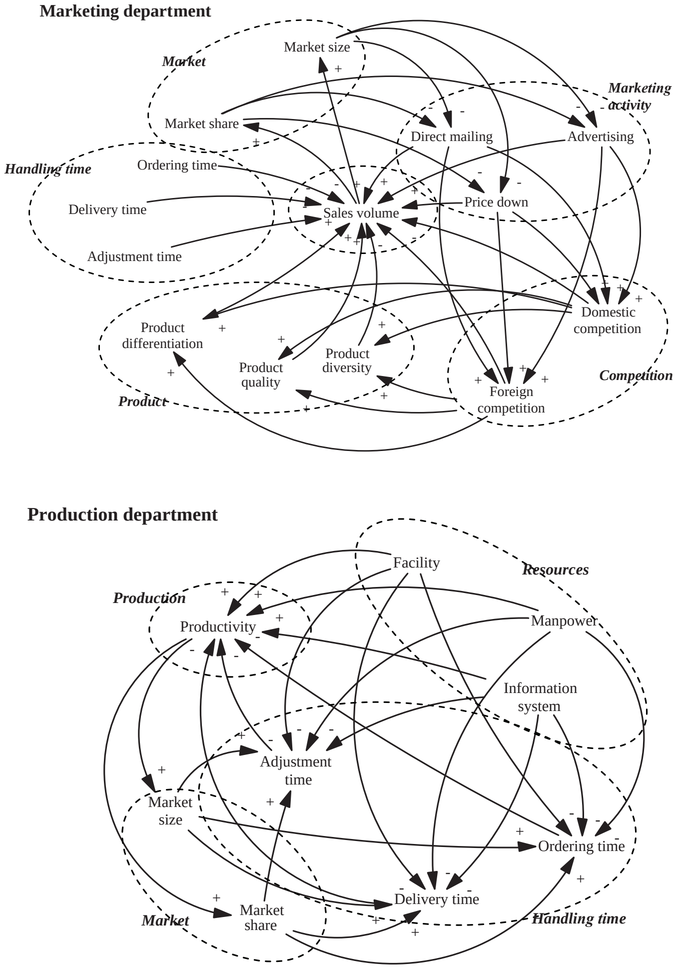
We applied the proposed decision support loop to a beverage company with an annual sales volume of about $600 million. The company was about to start a business process redesign implementation project, and before that, the management wanted to know the main target of the process redesign, especially across the marketing and production departments. Accordingly, we applied the proposed approach in finding the leverage points in decision making for increasing profit by identifying core factors and core activities.

The application of the proposed method was carried out by two researchers who had knowledge about the proposed method and cognitive map, along with the company's project team, which mainly consisted of members of related departments. Two researchers educated the project team about the procedure and the use of cognitive map, particularly, focusing on the knowledge elicitation of individual department. This study lasted for a month until the business process redesign implementation project started.

Individual Knowledge

Individual knowledge was gathered from the marketing and production departments. To generate a cognitive map for each department, a brainstorming session and interviews with participants from each department were held. Following the discussion and interviews, the participants established the goals for their respective departments. The marketing department set increasing sales as its goal, while the production department decided on improving productivity. Next, we attempted to extract all the causal factors for each department, including business-related activity concepts. The brainstorming technique again was used. When all the causal factors had been listed, they were clustered according to their functional similarity and behavioral homogeneity. Based on these clusters, the relationships between clusters were identified, along with their directions and polarities. A cognitive map was derived from the list of causal factor clusters and the cluster relationships; this was done by replacing clusters with their corresponding causal factors and making

Figure 3. Individual knowledge models of two departments



appropriate connections among causal factors. Then cognitive maps were generated from the two departments along with the relevant goals, as illustrated in Figure 3.

Organizational Knowledge

Knowledge related to organizational goals is dispersed across a company, and it is kept by the top management, departmental managers, and departmental staff members of the firm. This knowledge is identified and organized through "externalization" and "combination." Although some information or knowledge can be obtained from documents or databases, large portions of knowledge reside in mental models. In our case application, we conducted interviews with the top managers and the middle managers of the two departments to identify partial knowledge. By having these interviews, we could detect and resolve discrepancies between the cognitive maps of the two departments.

Combining the individual knowledge models of the two departments generated the organizational knowledge model as depicted in Figure 4. The synthesizing process revealed organizational knowledge that was not known explicitly to the departments. The two departments became aware of how elements in one department could affect the other department. For example, efforts to increase market share by the marketing department could lead to increasing ordering time and delivery time, thus resulting in diminished productivity, which is of interest to the production department.

Formulating and Testing the Knowledge Model

The organizational knowledge represented in the cognitive map was analyzed in terms of the causal paths and strengths among the elements to identify the leverage points in decision making. The causal impact paths among the causal factors as well as their values were computed. In this application case, core business activities were identified from the causal impact paths and values matrix, as illustrated in Table 3 (and also in Figure 5).

Figure 4. The organizational knowledge model between the two departments

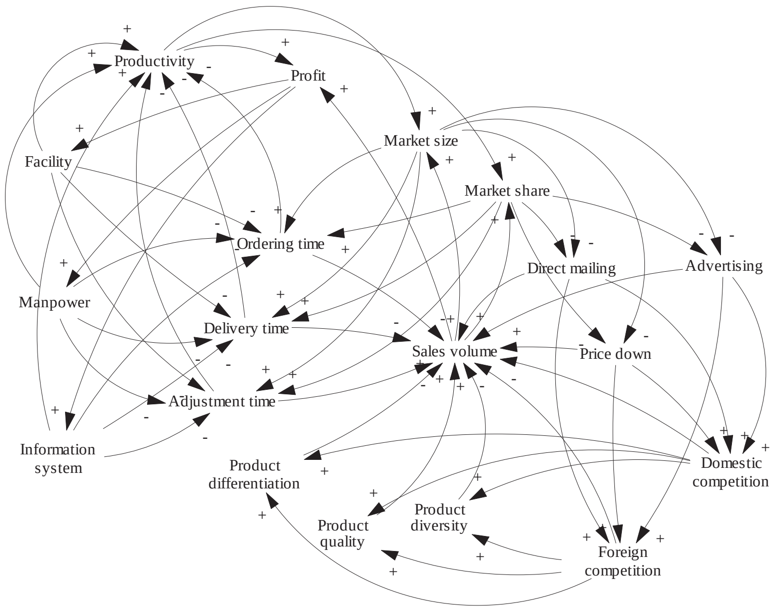


Table 3. Analysis of core business activities

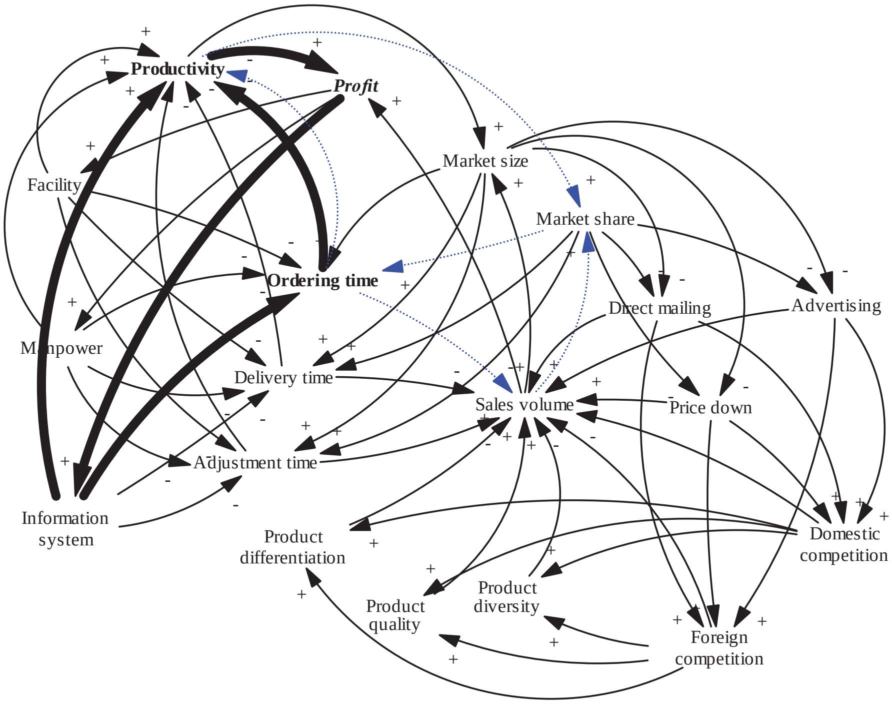
Causal factor		Feedback loops
The most positive impact factor: Productivity	Positive	Path = {Productivity - Profit – Information system - Productivity} Value = +0.52*
	Negative	Path = {Productivity - Market share - Ordering time - Productivity} Value = -0.19*
The most negative impact factor: Ordering time	Positive	Path = {Ordering time - Productivity - Profit - Information system - Ordering time} Value = +0.36*
	Negative	Path = {Ordering time - Sales - Market share - Ordering time} Value = -0.32*

** Values can be calculated based on the path of feedback loops and the corresponding causal values as follows: +0.52=(+0.67)*(+1.0)* (+0.77); -0.19= (+0.33)*(+0.83)*(-0.70); +0.36= (-0.70)*(+0.67)*(+1.0)*(-0.77); -0.32=(-0.57)*(+0.67)*(+0.83) (refer to Appendix 2).*

Figure 5. Feedback loops related to the target goal



When increasing profit was considered as a target goal, the two most effective causal factors were identified from the causal impact paths and values matrix (refer to Table 4). One was productivity, which was the most positive causal factor. It represented an opportunity to accomplish the organizational goal because productivity enhancement contributes most to increasing corporate profit. The other one was ordering time, which was the most negative causal factor. It represented a problem for the attainment of the goal because an increase in ordering time undermines profit increases through a decrease in sales volume. The objective was, therefore, to strengthen the positive causal factor ("productivity") and weaken the negative casual factor ("ordering time").

As can be seen in Table 3 and Figure 5, the causal factors—productivity and ordering time—possessed *positive* feedback loops of {Productivity–Profit–Information system–Productivity} and {Ordering time–Productivity–Profit–Information system–Ordering time}, respectively. In addition, the two factors possessed *negative* feedback loops of {Productivity–Market share–Ordering time–Productivity} and {Ordering time–Sales–Market share–Ordering time}, respectively. It seems clear that the paths, {Productivity–Profit–Information system} and {Ordering time–Productivity}, were the main drivers that could accelerate an improvement in productivity and a decrease in ordering time. Thus, by designating the above two paths of related activities as core business activities, it would be possible to focus on how to use information technologies in redesigning the processes related to productivity and ordering time.

Table 4. Part of causal impact paths and values matrix (causal factor "profit" column)

Cell	**Positive**		**Negative**

Note: 1 represents-profit; 2 represents sales amount; 3 represents DM; 4 represents advertising; 5 represents price down; 6 represents domestic competition; 7 represents foreign competition; 8 represents product differentiation; 9 represents product quality; 10 represents product diversity; 11 represents productivity; 12 represents facility; 13 represents manpower; 14 represents information system; 15 represents ordering time; 16 represents delivery time; 17 represents adjustment time; 18 represents market size; and 19 represents market share.

Decision Support

Based on the above organizational knowledge and consensus, the ordering process was identified as a candidate target process for possible redesign. The existing ordering process depended heavily on manual handling and required the intervention of the sales branches. This resulted in long ordering time and inefficiency in production and delivery. Including a new client-server system in the redesign of the ordering process could significantly reduce total ordering time.

In the redesigned ordering process, every agency could send its orders directly to the factory through the network without the intervention of the sales branches. Reducing the branches' role in order taking was expected to result in shorter ordering time, which in turn was likely to increase efficiency in production and delivery and, in the long run, contribute to profit. In addition to discovering the best decision option, the top management and managers at other levels came to understand the elements involved in the business process, the relationships among them, and the behavioural mechanism of the target business problem.

At the end of the application of the proposed method, the results and insights were presented to the top management of the firm and the two departments. The top management came to understand what factors affected organizational profit and how the factors were related across the two departments. In addition, the management could now perceive why the proposed decision guidelines would be effective. The two departments and the individual employees also could expand their department-constrained knowledge into cross-department knowledge. Thus, the proposed method facilitated understanding of the behavioural mechanism regarding the target managerial problem by linking knowledge integration to decision support.

In summary, the goal in the application case was to identify the decision options to increase profit. For company-level decision making, such as in the application case, knowledge integration (regarding how to increase profit and what factors affect profit) across functional areas is essential. As part of knowledge management, the proposed approach facilitates the identification and integration of partial knowledge (as in Figure 3) into organized knowledge (as in Figure 4). In decision making, there could be several decision options. Identifying the best option or core factors is one of the main goals in decision support (as in Figure 5). Thus, the matrix method enabled us to identify the core factors regarding the goal of decision making based on the combined knowledge model. In the case study, the management and the two departments gained newly identified knowledge through our proposed process.

DISCUSSION

Any problem is characterized by its complexity type: detail complexity and dynamic complexity (Senge, 1990; Sterman, 2000). Detail complexity arises when it focuses on the static aspect of a structured problem by highlighting the correctness of selected variables. Dynamic complexity arises when it focuses on the dynamic aspect of an unstructured problem by highlighting the interactions among the variables. Any problem characterized by detail complexity tends to entail mathematical modeling approach to find an optimal solution. In contrast, any problem characterized by dynamic complexity tends to entail the cognitive modeling approach to design a better behaved system by understanding the behavior mechanism. Organizational problems (or business management problems) are characterized by dynamic complexity, tacit knowledge factors, feedback effects over time, and unstructuredness (Sterman, 2001).Organizational problems especially require (tacit and explicit) knowledge gathering and integration across employees and organization units (Argote, McEvily, & Reagans, 2003; King, 2006). In addition, a systematic approach is needed to identify and capture knowledge within the organization (Cai, 2006; Nah, Siau, & Tian, 2005). Based on these needs, this study proposed a knowledge integration approach for organizational decision support by developing a cognitive modeling methodology together with the decision support loop. We believe the developed decision support loop and the methodology (including tasks and relevant methods in each step over the two common stages) is unique compared to other decision support approaches.

The case described in the previous section may be best discussed as an exercise in knowledge conceptualization. During the conceptualization process, the knowledge related to the target problem was identified and structured from the causal relationship perspective using cognitive maps. The analysis enabled decision makers to: (1) trace the basic causes of unexpected outcomes; (2) understand which decision factors had more significant impacts on performance; and (3) make trade-offs between decision alternatives. The reasoning process had effects on both the value of decision factors and the causal relationships.

Our proposed approach is characterized by its learning process and organizational memory. Learning allows individuals to obtain knowledge and insight from the results of experiences, and facilitates the application of this knowledge to future circumstances (Fiol & Lyles, 1985). Organizational learning aims to obtain knowledge, store it in the organizational memory, and revise it by experience; the accumulated organizational knowledge is thus diffused (Huber, 1991; Senge, 1990). Organizational memory refers to "the means by which knowledge from the past [is] brought to bear on present activities, thus resulting in higher or lower levels of organizational effectiveness" (Stein, 1995 p. 22). Ramesh (1999) suggested the development of organizational memory through the identification of information that should be provided as part of cognitive feedback, together with the interdependencies within this information. Organizations update their respective organizational memories that consist of knowledge through learning. Our proposed approach enables an organization to obtain of previous knowledge from individuals or organizational knowledge models, allows for the creation of new organizational knowledge, and allows for its revision by reasoning and new experiences. The management and teams of an organization can share the collective tacit/explicit knowledge to improve their understanding of the target situation, which will enable them to be more cooperative in their dealings with each other. The organizational knowledge model, thus, plays a role in organizational memory.

Compared to other general decision support approaches, our approach would be more appropriate to the decision-making context with highly constrained tasks involving resource allocation. Highly constrained tasks can be classified as mixed-motive negotiation tasks in which participants have mixed motives to compete and cooperate (McGrath, 1984; Rees & Barkhi, 2001). It is, therefore, important to understand the overview of the system, and this should be shared among participants with respect to how one part of a decision can affect other parts. Decision-making support should aid individuals or subunits in an organization in exchanging information and making coordinated decisions (Barkhi, 2001–2002). The proposed approach enables individuals or subunits in an organization to make decisions consistent with the organizational goals, leading them to collaborate with each other by linking organizational knowledge to decision support.

As part of the proposed approach, the matrix method seeks to provide problem-solving guidelines in a systematic way that is lacking in most cognitive map methods. The merit of our approach is that it quantifies the knowledge represented in the map and identifies core factors and the relationships among them. The identified factors and relationships are new knowledge that comes with the application of our method. Their importance is reflected in the fact that they are the main target for decision making. Therefore, our matrix method plays an important role in the proposed organizational decision support through knowledge integration across organizational units.

Our proposed matrix approach is more appropriate for testing linear problems, but many real-world problems (or systems) are characterized by nonlinearity. The main focus of system dynamics is to conceptualize and test the effect of nonlinearity over time. While our proposed approach captures nonlinearity in structuring a problem, the matrix method has its limitations in testing nonlinearity effects over time. Nevertheless, the limitation can be eased by combining the proposed matrix approach with the typical system dynamics approach. Based on the identified core loop and factors from the matrix approach, we can further test the model (or business problem) with the format of the stock-flow diagram of the system dynamics approach. In the testing, we could consider nonlinearity in the system; and we could validate whether the identified core loop and factors produce real leverage effect in the nonlinear system.

CONCLUSION

The core contribution of our study lies in proposing a methodology for organizational decision support based on knowledge gathering and integration across organization units and people. While most previous research on knowledge management has focused on identifying and sharing knowledge mainly for transaction processing in an organization, this study explains how organizations can apply knowledge management (i.e., knowledge gathering and integration across multiple individuals and organizational units) for organizational decision support. For this, we have developed and proposed the decision support loop. The decision support loop facilitates integrating individual knowledge into organizational knowledge, then formulating and testing it for decision support. For the knowledge representation, formulation, and testing, we used the cognitive modeling method, which enables decision makers to estimate the strength of the impact between causal factors. The generation of alternatives and the testing of those alternatives enable decision makers to appreciate the behavioural mechanism and the inherent structure of the target business problem. The application case showed the validity and usefulness of the proposed method.

Chapter 3.19

System Characteristics, Perceived Benefits, Individual Differences and Use Intentions:

A Survey of Decision Support Tools of ERP Systems

Emad M. Kamhawi
Zagazig University, Egypt

ABSTRACT

Limited research has considered the value derived from using enterprise resource panning (ERP) systems for decision making support. This paper aims to evaluate the impact of a set of individual differences, system characteristics, and perceived benefits of the system, on the intentions to use ERP systems for decision support. A field study was used to collect data from managers working in Bahraini enterprises that use ERP systems. The results indicate that individual differences concerning age, gender, level of education, and even computer self efficacy did not influence intentions of using the decision tools of ERP systems. The only individual difference that showed significant influence is the degree of knowledge of the system. In addition, both perceived shared benefits and system characteristics had significant influence on the intention to use the system for decision support tasks, through perceived ease of use and perceived usefulness. The paper discusses the implications of these findings and ends with possible extensions of the study.

INTRODUCTION

Over the past decade, organizations around the world have spent billions of dollars implementing ERP systems. Motives of adopters of ERP systems have focused primarily on revolutionizing transaction handling by improving business processes and integrating operations and data. The current generation of ERP packages holds the promise of improving online analytical capabilities to enhance the organization's business intelligence as well.

ERP systems could be defined as comprehensive software packages that seek to integrate the complete range of business processes and functions in order to present a holistic view of the business from a single information and information technology architecture (Gable, 1998). Implementing an ERP system is a costly and risky project. The cost of a full implementation in a large international organization can easily exceed $100 million. A recent survey of 63 companies—with annual revenues ranging from $12 million to $63 billion—indicated that ERP projects cost $10.6 million and take 23 months on average to complete (Umble & Umble, 2002). Moreover, their implementation environments are often very complicated. They usually require large-scale business process reengineering (BPR) undertakings, complex technical arrangements for integrating the core ERP technology with any existing or future software, as well as careful management of the contributions of several participants in the projects such as: functional departments, consultants, business partners, and vendors. All these requirements and more, magnify project management challenges for such projects, making them prone to implementation failure.

Despite these challenges, investments in these systems are increasing, making the ERP software one of the fastest growing markets in the software business. In the 1990s some statistics projected its eventual market size to be around $1 trillion by the year 2010 (Bingi, Sharma, & Golda, 1999). Moreover, expectations for keeping these interests in ERP investments are even bigger in the 2000s. This is because, though they were originally developed and implemented for transactional aspects, a growing need to use these systems for decision support has recently become clear. Lately, these software packages are incorporating decision support tools in order to take advantage of data storage, access, scrubbing, and integration capabilities facilitated by ERP systems (Turban, Aronson, & Liang, 2005). On the other hand, the confluence of ERP and decision support technology has begun to draw the attention of academia as well (Shafiei & Sundaram, 2004). Obviously ERP vendors, implementers, and researchers need to understand the factors that affect their usability. Based on this need, this article's main objective is to identify the main contextual variables that influence the acceptance of decision support tools of ERP systems. Three groups of variables were introduced in our theoretical model: (1) individual differences, (2) perceived shared beliefs of the decision support benefits of these systems, and (3) system characteristics.

The second section of this article reviews prior literature on ERP and decision support. In addition, it provides a brief explanation of TAM as the guiding basis for the theoretical framework of this research. The third section introduces the research model along with a discussion of the model variables. The fourth section describes the study's methodology. The fifth section reports findings on the factors that are found to be influencing the use of these systems. The last section concludes the study with a discussion of the main findings and suggestions for future investigations.

LITERATURE REVIEW

ERP and Decision Support

Very few studies have addressed issues related to incorporating ERP systems and decision support tools. This is mainly because ERP and decision support systems (DSSs) have independently evolved and adopted in the marketplace as well as in academia. Consequently, each subject has its own separate studies. On the other side, plenty of research efforts have been introduced for technology/information systems acceptance or usability. In the following paragraphs, we tried to briefly present the research most related to our study's main objective.

Starting with the ERP aspect, many researchers have provided frameworks and insights that tried to explain success of ERP systems implementation. We thought that these success factors' frameworks could be helpful in providing a basis for synthesizing an initial acceptance theory for incorporating ERP and DSS tools for our research. Akkermans and Van Helden (2002) and Al-Mashari, Al-Mudimigh, and Zairi (2003) for example, used a case study approach to provide rich accounts of the implementation processes for some selected individual companies. Other studies used a statistical approach to develop and test different theoretical models that identify several critical success factors, using samples of firms that have recently implemented ERP systems (Bradford & Florin, 2003; Hong & Kim, 2002). Examples of factors tested in such studies are: top management support; effective communication; project management; business plan and vision; software testing and trouble shooting; and monitoring and evaluation of performance. Another important direction this literature has tried to examine is how such critical factors differ in their impact or contribution to success, according to the different stages in the life cycle of the ERP implementation project (Markus, Tanis, & Van Fenema, 2000; Rajagopal, 2002).

Previous studies concerning DSSs use or adoption had other streams that could be used as well for building a relevant background for this study. For example, some researchers paid great attention to issues such as patterns of use or areas where such DSS tools are used and how these patterns affect perceived value and satisfaction (Vlahos, Ferratt, & Knoepfle, 2004). Others concentrated on how acceptance levels of these systems differ according to managers' individual differences, such as gender and cognitive and decision style (Bruggen & Wierenga, 2001; Lu, Yu, & Lu, 2001). One important development in this area is the steady growth of business intelligence and business analytics technologies' industry, with revenues reaching into low billions, according to some statistics (Turban et al., 2005). Moreover, tools concerning data mining, data warehousing, and knowledge management systems are becoming easier to use and consequently more promising for higher levels of usability. One of the surveys concerning these developments showed that approximately 35% of corporate management and staff directly used data mining tools (Nemati & Barko, 2001).

The confluence of ERP and DSSs is still in its initial stage, though clear interests could be cited. For example in a field study of six ERP implementations, Palaniswamy and Frank (2000) described organizations' need to digest the vast amount of information from the environment and make fast decisions. Shafiei and Sundaram (2004) explained that DSS tools take advantage of the data resident in ERP systems. Holsapple and Sena (2005), in their survey that examined the connections between ERP systems' objectives and decision support benefits, found that organizations did consider four objectives for decision support to be fairly important while planning their ERP projects. These objectives are: (1) shifting responsibility of decision making, (2) supporting interrelated decision making, (3) supporting multiple persons working jointly on a decision, and (4) supporting individual decision makers. On the other side, the survey showed that ERP systems do indeed provide substantial decision support benefits concerning the following: enhancing knowledge processing, improving competitiveness, reducing decision costs, and supporting multi-participants' decision making.

Technology Acceptance Model

Identifying factors that determine user's adoption of IS has drawn much attention in the last two decades. This is due to the realization that millions of dollars could be spent on these systems, while potential users may not even use them. TAM is an established model in explaining IS adoption behavior. It is based on theories in social psychology such as theory of reasoned action (TRA), and the theory of planned behavior (TPB). TAM has been frequently found to have better explanatory power than other models or theories used in the IS adoption subject (Davis, Bagozzi, & Warshaw, 1989; Taylor & Todd, 1995).

According to TAM, usage of an IS is determined by users' intention to use the system, which in turn is determined by users' beliefs about the system. There are two kinds of salient beliefs involved: perceived usefulness and perceived ease of use of the system. Perceived usefulness (PU) is defined as the extent to which a person believes that using the system will enhance his job performance. Perceived ease of use (PEOU) is defined as the extent to which a person believes that using the system will be free of effort. Furthermore, both types of beliefs are subjected to the influence of external variables. By manipulating these external variables, system developers can have better control over users' beliefs of the system, and subsequently, their behavioral intentions and usage of the system. A good review of this stream of research is provided by Lucus and Spitler (1999), and Legris, Ingham, and Collerette (2003).

TAM has been applied to a wide range of IS applications. However, very few have used it for complicated systems such as ERP. Amoako-Gympah and Salam (2003)—probably the first to extend using TAM in an ERP implementation environment—have examined the impact of training and project communications on shared beliefs about the benefits of the ERP technology and how these shared beliefs influence the TAM core framework. Amoako-Gympah (2005), in another study, looked at the influence of prior usage, argument for change, intrinsic involvement, and situational involvement on PU and PEOU of TAM. Also Calisir and Calisir (2004), based on data obtained from 35 end users in 24 companies, found that PU and learnability could be significant determinants of end-user satisfaction with ERP systems. In addition, PEOU and system capability seemed to affect PU, while user guidance seemed to influence both PU and learnability.

This article represents an extension to this line of studies. From one side, it tries to contribute to the current interests in integrating ERP and the decision support tools body of research. From the other side, it tries to meet the need to understand the main factors that affect the use of this side of the system. The few current studies, which investigated the acceptance of ERP systems, concentrated on the general use of ERP systems, which is more oriented towards the classical transactional part of these systems. We believe that the decision support part of ERP systems requires separate investigation concerning its usability.

It is important to note here that using TAM for this research was not for the sake of introducing another TAM example. We came to a belief in the beginning of this study that measuring the intentions to use the system is more appropriate than measuring its real use. We expect that the use of the decision support tools accompanying ERP systems is still relatively limited, as these systems are traditionally considered as transactional systems. Moreover, using TAM had many advantages for such research studies. Firstly, it informs researchers of what types of contextual factors could be included and how their relationships might be. Secondly, it provides an important basis for comparisons and extensions with previous research in IS. Thirdly, many of the academics feel comfortable with TAM, though some still do not feel relaxed with the link between intentions to use the system and its real use. However the big previous bulk of research concerning TAM, indicates a high level of acceptance of the model, which eases understanding of any future extensions.

RESEARCH MODEL AND HYPOTHESES

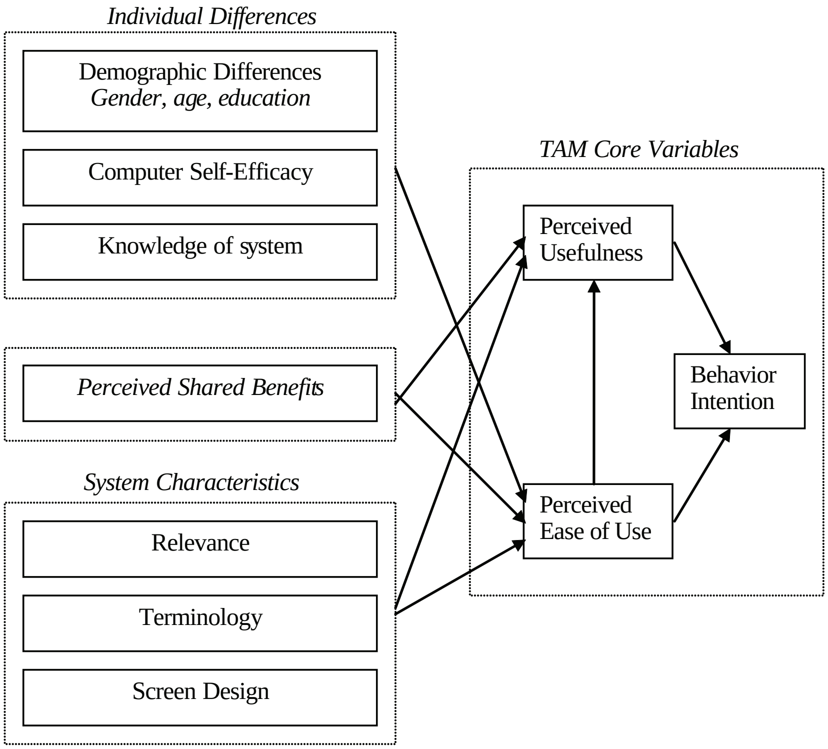
Many factors have been selected by prior studies as potential predicators for IS use intentions. Examples are: top management support, project management capabilities, and BPR competencies. However, our main concern was to include only those that are specifically related to the decision support part of the system. This criterion made us eliminate many factors that seemed more appropriate to the traditional transactional aspect of the system. In the end, three main categories of external variables have been selected, namely: (1) individual differences, (2) system characteristics, and (3) shared beliefs about the benefits of the system. We thought that it is fairly logical to expect that managers' intentions to use such a system rely more on how they perceive its specific benefits to their work, how friendly and relevant this system is to use, and other items related to their individual characteristics. These three groups of variables have been emphasized in most of the classical TAM research studies (Agarwal & Prasad, 1999; Davis, 1989; Igbaria & Iivari, 1995; Venkatesh, 1999). The proposed research model includes three individual difference variables and three system characteristics, besides shared beliefs items about the benefits of ERP for decision support (see Figure 1) and the selection of which are supported by prior studies in the IS literature. The following is a discussion for these variables.

Individual Differences

Individual differences are believed to be most relevant to both the decision-making process (Klenke, 2003; Lu et al., 2001; Smith, 1999) and ISs' use intentions (D'Ambra & Wilson, 2004; Kotey & Anderson, 2006; Lai & Li, 2005; Mafe & Blas, 2006; Olson & Boyer, 2003). In this study, we examined three variables concerning individual differences: demographics, computer self-efficacy (CSE), and knowledge of system.

The demographic variables or the personal characteristics selected for this research are: gender, age, and education. Previous research

Figure 1. Research model



efforts showed how information systems' use intentions differ between men and women (Lai & Li, 2005; Mafe & Blas 2006); how differences in age influence users' levels of computer anxiety and consequently use intentions (Kotey & Anderson, 2006; Lu, Yu, Liu, & Yao, 2003); and how computerized ISs' use is related to the users' level of education (Mafe & Blas, 2006; Olson & Boyer, 2003).

Besides demographics, CSE is one of the classical individual differences, usually found as an important predicator for IT usage (Compeau & Higgins, 1995) and PEOU of information systems (Agarwal, Sambamurthy, & Stair, 2000; Igbaria & Iivari, 1995). Knowledge of the system is another important individual difference that has been found as a significant contextual variable for IT/IS use intentions (Benbasat, Dexter, & Todd, 1986; Hong, Thong, Wong, & Tam, 2002). Apart from TAM suggestions of what variables to include in the research model, considering individual differences is especially important for DSSs, where higher levels of interactivity and mutual learning are expected to exist between the system and the user (Turban et al., 2005). Differences in individual characteristics will then influence how users interact with the system and consequently their use intentions.

According to TAM, individual differences usually influence PEOU, but not PU (Hong et al., 2002; Igbaria & Iivari, 1995), as shown in Figure 1. Based on the previous discussion, our related hypotheses are:

H1a: *Using ERP systems for decision making will be perceived easier for male than for female managers***.**

H1b: *Using ERP systems for decision making will be perceived easier for younger managers.*

H1c: *Using ERP systems for decision making will be perceived easier for managers with more education.*

H2: *Using ERP systems for decision making will be perceived easier for managers with higher levels of computer self-efficacy.*

H3: *Using ERP systems for decision making will be perceived easier for managers with higher levels of knowledge of the system.*

System Characteristics

The main logic behind including system characteristics in this framework is that the study deals with a relatively complex system. Consequently, we expected higher influences on factors related to how friendly their interfaces are and how relevant their functions are to the users' main tasks. The relationships between system characteristics and TAM beliefs' constructs have been investigated in many studies (Hong et al., 2002; Venkatesh & Davis, 2000). Researchers usually use a general construct that represents this variable, such as "perceived system quality" (Igbaria, Gumaraes, & Davis, 1995) or "output quality" (Venkatesh & Davis, 2000). This study relied on Hong et al.'s (2002) three system characteristics to be investigated in this research, namely: relevance, terminology, and screen design.

Relevance can be interpreted as the degree to which the system matches users' information needs. Terminology refers to the words, sentences, and abbreviations used by a system. Screen design is the way information is presented on the screen. Similar to individual differences, system characteristics are especially important for DSSs, to facilitate higher levels of interactivity between the system and the user.

However, the difference between system characteristics and the individual differences variable, according to TAM previous studies, is that it is expected to influence both PEOU and PU of TAM core constructs and not only PEOU as depicted in Figure 1 (Davis, 1989). According to the previous arguments, we expect that:

H4a: *Relevance of the ERP system will have a positive effect on perceived ease of use of the decision support tools of the system.*

H4b: *Relevance of the ERP system will have a positive effect on perceived usefulness of the decision support tools of the system.*

H5a: *Terminology clarity of the ERP system will have a positive effect on perceived ease of use of the decision support tools of the system.*

H5b: *Terminology clarity of the ERP system will have a positive effect on perceived usefulness of the decision support tools of the system.*

H6a: *Screen design of the ERP system will have a positive effect on perceived ease of use of the decision support tools of the system.*

H6b: *Screen design of the ERP system will have a positive effect on perceived usefulness of the decision support tools of the system.*

Perceived shared beliefs of benefits

A shared belief about the specific benefits of the system in the organization may play a significant role in shaping the usage intentions of that system. Obviously, this factor is important because the main benefits of ERP are traditionally referred to their transactional aspects. Therefore, it was included to investigate the items specifically related to the decision-making benefits that the system may bring. It is different than the PU variable in the TAM construct, which is usually used to measure the general usefulness of the system in question. Thus:

H7a: *Perceived shared beliefs of the decision-making benefits of ERP systems will have a positive effect on perceived ease of use of the decision support tools of the system.*

H7b: *Perceived shared beliefs of the decision-making benefits of ERP systems will have a positive effect on perceived usefulness of the decision support tools of the system.*

TAM Variables

Extensive research over the past two decades provided evidence of the significant effect of PEOU and PU on users' intentions to use an information system (Agarwal & Prasad, 1999; Davis et al., 1999; Hu, Chau, Sheng, & Tam, 1999; Venkatesh, 1999). These studies also showed that while PU has direct impact on use intentions, PEOU has direct and indirect impacts. Hence, we hypothesize that:

H8: *Perceived usefulness will have a positive effect on behavior intention to use the decision support part of the ERP system.*

H9a: *Perceived ease of use will have a positive direct effect on behavior intention to use the decision support part of the ERP system.*

H9b: *Perceived ease of use will have a positive indirect effect on behavior intention to use the decision support part of the ERP system through its effect on perceived usefulness of the system.*

METHODOLOGY

Study Context: The Kingdom of Bahrain

The Kingdom of Bahrain is a small Arabian island centrally located in the Arabian Gulf, with a monarchy rule form. Its economy depends on oil revenues. Facing declining oil reserves, Bahrain has turned to petroleum processing and refining imported crude. Also, it has transformed itself into an international banking center. Other important industries are aluminum smelting and tourism. Current population is approximately 688,000 residents of whom approximately 235,000 are not nationals. (For more details about the Kingdom of Bahrain, see http://www.odci.gov/cia/publications/factbook/geos/ba.html)

Measures

A survey methodology was used to gather data for this study. Straub's (1989) guidelines to validate the instrument of this research were followed. Items used in the operationalization of the constructs were drawn from relevant prior research and provided in Appendix A. One advantage of using TAM to examine the adoption of a specific IS is that it has well-validated measures. PEOU, PU, and behavior intentions constructs were measured by items taken from the previously validated inventory of measures and modified to suit the current context (Agarwal & Prasad, 1999; Hong et al., 2002).

The CSE instrument developed by Compeau and Higgins (1995) was used in this research. Knowledge of the system was assessed by two items suggested by Davies (1997): familiarity with using the system and knowledge about using the system for the users' specific decisions problems. Items for measuring the three system characteristics were taken from Hong et al.'s (2002) user survey and were rephrased for the context of the study's specific ISs. Perceived shared benefits were self-developed based on related previous studies such as Holsapple and Sena (2005) and Amoako-Gympah, (2005). Likert scales (1~7), with anchors ranging from *strongly disagree* to *strongly agree*, were used for all questions except for the items measuring CSE. The anchors of the items measuring CSE ranged from *not at all confident* to *totally confident*. The mean of the scores over all questions provided the composite score for each variable. The adopted instrument, along with all its items, was discussed with three industry executives from three different organizations experienced with using ERP for decision making and with two faculties. Based on their feedback, minor changes to reflect the research settings were made in the instructions and wording of some of the items. The subjects who had participated in this convenience pre-test were excluded from the final data collection and subsequent study.

Sample and Procedure

Only 10 companies were found to have prior experience in ERP systems in Bahrain. To come up with this list of companies, Vendors' Web sites (Arabian branches) were reviewed and brief telephone interviews were made with their representatives in Bahrain. The IT manager of each company was contacted to help us come up with a list of potential interviewees for the study.

The targeted informants are all the managers who use ERP systems to assist him/her in decision making. There were no restrictions on the organizational level of the manager, whether in top, mid-management, or operational level in the organization. Also, no restrictions were imposed on the functional activity where the decision makers work. The list of the potential informants had approximately 20 informants for each company. Consequently about 200 copies of the questionnaire were sent to the IT managers of these companies, who forwarded them to the targeted informants in their companies.

Before answering the questionnaire, respondents were asked whether they have enough experience in using the system for some decision-making activity or not. Only 84 interviewees returned the questionnaire (a response rate of 42%) from 8 companies. Nine of the questionnaires were dropped because seven of them had incomplete answers. The other two came from two managers who have not used the system yet, as was indicated by one of the questions in the questionnaire. Table 1 shows the companies participating in the study, while table two provides a profile of the respondents.

Validity and Reliability

Reliability

Reliability is the consistency or precision of a measuring instrument that is the extent to which the respondent can answer the same or approximately the same questions the same way each time (Straub, 1989). The internal consistency reliability was assessed by calculating Cronbach alpha values. The results of the reliability test conducted for the study's constructs are summarized in the fifth column of Table 3. All alpha scores were above 0.70, which suggest an acceptable level of reliability for the study's constructs (Field, 2000).

Discriminant Validity

Since each variable was measured by multi-item constructs, a discriminant analysis should be employed to check the unidimensionality of the items. Discriminant validity was checked by conducting a factor analysis. In Table 3, discriminant validity was confirmed when items for each variable loaded onto single factors with loadings of greater than 0.5 (Nunnally, 1978). Table 3 provides the loadings of each item of the independent and the dependent variables. Nine factors emerged with no-cross construct loadings above 0.5, indicating good discriminant validity.

Based on these examinations of the psychometric properties of the scales, we conclude that each variable represents a reliable and valid construct (Field, 2000).

RESULTS AND ANALYSIS

The means and standard deviations of all the variables of the study are summarized in Table 3. A multiple regression analysis was employed to identify which variables made significant contributions to predicting the dependent variables: use intentions, PU, and PEOU, to test hypotheses H1-H9a. Also, a path analysis was used for hypothesis H9b. Path analysis is a regression-based technique widely used for studying the direct and indirect effects in models encompassing mediating variables, similar to the research model proposed in this study. The intercorrelation matrix (Table 4) was first examined to assure the validity of the regression analysis, looking for possible multicollinearity problems. All intercorrelations among

exogenous variables were reasonably low. Hair, Anderson, Tatham, and Balck (1995) suggest that values of $r > 0.80$ indicate a multi-collinearity problem.

The results of the regression analysis, including *B* coefficient, *t*-statistic, and significance level for each independent variable, are reported in Table 5. The first regression model showed that both PU and PEOU were found to be significant determinants of the dependent variable namely, the intentions to use the decision tools of ERP systems. Also R^2 value of the model indicated that it explains 39% of the dependent variable total variance. However, the relative strength of their explanatory power was different. PEOU ($B = 0.46$, $p < 0.001$) was a much stronger predictor of managers use intentions as compared to PU ($B = 0.25$, $p < 0.05$). The results provided support for H8 (PU—use intention relationship); and H9a (PEOU—use intention relationship).

In the second regression model, PU was regressed on perceived shared benefits, system relevance, system terminology, and system screen design. This analysis yielded a regression function ($R^2 = 0.32$, $p < 0.001$) with three significant predicators: (1) perceived shared benefits ($B = 0.23$, $p < 0.01$), (2) system relevance ($B = 0.34$, $p < 0.05$), and (3) system terminology ($B = 0.33$, $p < 0.05$). The results provided support for H4b (systems relevance—PU) H5b (system's terminology—PU); and H7b (shared benefits—PU). The findings however, failed to support H6b concerning the relationship between system screen design and PU.

Also a multiple regression method was applied to determine variables influencing PEOU. The results reported in Table 5 showed that only system terminology ($B = 0.33$, $p < 0.05$), and perceived benefits ($B = 0.36$, $p < 0.01$) have significant effects on PEOU. These variables explained approximately 40% of the variance in PEOU. Based on these results, H5a (system terminology—PEOU), and H7a (perceived shared benefits—PEOU) were also supported. The analysis failed to support H1a, H1b, H1c, H2, H3, H4a, and H6a. These concern the relationships between gender; age; education; CSE; knowledge of the system; system relevance; and system screen design, and PEOU.

Following the suggestions of Cohen and Cohen (1983), a hierarchical multiple regression was used to test the mediation hypothesis (H9b). I regressed behavior intention on PU in the first step, with

Table 6. Hierarchical regression results

Regression step 1		***Regression step 2***		***Change in R^2***
R^2	*p*	R^2	*p*	
0.349	0.000	0.392	0.027	0.043

PEOU in step two. The unique contribution of PEOU (in explaining behavior intention) was examined over and above the PU variable. Table 6 showed that the change in R^2 after introducing project success into the equation is significant (R^2 change = 0.043, $p = 0.01$), giving support to the proposed mediation hypothesis (H9b). Table 7 summarizes hypotheses testing results.

DISCUSSIONS, CONCLUSIONS, AND LIMITATIONS

This study tried to contribute to the emerging research efforts concerning the convergence of ERP systems and decision support tools. We tried to provide an understanding of the different variables that influence manager's use intentions, which expectedly impact their level of adoption and usability of these systems. Following the research main framework and its groups of variables, we discuss the results as follows.

Individual Differences

In contrast with our hypotheses and most of the prior research, all the individual differences that have been considered in the research model did not influence Bahraini managers' perceptions concerning ease of use of these systems. It is interesting to find that CSE was a nonsignificant factor in this study. This might mean that man-

PEOU (indirect)	---	---	---	---	H9b	Yes

agers do not see technical or computer skills as a significant obstacle anymore. Supporting this argument, the degree of managers' knowledge of the system was found to not be statistically influential as well. Using computer systems in the past might have been difficult or at least require significant training in order to convince users to adopt them. Even for simple systems such as e-mail, word processing, and spreadsheets, prior research showed that sufficient computer skills were required (Agarwal & Prasad, 1999; Harrison & Rainer, 1992). At the present time, a new generation of managers who are immune from the difficulties of using ISs have taken over, and computer systems have become much easier than they were in the past. Moreover, using professional assistants to help managers in using advanced DSSs is one of the common ways for bypassing the difficulty of directly dealing with such systems (Turban et al., 2005).

Besides the technical skills, the results showed that demographic differences were also not statistically influential in this research. It seems that managers nowadays are more confident in using computers than they were in the past. Their intentions in using such systems do not differ whether they are old or young, male or female, having higher or lower degrees of education. One limitation for the finding concerning gender is that females represent only 19 % of the sample.

The previous findings simply suggest that implementation plans should not have different programs for enhancing system adoption according to such individual differences. This would save our time and efforts for other more significant factors.

System Characteristics

Not all three system characteristics had significant influence on TAM variables according to the results of this study. While system terminology had a significant effect on both PEOU and PU, system relevance had a significant effect only on PU. On the other hand, Screen design did not have any influence on either. These results suggest that the vendor of these packages should give more emphasis to the terms, language, and expressions that managers use in their decision-making activities, in order to enhance adoption levels of these systems. Although both screen design and terminology represent system interface, the results did not support the role of screen design on both TAM variables. This implies that what matters in these packages is the ability to reflect the language that managers use, and not imposing other technical or nonrelated terminology that might distract their use of these systems.

On the other hand system relevance was found to have influence on PU, but not PEOU. It seems logical to find this influence on managers' perceptions of the usefulness of the system, as relevance is more related to the content of the system—not to the interface, as in the other two system characteristics. This also supports prior studies concerning the effect of system relevance on system use (Venkatesh & Davis, 2000).

Perceived Shared Beliefs

Consistent to our hypotheses, we found significant support to our expectations that shared beliefs in the benefits of the decision tools of ERP systems affect TAM constructs. This finding is especially important as ERP systems are generally known for their transactional aspects. Managers need to know the specific benefits of these systems for decision making. If management can take appropriate steps to positively influence the belief structure concerning decision-making activities of these systems, this will then lead to more acceptance of ERP systems by the organization's managers.

It is clear from the results that this factor—besides system terminology—was found to be the most important influential factor of the study. Implementation programs should then give more attention to these two factors. Training and communication programs should help form these shared beliefs. Managers should directly understand how ERP decision tools provide such benefits.

The findings of this study have implications for developing usable ERP systems for decision-making tasks. Considering the millions of dollars that have been invested in such systems worldwide, it is of paramount importance to ensure that managers will actually use them. In order to achieve this goal, attention must be placed in designing user-friendly interfaces that emphasize manager-familiar terminologies. At the same time, developers of ERP systems should keep in mind that, although these interface-related system features may appeal to users in the early stages, their final decision on whether to use a system or not, depend on the content of the decision tools of these systems. Specifically, it depends on how relevant these systems are to managers' decision problems.

On the other hand, implementation programs for these systems should have a strong training and communication scheme in order to provide clear understanding of the specific benefits of these systems to decision makers.

This research has several limitations. First, we did not incorporate actual usage behavior in the proposed model. However, this is not a serious limitation as there is substantial empirical support for the causal link between intention and behavior (Venkatesh & Davis, 2000; Venkatesh & Morris, 2000). Second, there may be other individual and external variables that may affect the intention to use these approaches. Future research can incorporate other variables into the research model. Potential individual differences include managers' cognitive styles and decision styles, which have been repeatedly used in TAM applications in previous cases (Harrison & Rainer, 1992; Hong et al., 2002). Some other contextual factors, such as IT capabilities, outsourcing, and degree of strategic focus have been included in relevant research studies (Bhatt, 2000). Future research can examine whether these factors have any influence on the acceptance of decision tools of ERP systems.

APPENDIX A. SURVEY INSTRUMENT

The different opinions are indicated by the numbers 1: strongly disagree; 2: disagree; 3: somewhat disagree; 4: neutral; 5: somewhat agree; 6: agree; 7: strongly agree.

Perceived Usefulness (PU)

1- Using the system in my job enabled me to accomplish tasks more quickly.
2- Using the system in my job increased my productivity.
3- Using the system enhanced my effectiveness on the job.

Perceived Ease of Use (PEOU)

1- I found it easy to get the system to do what I wanted it to do.
2- It would be easy for me to become skillful at using the system.
3- In general, I would find the system easy to use.

Use Intension

1- I intend to use the system.
2- I intend to increase my use in the future.

Computer Self-Efficacy (CSE)

1- I could complete the job using the software even if there was no one around to tell me what to do.
2- I could complete the job using the software if I had only the software manuals for reference.
3- I could complete the job using the software if I had seen someone else using it before trying it myself.
4- I could complete the job using the software if I could call someone for help if I faced a problem.
5- I could complete the job using the software if someone else had helped me get started.
6- I could complete the job using the software if I had a lot of time to complete the required job.
7- I could complete the job using the software if I had just the built-in help facility for assistance.
8- I could complete the job using the software if someone showed me how to do it first.

Knowledge of the System

1- I am familiar with using the system.
2- I am knowledgeable in using the system to make my decisions.

Beliefs about using ERP system for decision support

1- The system enhances decision makers' ability to tackle large-scale complex problems.
2- The system shortens the time associated with making decisions
3- The system reduces decision-making costs.
4- The system encourages exploration on the part of decision makers.
5- The system enhances communication among decision-making participants.
6- The system improves coordination of tasks performed by an individual making a decision.
7- The system improves satisfaction with decision outcomes.
8- The system improves organizational competitiveness.

Terminology

1- I understand most of the terms used throughout the system.
2- The use of terms throughout the system is consistent.

Screen Design

1- The system commands are well represented by buttons and symbols.
2- The layout of the screens is clear and consistent.

Relevance

1- The resources in the system relate well to my work
2- The system has enough resources for my work

Chapter 3.20

Supply Chain Management and Portal Technology

Scott Paquette
University of Toronto, Canada

INTRODUCTION

The role of corporate portals as tools for managing organizational knowledge has been constantly changing throughout their short lifetime. An important recent advancement in the functionality of portals is their ability to connect companies together, joining internal and external knowledge sources to assist in the creation of valuable knowledge. Nowhere is this increased functionality and utility more evident than in the use of portals to manage the supply chain.

A common trend in supply chain management (SCM) is the formation of one central strategy for the entire production network, which involves going beyond an organization's external boundary. This represents a shift from a commodity-based approach to SCM to a more collaborative and relationship-building strategy. As this "extended enterprise" comes into being, an extended IT infrastructure is needed. Systems, such as portals, that assist in spanning organizational boundaries and ensuring a timely information exchange can help support this strategy. Portal technology allows the IT infrastructure of one firm to span multiple organizations and be utilized by many (Dyer, 2000). The globalization of supply chains also presents an opportunity for the utilization of portal technology (Tan, Shaw, & Fulkerson, 2000). Geographically dispersed organizations have an increasingly greater need to share information, even though they experience issues with systems spanning different processes, cultures, and vast distances. A portal's ability to utilize the Internet can assist in the networking of such distributed firms.

The fundamental resource required for these extended organizations is knowledge, whether it is knowledge of markets, supply conditions, manufacturing, and logistical strategies, or of a supply partner's needs and capabilities. As knowledge is a resource characterized by "perfectly increasing returns" (Dyer, 2000, p. 61), knowledge can flow within a supply network and dramatically add value for all members. A small innovation at one end can often have a ripple effect through the supply chain, and result in a significant development at the other end. All forms of supplier networks require supporting technology to facilitate the creation and utilization of supply knowledge, and portal technology is often fulfilling this need.

BACKGROUND

Supply chain management can be defined as " … a set of approaches utilized to efficiently integrate suppliers, manufacturers, warehouses, and stores, so that merchandise is produced and distributed at the right quantities, to the right locations, and at the right time, in order to minimize system-wide costs while satisfying service level requirements" (Mak & Ramaprasad, 2003, p. 175). This, in essence, states that SCM must create an infrastructure of knowledge and information that facilitates the integrated operations of supply chains. Knowledge supply chains emerge that are "… integrated sets of manufacturing and distribution competence, engineering and technology deployment competence, and marketing and customer service competence that work together to market, design, and deliver end products and services to markets" (Mak & Ramaprasad, 2003, p. 175).

Handfield and Nichols (2002) stress the importance of relationships in a supply chain, which they define as " … the integration and management of supply chain organizations and activities through cooperative organizational relationships, effective business processes and high levels of information sharing to create high-performing value systems…" (Handfield & Nichols, 2002, p. 8). In this view, the supply chain should encompass the management of information and knowledge systems in order to be successful.

Simply, a supply chain consists of the following processes within the network: buying raw materials, making and designing products, inventory management, selling to customers, and delivery of products (Poirier & Bauer, 2001). Whether done by one stand-alone firm (known as a vertically integrated firm), or a network of firms (dispersed in their business functions), each of these processes contributes to the product design, manufacturing, selling, and delivery to the customer. Portals, through their unique enterprise-wide architecture, contribute to the information and knowledge-sharing needs of each process. The following sections will examine the potential contribution of portal technology.

THE DEVELOPMENT OF SUPPLY CHAIN PORTAL TECHNOLOGY

Portal technology has emerged as an enabler of supply chain strategies, offering increased distributed access to partners through standard technology applications and processes. Initially, many larger organizations adopted electronic data interchange (EDI), an electronic messaging standard defining the data formats for the exchange of key business documents across private networks or the Internet. The Internet became important during the mid 1990s with the emergence of the World Wide Web and the adoption of HTML. Companies began to convert their EDI information exchange technologies to HTML, and later standardized XML formats in order to take advantage of greater selection of business applications, and the increased availability to all partners offered by the Internet. But for many organizations, the Web connection has become a strategic tool that strengthens the buyer-supplier relationship through establishing broad information connections that have a major impact on the overall supply strategy (Zank & Vokurka, 2003).

Initially, portals were used as an intrafirm system linking various functional areas of an organization together to share information. Usually linking various modules of an enterprise resource planning system (ERP), they allowed information to flow between the traditional silos of a business. Purchasing, engineering, manufacturing, logistics, and accounting could now receive and utilize data from all points along an internal supply chain (Handfield & Nichols, 2002).

Supply chain portals evolved to become the first interfirm portals to be commercialized and are now central to addressing the challenges of interfirm portals. Facilitating the flow of information and knowledge through every supply chain business process, supply chain portals extend the capability of members to share information and plan operations based on each other's activities. As production supply chains become more integrated as a result of increased information flows, the initial stage in the production chain, the product design and development stage, is increasing its level of interfirm information and recently knowledge sharing. Both formal and informal sources of knowledge contribute to the successful design and development of new products and processes, and much of this information must come from sources external to the organization such as customers and supply chain partners (Paquette & Moffat, 2005).

COLLABORATION IN SUPPLY CHAINS

In a supply alliance or collaborative agreement between two companies, the goals may include a reduction in transaction costs, the maximization of profit or increased learning, and knowledge transfer (Kogut, 1988). This knowledge transfer allows for supplier knowledge, engineering, and manufacturer capabilities to be an input into the product design process, which impacts the performance of new product development (Hong, Doll, Nahm, & Li, 2004). Supply-chain knowledge transfer requires integrating the flow of information and knowledge between various members of the supply chain to allow for the optimal management of supply.

Two different models of SCM are currently practiced in most industries (Paquette & Moffat, 2005). In traditional commodity-based supply-chain management, as practiced by most North American firms, suppliers are kept at arm's length in order to minimize commitments and dependence on specific suppliers and to maximize bargaining power. This *commodities supply chain model* is widely used with the goal of achieving cost savings under competitive pressures. In this model, supplier relationships are very limited to minimize switching costs. Networking technologies (such as portals) may be used to overcome the barriers of supply cost and complexity (Williams, Esper, & Ozment, 2002) and make decisions based upon efficiency benefits.

The commodity model operates in contrast to the "close collaboration" supply-chain model, which is based on the Japanese practice of creating strong partnerships through close collaboration with long-term supply partners. In the *collaboration* model, supply partners share more information and coordinate more tasks, use relation-specific assets to maintain lower costs, improve quality and increase speed, and rely on trust to govern the longer-term relationship (Dyer, Cho, & Chu, 1998). A key factor in the success of the *collaboration* approach is the close task integration between supply partners, which is enabled by the transfer of information and knowledge.

In this model, closely integrated and strategically developed supply networks with well-connected relationships at the core of the supply structure can be used to produce a strategic advantage (Williams et al., 2002). The same interfirm networking tools, including supply chain portals, are becoming the key enablers of supply-chain integration. Knowledge becomes a valuable asset and is shared through the use of these portal technologies, along with critical supply-chain information. Toyota, who has established portal-linked supplier knowledge networks that create shared goals, promote knowledge-sharing activities, and exchange best practices, is an excellent example. Not only is valuable knowledge created through the use of technology, but relationships within the supply chain are strengthened. The results have been output per worker increasing 14%, inventories reduced by 25%, and defect rates 50% lower than operations that supply Toyota's rivals (Dyer & Hatch, 2004).

SUPPLY CHAIN COLLABORATION WITH PORTAL TECHNOLOGY

As previously discussed, a supply chain incorporates processes involving buying, making, inventory, selling, and delivery. Each of these processes can benefit from an extended enterprise structure supported by portal technology. Through the increased information and knowledge sharing provided by portals, these functions can evolve into mature processes offering an organization a competitive advantage.

The buying function of a supply chain procures the necessary materials required for the product of the goods and services. In order to lower costs by leveraging combined purchasing volumes, a portal can link the network's buyers into one central purchasing function, allowing for controlled costs and the ability to negotiate lower costs based on volumes from the entire network. Standardized items can be designated, allowing for further standardization throughout the network. Tracking information for purchases can be made available to the entire network, allowing for production and sales planning at the other end of the supply chain. Notification of supply shortages or delays can be shared with network participants, allowing them to plan their schedules accordingly. Ultimately, a purchasing partnership may emerge, which is "... an agreement between a buyer and a supplier that involves a commitment over an extended time period, and includes the sharing of information along with a sharing of the risks and rewards of the relationship" (F.-R. Lin, Huang, & Lin, 2002, p. 148).

The making of goods and services, which would include the product design and development functions, can gain a great deal of value from portal technology. In supply chains following the collaborative model, network partners face the challenge of connecting with their partners to exchange product requirements information (Lin, Hung, & Wu, 2002). Portal applications supporting production chain collaboration should allow for the acquisition, sharing, optimization, and utilization of these requirements between customers and partners to detect any discrepancies or gaps within the requirements. Concurrent engineering (McIvor, Humphreys, & McCurry, 2003) supports collaborative product design processes through connecting multifunctional teams comprising of design and manufacturing employees and customers and suppliers. Portal technology linking supply chain applications can play a major role in supporting such concurrent engineering. Collaborative work applications implemented by all partners across the supply chain can be instrumental in the development of specifications, creation of interchangeable parts, part standardization or simplification, and part exclusion, all of which contribute towards cost reduction. Huang and Mak (1999) describe such a system consisting of ”virtual consultants” in ”virtual teams” organized within a “virtual office” equipped with “virtual design board,” available to all participants no matter where they are located, whether internal or external.

Cycle time is a key measurement for determining the efficiency of inventory processes. The goal is to reduce the time raw materials are delivered to customers in the form of finished products. Location of inventory can be a factor in reducing cycle time and ensuring prompt responses to a customer's needs. As well, excess or safety inventory must be managed through demand forecasting and tracking. Information and knowledge sharing can easily locate needed inventory stocks that maybe have been "hidden" to other partners in the past, or highlight ways to reengineer processes in order to speed the movement of inventory through the supply process. Initiatives, such as a continuous replenishment program (CRP), vendor-managed inventory (VMI), or quick response program, all rely on the dissemination of shipping and manufacturing information to externally distributed parties (Tan et al., 2000). Recently, portals have begun to play a key role in facilitating this information and knowledge sharing and enabling such programs.

The selling and marketing processes of the organization's goods and services are a large benefactor of portal technology. To ensure the products are targeted towards the correct markets, knowledge must flow across an organization's external boundary from its customers. Knowledge on product uses, market information, and channel information is necessary for the development of new successful products and services (Paquette, 2005). Information contained within customer relationship management (CRM) applications can also be supplied through portal technology to all members of the supply chain, ensuring a focus on the customer and consistent information throughout. Many supply chains with a mature portal technology infrastructure can directly link customers into their systems, allowing for point-of-sale ordering that creates an instant response and a rich stream of information (Kahl & Berquist, 2000).

In processes involving product delivery, logistical issues such as shipping dates, route mapping, delivery costs, and the development of a physical supply network arise. Just-in-time delivery has become a goal for many companies who wish to not only minimize the costs of carrying inventory, but manufacture and deliver the product based on information received from a customer. This requires all partners within the chain to have access to the same customer and manufacturing information, and an efficient supply network capable of handling such timely requests. Portals support this information, as when a customer order is received, all aspects of the chain can prepare for manufacturing and delivering the item, reducing the time for delivery and increasing customer satisfaction. Companies evolve from make-and-sell strategies to sense-and-respond capabilities (Bradley & Nolan, 1998). Trends in orders can be identified through this information, and capacity plans, material allocation, and supplier notification can all be adjusted accordingly (Handfield & Nichols, 2002).

COLLABORATIVE CHALLENGES

A common challenge with the networking of a supply chain is the integration of many technologies and applications that must work together to share similar information and knowledge (Cohen & Roussel, 2005). This problem of systems complexity can be minimized through the use of portal technology that integrates multiple applications and platforms in order to eliminate "application islands."

Specifically, the network of partners must come to an agreement on system interfaces and standards. Three kinds of system interfaces can create issues: (1) the agreement on or standardization of the interfaces of business processes that facilitate supply chain integration; (2) the agreement on or standardization of the interfaces of the systems and components that together constitute the product and services the supply chain delivers to the markets; and (3) the agreement on or standardization of the interfaces of the information systems that support the collaboration and integration of the supply chain's operations. Portals have an advantage through their use of "portlets," or small applications, that manage the interface with other applications and portals to allow for seamless information and knowledge sharing. All aspects of the portal's system interface must be in agreement and well developed in order for the supply chain's collaborative effort to be cost effective and efficient (Mak & Ramaprasad, 2003).

Access and security becomes a challenge when dealing with such a distributive network. As the access points of the system increase, so does the possibility of unauthorized or improper access to confidential information. Portals utilizing proper security measures, including firewalls, digital certificates and encryption, and virtual private networks (VPNs) for transmitting across public Internet networks, can minimize the risk of revealing proprietary and strategic information to competitors (Lee & Wolfe, 2003).

FUTURE TRENDS

As the role of information and knowledge becomes more important in the management of a supply chain, so will the role of portal technology. The demand for information to be timely, accurate, and detailed allows a portal to connect various members of a supply chain and deliver such information.

Previous research on the portal industry and its role in supply chains (Paquette & Moffat, 2005) has demonstrated that portal vendors will have to continually improve the functionality that both supports secure high-volume interfirm interaction across large geographical distances, and also functionality that supports the exchange of tacit and experiential knowledge to enable learning. New portal functionality specifically for collaborative design development and real-time test during the creation of new products will enhance the ability of portals to improve the efficiency and effectiveness of a company's new product development and delivery processes. Creating a shared environment that supports white-boarding, 3-D drawing support, video conferencing, document coauthoring and sharing will be part of a portal's role in supporting the collaborative supply chain.

CONCLUSION

As supply chains continue to move away from a commodity-based and more towards a collaborative model, their need for timely and accurate information throughout the supply network will increase. This demand allows for portal technology to be deployed in order to meet the interfirm information and knowledge-sharing needs. From the design and development of new products to their marketing and delivery, portals can supply the supply chain with the information required to meet the cost and time requirements of customers.

Portal technology can create a competitive advantage for a supply chain by enabling its information and knowledge-sharing capabilities to provide organizations with up-to-the-minute information regarding new products, customer demand, inventory status, and production schedules. As Internet technologies, and in particular portal applications, become more common amongst supply-chain members, their ability to create, identify, and utilize critical supply information will lead them to new levels of service, innovation, and success.

KEY TERMS

Collaborative Relationship: A form of supply-chain management relationships where supply partners share large quantities of information and coordinate many tasks, use relation-specific assets to maintain lower costs, improve quality and increase speed, and rely on trust to govern the longer-term relationship. A key factor in its success is the close task integration between supply partners that is enabled by the transfer of information and knowledge.

Commodity Relationship: A form of supply-chain management relationships where suppliers are kept at arm's length in order to minimize commitments and dependence on specific suppliers and to maximize bargaining power. It is widely used with the goal of achieving cost savings under competitive pressures by keeping supplier relationships very limited to minimize switching costs.

Just-in-Time Inventory: The process where inventory is delivered to the factory by suppliers only when it's needed for assembly. It facilitates the cost-effective production and delivery of only the necessary parts in the right quantity, at the right time and place, while using a minimum of facilities, equipment, materials, and human resources. Its purpose is to eliminate any function in the manufacturing system that causes overhead, slows productivity, or adds unnecessary expense.

Supply Chain: The integration and management of supply chain organizations and activities through cooperative organizational relationships, effective business processes and high levels of information sharing to create high-performing value systems.

Supply Chain Management: A set of approaches utilized to efficiently integrate suppliers, manufacturers, warehouses, and stores, so that merchandise is produced and distributed at the right quantities, to the right locations, and at the right time, in order to minimize system-wide costs while satisfying service level requirements.

Vertical Integration: A supply-chain strategy whereby one business entity controls or owns all stages of the production and distribution of goods or services. It is the extent to which a firm owns its upstream suppliers and its downstream buyers. Control upstream is referred to as backward integration (towards suppliers of raw material), while control of activities downstream (towards the eventual buyer) is referred to as forward integration.

Virtual Private Network (VPN): A data network that uses public telecommunications infrastructures, such as the Internet, but maintains privacy through the use of a tunneling protocol and security procedures. A VPN gives a company the same capabilities as a system of owned or leased lines to which that company has exclusive access.

Chapter 3.21

CRM Practices and Resources for the Development of Customer-Focused Multinational Organizations

Luciano C. Batista
University of Exeter, UK

ABSTRACT

This chapter aims to provide a complete characterization of the different perspectives of customer relationship management (CRM) and its potentialities to support knowledge management practices in a multinational context. It describes the strategic and technological dimensions of CRM and how its adoption supports the development of a learning and customer-focused organization, with special emphasis on multinational corporations. CRM strategic approach entails the adoption of customer-focused initiatives and the development of learning relationships with customers. On the other hand, its technological dimension integrates a variety of different information and communication technologies, which makes a powerful system for improving the process of knowledge acquisition. This way, different subsidiaries of a multinational corporation can develop their learning capability so that they can better identify local market demands. As a result, the corporation is able to more accurately create a global knowledge stock about its different markets in different regions of the world.

INTRODUCTION

The current world is witnessing profound developments in the areas of information technology and business strategy. In the technological area, recent developments have led telecommunication technologies to reach a high level of integration with computing technologies and vice versa. This trend has had a strong impact upon society, promoting, among other things, an enlargement of the conceptual focus of information technologies to embrace the notion of relationship technologies. Regarding business strategy aspects, companies are creating a sound and lasting competitive advantage by adopting "relationship" as the word of order. As a matter of fact, the confluence of changing customer demands, emerging marketing and business theories, and available information and communication technologies (ICTs) have been imposing a shift on the way organizations relate to customers. The gap between strategic marketing approaches and ICT deployment has been diminished over time, culminating in integrated business approaches that involve both strategic and technological dimensions at the same time. This chapter focuses on the integration of knowledge management (KM) and customer relationship management (CRM) approaches.

At the same time as the rise of new ICTs, there has been the development of CRM and KM approaches for enhancing both relationship strategies and organizational learning capabilities. For instance, the evolution and integration of different ICT over time enabled the adoption of different and more evolved marketing approaches, giving birth to the present CRM systems. These systems support the development of current relationship strategies, which, in turn, were delineated by the evolution of marketing relationship strategies over time. On the other hand, market knowledge—which is directly related to information about customers and other environmental elements—and internal knowledge have become a strategically important resource for an organization, serving as a basic source of competitive advantage (Cui, Griffith, & Cavusgil, 2005).

In practice, CRM systems provide the functionality that allows an organization to make its customers the focal point of all departments within the firm. This way, the organization will be able to respond to its customers on a continual basis. More specifically, customer information databases and integrated interactivity enable an organization to develop a learning relationship with its customers, creating organizational capability to differentiate customers and markets, and to develop personalized interactions so that tailored products or services can be offered. In the context of multinational organizations, the adoption of CRM practices and solutions can improve the process of knowledge acquisition in different local markets, allowing multinational corporations to define and develop both local and global strategies according to regional demands. For example, in a multinational environment, CRM allows different subsidiaries to develop long-term learning relationships with their local customers, which makes the creation of specific business intelligence concerning local market demands possible.

In other words, CRM can be considered as a key element for supporting knowledge management in multinational organizations. Its strategic approach entails the adoption of customer-focused initiatives and the development of learning relationships with customers. On the other hand, its technological dimension integrates a variety of different information and communication technologies, which makes a powerful system for improving the process of knowledge acquisition. This way, different subsidiaries of a multinational corporation can develop their learning capability so that they can better identify local market demands. As a result, the corporation is able to more accurately create a global knowledge stock about its different markets in different regions of the world.

The strategic and technological dimensions of CRM are extremely intertwined and, as a matter of fact, the emergence of CRM strategies, concepts, and practices would not be possible without the appearance of new and evolved ICT resources. This chapter aims to provide a complete characterization of the different perspectives of CRM, describing its origins, concepts, paradigms, technologies, and its potentialities to support knowledge management practices. Considering that the adoption of CRM practices and solutions can generate substantial knowledge about an organization's customers, this chapter aims to describe the strategic and technological dimensions of CRM and how its adoption supports the development of a learning and customer-focused organization, with some special emphasis on multinational corporations (MNCs).

By reading this chapter, the reader can get a better and deeper understanding of the following aspects:

- What CRM is
- The strategic and technological dimensions of CRM
- The main challenges of CRM implementation
- CRM measurement aspects
- Practical considerations regarding CRM adoption
- The main CRM supporting roles to KM in a multinational context

ORIGINS AND CONCEPTS OF CRM

The acronym CRM per se does not explicitly convey what it is about. Sometimes it represents an information system, other times it represents a strategic business approach. Different authors interchangeably use CRM to address one thing or another, which may cause some confusion as to whether they are talking about an information system or a business strategy. The problem is that CRM strategies have emerged together with the information and communication technologies that allowed their practical implementation and feasibility. In terms of technological developments, underlying technologies are becoming less operationally complex and less expensive, and so their facilities and resources are being increasingly used by people, enterprises, and governments. The Internet, for example, is a key information technology that can also be viewed as a relationship technology. It is perhaps as a consequence of the ubiquity of such technologies that organizations have been focusing on relationship strategies. Turning to the business strategy aspects, companies are creating a sound and lasting competitive advantage by developing long-term learning relationships with their customers. At the same time as the rise of new information and communication technologies, there has been the development of the CRM concepts for implementing relationship strategies that enable sound organizational learning capabilities.

The Origins of CRM

CRM has its roots in relationship marketing strategies and its antecedents. As a matter of fact, developing good relationships with customers is a very old practice; as Sterne (2000) well illustrates, since the mid-eighteenth century pharmaceutical retailers in Japan have been practicing relationship management with their clients. Individual families are regularly visited by sales representatives, who review the contents of their company-issued medicine cabinets. The items that have been used are replaced, and the items that have not are either removed or replaced according to their expiry dates. Of course, on a small-scale context, such practice is completely feasible; however, on a large-scale context it becomes unviable.

With the development of mass media communications such as the printed press, radio, and TV, companies became able to communicate to millions of people at once. Gummesson (1999) points out that, during the industrial era, mass manufacturing gave birth to mass marketing and mass distribution. There were no technologies to address individuals. As a result, the marketing focus has changed from customer to product and brand recognition. The approach of personalized services was disregarded until new technologies appeared to foster new approaches. Table 1 provides a complete view of the different evolutionary phases of marketing strategies over time.

Of course, direct sales force and telemarketing efforts have not vanished, nor have mass marketing strategies been totally discarded. Naturally, if a company is successful in acquiring new customers, then at some moment it will reach a large-scale context; consequently it will need mass approaches. In many companies, different

Table 1. Evolutionary phases of marketing strategies (Source: Adapted from Ling and Yen, 2001)

PHASE	TIME PERIOD	FEATURES	DRAWBACKS
Direct Sales	Since long ago	Small stores; personalized services; intimacy and knowledge about customers; developed loyalty and trust	Cost inefficiency; small scale of business
Mass Marketing	After industrial era	Centralized large-scale production; wide-geographic distribution; one-way communication; cost efficiency; measure of success: market share	Does not have the sense of connection; low loyalty
Target Marketing	Since mid-1980s	Use IT to target customers by mail or telephone; direct communication with the target; potential reception of direct responses; measure of success: response rate	Interaction at a superficial level, not far enough; lack of more detailed customer data
Relationship Marketing	Since 1990s	Develops intimacy by using IT and maintaining mass production and distribution; recognizes that both knowledge and personal interaction yield trust and loyalty	Difficult to implement; involves various business functions; mainly for consumers instead of industry

marketing strategies are being combined to approach customers. However, it has been reported that there is a lack of cohesion between these strategies, which sometimes leads to confusion as customers receive multiple and uncoordinated messages through separate channels (Ling & Yen, 2001).

Instead of perceiving CRM as a revolutionary business strategy that came to substitute all the ones that preceded it, it would be more coherent to perceive CRM as a business strategy that proposes personal interactions even in a mass context, taking advantage of the strengths of previous approaches. This kind of large-scale personalization is perfectly feasible through the application of current information and communication technologies. Indeed, the availability of highly evolved telecommunication and information technologies was crucial for enabling CRM practices.

Concepts of CRM

Generically speaking, CRM is a term interchangeably used to refer to ICT or business strategies that improve an organization's capability to develop lasting and learning relationships with its customers. These two perspectives of CRM (technological and strategic) are extremely intertwined; however, CRM is more than a different way of applying existing technological and marketing tools and managing them. From a strategic point of view, CRM can be understood as an organization's broad business strategy, which focuses on building customer-personalized interactions whatever the channel of contact between the organization and its customers (Business Guide, 2000). Given its amplitude, it is fundamental to be aware that the implementation of CRM strategy is not just the responsibility of the marketing department or other customer service sectors. For Ling and Yen (2001), CRM is a broad strategic business process that involves the organization as a whole, spanning across different business functions rather than just within a particular product or business unit. They also affirm that CRM comprises a set of enabling systems that supports a business strategy to build lasting and profitable relationships with customers. A better understanding of customer needs and preferences is the way to enhance customer value, and this aspect is one of the major objectives of CRM.

It can be argued that CRM concepts have also evolved alongside the evolution of information and communication technologies. Making an analogy with Peppers and Rogers' (1993) characterization of today's media, we can identify three important characteristics of today's information technologies: (1) they can address individuals, (2) they are two-way channels, and (3) they are economically accessible. These technological aspects support the implementation of a chief strategy that is at the core of CRM philosophy: the one-to-one approach, which is mainly based on the development of personalized interactions between an organization and its customers. This approach is considered by Kandell (2000), who affirms that CRM involves the use of technology to identify, interact, and track every transaction with individual customers, developing a learning relationship with them. A clearer and more straightforward definition of CRM is provided by Buttle (2004), according to whom:

> *CRM is the core business strategy that integrates internal processes and functions, and external networks, to create and deliver value to targeted customers at a profit. It is grounded on high-quality customer data and enabled by IT.* (p. 34)

Taking into account the definitions and concepts we have seen thus far, it is possible to notice that its holistic business approach and information technologies are elements usually present when the CRM subject is addressed. Therefore, it is imperative to further characterize these two dimensions of CRM in a more specific way for further discussion. In the next two sections, we are going to expand on the strategic and technological aspects of CRM.

STRATEGIC ASPECTS OF CRM

Marketing concerns have progressively shifted from developing, selling, and delivering products to developing and maintaining a mutually satisfying long-term relationship with customers, as enduring relationships with customers provide a unique and sustained competitive advantage that is hard for a competitor to duplicate (Buttle, 1996). This latter argument might explain the fact that recent surveys indicate that CRM is becoming a major element of corporate strategy for many organizations throughout the world, and its implementation is considered a key aspect for the future performance of organizations (Abbott, Stone, & Buttle, 2001; Hansotia, 2002). Looking at some statistics of CRM growth rates, according to a report from The Conference Board,[1] more firms are adopting CRM programs. Fifty-two percent of 96 global firms recently surveyed by The Conference Board have implemented a CRM system or solution. Among these, the top three strategic rationales for implementing CRM were to: (i) increase customer retention/loyalty (94%); (ii) respond effectively to competitive pressures (77%); and (iii) differentiate competitively based on customer service superiority (73%). Across all surveyed firms, half of the total marketing investments were toward driving revenue, while one-third went towards building relationships. The average strategic time horizon employed for the CRM project was almost three years, with an average estimated implementation time of four years. In terms of market value, the numbers show that CRM is a phenomenon not to be ignored. In 2000, Kandell (2000) commented that the CRM market would be worth more than $16 billion by 2003. Two years later, a Gartner Group report showed that organizations worldwide paid $23 billion for CRM services and software, and that amount was expected to rise to $76 billion in 2005 (Pang & Norris, 2002). It can be argued that the differences between the reported numbers were due to different analysis criteria. Despite the differences, the numbers showed that CRM is a billionaire market. The high amounts involved can be explained by the fact that the range of CRM solutions is very broad, and it requires integration and improvements in information and communication technologies to enable the adoption of customer-oriented strategies.

A central practice in CRM strategy is to exploit customer insight and information to create profitable customer relationships (Abbott et al., 2001). Indeed, each customer interaction produces extensive data; the purpose of CRM is to make inferences over this data in order to allow an organization to identify patterns of customers' consuming behavior as well as to identify customers' profiles, needs, wants, and preferences. To achieve continuous improvement, an organization should track the results of customers' interactions and use such knowledge to refine further actions (Ling & Yen, 2001). This practice is reputed to promote the following organizational benefits:

a. **Retention of existing customers** through the process of anticipating offers according to customers' expectations over time and delivering personalized goods and services according to the customers' profile (Sterne, 2000).
b. **Acquisition of new customers** by prospecting and analyzing peoples' first contacts so that potential customers' interests can be matched (Buttle, 2004).
c. **Building of customer loyalty** through the process of listening, understanding, and responding according to customers' needs, wants, and behavior (Business Guide, 2000).
d. **Raising of customer profitability** through the process of providing high targeted solutions according to the customers' value (Ling & Yen, 2001; Khirallah, 2000).

Other benefits such as the improvement of customer lifetime value, raising of customer satisfaction, execution of faster services, costs reduction, improvement of sales force, better response rates, and so forth are also claimed to be promoted by the adoption of CRM initiatives (Kandell, 2000; Khirallah, 2000; Sterne, 2000; Buttle, 2004). Besides, Silverman (2001) comments that successfully implemented CRM strategies can promote a high return on investment. He argues that statistics from different sources show that organizations that have successfully adopted CRM enjoy higher prices and profit margin, faster growth rates, lower customer turnover, and an increased market share.

The benefits addressed thus far constitute strong reasons for CRM adoption. In order to achieve the organizational benefits we previously commented on, an organization should develop the ability to efficiently and effectively leverage customer information so as to design and implement customer-oriented strategies. The development of customer-focused strategies represents the heart of CRM tenets. As Hansotia says, CRM strategies are:

> …*strategies that celebrate differences in customers' values, potentials, needs and preferences. It is about leveraging customer knowledge to get closer to customers by anticipating their needs and communicating intelligently with relevant offers and messages, while all the time nudging them to increase the breadth, depth and length of their relationship with the firm.* (Hansotia, 2002, p. 122)

Moreover, CRM entails the management of customer interactions so that an organization can leverage customer knowledge to design and provide unique services and memorable experiences that customers will value and will be willing to pay for. To have a long-term effect, each experience must exceed expectations adding to the customers' stock of goodwill toward the company. The interactions should be reasonably frequent, error free, and quickly meet customers' needs and wants (Hansotia, 2002).

It is important to point out that, in order to meet customer particularities at a maximum level, customers' differences and common patterns should be observed. These insights are obtained by developing segmentation schemes. As Hansotia (2002) describes, segmentation techniques can be used to characterize and help understand different customer groups. Segmentation methods aim to group customers according to their preferences for products, services, channels of interaction, and the magnitude and frequency of their interactions with an organization. Once different behavioral segments are identified, each segment can be further profiled with additional information, such as survey-based attitudinal and satisfaction data. In the end, the organization will be able to learn, for instance, what the most profitable customers look like, which customers have a high propensity to buy certain products or services, or who the high-risk customers are. Hansotia (2002) also warns that prior to selecting the basic variables and dimensions that will be used to construct the segments on which customers' differences are to be observed, significant discussions should take place.

Indeed, the adoption of CRM strategies requires the commitment of an organization's administrative first echelon, demanding wide organizational discussions that involve not only the chief executive officer (CEO), but also all his or her direct reports. This is because CRM adoption usually presses for fundamental cultural shifts within organizations as well as new forms of organizational structure that might challenge current norms and practices (Abbott et al., 2001). Therefore, it is paramount that an organization revisits its mission statement to certify that it clearly addresses the company's focus on the customer, ensuring that CRM strategies tie in with the overall organizational mission and related strategies (Hansotia, 2002). This latter aspect is further detailed next.

Further Strategic Considerations

Strategic management considerations are vital for successful implementations of CRM solutions. Knowing how to introduce strategic changes is the major challenge facing executives acting in a business environment characterized by rapidly advancing technology and fierce competitiveness.

Strategic management deals with the overall direction of an organization, involving decisions regarding very important issues such as financial investments, technological improvements, and the well-being of the people who might be affected by the firm's activities. According to Finlay (2000), the number of people contributing to strategic management has increased considerably over the past decade. This is because organizations are realizing that the implementation of successful change is easier when made by the people responsible for the implementation and by those affected by the change. In practice, lower-level managers interact much more with the organization's main stakeholders, picking up trends in the environment and marketplace, and passing the information to the senior managers who can authorize action. This way, strategic management can be seen as a process where each of an organization's sub-units initiates much of its own strategy, contributing to form the organizational strategy (Thompson, 1997). Despite the advantages, if the process is not conducted in a coordinated manner, the sub-units' initiatives will not be consolidated at a higher organizational level and the solutions will remain fragmented within the sub-unit silos. Another important aspect is that the sub-units' initiatives should meet and strengthen the corporate strategic goals.

Therefore, it is extremely important for an organization to establish and communicate its vision, mission, and strategic goals to all its stakeholders. Basically, the organizational vision can be understood as a view of a future intended by an organization. Based upon this vision, the organization formally states its mission, which is a formal statement of the broad directions that the organization wishes to follow. The mission should contain a broad indication of the organization's offers and customers. Finally, the strategic goals are a formal establishment of an organization's purpose, setting out the scope of the organization's operations. Finlay (2000) warns that suitable goals should be relevant to the mission. This latter aspect is also addressed by Rowe, Mason, Dickel, Mann, and Mockler (1994) when they comment that organizational goals are chosen to align the organization more closely with its values and mission. They also point out that establishing goals and finding strategies that lead there [to the goals] are fairly straightforward tasks. However, there are difficulties when organizations attempt to take the stakeholders' interests into account. This latter concern is shared by Finlay (2000) when he positions the organization's relationships with stakeholders among the major strategic management concerns, namely:

- Matching the organization and its environment
- Initiating and handling both evolutionary and transformational change
- Managing the organization's relationship with stakeholders
- Balancing short- and long-term considerations

Increasingly, diverse groups are making claims as stakeholders in organizations. A stakeholder analysis should begin with the identification of as many relevant stakeholders as possible (Rowe et al., 1994). In the sequence, strategic managers should identify assumptions about the stakeholders in order to figure out the contribution that relationships with them can make to the well-being of the organization, and then to establish and maintain good relationships with them (Thompson, 1997; Rowe et al., 1994).

Buttle (2004) comments that a customer-centric firm is a learning firm that continuously adapts to customer requirements and competitive conditions. To develop customer-oriented strategies, organizations should put the customer first, collecting, disseminating, and using customer information to create better value propositions for customers. Appropriately dealing with massive customer information on a large-scale context is not a simple task; this is when information and communication technologies come onto the scene.

TECHNOLOGICAL ASPECTS OF CRM

Technology is a crucial factor in the move to CRM. It would not be possible to implement CRM strategies without the use of the current information and communication technologies. In order to implement relationship strategies and exploit their relationship technologies, companies are deploying and integrating CRM systems with their legacy systems, as well as integrating CRM systems with their network channels and the Internet. When well managed, these integrations are reputed to constitute a successful combination of technologies that provide the necessary resources to make the execution of the strategies that will situate a company in a much desired position possible: closer to its customers (Ling & Yen, 2001). Getting closer to customers means developing the ability to know customers' needs and wants in a more accurate, efficient, and effective way, which allows the development of positive, lasting, and learning relationships with customers, hence improving an organization's corporate reputation. The results are extremely significant and positive in terms of long-term strategies and business leveraging.

From a simple perspective, CRM is fundamentally a customer data intensive effort (Hansotia, 2002). We can say that CRM is grounded on generating knowledge from customer data, and the process of knowledge generation is enabled by the deployment of a highly integrated technological infrastructure and the integration of organizational processes. Integration is vital for CRM; without the integration of technological resources and organizational processes, the CRM mechanism will not provide accurate customer information and, as a result, the identification of customer needs and wants will become a helpless guessing game (Business Guide, 2000). The high investments required by CRM adoption can be explained by the fact that the range of CRM solutions is very broad, and it may involve integration and improvements in information and communication technologies. According to Pang and Norris (2002), such integrations and improvements may include:

- Integration of computer telephony that can support call centers' activities, such as voice recognition for directing calls and matching calls against names in a database.
- Customer self-service Web sites that allow the customers themselves to conduct online transactions such as searching for relevant information, downloading forms and software, and requesting services or goods. Reducing a call center's inbound calls by automating the self-service features within the CRM system can result in lower labor and training costs.
- Improvement of business intelligence using segmentation and analytical tools that identify customers' patterns and needs. Detailed customer profiles allow a customized delivery of services and products; these profiles can be generated by CRM analytical tools that allow an organization to quickly identify target populations, this way reducing significantly a marketing cycle time (Berry, 2001).
- Implementation of mass customization processes through which goods and services are individualized to satisfy specific customer needs.

Moreover, CRM systems provide the necessary level of integration to allow seamless coordination between all customer-facing functions. Hence, productivity enhancement can be achieved by customer-facing personnel being able to do customer-related work more quickly and less painfully, since they no longer have to re-type customer information several times and do not have to look up a customer's overall dossier in multiple computer systems (Goldenberg, 2002).

Regarding processes integration, understanding the mechanisms of relationships with stakeholders allows a better definition of organizational processes, which can be seen as the frequency and direction of work and information flows linking the differentiated roles within and between departments of an organization (Hammer, 1996). Indeed, business processes are generally linked together to form a set that delivers a product or service to satisfy a specific stakeholder target—most usually the customers. Competitive success depends on transforming an organization's key processes into strategic capabilities that consistently provide superior value to the customers (Rheault & Sheridan, 2002). Furthermore, Warboys, Kawalek, Robertson, and Greenwood (1999) warn that organizational processes cannot be considered in isolation from the information systems (systems as applications and tools, or systems as infrastructure) that are potentially available.

Regarding the latter issue, one important set of applications that automates and tracks customer processes, as well as integrating these processes with back-office systems, is known as "workflow applications." This characteristic makes workflow products ideally situated to address the demand for CRM solutions. Chambers, Medina, and West (1999) have conducted a comparative assessment of workflow products focusing on how well workflow vendors have adapted their technologies to provide CRM solutions. They found that many of the workflow vendors have indeed responded with product offerings that can handle many of the key application requirements of CRM scenarios. Analyzing four key customer-related scenarios—new order processing, customer complaint handling, new product development, and call center—they identified two main techniques with which workflow vendors began to provide workflow-enabled CRM solutions. These are: (1) providing tightly coupled workflow and CRM capabilities, or (2) offering workflow solutions that can be easily embedded in any CRM platform. According to them, with so many workflow vendors contributing to CRM initiatives, it is clear that workflow as a standalone technology is disappearing and moving toward products that embed productivity, efficiency, and competitive advantage—such as CRM systems.

In fact, as we are going to see next, workflow application is only one of the many technologies that can be involved in the scope of CRM systems.

Main CRM Components and Functionalities

We previously commented that CRM can be understood as an organization's broad business strategy, which focuses on building personalized interactions with customers whatever the channel of contact between the organization and its customers. Each customer interaction produces extensive data, and the purpose of CRM strategy is to make inferences over this database in order to promote organizational benefits such as retaining existing customers, building customer loyalty, raising customer profitability, and so forth. However, there is no way of implementing any CRM strategy without information technology support. This way, different software developers have been developing a broad number of CRM systems, applications, or tools that combine existing ICT in different ways.

Generally speaking, the broad categories of CRM solutions involve a set of integrated applications that embody different aspects and functionalities. The core of CRM technologies can be classified into three general areas according to their general roles or purposes (Dean, 2001; Miles, 2002):

1. **Operational:** Technologies that manage customer service activities in storefronts, call-centers, and field service databases. These databases store historical data necessary for the construction of a single view of the customer.
2. **Collaborative:** Technologies that support field self-service applications on the Web, enabling different types of customers to work across a single service channel. This area embraces many communications media, including fax, e-mail, voice calls, text chats, and so forth.
3. **Analytical:** Technologies that provide sifting facilities through data created during customers' interactions to find or generate useful business information. These technologies encompass a collection of tools where data is combined with logical rules in order to generate insight. This area also maintains specific rules for acting on insights.

As we can see, a CRM system is not a single program or technology; it is a set of software, hardware, and network technologies that are integrated together to provide a more complete organizational capability to generate customer knowledge. In a more specific way, McKendrick (2000) describes CRM system or application as an umbrella term involving the four categories of applications below:

- **Sales Force Automation:** This is a set of tools for sales professionals. The set has functionalities such as calendaring, forecasting, contact management, and configuration models.
- **Marketing Automation:** This is a set of tools for automating marketing departments' processes and operations, including Web and traditional marketing campaigns.
- **Customer Service and Support:** This is a set of tools for leveraging and managing information in customer contact centers, such as call-centers or internal helpdesk.

- **Channel and Partner Management:** Also referred to as a partner relationship management (PRM) system, this is a set of tools that supports and tracks activities with distributors, sales channels, resellers, and retailers.

It seems that McKendrick has included PRM systems in the core of CRM applications, considering that partners' demands somehow represent end users' demands and tracking these demands allows a more comprehensive view of customers' needs and wants in general. This aspect is strengthened by Buttle (2004), who comments that partners have access to end consumers; thus, they can provide information on changing customer profiles, customer expectations, or sources of customer satisfaction and dissatisfaction.

Another important category of application called "employee relationship management" (ERM) is also being involved in the reach of CRM solutions (Callaghan, 2002). The reasoning behind this idea is that by using a CRM approach, HR professionals are beginning to better understand employees in a whole new way. More specifically, ERM deploys solutions similar to CRM solutions such as analytical and segmentation tools, smart Internet tools, and interactive technology to care about employees, allowing HR professionals to more accurately identify employees' motivations, needs, and preferences as well as better aligning employment practices to real needs, which minimizes staff turnover and, at the same time, maximizes staff retention by the definition of more appropriate recruitment profiles. The final results promoted by ERM adoption are better-equipped managers, employee loyalty, empowered employees, improved employee satisfaction, preferred employer status, and reduced costs (Dorgan, 2003).

In terms of system support information technology, there are some computer technologies that should be allocated in order to fully implement a CRM system with all its functionality. It is important to point out that these technologies were not developed exclusively for implementing CRM systems; they were developed in different periods and for several purposes. Their link with CRM exists because their resources and functionalities made the implementation of CRM systems a feasible process. Therefore, they are fundamental to support CRM initiatives. Some of the main technologies that can be considered as core components of CRM systems are:

- **Data Warehouse:** This is a special kind of database that can manage a large amount of data with very high performance; it is generally used to store historical data, and its advanced functionalities allow more flexibility when retrieving information. Most often, the integrations with legacy and external data sources are made through data warehousing technologies. In CRM systems, a data warehouse is generally used as the central customer database that provides a single view of customers. For example, the database can provide key information on customers' orders, requests, problems, and so forth. This sort of information assists service representatives to resolve problems in a more efficient and effective way. Data warehousing technologies are also used as recommendation engines that store predetermined customer treatment recommendations, which are updated after each customer interaction (Todman, 2001; Hansotia, 2002).
- **Data Mining:** This technology combines concepts of statistics and artificial intelligence to help users analyze and extract predictive information from large databases such as, for example, data warehouses. In CRM systems, data mining software uses historical information stored in customer databases to build a model of customer behavior that could be used to predict which customers are more likely to respond to new services

and product offers. Such information can then feed other touch point systems such as call centers, e-mail systems, direct mail, and so forth, so that the right customers receive the right offers (Berry & Linoff, 2004). Data mining tools can predict future trends and identify behaviors; this way, businesses are able to make proactive, knowledge-driven decisions.

- **Online Analytical Processing (OLAP):** This technology transforms information stored in databases into a summarized format that allows managers to quickly drill-down on tables and graphics to analyze where a certain problem may have arisen. One of its strongest resources is that the analysis tools can also support decisions in real time; for example, a call-center agent may be promptly informed about customer scoring or predictive measures while the customer is on the telephone. Such a characteristic is called "real-time CRM" by some vendors. Another powerful OLAP functionality involves the setting of trigger points by the users so that they can be automatically informed when, for instance, a customer calls more than a certain number of times in a month (Buttle, 2004).
- **Segmentation Tools:** These technologies provide the functionalities that allow an organization to identify and group its customers according to key characteristics such as demographic, socioeconomic, housing, behavioral characteristics, and so forth. This way, organizations have a better understanding of their customers' market behavior, tailoring their products and services according to the different customer segments or types present in a database. Customer segments can also be targeted through their preferred media or channels of contact (Doyle, 2002). For Todman (2001), the capability to accurately segment customers is one of the important properties of a data warehouse designed to support a CRM strategy. However, there are other segmentation tools in the market.

Besides the technologies mentioned above, other complementary technologies such as campaign management tools (technologies that support the designing of marketing campaigns and strategies), interfaces to the operational environment, and interfaces to the communications channels can also be allocated by CRM systems.

In practice, customers can interact with organizations through several different channels or means of contact, namely: face to face, by telephone or fax, by post, through the Internet, and so forth. Customer interaction management solutions enable front-office integration, providing an appropriate environment with resources and facilities that allow customer-facing staff to deal with all customer interactions, regardless of the channel of contact. In another layer, workflow functionalities provide integration of front-office with back-office. Workflow solutions play a major role in enabling CRM initiatives to provide a higher quality of service to customers, allowing organizations to design automated processes to enhance the productivity and responsiveness of their workforce (Ling & Yen, 2001). A central data warehouse provides a single customer view, enhancing front-office integration with back-office and integration with legacy systems, and improving organizational performance at the back- and front-office. Data mining and segmentation resources provide the intelligence that allows organizations to better understand their customers' attributes and get better results. Among these technologies, the Internet is one of the most powerful. The adoption of Internet functionalities and capabilities by CRM systems constitutes a specific set of CRM applications termed "e-CRM."

e-CRM

Electronic CRM or e-CRM can be seen as a set of applications that takes advantage of the potentialities of the Internet environment to implement relationship practices. Indeed, the "Web" is a powerful channel available for organizations to develop and enhance interactions with customers; this is why the Internet has become crucial in supporting CRM efforts. McKendrick (2000) argues that a robust CRM site must have strong customer service functionalities; in addition, the site should also provide interactive chat, browser and application sharing, personalization, e-mail options, and content management. The implementation of such facilities significantly varies from one organization to another; generally speaking, Sterne (2000) describes different evolutionary stages of Internet sites according to the use of e-technologies by organizations:

- **Phase 1:** This is a basic level. Organizations use the Internet only to exhibit catalogs or brochures on their Web sites.
- **Phase 2:** At this phase, organizations include on their Web sites additional information for promoting and selling their products or services.
- **Phase 3:** At this stage, organizations begin to offer additional functionalities and services to assist customers in making decisions or finding solutions on their Web sites.
- **Phase 4:** At this level, the organizations' Web sites have facilities to promote effective customer relationship management through highly interactive mechanisms for both supplying customers with enough information and services, and getting strategic information from customers' interactions.

Based upon the phases above and taking into account the Internet resources, accessibility, and affordability, we can infer that the Web is a popular way for an organization to gradually build customer relationships (from phase 1 to 4). In order to respond to marketing demands and maintain competitiveness, organizations are increasingly considering the strategic value of the Internet as a means of enhancing relationship strategies. E-CRM solutions are situated at the most advanced level of e-technologies applications. Therefore, e-CRM initiatives require a more advanced level of computer and telecommunication organizational infrastructure.

Wireless CRM

It is important to consider that the evolution of wireless technologies, such as Wireless Access Protocol (WAP) and devices such as mobile phones and personal digital assistants (PDA), may potentially change the face of CRM applications. The rationale for this argument is that salespeople and mobile service personnel will be able to access customer data through Web-enabled handheld devices wherever they may be, cutting companies' expenses and increasing their efficiency. Furthermore, the customers themselves will be able to access service applications using wireless devices. As Songini (2001) illustrates, the General Motors Corporation has a wireless customer relationship management program available to let drivers know what to do when the "check engine" light goes on. McKendrick (2000) also addresses the wireless tendency of CRM systems, commenting that mobile devices will significantly alter the CRM market; the widespread use of wireless and remote technologies will require CRM applications to have multiple entry points and be available on a 24-hours-a-day, 7-days-a-week basis.

Summarizing, the confluence of the technologies we have mentioned thus far, systematically coordinated and integrated by CRM systems, has enabled organizations to sift through large amounts of data to extract invaluable information and knowledge about their customer base. Without these technologies, the adoption of CRM concepts and practices would not be possible. Moreover, the integration of these technologies with other operational systems at the front- and back-ends of organizations provides the necessary seamless collaboration of resources, which is one of the main objectives of CRM. Unfortunately, the integration of different technologies is just the source of the main difficulties that organizations face when adopting CRM initiatives.

CHALLENGES OF CRM IMPLEMENTATION

CRM is one of many technologies touted as the panacea that led to excessive expectations and a high rate of implementation failure. Previous surveys show that as many as 60% of CRM implementations fail the first time (Silverman, 2001). A close examination of the problem reveals that CRM is an extremely broad area, which involves several categories of solutions and hundreds of products and services that focus on a wide range of business problems and technological opportunities. For instance, CRM embraces a wide range of processes such as product configuration, field service, customer service, and customer analysis (Reddy, 2001). The greatest challenge of implementing CRM initiatives is the deployment and integration of a number of diversified technological resources in different ways so that an organization can ensure that all front-office activities and customer interactions appear seamless to the customers. As Kandell (2000) exemplifies, CRM adoption requires:

- **Integration across all type of interactions:** marketing, sales, service, and support;
- **Integration across all media for interaction:** in-person, telephone, fax, e-mail, web site, and so forth; and
- **Integration across all channels of interactions:** sales force, telemarketing, retail, e-commerce, and so forth.

Moreover, the integration of CRM systems with back-office and legacy systems is also a crucial point for successful implementations. Gartner Group's specialists said that many CRM projects fail because they do not fully leverage and integrate all potential customer channels, and they are not fully integrated with legacy systems and back-office solutions (McKendrick, 2000).

Reddy (2001) mentions that lack of executive sponsorship, too much organizational change, and mismatched technology infrastructure are usually cited as the potential suspects of CRM implementation failure. However, he argues that these symptoms are not the root cause of the failure. Instead, the main cause of failure is the lack of an actionable CRM strategy. This latter argument is strengthened by Silverman (2001) when he comments that CRM can be highly effective if it is implemented in a strategic, focused, and holistic manner. He argues that:

> *Typical missteps involve implementing a CRM suite with the hope that it will address all of a company's objectives, a strategy that often ends in disappointment; or implementing a specific solution that is ultimately applied to the wrong problem. Some companies immediately jump into the implementation of a CRM solution without truly understanding the business issue they are trying to address…The CRM battlefield is littered with failed project corpses resulting from the 'ready, fire, aim' approach. As such, it is important to fully understand and prioritize the business problems or objectives you are trying to address rather than leaping to buy a CRM solution based on a strong vendor demonstration or industry hype.* (Silverman, 2001, p. 90)

Another problematic aspect is the fragmented universe of CRM applications; this characteristic may mislead organizations to wrongly implement CRM solutions. Payne and Frow (2004) address this problem, commenting that many organizations are adopting CRM solutions on a fragmented basis through a range of activities such as help desks, call centers, direct mail, and loyalty cards; and these activities are often not properly integrated. Considering the integration of different channels of interaction as one of the key cross-functional processes in CRM strategy development, they conclude that the adoption of a strategic perspective is fundamental for successful CRM initiatives.

Cultural Considerations

Organizational values are abstract ideas that underlie beliefs that managers have about the business and about people. Although they are very abstract, vague, and difficult to define, values are revealed by the actions people take, what they think, and how they allocate their time, energy, and skills (Rowe et al., 1994). The shared mindset regarding the basic or implicit assumptions that members of an organization unconsciously carry around with them is the organizational paradigm. In other words, the organizational paradigm can be understood as a set of concepts and perceptions shared by a group that determines how the group views the world (Finlay, 2000). Since the introduction of new technologies almost always requires changes in an organization's strategy and processes, organizational cultural aspects such as values and paradigms may impact positively or negatively on the introduction of innovations. According to Rowe et al. (1994), implementation failures are often attributed to the inability of an organization to consider its cultural aspects in order to understand how they are influencing the implementation of new strategies or processes within the organization. A positive posture supports the organization's mission and helps achieve its strategies. Contrarily, a negative posture may run counter to the expressed mission and strategies.

Generally, organizational values or paradigms cannot be easily changed. There is evidence that, in some circumstances, people's resistance may slow down radically or even completely impede the adoption of new business models and technologies (Margetts & Dunleavy, 2002). Since CRM implementation entails strategic, procedural, and technological redesign, we may therefore expect organizations adopting CRM initiatives to face resistance problems due to cultural aspects. More specifically, the adoption of customer-oriented strategies requires: (1) revision of organizational mission, posture, and strategic objectives toward customers; (2) process redesign in order to enhance organizational performance; and (3) introduction of new technologies to improve customer experience and staff efficiency. Therefore, it is fundamental to be aware that cultural barriers are potential problems likely to emerge when an organization is adopting CRM concepts and practices.

Through and beyond this, it is important to consider that cultural aspects largely determine the experience of employees in a company, which in turn is reflected in their behavior when interacting with customers (Buttle, 2004). A consequence of this fact is that customer-facing behavior can have a major impact on customers' sense of satisfaction and future buying intentions. One important aspect that strongly impacts on employees' experiences is the accessibility and sharing of customer information across an organization. Buttle (2004) points out that customer-facing employees are in a position where they have significant influence on customer behaviors, perceptions, and expectations; hence, they need to have access to a considerable volume of customer information so that they will be able to tailor their selling efforts and service performance to a specific customer or segment requirements. A potential problem that can emerge from this context is addressed by Bond and Houston (2003), who warn that cross-functional communication can be inhibited by strong functional identities and different customer unit domains. Indeed, previous research has shown that managers from distinct functional areas are likely to perceive strategic decisions from perspectives that originate in different functional subcultures, different self-identities and self-interests, and different beliefs about desired ends and their means of achievement. These differences generate conflict and poor communication among functions and sub-units, hindering the enactment of strategic decisions (Frankwick & Ward, 1994).

CRM MEASUREMENT ASPECTS

Measuring CRM aspects is still a challenge for most organizations. There is not a common pattern for gauging CRM initiatives. One of the reasons for this difficulty is that the concept of CRM is rather broad and one who wants to measure it should specify very clearly whether what is going to be measured is CRM as a business strategy or CRM as an application system, or even both. Another reason is that the variables considered to be measured vary from one company to another according to the company's activity or business, and these variables can vary even more largely from private to public organizations.

Regarding CRM as a business strategy in the private sector context, most of the attention concerning CRM measurement is focused on return on investment aspects. Two of the most used metrics for measuring the success of CRM efforts are revenue growth and margin growth (Ness, Schroeck, Letendre, & Douglas, 2001). However, some companies still prefer to consider classical parameters such as decreased costs and increased sales to measure CRM benefits (Khirallah, 2000). Given the amplitude of CRM consequences and effects, we think that the variables or parameters above are insufficient to give us an appropriate measure of CRM benefits.

Other authors consider the impacts that the implementation of CRM strategies can cause on a company's performance, focusing on the main organizational benefits that are supposed to be reached via CRM initiatives. For instance, Sterne (2000) points out the following aspects linked to CRM's payoff:

- Faster service,
- Lower costs,
- Larger profits (profitability),
- Improved retention (loyalty), and
- Higher customer satisfaction.

Khirallah (2000) agrees with Sterne when she affirms that loyalty, profitability, and satisfaction are customers' demonstrations of CRM efficacy. She adds to the list of variables above, suggesting that the following aspects should be considered in the analysis of CRM results, which should also be analyzed in terms of customer segments:

- Customer profitability,
- Customer satisfaction,
- Relationship duration,
- System availability,
- Response time,
- Response rates,
- Cross-sell ratio,
- Market share, and
- Wallet share.

Khirallah (2000) also draws our attention to the analysis of customer satisfaction over time. She claims that the measurement of customer satisfaction would produce a better CRM gauge if the process implied the measurement of customers' satisfaction with the interactions. She justifies her assumption explaining that customer satisfaction is not a static parameter. Actually, the satisfaction of customers oscillates over time according to whether their needs are being attended to or not; moreover, even though previous needs are fully attended to (which raises the satisfaction level), the satisfaction of customers might go down as soon as additional unattended needs appear over time. Based on this aspect, we conclude that although customer satisfaction represents a good indicator of CRM effectiveness, other variables or indicators should also be taken into account in the analysis of CRM impact.

It is important to point out that the variables or indicators above mainly focus on the analysis of CRM results or, we could say, post-CRM adoption analysis. Besides those aspects, it is also important to consider the analysis of pre-CRM factors, which are organizational factors linked to organizational readiness to CRM adoption. Since CRM adoption implies the establishment of customer-focused strategies, enhancement of organizational integration, and improvement of customer interactions, it is crucial to look at the extent to which organization strategies are oriented to customers and how supportive the organizational infrastructure is to the development of such strategies.

PRACTICAL CONSIDERATIONS AND REFLEXIONS

In our global economy, people's knowledge has become a valuable asset for private companies and governments. Due to the availability of current information and communication technologies such as the Internet, and mobile and wireless resources, customers have more information than they usually had a few years ago and they usually know the companies from which they regularly buy well. The development of lasting and learning relationships between an organization and its customers fosters the creation of mutual trust so that they start sharing responsibilities and interests. For example, through self-service facilities, customers can verify the availability of products, order their purchases, and trace their orders. Online access to technical databases, chat resources, and bulletin boards put customers in contact with technical staff and with other customers so that they can mutually help each other.

The development of mass customization capabilities is as important as the ability to conduct personalized interactions. While customization capability refers to an organization's capacity to project and adjust its products and services according to customers' needs, personalized interactions refer to an organization's capacity to deal with customers' singularities and particular needs. Both aspects require the correct identification of every single customer's needs and preferences. Increasing "customer share" might be a better strategy than to increase "market share." The more you know about your customers' business, the better you can serve them. To convince your customers to give you more of their business, let them know much about your business. Do not limit customer relationships within the scope of salespeople only; give your customers access to experts from several areas of the company. Your experts are better able both to identify what your customers' needs and preferences are, and provide more complete and accurate information about your business.

To work with quality, it is necessary to continually observe the view and perception your customers have about the products and services you deliver (Seybold, 2002). According to Seybold (2002) different research has shown that while internal staff members or employees of an organization think their products and services have improved, the external customers think exactly the opposite.

The purpose of CRM solutions and systems is to allow organizations to work with their customers in a learning manner, which yields effective results for both sides. For example, it is becoming quite common for software developers to let their customers test unfinished versions of their products rather than conducting laboratory tests. The result is the creation of a product that more precisely meets users' preferences. Of course, taking advantage of customers' competencies requires some caution: it is necessary to mobilize customer segments according to specific criteria, engage the customers in an active dialogue, and manage their differences. By active dialogue we mean the development of "knowledge-rich" dialogues. Companies should promptly process and share what they learned from the customers to maintain existing dialogues and keep customers' interests alive (Prahalad & Ramaswamy, 2002).

CRM adoption requires deep cultural change, which should mobilize and embrace an organization as a whole. We should be aware that the employees are the people who really interact and establish relationships with customers. Hence, only a sound corporate culture promotes commitment. Many organizations have already realized that it is the internal customers—the employees—who are capable of "delighting" the external customers. Highly motivated employees project their motivation to the external public. This phenomenon helps to build the corporate image itself, which is highly influenced by what is projected by the employees (Davies, Chun, da Silva, & Roper, 2003). Organizations should see their employees as allies to attract, please, and maintain customers. The relationship of an organization with its customers can be seen as a service made by its internal customers to the external ones.

Whatever the strategy, it is important to bear in mind that managing customers' experiences is not the same as managing different products. Rather, managing customers' experiences is managing their interactions and interfaces or channels of contact. As customers' needs change over time, products and services ought to evolve as well and be adjusted over time according to new customers' needs, wants, and preferences.

Global CRM

Multinational organizations are getting more and more serious about globalizing their CRM programs and taking their CRM strategies to a multinational level. Important considerations should be taken into account by MNCs endeavoring to develop CRM initiatives on a multinational scale. A basic premise is that different countries have different cultures, traditions, symbols, expectations, processes, languages, laws, and so forth. They do business differently, therefore it should be expected that customer behavior or business practices are different across international boundaries. In this sense, the CRM applications and tools used in each country must fit the reality of that country. The reason for this is that cultural customs, language, customer expectations, and privacy laws, for example, all vary from country to country. For this reason, although it is extremely important that an MNC creates global standards for its CRM applications, the company should provide its subsidiaries' business leaders and customer-facing managers with decision-making power to adjust their local CRM applications (Dyche, 2001).

In the multinational arena, a strong global CRM deployment trend is the centralization of customer information. MNCs are creating global customer data infrastructure by implementing a corporate data warehouse that acts as a common repository of customer and business knowledge which is made available to subsidiaries worldwide (Dyche, 2001). This practice is illustrated by Case 1.

In short, multinational organizations are deploying global CRM solutions to better manage their sales and delivery channels worldwide. A usual implementation practice is to centralize customer data in a globally shared data warehouse, which is accessed through a global CRM engine that can interact with local CRM applications that may vary from country to country. This provides global understanding, identification, and tracking of appropriate customer contact channels in any given region, allowing MNCs to better manage their customer interactions around the world.

Case 1. Kelly Services connected sales network across 30 countries and five continents [Sources: Adapted from Kelly Services (n.d.) and Salesforce (Kelly) (n.d.)]

Kelly Services, Inc. is a Fortune 500 company headquartered in the U.S., offering staffing solutions including temporary staffing services, staff leasing, outsourcing, and vendor onsite and full-time placement. With clients ranging from small local businesses to blue chip multinationals in various markets from pharmaceuticals to telecommunications, Kelly Services operates in 30 countries and territories providing employment to more than 700,000 employees annually. To manage its highly diverse universe of customers, the company needed a central repository to share sales information between branch managers, sales reps, and recruiters spread throughout 30 different countries. Additional challenges included the need to better capture historical sales information due to staff turnover, and easy remote access to the central repository. Through the adoption of CRM practices and systems, Kelly standardized its tracking and management processes, and provided more than 100 users with anywhere online access to a fully documented sales history on every account anytime. CRM adoption enabled the company to network its global, large account sales force across 30 countries and five continents in a seamless and coordinated manner. Kelly Services now shares real-time data and key account information with minimal internal infrastructure. The solution, which includes multi-language and multi-currency functionalities, increased efficiency and better tracking of sales processes, and allowed easier identification of emerging opportunities and the ability to take action to help close deals. Also, it became smoother to preserve information during staff transitions.

CRM AND KNOWLEDGE MANAGEMENT IN MULTINATIONAL ORGANIZATIONS

Considering the CRM strategies, practices, resources, and systems commented on in the previous sections, it is possible to identify a number of potential roles CRM can play to enhance organizational learning capabilities that are also of KM concern.

In general, the development of KM practices entails three interrelated processes, which are mainly concerned with knowledge acquisition, knowledge conversion, and knowledge application (Gold, Malhotra, & Segars, 2001). The knowledge acquisition process is concerned with the development of organizational capabilities to obtain and accumulate knowledge; the knowledge conversion process is more concerned with making existing knowledge useful, which entails the development of organizational capabilities to organize, integrate, coordinate, and disseminate knowledge. Finally, knowledge application is mainly concerned with the use of knowledge; this entails the development of organizational capabilities to retrieve, share, and apply knowledge (Cui et al., 2005).

The development of these organizational capabilities is especially challenging for multinational corporations (MNCs), which continually seek to establish competitive positions in the global marketplace by developing strategic capabilities through subsidiaries (Kogut & Zander, 1993). To achieve such competitive positions, it is necessary for MNCs' subsidiaries to develop their strategies according to local market demands. As Cui et al. (2005) argue, instead of implementing standardized strategies, MNCs' subsidiaries should have strategic flexibility so that they can develop proactive strategies in accordance with their specific environmental conditions.

In order to efficiently identify and respond to different market conditions and demands, MNCs should develop the learning capability of their subsidiaries. In a global environment, we can see an MNC as a nested learning system in which the learning process occurs at several different but interconnected units at the same time. Monteiro, Arvidsson, and Birkinshaw (2004) point out that the knowledge generated by subsidiaries with strong learning capabilities becomes increasingly valuable to the rest of the organization. Therefore, the knowledge generated in the local environment becomes an essential part of an MNC's knowledge stock.

According to Schneider and De Meyer (1991), external sources are of the utmost importance for the generation of competences in a subsidiary. They argue that external sources can enhance the effectiveness and scope of learning processes. Furthermore, Andersson, Forsgren, and Holm (2002) have found a direct link between external sources and intra-organizational influence on MNC strategy. They argue that the degree of external relations determines the degree of influence. For example, an intensive and long-lasting interaction between a subsidiary and its customers regarding the development of a specific product or service might influence the process of product or service development in the whole MNC (Andersson et al., 2002). This aspect is strengthened by Gammelgaard (2000) when he comments that changes in the customers' taste and attitudes demand the development of entrepreneurial activity, as relationships with customers often lead to requests for modifications of existing products and services, and sometimes, the development of new ones (Gammelgaard, 2000).

Taking into account the aspects mentioned above, we can conclude that the adoption of customer-focused strategies and practices may significantly increase a multinational organization's capacity to generate knowledge. In this sense, CRM can be seen as an enabler for the development of learning capabilities, as the adoption of its concepts, practices, and learning techniques allow the development of business approaches that support knowledge creation and sharing mechanisms.

CRM Supporting Roles to KM

Knowledge management is a corporate process that involves the development of organizational learning capabilities. It is important to point out that the process of organizational learning is not limited to a mere information system, a data warehouse, or specific analytical tools. Although the adoption of technical solutions makes it feasible for an organization systematically to collect, analyze, process, and disseminate information, strategic and cultural aspects should be carefully observed prior to any technical investment. The adoption of customer-focused strategies is of crucial importance to the processes of knowledge acquisition, conversion, and application. In this context, CRM practices, systems, and tools provide powerful resources to enable effective organizational learning capabilities that can significantly increase a multinational organization's ability to recognize not only customer demands in specific regions of the globe, but also to identify global patterns and common marketing trends that can guide global strategies. In the sequence, we identify and describe the main aspects and areas where CRM can play crucial roles in supporting knowledge management in multinational organizations. Each description is illustrated with a real-life case that shows how different MNCs are deploying their CRM solutions globally.

Customer Segmentation

Segmentation strategy means that an organization seeks to group its customers according to common patterns and characteristics determined in conformity with previously identified criteria. Segmentation methods are often used to characterize and help with the understanding of different customer groups. More specifically, segmentation aims to group customers according to their preferences for products, services, channels of interaction, and the magnitude and frequency of their interactions with an organization (Hansotia, 2002). This way, organizations can have a better understanding of their customers' wants and needs, tailoring their products and services according to different customer segments or types. In a multinational perspective, CRM segmentation allows the generation of valuable customer knowledge to support the establishment of corporate strategies and services according to the reality of local markets. An example of segmentation practice is illustrated in Case 2.

Case 2. Hard Rock Cafe turned to CRM to help bring customers back into the fold (Source: Jessup and Valacich, 2005)

Founded in London in 1971, the now U.S.-based Hard Rock Cafe International, Inc. was among the first chains of themed restaurants to come into existence. With 138 venues in 42 countries, and over 30 million customers a year, Hard Rock has become a truly global phenomenon. With the rise of many thematic eateries around the world, Hard Rock turned to CRM to help solidify its footing. In 2000, the company estimated that of its 30 million customers who come to its 138 venues each year, only about 10,000 names were in the company's customer database. The company began a detailed two-year customer survey to build out its data resources and gauge its potential for using CRM. The survey was the backbone of the company's CRM strategy, and it helped to build a database to host about 100,000 names as preferred customers. The database provides real-time customer information for several applications including e-commerce operations. The CRM solution allowed analysis based on different customer segments, and the company was able to figure out how customers responded to e-mail or coupons. It was possible to identify what kind of people were buying and why. By targeting customer preferences, the company increased memorabilia sales by 75% and improved customer service response by 85%. Hard Rock Cafe intends to extend its CRM deployment to the point where it can identify and reward customers at point-of-sale locations (restaurants), rather than exclusively through its member-based programs.

Customer Personalization

CRM is also seen as an organization's broad business strategy that focuses upon building personalized interactions with customers, whatever the channel of contact between the organization and its customers (Dean, 2001). It proposes personal interactions even in a mass context. Such a large-scale personalization is perfectly feasible through the deployment of CRM systems, applications, and tools (Ling & Yen, 2001). Organizational capability to develop personalized interactions with customers is therefore a remarkable characteristic of organizational focus upon customers. A summary of customers' preferences and profiles in each MNC subsidiary may potentially enhance global strategies. Case 3 shows how the Chase Manhattan Bank is implementing personalization capabilities.

Channels of Customer Interaction

Customers can interact with organizations through several different channels or means of contact such as telephone, in person, fax, post, e-mail, and so forth (Kandell, 2000). Logically, an organization that offers a diversified number of different contact channels strategically increases the possibility of customer interaction. The integration of such channels in the front-office provides an appropriate environment with resources and facilities that allow customer-facing staff to deal efficiently with all customer interactions regardless of the channel of contact (Sterne, 2000). For Payne and Frow (2004), the integration of different channels of interaction is one of the key cross-functional processes in CRM strategy development. The analysis of the volume of customer interactions per channel is an important source of knowledge that can support MNCs to undertake timely and highly accurate forecasting. This aspect is illustrated in Case 4.

Workflow

Workflow is an important set of applications that enable the automation and tracking of different customer processes by the integration of front-office with back-office. This characteristic makes workflow products ideally situated to address the demand for CRM solutions (Chambers et al., 1999). Embracing workflow functionalities, CRM systems play a major role in the provision of a higher quality of service to customers, allowing organizations to design automated processes to enhance the productivity and responsiveness of their workforce (Ling & Yen, 2001). Therefore, *Case 3. Chase Manhattan Bank gets closer to its customers (Sources: Adapted from Ptacek, 2000 and "JPMorgan Chase" ,n.d.)*

JPMorgan Chase & Co. is a world-leading global financial services firm with assets of $1.3 trillion and operations in more than 50 countries. Under the JPMorgan and Chase brands, the firm serves millions of consumers in the United States and many of the world's most prominent corporate, institutional, and government clients. The U.S. consumer and commercial banking businesses serve customers under the Chase brand. The bank has adopted a CRM system to let its 4,500 relationship managers worldwide share and gain access to constantly changing information about the profitability of their corporate customers. The system makes the managers' jobs easier by keeping them up to date on all aspects of their multinational, multifaceted corporate clients. Chase was one of the first corporate banks to implement CRM techniques that the industry had applied to the retail side. The CRM system has different degrees of customization, allowing managers to use different benchmarks to gauge customers' profitability. Customers and bankers can enter and view relevant information through the Internet. Customers also can get a daily report card on their banking activities and are encouraged to give the bank feedback. The bank is also letting institutional customers send messages to their relationship managers as they observe market events. Video technology will be deployed so that customers and bankers can interact face to face wherever they are around the world. Through an increasing variety of channels, including wireless devices, customers can do online self-service and online tracking.

Case 4. InFact deployed CRM system to undertake timely and highly accurate forecasting. (Source: Adapted from Oracle, 2006)

InFact Group is a global technology consulting organization with a world-class portfolio of customers in three continents. The company provides end-to-end project services, and delivers outsourcing solutions based upon its dedicated development platform in India. After its founding in 2000, the company grew very rapidly, increasing its breadth of customers, extending its global reach, and recruiting more than 60 employees. As a consequence, the company needed to replace the existing legacy systems it relied on to manage a growing number of increasingly complex customer relationships. The company turned to a CRM system to face this challenge. InFact deployed CRM systems in Europe, the U.S., and India to create a single, comprehensive view of its customers and partners across multiple channels and touch-points. By introducing a standard sales, marketing, and service methodology worldwide, the company is able to optimize sales performance by efficiently tracking and qualifying every sales opportunity. InFact can also identify top-performing accounts and conduct rigorous analysis of customer interaction by region, industry, and revenue. CRM has reduced the time it takes to close a sales opportunity by 15%. The system allows the company to undertake timely and highly accurate forecasting. InFact trades in multiple currencies around the world, and it used to take one person up to four days each quarter to pull together all the different currency rates and fluctuation allowances into one consolidated spreadsheet forecast. The new CRM system automatically undertakes all currency conversion, historical exchange rates, and rollups. This saves InFact $33,000 each quarter in reduced overhead. Managers can also analyze customers and prospects by industry, region, and even city. The company has recently targeted 300 companies in Asia Pacific with a direct mail campaign and was able to track the calls coming in from this campaign. It was immediately apparent how many inquiries InFact received and the total cost per lead. By providing one view of the customer, greater visibility into the sales pipeline, and analytic insight into key performance metrics, CRM has helped to transform InFact into a more agile, proactive consultancy, with the tools needed to provide the highest levels of customer service.

the organizational capability to track and/or follow-up automated customer processes also represents integration towards customers. For MNCs, the adoption of workflow functionalities may significantly facilitate and optimize the execution of global business processes. Case 5 shows how an MNC is adopting a CRM system to integrate disparate customer touch points and focus its business processes across the company around customer needs.

Case 5. Air Products adopted CRM to support its operations in more than 30 countries (Source: Adapted from "Air Products", n.d.)

Founded in 1940, Air Products and Chemicals, Inc. has built leading positions in key growth markets such as semiconductor materials, refinery hydrogen, home healthcare services, natural gas liquefaction, and advanced coatings and adhesives. With annual revenues of $8.1 billion, operations in more than 30 countries, and more than 20,000 employees around the globe, the company lacked a common approach for its many divisions to manage the information critical to maintaining its relationships and growing revenue with customers. To allow its employees to focus more attention on customer needs, Air Products is putting into place a CRM system. Companywide access to accurate information about customers, production, and distribution will form the backbone of the company's customer care concept. The CRM system will ultimately integrate disparate touch points, raise the quality of customer interactions, and focus business processes across the enterprise around customer needs. The new system will serve as a repository of information and allow the company to build accurate customer profiles based on the products it sells and the services it offers. A customer portal is expected to strengthen the relationships with customers by making business more convenient and friendly. The portal will be integrated with the corporate CRM system and other business systems so that the new tools and processes will provide customers with a greater level of service than ever before. The ultimate objective is to provide managers with access to customer information all the way through the product cycle, from order commitment to production scheduling to delivery to invoicing, making sure the company gets it right for customers the first time.

Marketing Knowledge

Obtaining customer information is crucial for allowing MNCs' prompt acquiescence to market demands, which allows the development of better products and services according to local specificities. Also, the analysis of local market demands and trends allows the identification of common points of demand in different regions around the globe; this knowledge helps MNCs to define global strategies for their products and services, as well as target communication with customers and delineate more responsive marketing campaigns. Case 6 shows how Ford is taking its main marketing team to better deliver coordinated cross-border marketing campaigns.

Customer Information Sharing

This aspect is mainly concerned with customer information gathering and usage. Getting basic information about customers' needs, wants, and preferences allows the development of better strategies for providing immediate responses to different situations and scenarios, which improves MNCs' ability to make complementary plans to respond to different market expectations. The sharing of customer information throughout the MNC allows better transparency, reporting, and communication across global teams. This aspect is illustrated in Case 7.

Consistent Global Corporate Image

Employees are the people who really interact and establish relationships with customers. When interacting with customers, MNCs' employees are implicitly building their own corporate image. A positive image can be built when customer-facing employees are empowered to respond to customer needs and when they feel trusted to run the business. Enabling employees to consistently interact with customers in a standardized, but not inflexible manner is how International Business Machines (IBM) Corporation created a consistent corporate image worldwide (Case 8).

In all the illustrative cases presented above, CRM is implicitly supporting knowledge acquisition, knowledge conversion, and knowledge application processes within the multinational organizations addressed. For example, CRM supports knowledge acquisition processes by

Case 6. Ford's CRM strategy has increased sales and productivity (Sources: Adapted from Ford, n.d.; and IBM, 2006)

With a recorded net income of $2.5 billion in 2005, Ford Motor Company is a global automotive industry leader based in Dearborn, Michigan. The company manufactures and distributes automobiles in 200 markets across six continents. With about 300,000 employees and 108 plants worldwide, the company's core and affiliated automotive brands include Aston Martin, Ford, Jaguar, Land Rover, Lincoln, Mazda, Mercury, and Volvo. Ford wanted to project a consistent company and product message throughout Europe while ensuring national marketing campaigns were tailored to regional needs. The company also needed to track customer responses and implement a lead qualifying process to focus sales efforts. To achieve these goals, Ford implemented a pan-European CRM solution into its three largest markets—the German, Spanish, and UK operations. Ford then needed to implement a centralized version of its CRM solution into additional markets across Europe, including offices in France, Italy, and Austria. The standardized CRM solution was integrated with key business processes and designed to transform simple marketing campaigns into responsive, targeted communications. The solution included campaign management processes and supporting tools that meet marketing needs at both the local market and pan-European level. This approach works in tandem with the consumer lifecycle management application that tracks marketing campaign responses. The system allows the company to track different communications ranging from a brochure request via the Web site to test drive inquiries to a call center. Identifying and coding the different customer communications set the basis for the solution's lead qualification process that allows customer representatives to prioritize and offer the most appropriate follow-up based on the potential customer's level of interest. The centralized approach enables Ford's main marketing team to better deliver coordinated cross-border marketing campaigns. The CRM initiative has improved customer service with faster, tailored responses to queries. The solution has generated more than 500,000 qualified leads to date.

Case 7. Nokia customizes CRM solution to meet the needs of sales teams on three continents (Sources: Adapted from www.nokia.com and Salesforce [Nokia], n.d.)

During the 1980s, Nokia strengthened its position in the telecommunications and consumer electronics markets through a series of European company acquisitions. Since the beginning of the 1990s, Nokia has concentrated on enhancing its core business, telecommunications. Currently, Nokia is the world's largest manufacturer of mobile devices; a leader in equipment, services, and solutions for network operators; and a driving force in bringing mobility to businesses. In 2005, Nokia's net sales totaled EUR 34.2 billion. The company has 15 manufacturing facilities in nine countries, and research and development centers in 11 countries. At the end of 2005, Nokia employed approximately 58,900 people. As Nokia's sales teams used three different reporting systems ranging from spreadsheets to homegrown solutions, it became very difficult to provide real-time visibility into the sales cycle and preserve consistency across different regions and functions. Through the adoption of a CRM solution, Nokia provided its traveling sales force with a customizable system with real-time visibility into business anytime and anywhere. The company is able to customize its CRM system on the fly to respond to changes in business models and requirements. CRM has also provided deeper understanding of customer buying habits and allowed better transparency, reporting, and communication across global teams. This has streamlined sales organization for improved collaboration and productivity, which resulted in a shorter sales cycle and more consistency across different regions and functions.

providing resources to manage the customer interaction channels through which MNCs can obtain and store worldwide customer information in corporate databases. By providing global managers with sharing capabilities to access these corporate databases, as well as integrating the workflow of cross-border processes, CRM is supporting MNCs to integrate, coordinate, and disseminate knowledge. Finally, the segmentation and personalization capabilities provided by CRM

Case 8. IBM standardizes its relationship processes (Sources: Adapted from www.ibm.com and ICFAI, 2004)

> With a revenue of $91.1 billion in 2005 and more than 329,000 employees in 75 countries, IBM is the world's largest information technology company. Worldwide, 45,000 business partners and 33,000 suppliers are connected to IBM through the Web. In January 2000, IBM undertook the largest CRM project known at that time. Termed "CRM 2000," the project aimed at ensuring that any point of interface between the company and its customers, through any of its channels of interaction, in any country, was dealt with uniformly, providing the same service level, applying the same tools and information. Ultimately, IBM wanted to show a unified interface to its customers across the world. Four years after the project, the company was well on its way towards achieving its objective, reporting significant improvements in customer satisfaction levels. At that time, IBM's vice president of worldwide CRM deployment said, "*By getting to know our customers better and enabling more effective collaboration around the customer and among multiple IBM organizations involving sales, marketing, and support, we can significantly enhance the value we bring to our customers, while generating additional revenues and cost efficiencies for our company. The concept of 'one IBM' is a cornerstone for the way we serve customers.*"

solutions, plus marketing campaign management resources and functionalities to adopt standardized relationship processes, strongly support MNCs in the process of retrieving and applying knowledge.

CONCLUSION

In this chapter we commented on concepts and characteristics of CRM, covering aspects from its origins to supporting roles to KM. The presented theory has shown that the confluence of changing customer demands, emerging marketing theories, and available information technologies have been imposing a shift on the way organizations relate to customers. In contrast to the old economy firm, which was more absorbed in achieving operational excellence through production and service delivery processes, the new economy firm reportedly has the customer at the center of its universe.

On one hand, the evolution of marketing business strategies over time delineated the current characteristics of CRM strategies; on the other hand, the evolution of information and communication technologies enabled the adoption of different and more evolved marketing approaches over time, giving birth to the current CRM systems. These two dimensions of CRM are extremely intertwined and, as a matter of fact, the emergence of CRM strategies, concepts, and practices would not be possible without the appearance of new and evolved ICT resources.

CRM systems provide the functionality that allows an organization to make its customers the focal point of all departments within the firm. This way, the organization will be able to respond to its customers on a continual basis. More specifically, customer information databases and integrated interactivity enable an organization to develop a learning relationship with its customers, creating organizational capability to differentiate its customers through lifetime value segmentation, to develop personalized interactions with customers, and to offer tailored products or services to customers.

A fundamental issue about CRM is that CRM is more than a mere product. If one sees CRM as a system that can be bought and installed in an off-the-shelf manner, then it becomes difficult to harvest the benefits promoted by such an expensive solution. CRM should be seen as a broad business strategy that implies the redevelopment of organizational structures so that there are new service units and new product offerings arranged around a refreshed understanding of customer needs. The real concept of CRM goes beyond the product, implying deep strategic and cultural concerns.

It is possible to identify CRM strategies, practices, and solutions that strengthen and support knowledge management approaches, especially in a more complex and diversified environment such as the one where multinational organizations are inserted. Regarding knowledge about customers, the adoption of customer-focused strategies supported by CRM systems can significantly strengthen the learning capabilities of MNCs' subsidiaries. These capabilities reflect on MNC headquarters in the form of increased corporate capacity to identify local and global trends concerning customers' preferences, cultural aspects, needs, and consumer behavior. This knowledge subsidizes the elaboration of more effective global strategies by multinational organizations.

Of course, CRM does not address the whole myriad of organizational aspects and issues that are of KM concern. Its focus is on developing organizational learning capabilities that can significantly enhance an organizational ability to acquire, process, and apply knowledge about customers. The objective of this chapter was to broadly present CRM characteristics, strategies, concepts, practices, solutions, resources, and concerns that can be explored by multinational organizations with the purpose of supporting the adoption of knowledge management strategies and practices.

Chapter 3.22

Capacity for Engineering Systems Thinking (CEST):

Literature Review, Principles for Assessing and the Reliability and Validity of an Assessing Tool

Moti Frank
Holon Institute of Technology, Israel

ABSTRACT

To successfully perform systems engineering and/or designing IT architecture roles, the systems engineers and IT architects need a systems view or a high capacity for engineering system thinking (CEST). This paper discusses the essence of this capacity, presents principles for developing a tool for assessing the CEST and presents a tool developed for use in selecting engineers for jobs that require CEST. A tool for CEST assessment may be useful for several purposes, one of which is the effective selection of candidates for engineering positions that require high CEST. The tool was tested and implemented in a pilot study aimed at examining its reliability and validity. Two types of reliability and four types of validity were checked. Then, a second study aimed at strengthening the results of the pilot study was conducted. The findings of the two studies indicate that the tool may prove to be a validated instrument.

INTRODUCTION: SYSTEMS ENGINEERING, IT ARCHITECTURE AND ENGINEERING SYSTEMS THINKING

Systems thinking, according to Senge (1994), is a discipline for seeing wholes. *Engineering Systems Thinking* is a major high-order thinking skill that enables individuals to successfully perform systems engineering tasks (Frank, 2002). To successfully perform systems engineering and/or designing IT architecture roles, both systems engineers and IT architects need a systems view or a high capacity for engineering systems thinking (CEST). Despite its importance, no high-quality tool exists as yet for CEST assessment, which may be useful, for example, in enabling a more effective selection of candidates for engineering positions that require high CEST. The current paper discusses the essence of this capacity, presents principles for developing a CEST assessment tool, and presents a tool developed for assessing the interest for job positions requiring high CEST and in selecting engineers for jobs that require CEST. The paper presents the results of two studies aimed at validating the tool.

As modern technological projects have increasingly become larger, more complex and interdisciplinary, systems engineering and designing Information Technology (IT) architecture have come to play an ever-increasing a major role in projects. In the IT sector, IT architects play the same role that system engineers play in engineering organizations, which is being responsible of seeing the whole picture of the system.

The main functions of systems engineering in technology-based and projects are: requirements analysis, functional analysis, architecture synthesis, systems analyses, verification and validation and optimally integrating individual components into a whole system that meets specific systems-level requirements (INCOSE, 2004). According to Sheard (1996), the twelve systems engineering roles are requirements owner, system designer, system analyst, validation and verification, logistics and operations, “glue”, customer interface, technical manager, information manager, process engineer, coordinator and “others”.

According to Frank and Waks (2001), *Engineering systems thinking* is the ability to:

1. **See the big picture:** the ability to: grasp and understand the whole system and the big picture, conceptually and functionally, without understanding all its minutiae and all of the system’s details; understand the interconnections and the mutual influences and interrelations among system elements/sub-systems/assemblies/components/parts; describe a system from all relevant perspectives (a well-known approach for categorizing the required views distinguishes between operational views, system views, and technological views); derive the synergy of a system from the very integration of the subsystems; identify the synergy and emergent properties of combined systems; understand the system as a whole and anticipate all the implications (including side effects) of changes in the system, engineering and non-engineering alike; understand and describe the operation, purposes, applications, advantages, and limitations of a new system/sub-system/idea/concept immediately after receiving an initial explanation, and remedy system failures and problems.
2. **Implement managerial considerations:** the ability to grasp and implement managerial, organizational and broad-perspective considerations.
3. **Acquire and use interdisciplinary knowledge:** the ability to: deal with multi-tasking and interdisciplinary knowledge; use this knowledge for developing the concepts of operation, logical solutions (functional analysis), and physical solutions (architecture synthesis); make analogies and parallelisms between systems; implement systems design considerations; conduct –ilities analyses (availability, maintainability, etc.), and run simulations and optimization analyses (Frank, 2002).
4. **Analyze the needs/requirements:** the ability to capture, understand and analyze the customer/market requirements/needs and future technological developments.
5. **Be a systems thinker:** the ability to be curious and innovative, to be an initiator and independent learner, and to have the ability to develop and ask good questions**.** CEST is also required in designing and managing information systems.

Similar results were found in a study conducted in Australia (Frampton et al., 2005) aimed at identifying the capabilities of successful IT architects. A comparison between the two studies is presented in Table 1.

Systems engineers with high CEST are more capable of (1) analyzing customers' need and requirements, (2) developing the concept of operation, (3) conceptualizing the solution, (4) generating a logical solution (functional analysis) and a physical solution (architecture synthesis), (5) using simulations and optimization and (6) implementing systems design considerations and conducting trade studies wherein it is necessary to generate several alternative solutions (Frank, 2002; Davidz, 2005). More meaningful attributes of those reputed to be systems engineers (vs. those who are not), and evidence that those reputed to be systems engineers were associated with successful systems, are reported in other studies (Frank, 2006; Frank, Frampton, Di-Carlo, 2007).

Some authors refer to CEST as an innate ability. For instance, Hitchins (2003) states that the human brain has the ability to see similarities of patterns between disparate sets of information, which presumably emanate from its drive to reduce perceived entropy. He also implies that some people are gifted in this respect. However, Frank (2002) and Davidz (2005) concluded that this ability is most likely a combination of innate talent and acquired experience and offered a course outline directed at developing CEST.

According to Warfield (2006), all sciences, including systems science, have three foundations in common – the human being, thought and language. A human being exhibits both creativity and fallibility (both are attributes of human beings). Starkermann (2003) focuses on the effects of interpersonal relationships and people's competencies, styles and attitudes - both conscious and unconscious - regarding any entity behavior. Indeed, in a prior study (Frank, 2006),

Table 1. Capabilities of successful systems engineers and IT architects

Category	Systems Engineers (Frank, 2002)	IT Architects (Frampton et al., 2005)
Background	Interdisciplinary knowledge. Understanding the whole system and seeing the big picture	Generalist
	Broad experience - job rotation, systems work roles	Broad experience
Personality traits	Think creatively	Creative
	Curious, innovator, initiator, promoter, originator	Open-minded
	Willing to deal with systems	Passionate
	See failures and screw-ups as challenges for development, not as "the end of the road."	Resilient
Capabilities	Requirements, needs and concept of operation analysis, Understanding interconnections.	Analysis
	Taking into consideration non-engineering factors such as economic/business considerations	Business related
	Good communication and interpersonal skills.	Communication skills
	Team leader, team player,	Middle-ground
	Conceptualizing the solution	Conceptualization
	Generating the logical and physical solutions	Problem solving
	Taking into consideration political issues	Situational politics
	Seeing the future	visionary

both creativity and strong interpersonal relationships were found, to be essential qualities of successful systems engineers. However, the issue of creativity deserves a special focus and will not be discussed in the current paper. Many tools and tests for assessing creativity have already been suggested (e.g. Lees-Haley, 1978). Therefore, the tool presented in this paper does not pretend to assess creativity.

The Tool for Assessing Interest Towards Jobs Requiring CEST

Despite its importance, no high-quality tool exists as yet for CEST assessment, which may be useful, for example, in effective selection of candidates for engineering positions that require high CEST. The principles for developing a tool developed for such purpose were first presented by Frank & Elata (2004) and further discussed by Frank, Zwikael and Boasson (2006). This paper extends the discussion and presents the results of a follow-on study. Actually, the proposed tool is an interest inventory. Interest inventory is a very common tool used for helping people choose a profession and as a selection tool in the recruiting process (Anastasi, 1988).

An earlier study was carried out before developing the propose tool. This study included three stages. The first involved a pilot study in which 11 in-depth, open, non-structured interviews were conducted with key figures in hi-tech industry. The second involved 17 semi-structured interviews in the role of 'the-observer-as-participant,' conducting on-site observations at the workplaces of two hi-tech companies. The third stage of the early study consisted of a survey based on a pilot questionnaire (N=31) and a final questionnaire (N=276).

The proposed tool was then developed and the content validity was achieved by basing the items of the interest inventory discussed here on the findings of a previous study whose primary aim was to identify the characteristics of engineers who have a high capacity for engineering systems thinking (Frank, 2002), experts' judgment, and literature review including the INCOSE SE Handbook version 2a (INCOSE, 2004), laws of the fifth discipline and systems archetypes (Senge, 1994), systems thinking principles (Kim, 1994; Waring, 1996; O'Connor and McDermott, 1997; Sage, 1994), some principles of systems dynamics (Sweeney and Sterman, 2000; Ossimitz, 2002) and the seven 'thinking skills' of systems thinking (Richmond, 2000).

The tool does not consider the knowledge and skills required from systems engineers. Much work in this field has already been done by the International Council on Systems Engineering (INCOSE) work group - the INCOSE Certification of Systems Engineers Exam (Muehlbauer, 2005), which is based on the INCOSE SE Handbook version 3 (INCOSE, 2006).

Usually, the items in interest inventories deal with preferences, specifically likes and dislikes regarding a diverse group of activities, jobs, professions or personality types. Likewise, the items included in the tool discussed in this paper refer to ranges of likes and dislikes regarding systems engineering activities (i.e. leading integration teams, conducting systems analyses, etc.), various disciplines and knowledge required from systems engineers (interdisciplinary knowledge, deep and detailed knowledge, etc.), systems engineering activities (i.e. leading and participating in design reviews, dealing with the whole system, etc.), and types of people involved in projects (i.e. customers, stakeholders, etc.).

The tool is comprised of 40 pairs of statements. For each pair, the examinee has to choose between the two statements according to his/her preference. The examinee checks answer "A" if he/she prefers the first statement or answer "B" if he/she prefers the second statement or answer "C" if he/she prefers either none of them or both of them. Several sample items will be presented in the presentation at the conference. In order to improve the questionnaire's reliability, questionnaire items were reorganized, so in some cases "A" represented the systems thinking answer and in other cases "B" represented the systems thinking answer. Each "A" answer received two points, while each "B" answer received one point. Thus, the range of the mean score of each participant was between 1 and 2.

Here are two example items based on the characteristic 'seeing the whole':

Item No. 2

A. When I take care of a product, it is important for me to see how it functions as a part of the system.
B. When I take care of a product, it is important for me to concentrate on this product, assuming that other engineers will take care of the other parts of the system.

Item No. 6

A. I don't like to be involved with details; I prefer to deal with the system's aspects.
B. In areas in which I'm involved, I like to understand all the details.

Please see several more sample items in the appendix.

The Need. A CEST assessment or selection tool can serve several needs. The first use is to better select candidates for engineering positions that require a high level of CEST. In the selection process, the tool can be used to help make decisions about whether to recruit or reject a potential candidate. When assessing new (recruitment) or current (promotion) of employees, the tool can augment other evaluation tools. The second use of the tool might be to improve the placement process by identifying the right candidate for systems engineering positions that require high CEST (the right person for the right job). Finally, once this tool is validated, it could be used for evaluating the effectiveness of CEST development programs and systems engineering courses.

The Pilot Study

The tool was tested and implemented in a pilot study (Frank, Zwikael & Boasson, 2006), aimed at examining its reliability and validity. The pilot study included 54 participants from a large hi-tech organization who completed the questionnaire. Twenty-nine of the participants are systems engineers, while the other 25 participants work as professional engineers (not in systems engineering positions). Two types of reliability – inter-judges reliability and Alpha reliability coefficient, and four types of validity – content validity, concurrent validity, contrasted group validity and construct validity – were examined.

A measurement's reliability is represented by the extent to which it is accurate (Anastasi, 1988) and can be checked by using several techniques. The first one is *inter-judges reliability*. The questionnaire was first sent to five senior systems engineers, who were asked to complete it and evaluate each item's suitability to the subject tested. Wide agreement among all referees was demonstrated. The second method used to check the reliability was calculating the Alpha reliability coefficient (Cronbach's alpha). The result - 0.836 – is higher than the minimum value required by the statistical literature. Cronbach's alpha measures how well a set of items (or variables) measures a single unidimensional latent construct. When data have a multidimensional structure, Cronbach's alpha will usually be low.

The validity of a measurement is the extent to which it represents the measured quantity (Anastasi, 1988). *Contrasted Groups Validity* is determined by comparing the grades of two contrasted groups. In the pilot study, the two groups were systems engineers and other types of engineers. It was found that systems engineers achieved significantly higher scores, as compared to professional engineers. A one-way ANOVA test was conducted using SPSS to analyze the differences between the groups (0.12), which were found to be significant (p-value=0.004). A summary of the analysis is presented in Table 2.

Concurrent Validity is the correlation between the scores obtained by two assessment tools. In the pilot study, the concurrent validity was checked by calculating the correlation between the participants' scores using the proposed tool and the appraisal of their supervisor. It was found that the Pearson Correlation Coefficient was close to 0.4 (p=0.05). This result is very similar to the predictive validity of other selection tools. The Pearson Correlation Coefficient measures the correlation of two variables (measures the tendency of the variables to increase or decrease together.

Construct Validity indicates the extent to which the tool measures a theoretical construct or characteristic (Anastasi, 1988). The construct validity was checked by factor analysis. Actually, this was a Confirmatory Factor Analysis (CFA). Indeed, the analysis revealed five factors that may be labeled as follows: seeing the big picture, implementing managerial considerations, using interdisciplinary knowledge for conceptualizing the solution, analyzing the needs/requirements, and being a systems thinker. These results are compatible with the factors found in a previous study (Frank, 2002)—see the definition of *engineering systems thinking* above. For example, Table 3 presents the rotated component matrix and the loadings for factor number 1 - "seeing the big picture." The table is a correlation matrix presenting the loading of each factor on each item.

The Second Study

The second study, aimed at strengthening the results of the pilot study, included 78 students – 37 senior Electrical Engineering students and 41 senior Technology/Engineering Management students – and 54 engineers, thirty of which are systems engineers, while the other 24 work as professional engineers. The objectives of this second phase were to test the: (1) *concurrent validity* by calculating the correlation between the results from the questionnaire for part of the engineers with the assessment of the employees' senior supervisor who has been familiar with their systems thinking capabilities for many years, (2) *contrasted groups validity* by comparing the CEST scores of senior EE students, senior Technology/

1	0.462	0.059	0.195	0.110	0.296
39	0.426	-0.293	0.031	0.120	0.265

Engineering Management students, systems engineers and professional engineers.

The method used in this second phase to check the reliability was calculating the Alpha coefficient. The result - 0.855 – is a little bit higher than the result obtained in the pilot study – 0.836. Both results are higher than the minimum value required by the statistical literature.

In this second phase of the study, the *concurrent validity* was checked by calculating the correlation between the twenty-four systems engineers' scores using the tool and the appraisal of their supervisor. The supervisor had been familiar with the participants' systems thinking capabilities for many years. The subjective assessments were all made by the same senior supervisor to increase bias. The supervisor was asked to assess the Capacity for Engineering Systems Thinking of each engineer on a scale of 1 = very low to 7 = very high. It was found that the Pearson Correlation Coefficient between the participants' scores and the supervisor assessments was 0.496 (p=0.014). This result is higher than the result obtained in the pilot study – 0.4 (p=0.05). Both results are very similar to the predictive validity of other selection tools.

The *contrasted groups validity* was checked in the second phase by comparing the tool's CEST scores of four groups – senior Electrical Engineering students, senior Technology Management students, systems engineers and professional engineers. One-way ANOVA test was conducted to analyze the differences between the four groups' mean scores. A significant difference was found (p-value=0.00) – see Table 4. Analysis Of Variance (ANOVA) compares means by splitting the overall observed variance into different parts. One-way ANOVA is used to test for differences among three or more independent groups. Here we had four groups (senior Electrical Engineering students, senior Technology Management students, systems engineers and professional engineers).

A Post-Hoc test (Scheffe test – see Table 5) revealed that: (1) the systems engineers achieved significantly higher scores than the professional engineers, (2) the systems engineers achieved significantly higher scores than the Technology Management students and the Electrical Engineering students, and (3) the forty-one senior Technology/Engineering Management students achieved significantly higher scores, as compared

Table 4. One-way ANOVA test results: Descriptives

to the thirty-seven senior Electrical Engineering students. The latter result supports the pre-assumption that the curriculum of Engineering Management deals with some systems issues while the curriculum of Electrical Engineering focused mostly on details. This result is not surprising because EM/TM students are trained to look at problems holistically.

It was also found that EM/TM students dealt poorly with issues related to pure technology/engineering. Based on this result and the result presented above, it is suggested that issues related to systems thinking, system dynamics, and systems engineering will be added to the traditional electrical engineering curriculum, while several topics related to electrical and mechanical engineering will be added to the technology management curriculum.

It was also found that there was no significant difference between the senior Technology Management students and the professional engineers. At first, this result was surprising. The pre-assumption was that, in general, the CEST of engineers is higher than the CEST of students, since undergraduate students are mostly educated to know and understand details. One explanation for this surprising result may be that the engineers who participated in this part of the study dealt with the development of cards, modules and components (i.e. dealing more with details rather than with large-scale systems).

Construct Validity indicates the extent to which the tool measures a theoretical construct or characteristic (Anastasi, 1988). The construct validity was checked by factor analysis. Table 6 presents the rotated component matrix - the loading of each factor on each item:

Extraction Method: Principal Component Analysis

Rotation Method: Varimax with Kaiser Normalization. Rotation converged in 6 iterations.

Note: Items 5, 18, 20, 34, 40, 45, 46 and 47 were omitted in the first phase of the study.

Indeed, the analysis revealed six factors that may be labeled as follows:

Table 5. Scheffe test

* The mean difference is significant at the .05 level

Factor 1 – Seeing the big picture: Items 1, 2, 3, 4, 6, 10, 11, 12, 14, 15, 23, 25, 26, 27, 31, 32, 39.

Factor 2 – Using interdisciplinary knowledge for conceptualizing the solution: Items 7, 8, 9, 16, 17, 19, 48.

Factor 3 – Analyzing the needs/requirements: Items 21, 22, 33.

Factor 4 – Being a systems thinker: Items 35, 43, 44.

Factors 5 and 6 – Implementing managerial considerations: Items 13, 30, 36, 41, 42.

These results are compatible with the factors found in a previous study (Frank, 2002)—see the definition of *engineering systems thinking* above (except 5 items – 24, 28, 29, 37 and 38 – which were not loaded according to the "right" factor).

CONCLUSION

The current paper introduces principles for developing a tool for assessing engineers' interest regarding systems engineering job positions and the results of two studies aimed at examining its reliability and validity. In the first study, two types of reliability were calculated - inter-judges reliability and Alpha coefficient reliability. One of the objectives of the second study was to re-check the Alpha coefficient reliability. Both results – 0.855 and 0.836 were higher than the minimum value required by the statistical literature. In the first study four types of validity were presented – content validity, concurrent validity, contrasted group validity and construct validity. One of the objectives of the second study was to re-check the concurrent validity and the contrasted groups validity. The Pearson correlation between the participants' scores and the assessment of their supervisor was found to be 0.496 (p=0.014) in the second study and 0.4 (p=0.5) in the first study. Both results indicate that the tool's concurrent validity is similar to the concurrent validity of other selection tools.

In the first study, the contrasted groups validity was checked by calculating the difference between the scores of systems engineers and professional engineers. In the second study, it was checked by calculating the difference between the scores of (1) senior Engineering Management and Electrical Engineering students, (2) senior students and systems engineers, and (3) systems engineers and professional engineers. In both studies, the difference between the groups was found to be significant.

The findings of the two studies indicated that the tool might prove to be a powerful instrument, to be used by industry organizations as well as systems engineering researchers and educators alike. Such a tool can be used to distinguish between individual engineers according to their systems thinking capabilities and engineering interests and abilities. However, there is still quite a long way to go before officially releasing the tool for use in SE organizations. Hence, a series of additional and more extensive tests must be conducted using the proposed tool in other cultures, sectors and organizations with a larger number of participants. The results of the reliability and validity checks presented in the current paper are quite satisfactory; however, they still await verification and validation by others.

The next step is to test the following hypothesis: A positive correlation exists between the scores achieved by systems engineers using the CEST tool and the extent to which the systems projects meet their objectives. This will be further examined in a follow-up study.

APPENDIX

CEST INVENTORY: SAMPLE ITEMS

Note: the full instrument is copyrighted.

Factor 1: Seeing the big picture

Item No. 2

A. When I take care of a product, it is important for me to see how it functions as a part of the system.

B. When I take care of a product, it is important for me to concentrate on this product, assuming that other engineers will take care of the other parts of the system.

Item No. 3

A. It is important for me to identify the benefits derived from embedding several products/sub-systems/systems.

B. I prefer not to deal with combinations of products/sub-systems/systems but rather to concentrate on the product for which I am responsible.

Item No. 4

A. It is important for me to know what other employees in my department/project do.

B. It is important for me to do my best and not interfere to the work of other employees in my department/project.

Item No. 6

A. I don't like to be involved with details; I prefer to deal with the system's aspects.

B. In areas in which I'm involved, I like to understand all the details.

Item No. 11

A. When I deal with a product, I always look at the interconnections and mutual influences between the main product and the peripheral products.

B. I prefer to thoroughly take care of the part for which I am responsible and leave the issue of interconnections between a system's parts to the integration engineers.

Factor 2: Using interdisciplinary knowledge for conceptualizing the solution

Item No. 17

I think that every employee should gain interdisciplinary knowledge and general knowledge in several fields.

B. I think that every employee should become an expert in his/her field. Learning more fields may lead to sciolism (to know a little about many subjects).

Factor 3: Analyzing the needs/requirements
Item No. 22
A. I like to discuss the needs with the customer.
B. I prefer to leave the contact with the customer to marketing experts.

Factor 4: Being a systems thinker
Items No. 43
A. It is important for me to continuously think what else can be improved.
B. It is important for me to determine finish line and to finish my jobs in time.

Factors 5 and 6: Implementing managerial considerations
Item No. 30
A. I like to integrate and to lead interdisciplinary teams.
B. I'm a professional; I prefer not to be involved with managerial issues.

Section IV
Utilization and Application

This section introduces and discusses the utilization and application of strategic information systems. These particular selections highlight, among other topics, optimizing the relationship between business and information technology, applications of decision making and support systems, and the ways in which strategic intelligence has been applied in society. Contributions included in this section provide excellent coverage of today's strategic environment and insight into how strategic information systems impact the fabric of our present-day global village.

ABSTRACT

This document summarizes the initial findings of the I-Fit research project that started in August 2006 as a joint activity of a regional ICT consultancy and a university research center. The main goal of the project is to help the consultants to improve alignment between business and IT in the client organizations. The I-Fit project takes the perspective of the business manager: how a business manager can influence and increase the value of the IT services that he receives. Based on the literature on strategic alignment and Information quality, we develop the I-Fit model. The model assumes causal relationships between IT governance, Strategic Alignment, Information Quality, and Business Performance in an organization.

INTRODUCTION TO I-FIT PROJECT AND ITS OBJECTIVES

The I-Fit research project is a joint effort between KZA and Tilburg University and aims to further develop the alignment model.

The objectives of the I-Fit project are: To predict the impact of the business environment on the IT function in an organization, and to identify and manage the factors that influence the Information services in an organization.

The starting point of both the I-Fit project (and this chapter) is the well-known Strategic Alignment Model (Parker, Benson, & Trainer, 1989; Henderson & Venkatraman, 1991). Strategic alignment, or "business-IT alignment," intends to support the integration of IT into business strategy. The classic "Strategic Alignment Model" distinguishes between the business domain (business strategy and business processes) and the technology domain (information strategy and IT processes, including systems development and maintenance) in an organization.

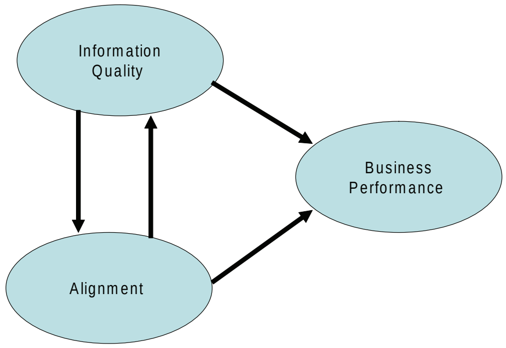
The I-Fit project focuses on three issues: identifying the key alignment processes, identifying performance indicators for alignment processes, and developing methods to improve alignment.

The deliverables of the I-Fit project include instruments or tools:

1. To provide insight for business managers in the IT consequences of decisions on Information services,
2. To support business managers to control Information services , based on alignment processes, and
3. To design strategies for the IT domain in order to maximize IT value added for the business, and (possibly) for benefits management.

This chapter summarizes the first three building blocks (Information Quality[1], alignment, and Business Performance (Figure 1)) for the creation of these tools. We briefly discuss two case studies within the project, and conclude with a generic framework addressing the relations between IT governance, Alignment Processes, Information Quality, and Business Performance. We also discuss the next steps of this I-Fit project for interested readers.

Figure 1. Building blocks for the I-Fit project



Note: The arrows indicate some possible relations between alignment, information quality and business performance

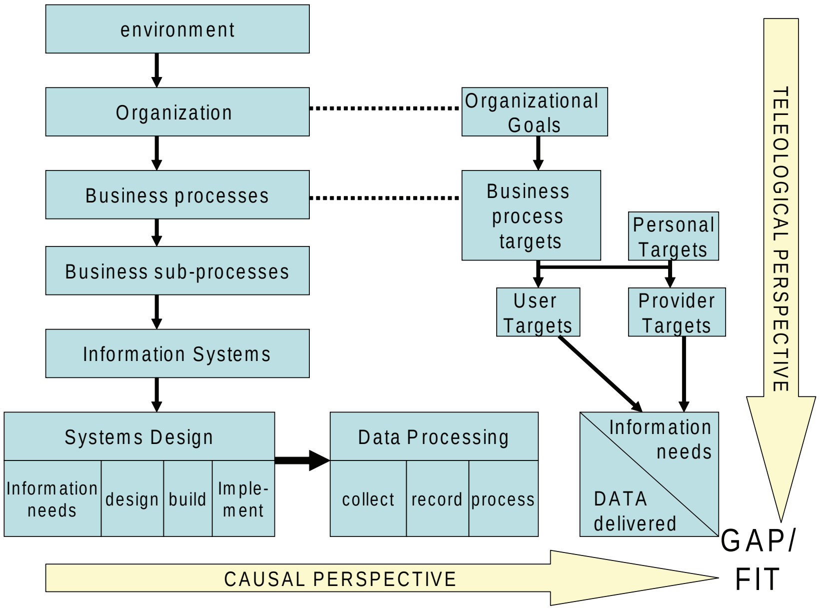
LITERATURE REVIEW

Information Quality

Our work is based on Roest (1988), Van der Pijl (1994a, 1994b), and Vermeer (1999) and denotes a typical Dutch or European perspective on information management. In this perspective, the quality of information (coming from information systems) is the key issue to explain business success. The USA approach differs since it aims to explain business success not by focusing on information, but on information technology and information systems.

The well-accepted definition of information quality is "the degree to which information is fit for use" or "fitness for purpose" (Klobas, 1995). Therefore, information quality on the highest level can simply be determined by asking for user satisfaction. However, this does not provide insight into the origins of quality failures. To analyze the origins, information Quality can be determined in two distinct ways, also known as the teleological and the causal perspective (Van der Pijl, 1994a) (Figure 2 shows these two perspectives). In the I-Fit project we use these two perspectives to determine the quality of information.

Figure 2. Causal and teleological perspectives on quality of information



Teleological Perspective

In the teleological perspective, information quality is the degree to which the information (data) that is delivered to the business fulfils the business needs. In the teleological model the quality of information is determined by the objective for which the information is intended to be used. Van der Pijl (1994a) argues that information depends on personal objectives that in their turn (partly) depend on organizational objectives. The importance of the teleological model is that it introduces organizational and business process objectives next to personal (e.g., user) objectives in the concept of information quality. From the teleological point of view the quality of information is seen as the degree to which it satisfies "stated or implicit needs," derived from the situation in which it is used.

Typical indicators for Information quality in the teleological perspective (Van der Pijl, 1994a) are: timeliness, accurateness, relevance, availability, and completeness[2]. Also, the flexibility of information (services) is important: how fast can Information services be changed in case of changes in the business needs? Note that, for instance, faster management reporting can relate to administrative requirements ("boekhoudkundige tijdigheid") and improved logistics of information processing.

Causal Perspective

Another perspective on Information quality is found in the causal model. In this perspective, Information quality is the degree to which the information that is delivered to the business is the result of a clear and correct chain of activities. These activities can be grouped in two phases: the information system development phase and the information system operation phase. The importance of the causal model of Information quality is that it is not possible to measure all aspects of the quality of information only from the information itself. The reliability of information also depends on the measures that are taken in the IS development and operational phase.

From the *causal perspective*, the quality of information is seen as the result of the quality of the processes in which it is produced. The first step in these processes is information analysis. During this stage the link between the organization's needs and the information systems is established. First the information policy is formulated and then the more detailed information needs are derived. The essence of the causal point of view in ex-post quality assessments is that not all aspects of the quality of information can be measured from that information itself. For some features it is necessary to look at one or more of the steps of the production process.

Typical indicators for Information quality from the causal perspective (Van der Pijl, 1994a) are "the information is provided according to the existing service level arrangements," "the information creation process is accountable for and transparent," and "it is SOX compliant."

Interestingly, the variety of Information quality indicators from the two perspectives create the need for business managers to balance between timeliness, completeness, accurateness, and the flexibility of information services . Aiming for the maximum performance on all quality indicators leads to high costs for information services.

Strategic Alignment

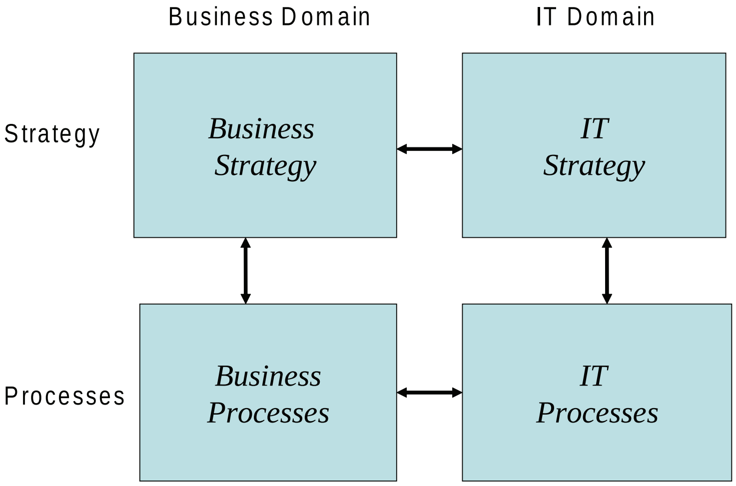
Three concepts are important to determine the impact of IT on information quality (previous section) and Business Performance (final section). In this section we define alignment, fit, and IT governance.

Henderson and Venkatraman (1993) introduced "business-IT alignment," in short "alignment," intended to support the integration of IT into business strategy. They distinguish in their classic "Strategic Alignment Model" (Figure 3) between the business domain (consisting of "business strategy" and "business processes") and the technology domain (consisting of "IT strategy" and "IT processes," including systems development and maintenance) in an organization.

Since 1990, various changes have been proposed to the Strategic Alignment Model, refocusing IT strategy into Information Systems Strategy (Strategic Information Systems Planning) and Information Strategy, showing more focus on business relations.

Information strategy is a complex phenomenon. In many organizations and in much of the information systems (IS) literature different terminologies are used. We define information

Figure 3. The Strategic Alignment Model (based on Henderson and Venkatraman (1993) and Parker, Benson & Trainor (1988))



strategy as: "a complex of implicit or explicit goals, visions, guidelines and plans with respect to the supply and demand of formal information in an organization, sanctioned by management, intended in the long run to support the objectives of the organization and adjusted to the environment."

Operationally expressed, information strategy is an instrument to manage Information services and technology in an organization. A frequently used term, related to information strategy, is strategic information systems planning (SISP) (Earl, 1993; Galliers, 1991; King, 1988; Lederer & Sethi, 1988; Ward, Griffiths & Whitmore, 1990). SISP is defined as "the process of deciding the objectives for organizational computing and identifying potential computer applications which the organization should implement" (Lederer & Sethi, 1988). The two definitions look very similar, but a strict comparison shows that the SISP definition tends to focus on explicit objectives and on applications and technology. Our definition concentrates on the use and the importance of information in an organization, starting with the planning of information (in the end influencing IT, as well as influenced by IT). We preferred this definition as a starting point to investigate how contemporary organizations deal with their needs for information and the planning of IT.

Strategic alignment is pursued along two dimensions in Figure 3: strategic fit: the (vertical) fit between strategies (business and IT) and internal infrastructures and processes, and *functional integration*: the (horizontal) fit between the business and the technology domain) (Henderson & Venkatraman, 1993).

Alignment is an elusive concept (Chan, 2002). Definitions of alignment range from high level, broadly encompassing definitions such as:

The fit between an organization and its strategy, structure, processes, technology, and environment.

A more focussed definition is:

The convergent intention, shared understanding and coordinated procedures.

Well-received views are that IS alignment is:

the degree to which the IT mission, objectives, and plans support and are supported by the business mission, objectives and plans (Chan, 2002), and *alignment is not a state, but a journey – one that is not always predictable, rational, or tightly planned* (Ciborra, 1991; Sauer & Yetton, 1997).

Chan (2002) defines IS alignment as:

- **IS alignment:** The "bringing in line" of the IS function's strategy, structure, technology, and processes with those of the business unit, so that IS personnel and their business partners are working toward the same goals while using their respective competencies.
- **IS strategic alignment:** The subset of IS alignment that concerns IS strategy and Business Unit Strategy. This component includes both strategy and processes.
- **IS structural alignment:** The subset of IS alignment that concerns the formal structure of the IS function and the business unit structure.

In the remaining discussion on this topic in this chapter, we focus on two aspects of alignment: (1) alignment as a process consisting of driver, levers, and impact, aiming to improve fit and (2) alignment as the degree of strategic fit and functional integration. Additionally, IT governance is introduced as the control structure in an organization to realize effective alignment processes.

IT Governance Defined

IT governance is defined as the way in which IT in an organization is controlled and coordinated (Brown 1997; Sambamurthy & Zmud 1999). More precisely, IT governance is about the focus of IT decision-making authority (centralized vs. decentralized control) and the processes that are in place to communicate IT decisions (Peterson, 2002).

Effective IT Governance Leads to Successful Alignment Processes

Governance comes from "kybernan" (Greek) and is related to "cybernetics" (Wiener, 1948), meaning "to steer" and "keeping a ship on its course in the midst of unexpected changing circumstances" (Peterson, 2002). Governance can be regarded as "control" in a broad perspective, meaning that governance includes the total set of controlling activities that keep the system (ship, organization) on the right (chosen) course (Malone & Crowston, 1994). Governance is a purposeful intervention in order to achieve a desired output, and describes a subsystem of decision-making units for directing and coordinating operational subsystems. The governance paradigm is based on a general systems approach of organizations (Ashby, 1956). Control is governance in a limited perspective, related to directing one subsystem.

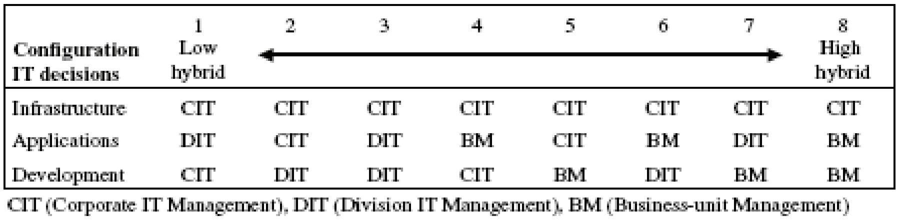
Traditionally, three configurations have been distinguished for IT governance (Sambamurthy & Zmud, 1999). In each configuration, stakeholder constituencies take different lead roles and responsibilities for IT decision making:

- **Centralized:** In this configuration, corporate IT management has IT decision-making authority concerning infrastructure, applications, and development.
- **Decentralized:** In this configuration, division IT management and business-unit management have authority for infrastructure, applications, and development.
- **Federal:** In this configuration (a hybrid configuration of centralization and decentralization), corporate IT has authority over infrastructure, and division IT and business-units have authority over applications and development.

In general, it is argued that centralization provides greater efficiency and standardization, while decentralization improves business ownership and responsiveness (Brown 1997). Table 1 shows eight types of IT governance, varying from centralized to decentralized decision making.

Peterson (2001) indicated that as companies experience increased uncertainty and complexity, and adopt multifocused strategies, IT governance designs are more hybrid with increased coordination needs. Figure 4 shows how the strategic (business) context influences the type of governance design and the integration mechanisms for IT governance, ultimately influencing IT perfor-

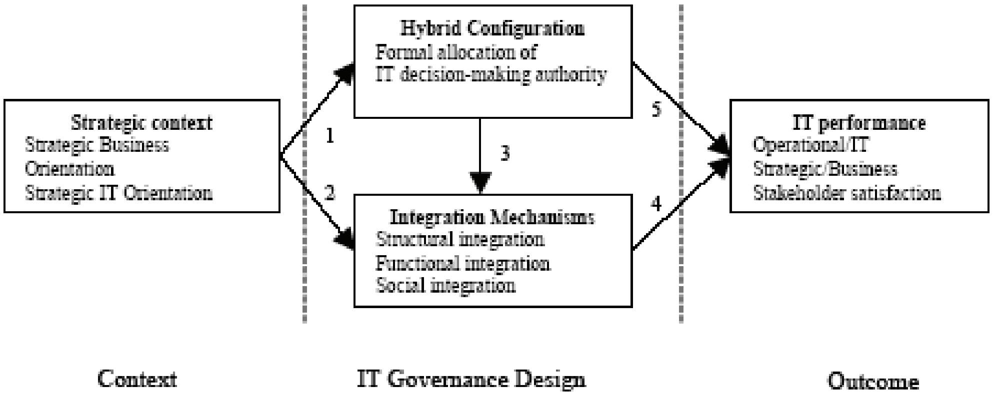
Table 1. Hybrid configurations for IT governance



Configuration IT decisions	1 Low hybrid	2	3	4	5	6	7	8 High hybrid
Infrastructure	CIT	CIT	CIT	CIT	CIT	CIT	CIT	CIT
Applications	DIT	CIT	DIT	BM	CIT	BM	DIT	BM
Development	CIT	DIT	DIT	CIT	BM	DIT	BM	BM

CIT (Corporate IT Management), DIT (Division IT Management), BM (Business-unit Management)

Figure 4. IT governance design (Peterson, 2001)



mance. Peterson showed that for organizations in a dynamic strategic context, the best IT governance structure is decentralized decision making, combined with rich integration mechanisms.

For I-Fit, it is shown later in this chapter that we have added two types of governance (information system (IS) and information (I)) to the classic IT governance definitions (e.g. the ISACA definition: "IT governance is the responsibility of executives and the board of directors, and consists of the leadership, organizational structures and processes that ensure that the enterprise's IT sustains and extends the organisation's strategies and objectives" (COBIT 4.0, www.itgi.org)).

Business Performance

Melville, Kraemer, and Gurbaxani (2004) reviewed the literature on IT and Organizational Performance and developed an integrative model of IT Business value (Figure 5). The term IT business value is commonly used to refer to the organizational performance impacts of IT, including productivity enhancement, profitability improvement, cost reduction, competitive advantage, inventory reduction, and other measures of performance.

The core of the model shows the impact of IT and complementary organizational resources on business processes and business process performance. Mediating variables are trading partner resources, industry characteristics, and country characteristics. The term performance is used to denote both intermediate business process level measures (also indicated as first order effects) as well as organizational measures (indicated as higher level variables, such as market share).

The IT business value literature does not provide a convention regarding the incorporation of costs of system development and implementation.

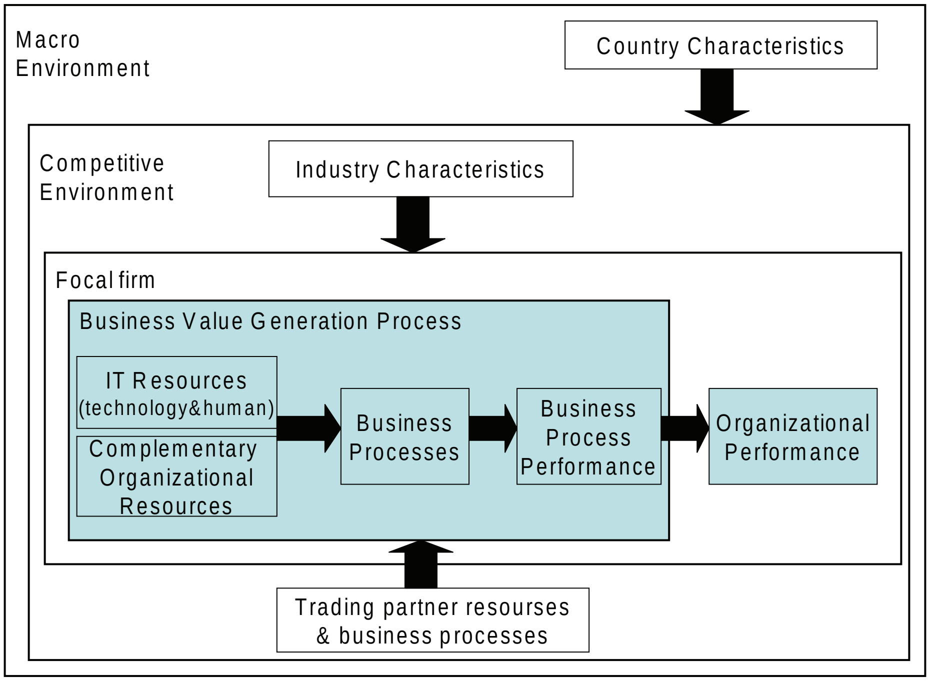
ISSUES AND SOLUTIONS FOR I-FIT PROJECT

Addressing Information Quality

Issue: Linking Information Quality to Business Objectives

In both perspectives, the quality of information relates to the degree to which information supports the goals (strategies, objectives) of the organization in which it is used. We outline these goal categories below (Van der Pijl, 1994b):

Figure 5. The IT business value model indicating the effect of IT resources on business processes, business process performance and organizational performance (Melville et al., 2004)



- **The organizational goals**. Almost every organization is characterized by the fact that its members come together to realize some kind of common goal. This common or organizational goal reflects the expectations, ambitions and aspirations of those who depend on the organization. At the level of the organization as a whole, organizational goals have to be translated into strategies that describe how these goals can be reached. Strategies arise in an interaction between structure, culture and goals of the organization. Traditionally we suppose that information has to support the organization's strategies. Recently we see, however, that information systems can also be used to shape, instead of support, organizational strategies and that they make it possible to aim for new goals.
- **The business process goals**. The existing division of labour in the organization is the basis for translating organizational goals and strategies into targets for each business process, department and individual within the organization. The degree of detail to which these targets have to be described when studying the quality of information depends on the organizational level that is chosen as a starting point for the analysis. Some organizations have explicit mechanisms for adjusting organizational goals and business process targets for different processes and hierarchical levels, while others do not. In some organizations there even is no strictly hierarchical relationship between goals and targets at all levels (operations, managerial, and strategic).
- **The personal interests**. Each individual in the organization also has its own individual interests. Status, power, responsibility, prestige and money are well known examples of personal aims, which can be influenced by background, experience and knowledge. Since the information needs of a person in

a certain function in the organization are influenced by both business process targets and personal interests, a judgement of the quality of information available to the individual has to take both elements into account.

- **The user's targets and the provider's targets**. Goals and targets can not only be subdivided according to levels in the organization but also into targets of those who are using information and targets of those who are providing others with information. A difference in position may lead to differences of opinion on the quality features and characteristics of the information received or provided.

Judging the *teleological aspects* of the quality of information in an organization means assessing the degree to which the information systems in the organization contribute to each of the goals and targets listed previously.

It is also possible to take only a subset of goals and targets into consideration. If we look at individual systems at the level of user's or provider's targets, we can study in detail which quality features and characteristics determine the contribution of systems to reaching the targets and how well the systems do so for each of these. If we look at the configuration of systems available to the organization as a whole, we take a much more global view. In that case we ask ourselves which functional contribution the systems make to the goals and targets of the organization without specifying detailed quality characteristics. Thus the detailed view of quality is replaced by a more global view in which quality of information in the organization is understood as the degree of fit between the goals and targets of the organization and the information systems that support the organization.

The causal and the teleological point of view are combined in Figure 2. At the bottom of the figure we see the steps of the process that has to be studied in the causal approach. On the upper right-hand side of the figure the set of goals and targets are shown, to be considered in the teleological approach. The vertical lines indicate the correspondence between the different levels of goals and targets and the hierarchical levels of the organization depicted on the left-hand side.

Solution: Measuring Information Quality

We see two opportunities or tools to measure the quality of information.

The first tool is the INK Information Mirror (in Dutch "informatiespiegel"), published in "Perfect Information Services (in Dutch: Excellente Informatievoorziening. Luiten, www.ink.nl). The Information Mirror consists of 25 questions from both the causal and the teleological perspectives. Answering the questions on a four-point Likert scale leads to a total score indicating the quality of Information services . *Note that this tool aims to determine the quality of Information services and not –only- the quality of information that is the result of the services.*

The second tool is the method by Van der Pijl (1994b, pp. 119-124), adapted from Bedell (1985), and focusing on the teleological perspective. The method consists of 12 steps, starting with (1) describing the objectives of the organization, the process, and the individuals involved, and (2) describing the information systems in the organization. In the next step the information systems are related to the business processes and process objectives per process. Then the relative impact of each information system to each objective and process is estimated. By adding the scores for all information systems and business processes, the total value of all IS for the organization is calculated. *Note that this tool aims to determine the quality of (the functionality of) information systems, and not the quality of information!*

Addressing Strategic Alignment

Issue: Alignment as a Process: Driver, Lever, and Impact

Henderson and Venkatraman described four types of alignment. Two alignment types are driven by business needs: (1) *Strategic execution:* business strategy drives organizational infrastructure and processes, ultimately influencing IS infrastructure and processes, and (2) *Technology transformation*: business strategy drives IT strategy, ultimately influencing IT processes.

Two other alignment types are driven by IT opportunities: (3) *Competitive potential*: information strategy influences business strategy, ultimately influencing organizational infrastructure and processes, and (4) *Service level*: information strategy influences IT infrastructure and processes, ultimately influencing organizational infrastructure and processes.

Luftman (1996) found empirical evidence that alignment can be seen as a process with a typical sequence of activities. Each alignment process has three major components that form a complete pattern of strategic change: a driver, a lever, and an impact (see also Hsiao & Ormerod, 1998). In the first perspective the business strategy is the driver for business processes or information strategy (called "levers"), ultimately affecting the IT processes ("impact"). Analysis of driver-lever-impact sequences can be found in Smits and Huisman (2007) and Alt and Smits (2007).

Similar refinements of the original alignment model can be found in Hsiao and Ormerod (1998) and Sauer and Yetton (1994), who also analyzed the relationships and different patterns of influence (different sequences of drivers, levers, and impacts) between strategy, structure, technology, and management.

Chan (2002) and Sauer and Yetton (1994, 1997) acknowledge that alignment is not a state (a situation of equilibrium between the domains that an organization can reach), but a journey ('a continuous managerial effort, not always predictable, rational, or tightly planned').

This journey and process perspective on alignment is fully in accordance with our definitions of information quality and the gap between information services and information needs:

- Alignment is a process in an organization that aims to reduce the gaps between the business domain and the technology domain, and between strategies and processes, and, ultimately the gap between information needs and information services.

Solution: Alignment and Organizational Effectiveness

The IS literature has repeatedly outlined the fundamental importance of alignment for organizational effectiveness and several attempts have been made to define the alignment concept more precisely and to develop the strategic alignment model into more concrete managerial guidelines and tools (Chan, 2002). Based on a review of literature and practice, alignment is defined by Chan as a multidimensional phenomenon, and as "a superset of multiple, simultaneous component alignments that bring together an organization's structure, strategy, and culture at multiple levels (IT, business unit, and corporate) with all their inherent demands"

Cragg et al. (2002) aimed to focus on the relationship between alignment and organisational performance, based on the argument that strategic fit has performance implications. Generally spoken: the better the fit, the better the performance (Fry & Killing, 1989). More specifically, the study wished to focus on one aspect of IT alignment, that is, the alignment between business strategy and IT strategy (Henderson & Venkatraman, 1989). In the Cragg et al. (2000) study, IT alignment was viewed as the fit between business strategy and IT strategy, similar to Chan et al. (1997). Two approaches were modelled—fit as "matching" and fit as "moderation"[3] which both rely on the close correspondence between the nine IT strategy items and the nine business strategy items. Fit as matching was based on the difference between each of two pairs of related items. Fit as moderation was modelled as the interaction between each business strategy and the related IT strategy. Thus, a gap analysis is created as to the closeness of fit to purpose.

This concept of "alignment" or "fit" expresses an idea that the object of design, e.g. an organisation's structure or its information systems, must match its context in order to be effective (Iivari, 1992). Parsons (1983) was one of the first to argue that IT can affect a firm's ability to execute their business strategy. Since then, many others have emphasised the need to develop a fit between information technology strategies and business strategies (Chan et al., 1997; Galliers, 1991; Henderson & Venkatraman, 1993; Venkatraman, 1989).

Addressing Business Performance

Issue: Frameworks for Organizational, Process, and Network Performance

The Operations Research and Management Science disciplines have provided guidelines to measure Business Performance of individual companies as well as the performance of business networks and supply chains (SC). A well-known example is the Balanced Scorecard (Kaplan & Norton, 1992), distinguishing between performance in four domains: financial, customer, process, and innovation.

The Supply Chain Operations Reference model (SCOR) for supply chain process benchmarking and performance measurement within as well as across firms, is based on five distinct management processes: plan, source, make, deliver, and the return process (Supply Chain Council, 2005). The SCOR model shows that performance can be evaluated in many ways, for example, higher flexibility, customer orientation, customization, flexibility and better cost-effectiveness. Gunasekaran et al. (2004) use the SCOR perspective and conclude that supply chain performance refers to meeting the end customer requirements, including product availability, on-time delivery, and all the necessary inventory and capacity in the supply chain to deliver that performance in a responsive matter. So, performance can be regarded "good" when the performance objectives are achieved on all levels and as set by all managers and organizations involved. Obviously, matching all these objectives is not an easy task (Hausman, 2002).

Kleijnen and Smits (2003) investigated the metrics used by organizations to evaluate Business Performance in a SC. Starting point is the set of five classic SC performance metrics reported in SC literature and practice from a single company perspective: (1) Fill rate (the percentage of orders delivered "on time"; that is, no later than the delivery day requested by the customer); (2) Confirmed fill rate (the percentage of orders delivered no later than the day agreed between the customer and the supplier); (3) Response delay (the difference between the requested delivery day and the negotiated day); (4) Delay (actual delivery day minus confirmed delivery day); (5) Stock (total Work in Process (WIP)). Kleijnen and Smits (2003) conclude that organizations now often use multiple metrics (balanced scorecard) because a single measure does not suffice.

Recently, SCOR related frameworks have become available to evaluate multiple metrics across organizations in a supply chain to support supply chain integration:

- Lambert and Pohlen (2001) present a framework in which Customer Relationship Management and Supplier Relationship Management are the two processes that capture the overall performance of a SC. The two processes must be analyzed in every supplier-customer link in a multi-tiered network to provide the supply chain metrics.

- Gunasekaran et al. (2004) developed a framework for SC performance measurement distinguishing between twelve metric types based on three management levels or responsibilities (strategic, tactical, and operational) and –per level- the four major SC activities (Plan, Source, Make, Deliver). Gunasekaran lists 44 examples of different metrics, for instance, "supplier delivery performance" is a metric for "sourcing" at the "tactical level."

Fairchild, Ribbers, and Nooteboom (2004) distinguish seven success indicators for business networks. Four indicators relate to market context and three to market processes. Market context success indicators can be summarized as (1) a high number, high volume, high variability, and high frequency of the transactions, (2) low complexity, low specificity, and high value of the product, (3) convergence of stakeholder motives, and (4) the presence of government regulations. Market process success indicators can be summarized as (1) low learning costs and low entry barriers, (2) availability of multiple transaction mechanisms, (3) trust, based on neutrality of the market, partnership with domain experts, high quality of product- and trading partner information, security of information, and a local focus.

Solution: From Alignment to Performance

Chan et al. (1997) use a well-accepted model to link Business Strategic Orientation and IS Strategic Orientation to IS Strategic Alignment, Business Performance and IS Effectiveness.

Chan et al (1997) define IS Strategic Alignment as "the alignment between Business Unit Strategic Orientation and IS Strategic Orientation" and calculate IS Strategic Alignment as the degree to which a company employs the systems that supported the strategic orientation. Note that this is only part of the total alignment processes represented in the strategic alignment model.

Chan et al. (1997) examined whether the impact of IT on performance may not be a direct one, but intermediated by other factors, such as the alignment between Business Strategy and IT Strategy. They modified the well-known STROBE model (STRategic Orientation of Business Enterprises) of Venkatraman to include performance at the IS level as well as at the business unit level. The constructs are defined in Table 2.

I-FIT MODEL: COMBINED BUILDING BLOCKS

This document has summarized the three building blocks Information quality, Alignment, and Business Performance for the creation of tools:

- To provide insight for business managers in the IT consequences of decisions on information services,
- To support business managers to control I services, based on alignment processes, and
- To design strategies for the IT domain in order to maximize IT value added for the business, and (possibly) for benefits management.

Information Quality can be determined in two perspectives: the quality of the information that is provided to the business (the causal perspective) and the quality of the information that is needed by the business (the teleological perspective). The difference between the two quality indicators illustrates the "gap" showing a certain degree of (miss-) fit. We aim to qualify the gap by distinguishing between four types of information, following the balanced score card perspectives: financial, process, customer, and innovation related information.

Strategic Alignment[5] in an organization can be determined by analyzing the alignment processes that occur in an organization (from driver, to lever, and impact) and to assess the IT governance structure and integration mechanisms in

Table 2. Dimensions to assess IS strategic alignment and business performance

Key Construct	Indicators	Key informants
STROBE (Strategic Orientation of Business Enterprises)(= Realized Business Strategy)	Company analysis, Company internal defensiveness, Company external defensiveness, Company futurity, Company proactiveness, Company Risk Aversion, Company Innovativeness	Chief Executive Officers
Business Performance[4]	Market Growth, Financial Performance, Product-Service Innovation, Company Reputation	Chief Financial Officers
IS Effectiveness (i.e., Current Value and Business Contribution of IS)	Satisfaction with IS staff and services; Satisfaction with the Information product; satisfaction with End User Knowledge and Involvement IS Contributions to Operational Efficiency, Managerial Effectiveness, Establishment of Market Linkages, Creation and Enhancement of Products and Services.	Vice Presidents of end-user, mission critical departments
STROEPS (Strategic Orientation of the Existing Portfolio of IS applications)(= Realized IS Strategy)	IS Supports for Aggressiveness, Analysis, Internal Defensiveness, External Defensiveness, Futurity, Proactiveness, Risk Aversion, Innovativeness	Executives familiar with the information systems used in the business unit (Chief Information Officers)
IS Strategic Alignment	This construct is calculated from the scores on STROBE and STROEPS	

an organization aiming to manage alignment and to reduce the gap between information needs and Information services.

Business Process Performance in an organization can be determined by assessing performance at the business process level using balanced scorecard like performance indicators.

For the I-Fit project, based on the literature review in the previous sections, we propose the I-Fit model (Figure 6), to analyze alignment (the current situation IST) in an organization. Key hypothesis in Figure 6 is that "good alignment (effective driver-lever-impact processes and good IT governance) leads to good information quality (good fit between causal and teleological quality indicators), ultimately improving Business Performance."

Key questions for analysis of the current situation (IST) in an organization are:

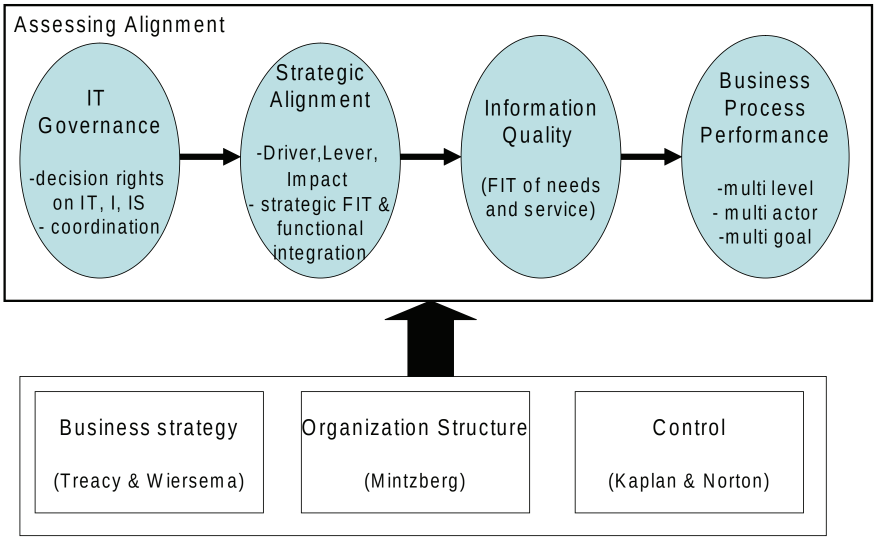
- How is IT governance implemented in the organization?
- How do alignment processes exist in the organization?
- Are existing information systems aligned with the business strategy in the organization
- Do the Information services fit with the information needs in the organization?
- How mature is the IT and business organization? (similar to the concept of CMMi?)

Answering these questions means that there is a "FIT" between the four circles in Figure 6. If there is no "fit," a new situation should be designed (SOLL), by changing one or more circles. This design process would be a joint effort of consultants and the client organization: the effort can be considered successful if insight in the IST situation has increased, and if a shared basis for implementation of improvements has been accomplished.

Cases to be Assessed in the I-Fit Project

The primary vertical focus of our initial cases is the financial industry in continental Europe. Both

Figure 6. The I-FIT model: A framework for tools to analyze alignment in an organization



banks discussed here have their names withheld for privacy reasons.

Bank "A": Within Bank A"s IT and change organization, there are a significant number of improvement initiatives, which currently driven by business process improvement (BPI) metrics. These include not only process improvement, but also compliance. Both budget allocation and required cost cutting measures currently take place based on business process improvement (BPI) metrics. This is not a very transparent process for the client internally.

This bank's business model is transforming from a traditional insurance company towards an "issuance factory". The factory model is a shared service center for insurance companies. BPI is responsible for the transition. This means, in practice, that the regular business gets little attention from BPI.

In this context, we are introducing I-Fit to make things transparent and give insight in the consequences of the current state of alignment.

Bank "B": Bank "B" is a cooperation that has recently centralized the IT function ("Group ICT") and is now outsourcing portions of this organization. Within Bank "B", its international organization has its own IT function (IS&D). Nevertheless it also uses of "Group ICT" in some areas. Sometimes the international business contacts Group ICT directly; sometimes an internal intermediary handles the responsibility. Therefore, the consequences are:

- Miscommunication;
- No clear picture of who is responsible for what;
- Internal politics, along with;
- Internal bureaucracy.

We believe that the introduction of I-Fit will play a role in making the problem transparent, as well as give insight in the impact of certain problems.

CONCLUSION: FUTURE RESEARCH DIRECTION

The tools for I-Fit are in development between the two organizations. We propose to continue this research with:

- Further defining the tools for assessing fit, information quality, alignment, and business performance.
- Validating the tools by applying them in some business situations (case analysis).
- Assessment of the validity of the hypothesis in qualitative and quantitative research.

The next step for each of the building blocks is outlined below.

Next Steps to Determine Information Quality

The two tools that are available from theory do not completely match our needs. Therefore we aim to define a tool that helps us to define and determine the quality of the information that is provided (causal perspective) and confront this with the quality of the information that is needed (teleological perspective).

A possible approach to assess the quality of information as the gap between (or the fit of) information needs and Information services in an organization. Information needs are determined by surveying a set of business managers and grouping their information needs on the four dimensions of the balanced scorecard (financial information, information on business processes, information on customers, and information on business dynamics and innovation). Information services are determined by analyzing the information output in the (main) management reports. Comparison of the needs (in four balanced scorecard perspectives) and services (in the same perspectives) shows the gaps in financial, customer, process, and innovation perspectives.

We expect always to find a discrepancy (gap) between the information provided and the information needed, showing a certain degree of (miss-) fit. Key questions are:

- How much fit is there now?
- Is the gap acceptable?
- How dynamic are the business needs?
- Can fit remain when the business needs are changing?

One approach to determining the gap between information services and information needs in the current situation and the future situation is based on making an inventory of information needs and information services. We aim to distinguish between four types of information, following the balanced score card perspectives: financial, process, customer, and innovation related information.

Next Steps to Determine Alignment and Governance

In order to analyze alignment in an organization, we aim to select tools

- To assess the alignment processes that occur in an organization: describe examples of alignment (from driver, to lever and impact), and
- To assess the IT governance design and integration mechanisms (Peterson, 2001) in an organization, aiming to manage alignment processes and to reduce the gap between information needs and information services.

Instead of focusing on IT governance, we might prefer to develop tools for assessing IS governance, or maybe even better information governance because this might fit best our focus on Information quality.

In the previous sections we have addressed “IT governance,” “alignment processes,” and “information quality.” In the next section we address “business performance.”

Next Steps to Determine Business Performance

Summarizing, Business Performance should be measured by using multiple metrics per organization, and by using the same metrics on the supply chain level to avoid suboptimization. In practice, performance metrics vary across supply chains, across organizations in a supply chain, and depend on the strategic drivers for the actors involved. This implies that supply chain performance can be successful according to one actor and a failure when evaluated by others.

To be included in the tools to assess Business Performance are topics such as:

- Six Sigma
- How we address stakeholder perspective and types of metrics depends on the types of firms assessed and the industries they participate in.

Chapter 4.2

Stability and Creativity as Contradicting Values in Information Management

Timo Leino
Turku School of Economics, Finland

EXECUTIVE SUMMARY

This case represents the situation at a North European business school in 1996 and the development process since then. At this school, the IT environment was quite heterogeneous and unstable, causing low user satisfaction. We describe the strategic actions taken and the successful consequences of those actions. Finally, we reflect on the lessons learned in our case for the current situation, where modern organizations are planning to implement Windows Vista and Office 2007, and the school in case is facing a new organizational challenge.

ORGANIZATION BACKGROUND

Turku School of Economics (TSE) is a Finnish business school that provides research and higher education in the field of business science. The school is very active in research, and offers graduate, postgraduate and continuing education. Expert consulting services form an increasing part of the School's activities. There are approximately 2,000 undergraduate students and about 300 doctoral students at the School. The teaching and research staff numbers more than 200 and other staff about 100.

The school is organized in departments. There are five departments for teaching and research: management, accounting and finance, marketing, economics, and languages. Two departments are dedicated to consulting, research and management education services: Business Research and Development center and Finland Futures Research center. Beyond these departments, information services units (the library, IT center and communication office) and the Office for Administrative Services are taking care of supporting activities.

More detailed information of TSE can be found on www.tse.fi. Naturally, the situation is not exactly as it was in 1996 anymore, but no major changes have taken place.

The top management of TSE consists of the rector and the vice rector, the administrative director, and the board. The rectors and the administrative director are permanent board members whilst the other members are elected every third year. Students have four of the 13 seats in the board. The management model may be regarded as quite democratic, in the usual manner of Finnish universities.

In 1996, the budget of TSE was around 90 million FIM (approximately 18 million U.S. dollars). As a state-owned university, TSE got 60–70 percent of the budget from the Ministry of Education; the rest came from outside financial sources such as scientific foundations, or companies buying e-MBA courses or research projects. The main part of the budget was spent on personnel costs. In the field of economics and business administration, no major investments (e.g., equipment or laboratories) are needed to produce high quality scientific research, education or services.

In 1996, an intensive strategic planning process was undertaken in TSE. As a business school, TSE had strategic planning as one of the principal topics in teaching and research. The process, therefore, was "by the book." The newly elected Rector wanted the School to define a new vision and strategy, and he launched a planning process where almost every member of the staff was contributing in some way. The new strategy was approved by the board in September, 1996. The main message of the strategy was growing from a local teaching school to an international research organization.

Ten years later, a strong national trend for bigger university units and more international operations is evolving in Finland. The Ministry of Education is driving for cooperation or even fusions between universities. As a part of this evolution, TSE and University of Turku are enforced to rethink their positions in the Finnish academia. That led to a decision to form a consortium of these two universities with a common board. The decision was made in a very positive and constructive atmosphere in 2006. The future shared organization will get its concrete form in the years to come, and the actual deepness of unification remains to be seen. Cooperation in teaching and research is to increase, and possibly some restructuring of administration will take place.

SETTING THE STAGE

The IT architecture of TSE in 1996 was a typical mixture of the technology at that time. The LAN had been implemented some years previously, every member of the staff already had a PC on her or his desk and e-mail had been taken into use throughout the organization, though utilizing the Web was still quite novel. No mainframes were in use: a type of client/server architecture was implemented based on file servers, e-mail and Web servers. Most administrative systems such as the student information system or payroll system were installed in the computers at Åbo Akademi University, an institution with Swedish as its language of instruction also located in Turku. The network connections outside the school were developed and maintained in cooperation with Åbo Akademi University and the University of Turku. Each of these three universities boasted their own IT centers and IT resources, but cooperation was quite active and the relationships between IT professionals were excellent.

The most widely used applications in TSE were word processing, e-mail, spreadsheet, library databases, statistical analysis software and the Web. Both Windows and Macintosh were in use, the ratio of Macs at about 15 percent. The blend of applications was quite diverse:

- For e-mail, Windows users had only one option (MS-Mail); Mac users had several

programs, Eudora being the most popular.
- For word processing, Windows users had MS-Word (ver 2) or WordPerfect (DOS version); Mac users had several options, MS-Word being the most popular.
- MS-Excel was used for spreadsheet creation by all users except for a few devoted Lotus 1-2-3 users.
- For statistical analysis, both SPSS and SAS were used; SPSS was installed in a mainframe of Åbo Akademi University.
- For other purposes, users could choose their personal favorite software within budget limits.

TSE's centralized IT center consisted of the IT manager and seven full-time professionals. Besides this, part-time students were employed to assist personnel in utilizing the new technology in the IT center as well as in some other departments. The IT manager was responsible for the IT center. He had his own budget for covering the general IT expenses of the school. Those costs included the network (LAN and Internet connection), servers and the internal expenses of the IT center. Other departments paid for their hardware and software themselves. The heads of the departments made the purchasing decisions with regard to PCs and software whilst the IT center took care, in most cases, of the purchasing operations.

The IT manager reported to the administrative director. Additionally, there was an IT board consisting of the IT manager and representatives of users, students and IT professionals. However, the IT board had no real power—one professor said that it was a body in which the IT manager managed himself while coffee was being enjoyed.

CASE DESCRIPTION

In this article, we first discuss the management of end user computing (MEUC) in general. Then we reveal the information management strategy (IMS) planning task at TSE from MEUC's point of view, taking the point of time into account. The situation in TSE in 1996 was a typical consequence of loose management and therefore has more general value. We discuss the creation and implementation of an IMS in TSE. The rector nominated a working group to plan the strategy in October, 1996. The group found out that users were dissatisfied with the current state of IT, but quite keen to take advantage of the new technology. At the end of the chapter we will reveal the results of personnel user satisfaction studies that show a highly interesting connection between standardization and satisfaction.

Management of EUC

In the IS literature, users have been divided into two groups: end users and IT professionals. This line of thinking goes back to McLean (1979), who used the terms data processing professionals and data processing users. Rockart and Flannery (1983) found six categories on a continuum: nonprogrammers, command level users, end user programmers, functional support personnel, end user support personnel and data processing programmers. The basic distinction between end users and IT professionals is the relationship to IT. Professionals create applications for others; end users deploy the applications (Cotterman & Kumar, 1989).

Classification into two groups is sensible, because in a real-life organizational setting, the end user group creates a demand of services to be supplied by the IT/IS department (Leonard, 2001). Although this kind of demand/supply approach has been criticized and the alignment approach has been emphasized (Duchesi & Chengalur-Smith, 1998; Henderson & Venkatraman, 1992; Zee & Jong, 1999), the two groups and the interaction between them remain. Unfortunately, mistrust often characterizes this interaction, preventing a sound alignment.

The relationship between the IT/IS department and end users may be disturbed because of the power unbalance caused by the nature of the relationship. The supply side can perform its tasks adequately at best. In many cases, the system failures or users' low participation in IT projects cause dissatisfaction with the IT/IS department (Kettinger & Lee, 2002). Smith and McKeen (1992) interviewed line and IT managers, and both groups seemed to have suspicious attitudes: "IS people are techies and don't understand business...[they] don't have interpersonal skills"; and "The users don't know what they want." Clearly, the stereotypes of these two groups are somewhat different to each other. Couger and Zawacki noted already in 1980 that IT professionals want to have more challenges and fewer human contacts than other people—and that is probably still a valid notion.

IT/end user's alignment culminates in the standardization policy of the organization. The discussion on standardization started already during the 1980s, when the EUC was a new phenomenon. By 'EUC' we mean the voluntary use of computers in the broad sense of the term. An essential feature in EUC is the user's free choice of tools and their use (Igbaria, 1990). Additionally, there is a more narrow approach to the EUC concept in the literature, defining EUC as systems developed by end users to support their decision-making (e.g., Aggarwal, 1994). Gerrity and Rockart (1986) introduced the idea of monopolistic (standardization) versus laissez-faire strategy. Munro and Huff (1988) stated that most organizations evolve from laissez-faire strategy to controlled growth strategy, either through control or acceleration. Henderson and Treacy (1986) explained the evolution using a state model, according to which the growth of a new technology and controlling its use always follow each others in cycles.

The essential issue in standardization is the power balance between the IT/IS department and the user organization. Trust and respect for each other is the key to healthy communication (Leonard, 2000). Halloran (1993) stresses the clear domains of responsibilities as a key to the success of information systems. It is fairly easy to bring forward arguments for a strict control strategy. Having such a strategy, the organization may achieve advantages in purchasing IT, organizing user support or training and maintaining user work stations and the infrastructure.

The users' or departments' power to locally plan and control IT resources is the counter-argument. From the point of view of a middle manager it may be hard to understand the IT/IS department's argumentation for a "one for all" policy. Thus, coordinated development and greediness for power compete with each other. The former is based on synergy and rationality; with the latter, the motivation is merely emotional. The weighting of these two options varies case by case—the determining factor in most cases rests in opinions of the most powerful persons in the organization. These kinds of decisions are usually more politically than rationally based.

The Starting State

Strategic IS planning (SISP) had been one of the areas of priority in TSE's teaching and research for several years, and the Rector himself had been the leading researcher in this field (see for example, Reponen, 1994). With this background, setting up an IMS planning project was an eloquent decision. The aim was to create an IMS that well supports the strategy of the school.

Lecturer T was appointed to the project champion. He had experience in IMS planning processes in companies and had taught SISP and information management for several years. Other 10 members of the project group represented different departments. The team's work took four months, including the following actions:

- A survey for the personnel. A questionnaire based on the UIS model (Bailey & Pearson, 1983) and EUCS model (Doll & Torkzadeh,

1988) was constructed in order to determine personnel satisfaction on services and tools, and opinions on the importance of possible focusing areas. Such areas as the development of infrastructure and systems, the improvement of user skills or user support services were presented. The questionnaire comprised close to 70 questions, with a Likert-like scale from 1 to 5 covering the following areas: the success of SISP, the IT/IS policies, the service level of IT center, the IT/IS in users' disposal, user skills and the focus of IT deployment. The satisfaction with regard to specific administrative systems was not studied. The questionnaire was delivered to the personnel as a whole, the response rate being over 70 percent. The results provided extremely useful guidance for focusing on development actions.

- 22 interviews in which the viewpoints of various stakeholders were examined more deeply. A prominent set of problems and suggestions emerged.
- Several meetings of the project group. In most cases, lecturer T wrote drafts that were discussed and elaborated by the group. Lecturer T had a strong position in the entire process. Besides being the chairman and the writer, he carried out both the survey and all the interviews. One could criticize the methods being too much on the "planning school" side and that a more "learning school" kind of approach (Minzberg, 1987) would have been more fruitful. However, the plan was finalized in January 1997 and approved by the board in March 1997, after which the implementation started with a kickoff seminar having a very enthusiastic atmosphere in May, 1997.

According to the survey and the interviews in 1996, the situation at the school was more or less chaotic and user satisfaction was low. Several problems were identified:

- Incompatibility problems when users changed data between each others or with outsiders.
- The service level of IT center was found to be very low. The professionals were hard to reach and their attitude towards users was not adequate.
- Internal communication was not on a satisfactory level. The main method of informing the personnel was a leaflet delivered to everyone every 2–3 weeks.
- Some administrative processes were inefficient, this based partly on deficient information systems, partly on deficient working procedures, and partly on problems in human relationships.

The discussion concerning Macintosh versus Windows was quite lively. In the IT center, Mr. V was dedicated to serving all Mac users. As a matter of fact, Mr. V refused all assignments that were not Mac-related. He was a Mac enthusiast and promoted that option heavily. The choice between Mac and Windows was done by every user freely and seemed to be somewhat random. A kind of competition or even 'war' was going on. The students had both options: one of the four computer labs was supplied with Macs, and both systems were used in teaching, which was also based on the personal preferences of the IS teachers. For instance, lecturer T taught DSSs by using Excel in the Windows environment, but also PageMaker by using Macs.

Incompatibility was an everyday source of displeasure. Usually, problems came up when a Windows user received a file from a Mac user. The file could not be opened or the layout was damaged. The IT center was not very willing to help in these cases because of each person's antipathy against one of the two systems. Most users, however, were rather neutral and used the system they had incidentally received on their desks. Only a small—but loud—group of users participated in the "war." During the IMS planning process, Lecturer T's mailbox was the target of heavy 'bombing', with comments in favor of Macintosh. Lecturer T himself was quite indifferent on the matter: he liked Mac as a personal tool but understood very well the arguments towards organizational control.

The Challenge of the IMS Planning Group

During TSE's planning process, many interviewees presented promising new ideas of using IT in research, teaching or administrative activities. Lecturer T realized that the full potential of resources—both human and technical—had not been exploited. As a university, TSE can be categorized as a "professional" organization, in Minzberg's (1991) typology. In this kind of setting, EUC should be the main focus of IT development, because usage typically takes the form of personal computing, for example, word processing.

The IMS planning group had to decide on future actions. Clearly, some dramatic change was required. Most users were annoyed with the current state of affairs, this being a result of a long history of "driftwood management." Users understood that problems were resolvable if the IT services were organized in a new way. The IMS planning group faced a heavy stress on change and, on the other hand, a strong hopefulness and optimism concerning the future. The general technological development at that time (Internet usage growth, EUC growth, emerging e-learning technology, etc.) was changing the way universities operated. In terms of the strategic grid by MacFarlan (1984), the academic world was in a "turnaround mode"; IT was evolving from support to a more strategic role.

The selection of operating systems and basic software (i.e., applications that are used by every user) seemed to be the most crucial issue. Should the planning group suggest a monopolistic strategy or a laissez-faire strategy? So far, there had been no well-defined strategy, EUC had grown rapidly without management policies. This was the case in most organizations in the early stages of end user computing (Munro & Huff, 1988).

A monopolistic strategy had its supporters. Professor S, a strong person inside the school, promoted stability, because researchers and teachers are loaded every day with deadlines, and the tolerance against interruptions is quite low. Students as well as many researchers and teachers wanted the school to be a modern pioneer in deploying new technology. They were afraid that too much control would limit creativity.

The IMS planning group had to make a choice. Should stability be the objective, or creativity? These are justifiable but conflicting demands. Other issues where the planning group needed to take up a stand were at least the following:

- The organizing of user support. The current situation was unsatisfactory.
- The centralization versus de-centralization of IT services. Some departments were quite satisfied with the students they had hired for assistance. Some heads of departments even claimed that user support could be arranged in a more effective way by themselves instead of the IT center.
- The cooperation level with the IT centers of the University of Turku and Åbo Akademi University. TSE was clearly the smallest of the three universities in town and had the lowest number of users and IT professionals. On the other hand, IT investments per employee were higher in TSE than in the neighboring universities.
- The development of user skills. Most users were not satisfied with their ability to utilize the tools in their possession.
- The development of the infrastructure. Users were annoyed with e-mail interruptions as well as with their Internet connections or even the applications in their workstations. A more stable environment was required.

IMS Approval and Implementation

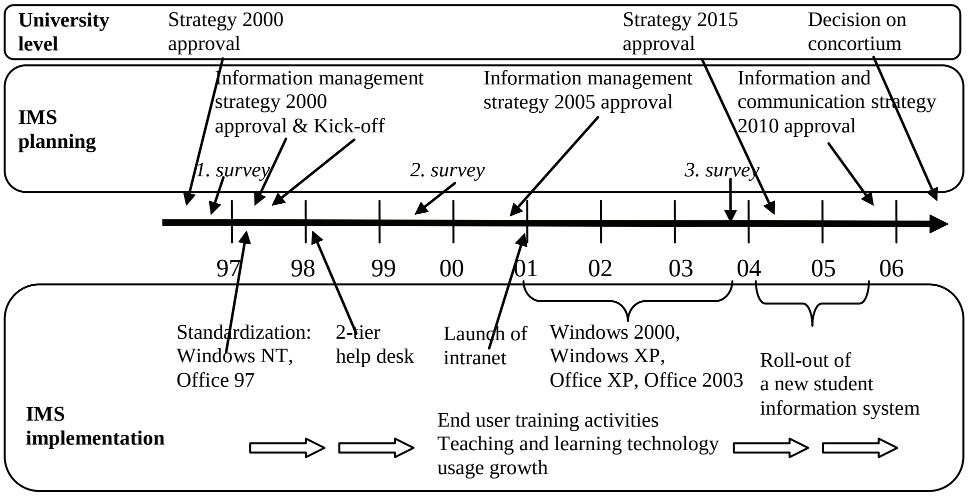
After a planning process lasting four months, the working group formulated a suggestion for an IMS. The strategy, called IMS2000, was approved by the board in March, 1997. After that, a strong and enthusiastic implementation project was started, focusing on development ideas presented in the strategy. The three most effective actions taking place were the following:

- The standardization of operating systems and office software. Windows NT and Office 97 were defined as the only options in use. Macintosh users were given one year to shift to a Windows environment.
- A two-tier help desk was established inside the IT center. A team consisting of part-time students was set up to take care of the front-end service, supported by the IT professionals as a back-end team. End users (both personnel and students) were provided with one contact point they could reach by phone, e-mail or visiting the office.
- An end user training program was launched. The IS teachers responsible for students' EUC courses agreed to teach personnel as well. The content of the training sessions was planned for each group (e.g., researchers) task-specific. Goals of the training should be linked to goals of the organization (Mahapatra & Lai, 2005), and the use of tools should fit the users' tasks (Goodhue & Thompson, 1995).

Figure 1 depicts the strategic development of IT in TSE since 1996. The process of planning the IMS2000 was described in detail. The resulting plan and its implementation covered the years 1997–2000. When coming to the end of this period, the Rector nominated a new working group to update the IMS, which was done quite smoothly and a new strategy, called IMS2005, was approved by the board of the school in December, 2000. In that point there were no major development efforts.

The recent history is as follows. In 2004, a new strategy for the school (Strategy 2015) was approved by the board. Consequently, a new IMS was to be written. The strategy called "Information and Communication Strategy 2010" was approved by the board at the end of 2005. This time the strategy includes all the "information services", i.e., IT services, communication services and library services. These services are offered by three separate administrative units now integrated

Figure 1. The strategic development of IT in TSE since 1996



tighter than before. At this point, the useless IT board was discontinued.

The Development in User Satisfaction

When planning the IMS first time in TSE, we carried out an UIS survey. The survey was then repeated in 1999 and again in 2003, and the results showed that the IMS process was quite successful. UIS represents the only measurements that were done: no economical input/output analysis is available. However, the IT budget has increased quite moderately since 1996.

The most interesting results from the surveys are presented in the following. They are scientifically interesting and exceptional because of the longitudinal nature of our study. We studied the user satisfaction before and after certain activities, so that we can draw conclusions of those activities' influence on user satisfaction. The response rates were so high that we may well regard the averages as the general opinion of the personnel as a whole (over 70 percent in 1996 and in 1999, about 40 percent in 2003). Satisfaction measures do not vary significantly between subgroups (Doll et al., 2004), and therefore no further subgroup analysis is required. Table 1 shows the averages of answers to selected questions. The average of all answers with the same kind of scale was 3.57. This figure represents a "general mental average" against which the average of a specific question may be contrasted.

Our study provides exceptional insight into the influence of standardization in the long run. The argumentation for strict control strategy is usually based, from the organizational development point of view, on rational thinking. The counter-arguments are usually based on user satisfaction, which is threatened by the power loss. Our case shows that, as a matter of fact, the control strategy increases the end user satisfaction in the long run. Such a strategy makes the user environment more homogenous and stabile. The stability is what users most desire, because it enables them to perform their tasks more efficiently and effectively. Our results, which strongly support this line of thinking, are presented in Figure 2. Also, the averages in Table 1 show the high and increasing importance of stability.

The main information management activities in TSE since 1996 have been standardization, the

Figure 2. The standardization policy: free choice of operating system (i.e. Windows versus Macintosh or Linux)

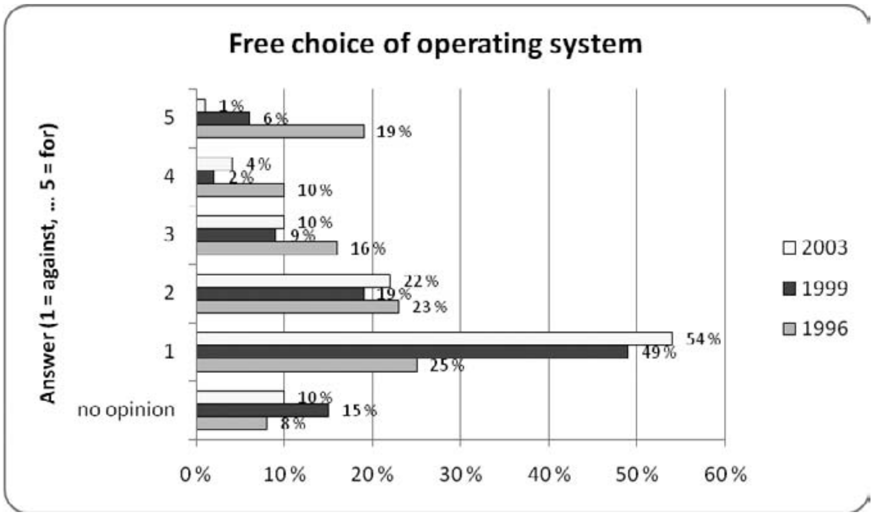


Table 1. Averages of answers in 1996, 1999 and 2003

Question	***Average of answers 1996 (N=176)***	***Average of answers 1999 (N=169)***	***Average of answers 2003 (N=105)***
Selection of operating system:			
Everyone should have the right to choose between Macintosh and Windows (1=Absolutely not, 5=Absolutely yes)	2.71	1.79	1.62
Focus of development:			
Importance of the stability of the workstation and its software (2 questions)	4.71	4.74	4.74
Importance of the stability of the network (2 questions)	4.09	4.15	4.44
Importance of workstation processing power	3.84	3.97	3.98
Importance of the novelty of software and hardware (3 questions)	2.88	2.80	2.46
Importance of user skills	4.17	4.27	4.35
Importance of www as a communication media (2 questions)	3.72	4.11	4.32
Importance of e-mail as a communications media (3 questions)	4.16	4.36	4.26
Importance of teaching technology (computer labs, audiovisual systems, etc. 4 questions)	3.88	4.05	4.07
Satisfaction with IT services and management:			
Satisfaction with the services offered by the IT center (12 questions)	3.35	3.52	3.52
Satisfaction with purchasing policies (5 questions)	3.96	4.18	3.79
Satisfaction with the desktop computer in use	4.21	4.49	4.19
Satisfaction with printers and other peripheral devices in use (3 questions)	3.63	3.88	3.51
Satisfaction with own computing skills:			
Satisfaction with personal skills in using e-mail (4 questions)	4.13	4.46	4.54
Satisfaction with personal skills in using the Internet (5 questions)	2.94	3.26	3.40
Satisfaction with personal skills in using operating system and computer in general (5 questions)	3.61	3.57	3.53
Satisfaction with personal skills in using general-purpose software such as Office (7 questions)	2.94	3.42	3.60
Satisfaction with personal skills in using library databases	2.89	n/a	3.74

Key: 1=Not at all important/Very dissatisfied, 5=Very important/Very satisfied (if no other explanation given) establishment of a help desk, end user training and the intranet launch (see Figure 1). User satisfaction measures show that these efforts have been worth taking. Figure 3 shows the clearly increased satisfaction to user support and Figure 4 to the training; averages in Table 1 show the same effect. The increase of computing skills (see Figure 5) based on self-assessment may be a consequence of training, but there may be other influencing factors as well.

CURRENT CHALLENGES FACING THE ORGANIZATION

In this chapter, we shall shift the focus from past to present. Although the situation in the mid-00s is quite different than in 1996, there are certain similarities in the state of technological development and in the decision-making challenges of strategic IS planning. We will reveal the latest development in the literature of IT management, discuss Windows Vista as the most important issue of the current state of technology, and conclude with presenting the future challenges of IT management in TSE.

Contemporary Issues in Management of EUC

The phenomena of EUC started in the early 1980s and became "business as usual" during the late 1990s. McLean and Kappelman stated already in 1993 that EUC was not an independent phenomenon anymore but rather is integrated in organizational computing. Later on, the management of EUC has not been in the core of IT/IS research or practical IT/IS management. During the last few years, the alignment of IT and business has become a very popular issue. End users receive and use IT services, and the crucial management question is how the organization uses resources to deliver a portfolio of services to the end users (Peppard, 2003). Zee (1998) stressed the cultural change in the role of the IT function: the focus was (at the end of the 1990s) moving towards customer orientation, that is, to the delivery of measurable and negotiable service products. The IS function was not to be treated anymore as the deliverer of computer systems but merely as a service provider (Peppard, 2003).

Discussion of satisfying end users' needs and achieving a balance of supply and demand of IT services has lead to the concept of SLA—the ser-

Figure 3. Satisfaction with user support

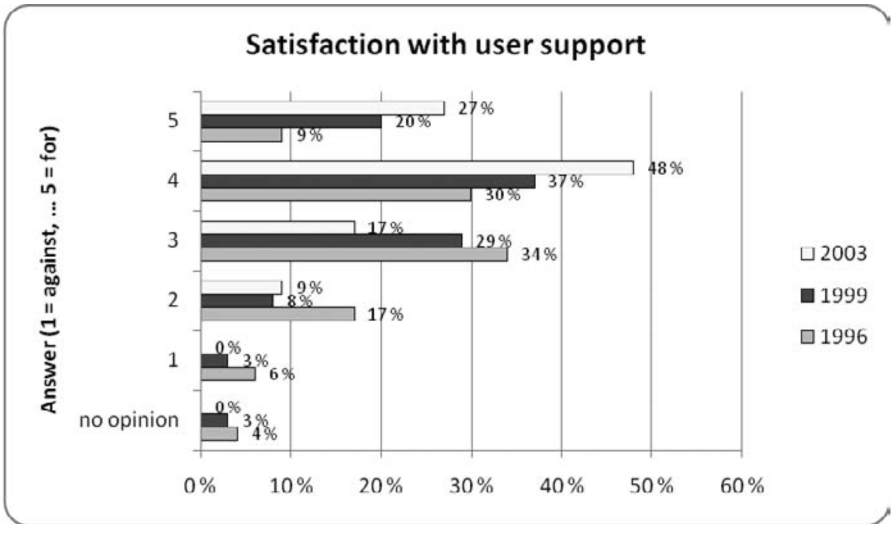

Figure 4. Users' satisfaction with training

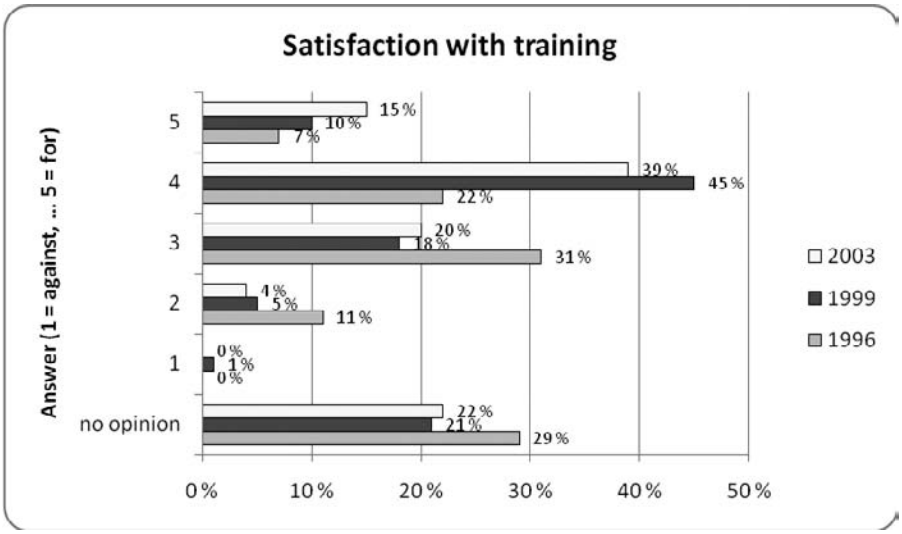

Figure 5. Users' self assessment of their skills (average of 21 questions)

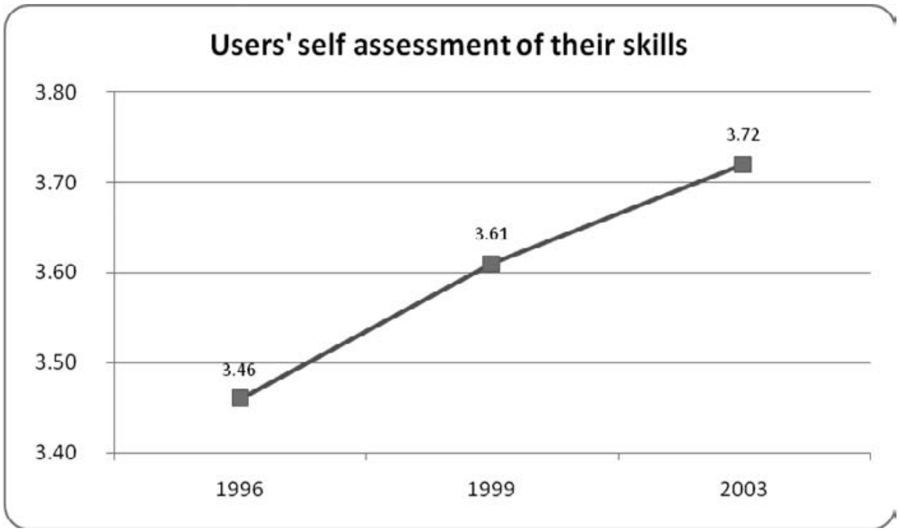

vice level agreement. It is an agreement between the supplier of an electronic service and the users of the service that defines and quantifies the minimum quality of service which meets business needs (Hiles, 1994). The service provider may be an internal IT/IS department, or the provision may be outsourced from an outside operator. Outsourcing continues to grow as a business practice when ASP, Web hosting or other such services become more popular (Fitsilis, 2006).

The growth of users' needs is endless. They need more sophisticated support when skills improve (Guimaraes et al., 1999). At the same time, the improving cost-awareness of line management puts stress on leaning IT operations. These conflicting trends combined with the recent discussion on the "commodity character" of IT (Carr, 2003) have increased the requirements for IT/IS management. The use of "best practices" is becoming a common solution to respond to the growing requirements. IT service management methodologies and standards such as ITIL, COBIT, eSCM, BS 15000 or ISO 17799 are well-recognized in the business world.

These methodologies like ITIL certainly help IT management to organize services. ITIL is obtaining the role of a de facto standard, especially in Europe. It organizes IT service activities round two key process areas: service support and service delivery. The processes are well-defined in the ITIL literature and fairly easy to apply in any organization. However, there are some challenges in applying them. Forte (2007) notes that ITIL as such is insufficient and its overly blind utilization may mechanize processes and prevent the sound development of services. Feldman (2006) recommends analyzing the organization's own weaknesses and apply "best practices" such as ITIL only selectively where needed.

Although there is much evidence with regard to the advantages of SLAs in IT service management, research has identified major problems in applying them (Antonio, Arienzo, Esposito et al., 2004; Hiles, 1994; Trienekens, Bouman, & Van Der Zwan, 2004). Fitsilis (2006) categorizes these problems in two areas: problems related with traditional service level management, such as developing SLA semantic models; cost models; better understanding of SLA terms, and so forth; and problems that arise from technology and marketplace evolution such as SLAs for federated environments, for aggregated services and for on-demand services, and so forth. Trienekens et al. (2004) explain that the problems arise from SLA specifications: specification of effort versus specification of results, or unclear service specifications. Another mistake on the customer side is to make "dead-end" agreements that are not dynamic and prevent further development (Trienekens et al., 2004).

Problems with SLAs are apparently related to the lack of management skills in defining the needs of various services and dealing with vendors. The speed of technological development and emergence of new operation models such as ITIL have simply been too demanding for IT management—there is currently a lack of formalism in the specification and metrification approach (Trienekens et al., 2004). In that sense, the current circumstances are reminiscent of the situation during the early stages of EUC when companies failed to incorporate its management into strategic IS planning (Hackney, Kawalek, & Dhillon, 1999).

Windows Vista as the Next Challenge

The technological mainstream during the last fifteen years has supported the implementation of various versions of Microsoft's Windows. In the mid-2000s, most organizations are using either Windows XP or Windows 2000 as the primary operating system: use of Macintoshes or Linux is rather marginal. After the launch of Windows NT (1996) and Office 1997, organizations faced a rather heavy transformation to the new environment, including infrastructure upgrade and user training. Since that time, the upgrades have been effortless. The next step, Windows Vista and Office 2007, is once again causing more pain.

There are widely reported advantages in the new operating system (Garcia, 2007; Malik & Perry, 2007; Potter, 2007; Stokely, 2007):

- A more reliable computing system.
- Increased manageability and better controlling tools for the administrators through dramatically improved Group Policy implementation.
- New ammunition to keep malware off the workstations.
- New technologies focused on keeping stored data safe.
- Glitzy 3-D windows are enjoyable for the end users.

However, companies are indecisive in implementing Windows Vista and Office 2007. The first sales figures after Vista's market launch were disappointing (Sliwa, 2007). The transformation will be troublesome for both IT departments and end users. Many companies are waiting for service packs and implementing new systems only one-by-one as new computers are purchased (Lewis, 2007). There are several good reasons for hesitation on the part of management (Malik & Perry, 2007):

- The new graphical interface does not really improve effectiveness, though is nice to have.
- The current stable environment will be disturbed during the transformation process.
- Compatibility updates by third party software and hardware vendors will take some time.
- End users are put to a new learning curve.

On the other hand, there is pressure to start the roll-out process, because Microsoft has announced that support for older operating systems will stop in 2009 (Malik & Perry, 2007). The promises of better security and other new features make the upgrade quite compelling. Many users and IT professionals are eager to benefit from the system. Decision-making will be based on opinions and emotions; no particular wisdom on when to start is available. Waters (2007) expects companies to first implement Office 2007 and then Vista. He predicts that Vista will be the last workstation-based operating system and the end of the PC era. An Internet-based, ASP type of software delivery may take over after Vista.

The Future IT Services in TSE

In previous chapters, we have described a 10-year process of strategic IT development at a business school. Various development patterns could have taken place in, for instance, the use of Macintoshes or in organizing IT services. According to the satisfaction measures, the decisions made and actual actions taken may be considered rather successful. However, the standardization and training approach taken ten years ago may not be sufficient in the future situation. The modern method of standardization observes an SLA type of setting. Although it evidently has advantages, applying SLA in an organization may freeze the service to stay on the minimum acceptable level, where routine operations are well-supported but innovativeness does not flourish. The end users' own application development is increasing, and they deploy IT in more sophisticated ways, for example, by participating in wiki and blog-like environments (Ferneley, 2007). These new trends are contradictory to the standardization approach and may impair the balance of using and supporting services: that is, the relationships between the IT department and the user organization. End users want to be involved in IT development and decision-making: otherwise, authorities are resisted (Rondeau, Ragu-Nathan & Vonderembse 2006).

The main future challenge of information management in TSE is to respond to the organizational changes that the school quite probably will face during the next few years. A strong national development towards bigger university units is in progress in Finland. There are three universities in Turku, and thus a discussion of new structural options is natural. Due to language reasons[1], the Swedish-speaking Åbo Akademi University will remain independent, though there will be an increase in cooperation with the neighbours. TSE and the University of Turku are nevertheless forming a consortium with a common board. The new structure will apply in August, 2008. The actual form of the future organization is still under working development, but the main objective is to enhance cooperation in teaching and research.

Some restructuring of the administration may also be anticipated. Considering IT services, there are apparently several options that have to be investigated and evaluated in the near future. Examples of such options are:

- Continuing as before without any major changes,
- Merging the IT/IS departments of TSE and the University of Turku,
- A new kind of division of responsibilities between the IT/IS departments of these two universities, or
- Selective outsourcing of IT services (e.g., infrastructure maintenance).

In a situation where the future structure of the organization is blurred, the strategic planning of IT is extremely difficult. On the other hand, the general development of technology is requiring rather urgent charting of the roadmap in infrastructure development. The (possible) transition to Windows Vista and Office 2007 is a heavy process that requires all the resources the school can allocate. In TSE's case, external pressures, technological pressures and end users' increasing requirements are now challenging the strategic information systems planning.

Chapter 4.3

Strategic Management of International Subcontracting:

A Transaction Cost Perspective

Yue Wang
University of New South Wales, Australia

ABSTRACT

Research on international subcontracting has been policy-oriented and industry-focused. There is a lack of understanding of the phenomenon from strategic management and international business perspectives. This article conceptualizes international subcontracting as a type of relational contract formed by buyers and suppliers from different countries, aiming to facilitate the sourcing of products or components with buyer-specific requirements. It builds a transaction cost model for studying the strategic choice of international subcontracting as an intermediate governance structure, sitting between arm's length outsourcing arrangement and vertically integrated multinational enterprises (MNEs). A set of propositions are developed to aid future empirical research and to provide managers with some guidelines for organizing supply chain across borders. The model also allows managers to examine the complex nature of a range of subcontracting relationships and identify the specific mechanisms that can be used to preserve and manage the dyadic principal-subcontractor exchanges.

INTRODUCTION

International subcontracting is an important phenomenon in international business (IB) studies (Casson, 1990) and has been an effective means of accelerating industrial development since 1960s, fostering the specialization among countries that reflects comparative advantages (Germidis, 1980). Through such measures as the establishment of free trade zones, developing countries encourage local firms to undertake subcontracting jobs for foreign firms to earn hard currency and to accumulate technological know-how (Hamada, 1974). Firms from developed countries are frequently attracted into subcontracting arrangements to exploit low labour and production costs in developing countries. The studies of international subcontracting are mainly policy-oriented (Cohen, 1975; Riedel, 1975; Sengenberger & Pyke, 1991) and geography or industry-focused (Kashyap, 1992; Lawson, 1992; Rogerson, 1995). Few have examined why firms from developed countries choose to use subcontracting arrangements in the first place. Moreover, despite some classifications of international subcontracting activities according to functional or market criteria (Gereffi, 1993; Holmes, 1986), the nature of subcontracting relationships remains unexplored due to the lack of theoretical underpinning of international subcontracting as a form of international business organization. Grounded on transaction cost theory (Buckley & Casson, 1976; Hennart, 1982; Rugman, 1981; Williamson, 1975, 1979, 1985), this article aims to provide a firm-level analytical framework for analysing the subcontracting choice and the nature of subcontracting relationships, complementing the existing literature's emphasis on studying international subcontracting as a macro-economic phenomenon. The framework will also aid managers in choosing strategically between outsourcing, subcontracting, and vertical integration when organizing their supply chain.

Although "transaction costs differ depending on both the nature of the transaction and on the way that it is organized" (Coase, 1937, p. 386), transaction cost economics (TCE) as formally developed by Williamson (1975, 1979) is not mainly concerned with the transaction itself, but with the contractual arrangements (the ways) through which transactions are organized (Cheung, 1983). Contractual or institutional arrangements, normally referred to as governance structures, are "the institutional matrix within which transactions are negotiated and executed" (Williamson, 1979, p. 239). Drawing upon the legal concept of generic contracting forms (Macneil, 1974, 1978) and relating them to the nature of transactions, Williamson (1979) matched the transactions to the contracts. By so doing, he provided a framework 'to assess the efficacy of alternative means of contracting' (Williamson, 1990, p. 8) and illustrated which governance structure (including the firm, the mark and intermediate contracts) has the lowest cost under given circumstances.

Despite the criticisms (some are highly theoretical and sometimes obscure or even mistaken on what they are criticising) (e.g., Conner & Prahalad, 1996; Ghoshal & Moran, 1996), empirical studies show Williamson-type of transaction cost-comparative contracting approach has more predictive power than other major IB theories such as resource-based view (RBV) in informing the choice between different forms of governance structures for organising firm interdependence (e.g., Hennart, 1991; Reddy, Osborn, & Hennart, 2002). Much of the RBV (Barney, 1991; Peteraf, 1993; Wernerfelt, 1984) and its closely-related competence perspective (Foss, 1996; Knudsen, 1995) entail ex post rationalizations for success and has been remiss in predictive respects (Williamson, 1999). This article therefore employs TCE as an analytical framework for examining the choice of international subcontracting.

THE CONCEPT OF INTERNATIONAL SUBCONTRACTING

There is a great deal of ambiguity on the definition of subcontracting in the existing literature (Hovi, 1994). However, there are some essential features about the international subcontracting as a form of investment. First, international subcontracting involves two independent units located in different countries, reflecting a type of cross-border inter-firm relationship. But the fact that a firm is legally independent does not necessarily mean that it will be economically independent. The relationship between subcontracting parties is defined as "quasi-integration," in which subcontractors from less developed countries are often dependent on principals from developed countries, where the demand of subcontracting is derived (Germidis, 1980). Second, in a subcontracting arrangement, the subcontractor provides the principal with products or services on agreed terms and conditions set by the principal, where certain business activities such as marketing or product design may not be carried out by the subcontractor (Halbach, 1989). The goods produced are required to conform to specifications intended for a definite principal, making it impossible or very difficult to sell them to other customers (Germidis, 1980). Third, the principal usually provides specialised physical equipment and/or ongoing technical assistance to the subcontractor to assure product specifications and quality (Sharpston, 1977). The enforcement mechanisms are usually between principals and subcontractors themselves and no third party oversees the execution of the contract. The bond linking them together is thus out of market (Germidis, 1980). Consequently, a significant level of transaction-specific investment has to be undertaken both by subcontractors to meet the specifications set by principals and by principals to ensure the performance of subcontractors. These basic characteristics reveal that the nature of international subcontracting conforms to Williamson's (1979, 1985) notion of a relational contract with a bilateral governance structure. Casson (1987) identified subcontracting as a distinctive type of intermediate contractual arrangement, an alternative to the vertically integrated multinational enterprises (MNEs).

The lack of a clear definition of subcontracting in the existing literature is due to the lack of theoretical underpinning. Based on the essential features identified above and in line with Williamson-type of transaction costs-comparative institutional framework, this paper defines international subcontracting as a type of long-term relational contract between buyers and suppliers in different countries that aims to facilitate the sourcing of products or components with buyer-specific requirements. This definition distinguishes international subcontracting from common arm's length industrial outsourcing and in-house supply within an MNE's network, providing the basis for conducting an analysis of the choice of international subcontracting over its alternatives and for developing some testable propositions regarding such a choice.

THE CHOICE OF INTERNATIONAL SUBCONTRACTING

The previous conceptualization allows us to examine the choice of international subcontracting as an intermediate relational contract, lying between arm's length outsourcing arrangement and internalised MNEs, and to develop some testable propositions based on the comparison between international subcontracting and its market and hierarchy alternatives.

The Choice of Subcontracting over Outsourcing

In transaction cost framework, the choice of a relational contracting form is made when transactions between buyers and suppliers are characterised by mixed asset specificity, recurrent exchange and a low degree of uncertainty (Williamson, 1979, 1985). Central to the framework is the concept of asset specificity (Williamson, 1975). Also labelled transaction/relationship-specific assets or dedicated assets (e.g., Dyer, 1997; Dyer & Singh, 1998; Dyer & Nobeoka, 2000), asset-specificity refers to durable human and physical investments undertaken to support particular transactions (Williamson, 1985) and cannot be redeployed to another transaction without some loss in the productivity of the asset or some increase in the costs in adapting the asset in the new transaction (Besanko, Dranove, & Shanley, 2004). In a buyer-supplier exchange relationship, relationship-specific investments are nonfungible signals of commitment that create economic losses if the relationship is prematurely terminated (Jap & Anderson, 2003). The requirement for transaction or relationship-specific investments creates potential costs in the market execution of transactions. When the asset specificity feature involved in transactions is low, buyers and suppliers keep their relationship at arm's length.

A common industrial outsourcing activity refers to such market-based transaction of standard products or components which involve little transaction-specific investment. In outsourcing, both buyers and suppliers capitalise on their comparative advantages of trading and realising economies of specialization (Sharpston, 1977). While outsourcing may involve a long-term relationship between buyers and suppliers, it does not require the support of long-term contract. The products and components in common outsourcing activities are non-specific and there are many buyers and sellers. Some buyers and suppliers may be engaged in the trading of standard goods for a long time. But they are not bonded by contracts requirement and each side can switch to other trading parties easily due to the low asset specificity in their trading relationship.

When products or components contain some degree of product specifications and are not "off the shelf," they can no longer be bought on the spot market. Buyers look for long-term contractual arrangements to assure the supply of the specialised inputs and products. As previously defined, subcontracting is a kind of long-term contract that aims to facilitate the sourcing of products or components with buyer-specific requirements. This clarification is important because the term "subcontracting" is often misunderstood as an exclusive portrait of buyer-supplier relationship and therefore the distinction between common outsourcing and subcontracting is blurred (Wang, 2007). As such, asset specificity is an important reason for making long-term contracts (Kay, 1995), explaining the choice of subcontracting over outsourcing. To protect themselves from exposure to transaction costs arising from making asset-specific investments, both parties involved in subcontracting relations have incentives to form a long-term relational contract. Thus, we suggest:

Proposition 1: *International subcontracting is chosen over outsourcing when there is a high level of asset-specificity in the purchasing/supplying transaction.*

The Choice of Subcontracting over Vertical Integration

The economic rationale of international subcontracting is to realise economies of specialization through externalising non-core production activities to achieve cost advantage (Sharpston, 1977). But firms can acquire existing low-cost suppliers in developing countries as their subsidiaries or set up plants in low-cost regions and relocate non-core activities to the new ventures. On the other hand, if the aim is to access technology expertise or other proprietary know-how held by suppliers, the buyer firm could still acquire them through equity integration with suppliers. Therefore, other than achieving production cost economies and acquiring complementary assets, there must be additional reasons for firms to choose subcontracting rather than vertical integration through acquisitions or greenfield.

Engaging vertical integration through acquisition to exploit low production costs or to access complementary assets overseas would entail significant transaction and information costs, which justify the choice of subcontracting. First, the desired assets of the acquied firm are hard to disentangle from the non-desired ones, which impose a high cost on acquiring suppliers (Hennart, 1988). Under this circumstance, purchasing the target overseas firm would force the buyer to enter unrelated fields or to expand suddenly in size, with the attendant management problems

(Hennart, 1991). This cost is particularly high for firms that rely mostly on cost rather than differentation to survive. Thus, we suggest:

Proposition 2: *International subcontracting is chosen over acquisition of overseas suppliers when the desired assets of the acquied firm are hard to disentangle from the non-desired ones.*

Second, management costs after the acquistion make subcontracting preferrable. Acquisition of a foreign supplier means the buyer also takes over an existing labor force and a well-established administrative structure. Considerable difficulties might be expected by the buyer in managing the foreign supplier firm that has cultivated its own organizational routines and corporate culture, in addition to the nationial culture distance (Hennart & Park, 1993). Hence, a subcontracting arrangement may be desirable as it avoids the post-acquisition management costs by leaving the management of supplier firm to the overseas subcontractor itself. Thus:

Proposition 3: *International subcontracting is chosen over acquisition of overseas suppliers when the post-acquisition management costs are expected to be high.*

Third, information costs in assessing the value of the target firm inhibit the acquisition (Hennart & Park., 1993). Buyers may not acquire overseas suppliers for the purpose of establishing low-cost supply bases but for the potential gain from complementary assets held by suppliers. But it may be difficult to assess the true value of these complementary assets due to the intrinsic bounded rationality constraint and the expectation that overseas suppliers may opportunistically exaggerate the value of their assets. A subcontracting arrangement retains the possibility for principals to gather information on the value of overseas subcontractors' complementary assets without financial exposure in an equity relationship, and may be used as a transitional arrangement for future acquisition of the overseas supplier. Hence, we propose:

Proposition 4: *International subcontracting is chosen over acquisition of overseas suppliers when the pre-acquisition costs in assessing the value of the target firm are high.*

Fourth, high exit barriers in an equity relationship may jepodize the flexibility valued by the firms. In contrast, a subcontracting arrangement allows the buyers to rescind the contractual relationship with suppliers at a relatively low exit cost. In addition, impediments to acquistions arising from governmental and institutional barriers are not uncommon. Many developing countries discourage and restrict the foreign equity control of local companies while the pervasive anti-trust legislation in developed countries also acts against acquisitions (Wang, 2007). We therefore suggest:

Proposition 5: *International subcontracting is chosen over acquisition of overseas suppliers when there are institutional barriers to acquisition*

When making the choice between subcontracting and building new plants (greenfield) in low-cost countries, the following factors need to be considered. First, relocating low value-added operations to newly established greenfield plants may achieve a similar level of cost reduction in labor and other production factors. But relocation to another country through greenfields requires additional knowledge in managing labor and production in an unfamilar environment, and becoming acquainted with the specific local cultures and environment is a time-consuming process (Bell, 1996). Greenfield investments may be necessary for companies that aim to develop foreign markets for their products, but not for firms that simply seek a low cost supply base overseas. When the cost of learning cannot be recovered quickly, a subcontracting arrangement rather than a greenfied will be sufficient to achieve the objective of cost reduction.

Second, even when the buyer firm plans to develop the foreign market in the future, subcontracting may still be a preferred entry mode as it allows the firm to acquire knowledge of local market before the subcontracting arrangement is replaced by a wholly-owned subsidiary (Kogut, 1988). In this case, the choice of subcontracting economises on the cost of acquiring local knowledge, allowing the prospective entrant to test the potential of the local market while exploiting the foreign country as a low cost supply base in the mean time. Hence:

Proposition 6: *International subcontracting is chosen over greenfield when there are sigificant costs involved in learning how to operate greenfield plants overseas*

THE RANGE OF SUBCONTRACTING RELATIONSHIP

Transaction-specific investments bond principals and subcontractors in a relational long term supply arrangement, but it also leaves room for parties to bargain, shirk, or break the relationship for short-term gains (Williamson, 1985). The so-called hold-up problem often arises when one party in an exchange relationship commits transaction-specific or relationship-specific investments (Wathne & Heide, 2000). The asymmetric investments in specific assets allow a firm to behave opportunistically to increase its short-term, unilateral gains in a dyadic channel relationship (Brown, Dev, & Lee, 2000). In a subcontracting relationship, whether and how to preserve the contractual arrangement is primarily a matter of the nature of the relationship between the principal and the subcontractor concerned.

There is a whole range of international subcontracting relationships in terms of the degree of interdependence and bargaining power between principals and subcontractors. The perceived dependence and bargaining power are the function of the combination of many factors, including the degree of asset-specific investments, frequency of transactions and uncertainty (Williamson, 1979, 1985). Variations along those transactional dimensions determine the degree of interdependence and bargaining power between subcontracting parties, which in turn constitute a variety of subcontracting relationships. This section not only examines a range of subcontracting relationships but also their corresponding governance mechanisms. In studying how firms mitigate opportunism in marketing channels, Brown et al. (2000) identified three specific mechanisms: (1) ownership, (2) investment in transaction-specific assets, and (3) development of relational exchange norms such as role integrity, flexibility, and long-term orientation. As ownership does not apply to the governance of subcontracting relationship, which is essentially a commercial exchange, we focus on the efficacy of the other two mechanisms in preserving and managing subcontracting relationships.

First, a loose subcontracting relationship denotes a low interdependence degree between principals and subcontractors, the switching cost for both parties is low as neither side makes significant asset-specific investments. The principal does not rely on a particular subcontractor or subcontractors for supply and the subcontractor also has a broad customer base. The principal only need to provide minimal technical assistance to the subcontractor and the subcontractor does not need sophisticated machinery and skills to perform subcontracting jobs. The frequency of orders has little impact on the relationship since both sides are loosely tied to each other and the exit costs are low for both sides when facing market demand fluctuations. Examples abound in commercial subcontracting (Gereffi, 1993). In this case, neither the principal nor the subcontractor has strong incentive to maintain a long-term association with each other. Consequently, neither investment in transaction-specific assets nor development of relational exchange norms will be necessary.

Second, a subcontractor is more dependent when the principal has stronger bargaining power. This occurs when asset-specific investments made by the parties are asymmetric. The buyer commitments are usually confined to specific physical capital, including specific dies, moulds and tooling for the manufacture of a contracted product (Nishiguchi, 1994). The subcontractor, on the other hand, has to invest in special-purpose equipment, employ skilled workers and engineers who are devoted to customer-specific operation; expand production capacity to meet the principal's requirement. The industry structure is such that many suppliers from developing countries are competing for relatively few buyers from developed countries. It is difficult for a subcontractor to diversify its customer-base and its sales revenue. To secure long-term orders from the principal, the subcontractor has to invest a greater degree of specific assets, which in turn leave them vulnerable to the potential hold-up by the principal. However, such an unbalanced subcontracting relationship may not be unstable. Although buyers from developed countries have much leverage among many suppliers in developing countries, stable long-term relationships with their suppliers can enhance performance certainty by reducing the costs in seeking suitable overseas suppliers, in drawing up multiple contracts, and in monitoring multiple suppliers in different countries. All of these benefits would be lost in a frequent shift of suppliers. Opportunism by one party can erode the long-term gains potentially accruing to both parties in a dyadic buyer-supplier relationship (Brown et al., 2000). These are also the reasons why arm's length outsourcing may involve a long-term relationship. But the higher degree of asset specificity points to a more inter-locked pattern of relationship in subcontracting than in outsourcing. Both the principal and the subcontractor have incentives to maintain the long-term relationships. Consequently, both sides may invest in transaction-specific assets and develop relational exchange norms in order to consolidate the relationship.

Third, situations where a principal is more dependent on a subcontractor are less common. They happen when the overseas subcontractor holds know-how crucial to the principal's production cycle. Some once-off and occasional large purchasing orders that involve sophisticated work such as in aerospace (Esposito & Storto, 1994) and shipbuilding industries (Smitka, 1991) might qualify as examples, since they require highly specialized expertise and more importantly there are more buyers than suppliers in the global market. Subcontractors enjoy stronger bargaining power when they are not merely producing certain products or components, but serve as intermediates for transferring knowledge of the local market to foreign buyer firms. In this case, a local subcontractor's bargaining power stem not from the transaction characteristics, but from the foreign buyer's strategic purpose in developing the local market with the help of the local supplier (Wang, 2007). Nevertheless, the subcontractor may be unaware of the principal's strategic motive and fail to materialise its power advantage in dealing with the foreign principal firm.

Fourth, when the principal and the subcontractor are mutually and heavily dependent on each other, the demand for equal collaboration is high. Subcontracting of this type requires highly specialized investments from both sides and the relationship is balanced (Wang, 2007). In such a subcontracting relationship, the principal typically contracts out the assembly of a final product. The principal commitments contain a high degree of asset specificity since complete assembly requires the highest integration of contract-specific physical facilities, including dedicated assembly lines, tooling and testing equipment (Nishiguchi, 1994). Moreover, the principal will incur human asset-specific investments in the form of managerial training and technical assistance to the overseas subcontractor to attain the production specifications (Sharpston, 1977). For subcontractors, end-product assembly for a particular overseas buyer will require specific investments both in human capital (e.g., employ highly skilled workers or provide special training) and in physical assets (e.g., purchase specialised machinery and equipment). Therefore, principals and subcontractors commit a similar level of asset-specific investments, which support an equal collaborative relationship characterised by common interest, mutual obligations, and trust (Morris & Imrie, 1992; Smitka, 1991). Under this circumstance, the principal and the subcontractor rely on both mechanisms to govern their ongoing exchanges and mitigate opportunism: investments in transaction-specific assets that create a mutual hold-up situation and development of shared relational exchange norms such as role integrity and harmonious conflict resolution (Brown et al., 2000).

CONCLUSION

International subcontracting is often studied as an important instrument for industrial development at the policy level. Few studies have looked at the phenomenon from international business and strategic management perspectives. In line with Williamson-type of transaction cost-comparative contracting approach, the article defines international subcontracting as a type of long-term relational contract between buyers and suppliers in different countries, aiming to facilitate the sourcing of products or components with buyer-specific requirements. Building rigorously on the transaction cost theory, the paper develops an analytical framework to investigate the choice of international subcontracting over its market (arm's length outsourcing) and hierarchy alternatives (vertical integrated MNEs).

The comparison between subcontracting and its alternatives provides both prescriptive and pridictive value for international managers who face the strategic choice between outsourcing, subcontracting and vertical integration when organizing the supply chain across national borders. Table 1 summarizes the major transaction characteristics, advantages, and distantages of the different forms of supply chain organization.

Based on the framework, we developed a set of testable propositions that can be used not only for future empirical research but also to aid managers in making strategic choice between outsourcing,

Table 1. Outsourcing, subcontracting, and vertical integration

	Transaction characteristics	Advantages	Disadvantages	When to use it
Outsourcing	Arm's length contract	Better for realizing economies of specialization and comparative advantages	Unstable exchange relationship due to low switching costs	Most suitable for facilitating trading of standard goods and services
Subcontracting	Relational contract with bi-lateral governance	Stable long-term relationship between particular buyers (principals) and suppliers (subcontractors)	High switching costs to alternative trading partners due to higher degree of asset-specific investments	Most suitable for facilitating purchasing and supplying of goods and services containing some degree of asset-specific investments
Vertical integration	Relational contract with unified governance	Complete hierarchical control over the supply of goods and services within the boundary of the firm	High agency costs in incentivising and managing in-house suppliers	Most suitable for organizing purchasing and supplying of highly idiosyncratic goods and services

long term subcontracting, and vertical integration (Greenfield or acquisition) for organizing supply chain across borders. For example, we suggest that international subcontracting should be chosen over outsourcing when there is a higher level of asset-specificity in the purchasing/supplying transaction. It should be chosen over greenfield when there are sigificant costs involved in learning how to operate greenfield plants overseas. When choosing between international subcontracting and acquisition of overseas suppliers, managers should consider a range of factors, including how difficult it is to disentangle the desired assets of the acquied firm from the non-desired ones, how costly it is to assess the true market value of the acquisition targets ex ante and in managing the acquired firms ex post.

The framework also allows us to examine the specific nature of a range of subcontracting relationships. We identify four types of subcontracting relationships in terms of the degree of interdependence and bargaining power between principals and subcontractors. We demonstrate how the variations along transactional dimensions, especially asset-specific investments by the principal and the subcontractor, shape the different dyadic exchange relationship. We also argue that the two major governance mechanisms, investments in transaction-specific assets and development of relational exchange norms, have different efficacy in preserving and managing a range of subcontracting relationships. The paper thus offers a conceptually coherent foundation for researchers and managers to analyse international subcontracting as a form of international business organization at the firm level, complementing the existing literature's emphasis on studying the topic as a macro-economic phenomenon.

Chapter 4.4

EBBSC:
A Balanced Scorecard-Based Framework for Strategic E-Business Management

Fen Wang
University of Maryland, Baltimore County, USA

Guisseppi Forgionne
University of Maryland, Baltimore County, USA

ABSTRACT

E-business is far more about strategy than technology, and the strategy of e-business is very important in today's dynamic and competitive environment. In this article, we describe a balanced scorecard-based framework in detail and discuss its potential e-business uses. This framework enables e-business managers to plan and allocate resources more effectively and align strategic objectives with performance results. It also provides a stable point of reference for e-businesses to understand and manage the fundamental changes introduced by e-business initiatives.

INTRODUCTION

The Link of Objectives to Strategies

E-business has rapidly developed from being a vision of the future world of business to being "the" way of doing business (Whelan & Maxelon, 2001). This business opened new channels for communication and selling, a new source of data on customers and competitors, and changed the face of competition tremendously (Koutsoukis, Dominguez-Ballesteros, Lucas, & Mitra, 2000; Porter, 2001). Clearly, business processes of the 21st century must be more efficient and dynamic to build and sustain value across the organization, though having a dot-com presence does not necessarily point to success. As Raisinghani and Schkade (2001) pointed out "perhaps, one of the best ways to succeed in the world of e-business is to start off with a dynamic and new e-business strategy" (p. 601).

E-business is far more about strategy than technology. An effective e-business strategy is an elaborate and systematic plan of action that incorporates different organizational levels, different parties, different elements, and growth pattern features (Bakry & Bakry, 2001). Unlike traditional business strategy, e-business strategy considers a company's business management architecture and how it can be improved, integrated and automated by instant and global Internet communication. Indeed, the Internet has spawned new e-business strategy and radically transformed existing models (Basu & Muylle, 2002; Pant & Ravichandran, 2001). These new models incorporate Internet technology, universal connectivity, and Web browser capabilities to integrate business processes within and beyond an enterprise. As a result, old business models should be adapted to the new conditions, and companies worldwide should develop an effective e-business strategy to fit the new conditions (Whelan et al., 2001).

What distinguishes many of the dot-coms from traditional organizations is not their new technical power, but their innovative and imaginative new business models (Hamel, 2000). This study proposes a balanced scorecard based e-business framework for the development and assessment of e-business strategy in this new age. Aided by this innovative and comprehensive e-business framework, managers can identify the major decision factors involved in their e-business strategies, specify the direct and indirect relationships among the factors, and generate strategies that would improve overall business performance.

BACKGROUND REVIEW

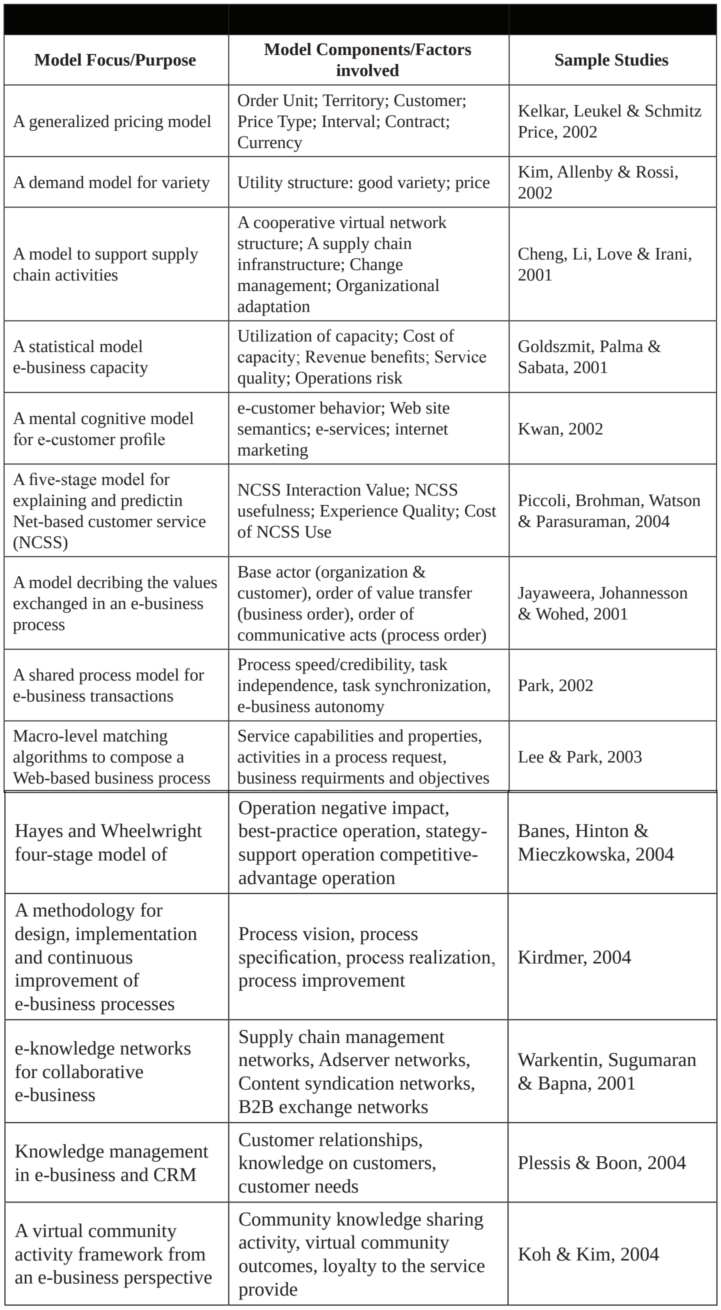
The Evolution of E-Business Models

A commonly cited reason for e-business failure has been the lack of a workable and concrete strategic business model to guide e-business efforts (Paper, Pedersen, & Mulbery, 2003). While a comprehensive framework for strategic e-business management seems desirable, there are few studies that offer complete and integrated views of e-business strategy (Dubosson-Torbay, Osterwalder, & Pigneur, 2001). In the business model literature, many academic studies have provided a theoretical basis for, and some empirical testing of, the models (Horsti, Tuunainen, & Tolonen, 2005). These studies fall into two broad categories. The first group develops subsystem models in support of a specific aspect of e-business applications, while the second group involves generic frameworks to reflect e-business reality.

Table 1 provides a brief overview of the existing subsystem model studies. As this table demonstrates, although each of the subsystem models involves operationalized views of a particular aspect of e-business, none offer a complete and integrated view of e-business strategy as a whole.

Among the generic e-business strategy models, Whelan et al. (2001) proposed a five element e-business architecture. The five elements are product, channel, customer management, resource management, and information. Afuah and Tucci (2001) presented a more detailed list of model components including scope, customer value, revenue sources, connected activities. Like Whelan et al. (2001), these researchers did not specify the interrelationships and causality between these components. Hamel (2000) offered a more complete model than the others. This researcher used a four part framework that describes links between model components (e.g., "Configuration" to connect the "Core strategy" and "Strategic resources"). Similarly, Dubosson-Torbay et al. (2001) used a framework to analyze e-business with four principal components: product innovation, customer relationship, infrastructure management, and financial aspects. Damanpour (2001) also identified four elements of e-business from a systematic perspective: business/financial models, relationships, commerce, and responsiveness. Still another e-business model is composed of a value cluster, marketing offering, resource system, and financial model (Rayport & Jaworski, 2001). Going beyond the segment frameworks, De, Mathew, and Abraham (2001) developed a pragmatic framework that offers a series of different perspectives for the analysis of e-business: transaction costs, switching costs,

Table 1. The first group sub-system e-business model studies



Model Focus/Purpose	Model Components/Factors involved	Sample Studies
A generalized pricing model	Order Unit; Territory; Customer; Price Type; Interval; Contract; Currency	Kelkar, Leukel & Schmitz Price, 2002
A demand model for variety	Utility structure: good variety; price	Kim, Allenby & Rossi, 2002
A model to support supply chain activities	A cooperative virtual network structure; A supply chain infranstructure; Change management; Organizational adaptation	Cheng, Li, Love & Irani, 2001
A statistical model e-business capacity	Utilization of capacity; Cost of capacity; Revenue benefits; Service quality; Operations risk	Goldszmit, Palma & Sabata, 2001
A mental cognitive model for e-customer profile	e-customer behavior; Web site semantics; e-services; internet marketing	Kwan, 2002
A five-stage model for explaining and predictin Net-based customer service (NCSS)	NCSS Interaction Value; NCSS usefulness; Experience Quality; Cost of NCSS Use	Piccoli, Brohman, Watson & Parasuraman, 2004
A model decribing the values exchanged in an e-business process	Base actor (organization & customer), order of value transfer (business order), order of communicative acts (process order)	Jayaweera, Johannesson & Wohed, 2001
A shared process model for e-business transactions	Process speed/credibility, task independence, task synchronization, e-business autonomy	Park, 2002
Macro-level matching algorithms to compose a Web-based business process	Service capabilities and properties, activities in a process request, business requirments and objectives	Lee & Park, 2003
Hayes and Wheelwright four-stage model of	Operation negative impact, best-practice operation, stategy-support operation competitive-advantage operation	Banes, Hinton & Mieczkowska, 2004
A methodology for design, implementation and continuous improvement of e-business processes	Process vision, process specification, process realization, process improvement	Kirdmer, 2004
e-knowledge networks for collaborative e-business	Supply chain management networks, Adserver networks, Content syndication networks, B2B exchange networks	Warkentin, Sugumaran & Bapna, 2001
Knowledge management in e-business and CRM	Customer relationships, knowledge on customers, customer needs	Plessis & Boon, 2004
A virtual community activity framework from an e-business perspective	Community knowledge sharing activity, virtual community outcomes, loyalty to the service provide	Koh & Kim, 2004

infrastructure investment, revenue models, and other elements.

Table 2 summarizes the scope and model components of the generic e-business frameworks. As this table illustrates, no operational generic models have been offered, or implemented, by the proponents. The generic frameworks, instead, provide theoretical guidance on components that could be included in a comprehensive and integrated e-business strategy model.

One exception is the high level e-business framework, with preliminary empirical evidence, proposed by Hasan and Tibbits (2000). These researchers developed a BSC-based case study for e-business management in an Australian state-government utility. The researchers, however, did not identify and formulate the goals, measures, and targets in each scorecard perspective.

As Tables 1 and 2 indicate, the literature has not offered a comprehensive and concrete model of e-business strategy. The electronic business balanced scorecard (EBBSC) model proposed in this study attempts to close that research gap by linking business strategies to a broad range of measures, examining important business issues facing e-business managers, and providing a complete and integrated view of e-business management.

EBBSC FRAMEWORK SPECIFICATION

The proposed EBBSC framework identifies four essential perspectives. These perspectives include the financial, customer, internal processes, and learning and growth views. First introduced in the early 1990s as the balanced scorecard (BSC), these views provide a balanced picture of current operating performance as well as the drivers of future performance in traditional businesses (Kaplan & Norton, 1992, 1996). The underlying motivation for this vision and strategy has been explored repeatedly (Dutta & Manzoni, 1999; Lee & Ko, 2000; Lohman, Fortuin, & Wouters, 2004; Marr & Schiuma, 2003; Soliman & Youssef, 2001; Sandstrom & Toivanen, 2002) and is therefore not repeated here.

Table 2. 2nd group generic e-business framework studies

Afuah & Tucci (2001)	**Damanpour (2001)**	**De et al. (2001)**	**Dubosson et al. (2001)**	**Hamel (2000)**	**Hasan & Tibbits (2000)**	**Rayport & Jaworski (2001)**	**Whelan & Maxelon (2001)**
price, revenue sources, sustainibility (what is difficult to initiate of the business model)	business financial models (business model and opportunities)	Revenue models (Advertising, retail, banking & information harvesting)	Product innovation (market segment, value proposition), Financial Aspects (cost & revenue structures)	Core Strategy (business mission, product/market scope, differentiation basis), Pricing structure	Finance/ Business value	Financial model	Product
Customer value (distinctive offering or low cost), Scope (customer & products/ services)	Relationships (relationships & collaboration management)	Transaction and Switching costs, User Experience, Models, Versioned products/niche marketing	Customer Relationship, Infastructure Management I (partner network)	Customer Interface (support. info & insight, relationship dynamics); Customer benefits	Customer User perspectives	Marketing offering	Customer management
connected activities (interdependency between different activities)	Responsiveness (efficiency & timing of transactions) Commerce (e-buying & selling mechanism)	Network externalities, Infastructure investment	Infastructure Management II (activities & processes)	Strategic resources (core processes); Configuration; Value network, company boundaries	Internal business/ Process	Value cluster	Channel
Implementation (resources needed); Capabilities (skills needed)	--	--	Infastructure Management III (resources/ assets)	Strategic resources (core competencies, strategic assets)	Innovation/ Learning future readiness	Resource system	Resource management; Information

Because the methodology of the BSC explicitly focuses on links among business decisions and outcomes, it is intended to guide strategy development, implementation, and communication, and to provide reliable feedback for management control and performance evaluation (Malina & Selto, 2001). Although most implementations emphasize BSC success as a commercial product, the rationale behind the BSC does appeal to managers who face new challenges in the modern business environment (Hasan et al., 2000).

As indicated by Hasan et al. (2000), the real challenge is to determine how the BSC can be successfully applied in the context of e-business. E-business functions in a constantly changing environment of interdependencies, which has been perceived as highly uncertain, stemming from increased information visibility and dynamic market structures (Golicic, Davis, McCarthy, & Mentzer, 2002; Wang, 2001). In this environment, traditional success measures may be incomplete, and possibly misleading, and the original BSC framework may require radical modification.

Using literature findings and underlying theories, we adapted the original BSC into the comprehensive e-business management framework (EBBSC) shown in Figure 1. As this figure indicates, the EBBSC consists of four perspectives, including the business core, analytic e-CRM, process structure, and e-knowledge network.

Tables 3 and 4 compare this EBBSC concept with the subsystem and generic model studies. As this comparison indicates, the EBBSC framework is based on the e-business model literature but represents a more complete, explicit, and integrated view of e-business strategy. Such a framework can be utilized to translate e-business strategies into conceptual blueprints for strategic management control and performance evaluation. The EBBSC framework also provides a stable point of reference for e-businesses to understand and explore e-business initiatives effectively.

Business Core Perspective

Although e-business models differ somewhat from traditional brick and mortar models, the fundamental needs of consumers and businesses remain the same. Consumers want desirable products and services at competitive prices, while businesses want profitable marketing and production. The focus should be on long-term and short-term decision making in the dynamic, competitive, and compressed business cycles of the global e-era. Figure 2 depicts the business core perspective in the framework. As indicated in the figure, the primary objective is profit maximization.

Within the e-business value cycle, many intangible and tangible firm and industry-specific factors may affect profit through revenue and cost influences (Spanos, Zaralis, & Lioukas, 2004).

Figure 1. Adapted four perspectives for strategic e-business management (Adapted from Wang & Forgionne, 2005)

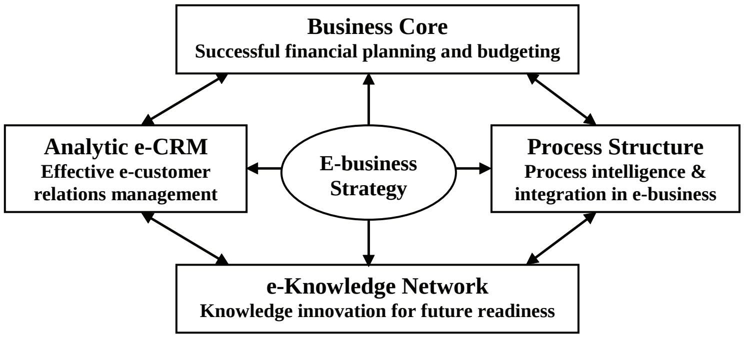


Table 3. The first group sub-system e-business model literature comparison

EBBSC Framework Perspectives	Comparative Model Components in Literature	Sample Representative Studies
Business Core Successful financial planning and budgeting	Profit maximization, Pricing mechanisms, Price structures, Revenue sources, Demand uncertainties, Budget mode, Financial performance, Market optimization, Internet marketing	Kelkar, Leuke; & SchmitzPrice, 2002: Kim, Allenby & Rossi, 2002; Valadares Tavares, Pereira & Coelho, 2002; Motiwalla & Riaz Khan, 2003; Liu, Wynter & Xia, 2003; Chen, Liu & Song, 2004
Analytic e-CRM Effective e-customer relations management	Customer value, Customer knowledge, E-customer profile, Customer efficiency, Consumer power, Customer needs, e-CRM essence, Customer perception, Mass customization model	Bielski, 2000; Rowley, 2002; Mei & Harker, 2002; Wan, 2002; Fletcher, 2003; Olsson & Karlson, 2003; Wang & Tang, 2003; Vrechopoulos, 2004; Piccoli, Brohman, Watson & Parasuraman, 2004
Process Structure Process intelligence & integration in e-business	Process patterns, E-logistics platform, Process (semi)-automation, Process independence & sychronization, Operation management, Value (e) -chain, Process networks	Jayaweera, Johannesson & Wohed, 2001; Par, 2002; Lee & Park, 2003; Oh, Hwang, & Lee, 2003, Barnes, Hinton & Mieczkowska, 2004; Kirchmer, 2004
E-Knowledge Network Knowledge innovation for future readiness	Knowledge Management, E-knowledge networks, E-knowledge decision model, Knowledge exchange, Customer knowledge, Knowledge chain model, Knowledge sharing	Malhotra, 2000; Warkentin, Sugumaran & Bapna, 2001; Raisinghani & Mead, 2002; Malhotra, 2002; Rowley, 2002; Allard & Holsapple, 2002; Plessis & Boon, 2004, Koh & Kim, 2004

Some factors involve Internet considerations, such as network performance (e.g., network security and e-capacity). Risk and uncertainty will be created by intangible organizational and environmental factors (Palmer & Wiseman, 1999). Representative decision factors in the business core perspective as a result of the Internet effect are highlighted in Figure 2.

Revenues increase from product and service expansions, new customers and markets, and higher value re-pricing. Price, capacity, supply chain management efficacy, and staff proficiency are the major determinants of the quantity supplied. Capacity is limited by the equipment and/or available personnel, but also by the limit associated with network technology (Goldszmidt et al., 2001). A stronger emphasis on supplier relationship management reduces uncertainty (Craighead et al., 2003; Golicic et al., 2002). Supply chain management efficacy can be used as an indicator of the bargaining power of suppliers (Porter, 2001).

On the demand side, there are traditional determinants, including customer retention and the marketing mix, and new e-business factors. Customer retention measures the company's customer loyalty (Smith, 2002) or stickiness (Ingsriswang et al., 2001). Since customers can now compare prices and services with a-click, it is more challenging to attract and retain customers in the virtual business world.

The marketing mix, coined by Borden (1965), consists of traditional price, product, promotion, and place (Borden, 1965; Brooksbank, 1999; Kotler & Armstrong, 1997; Smith & Saker, 1992), as well as enhancements unique to e-business. For example, pricing must be adjusted to the specific requirements of e-procurement (Kelkar et al., 2002). The original "Place" factor is decomposed into e-marketing presentation and distribution effort. Similar to the store design of a physical shopping mall, the Web presentation style and structure can attract online customers and build

Table 4. The second group generic e-business framework comparison

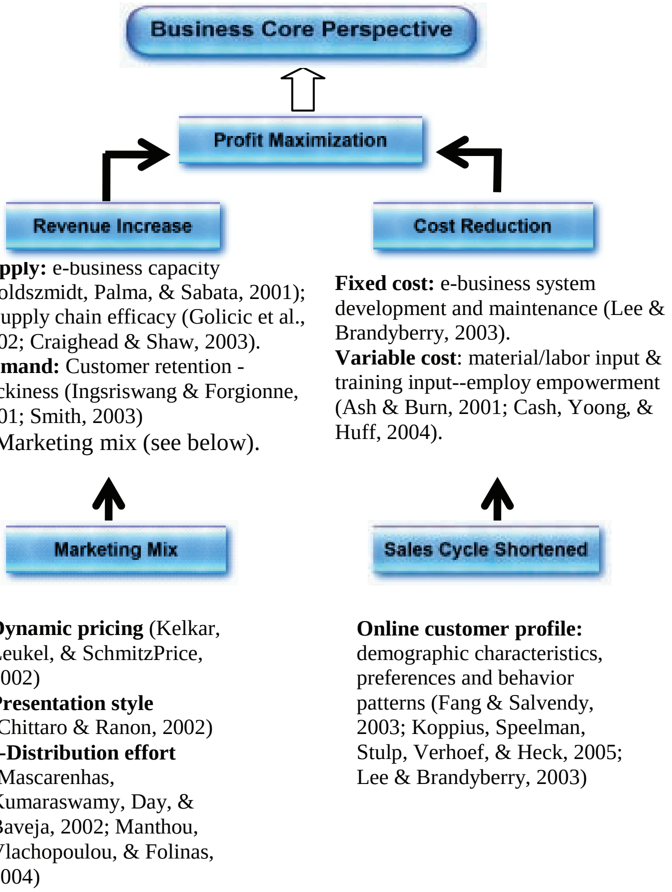
Framework commonality	**Afuah & Tucci (2001)**	**Damanpour (2001)**	**De et al. (2001)**	**Dubosson et al. (2001)**	**Hamel (2000)**	**Hasan & Tibbits (2000)**	**Rayport & Jaworski (2001)**	**Whelan & Maxelon (2001)**
Business Core Perspective	price, revenue sources, sustainibility (what is difficult to initiate of the business model)	business financial models (business model and opportunities)	Revenue models (Advertising, retail, banking & information harvesting)	Product innovation (market segment, value proposition), Financial Aspects (cost & revenue structures)	Core Strategy (business mission, product/ market scope, differentiation basis), Pricing structure	Finance/ Business value	Financial model	Product
Analytic e-CRM Perspective	Customer value (distinctive offering or low cost), Scope (customer & products/ services)	Relationships (relationships & collaboration management)	Transaction and Switching costs, User Experience, Models, Versioned products/niche marketing	Customer Relationship, Infastructure Management I (partner network)	Customer Interface (support. info & insight, relationship dynamics); Customer benefits	Customer User perspectives	Marketing offering	Customer management
Process Structure Perspective	connected activities (interdependency between different activities)	Responsiveness (efficiency & timing of transactions) Commerce (e-buying & selling mechanism)	Network externalities, Infastructure investment	Infastructure Management II (activities & processes)	Strategic resources (core processes); Configuration; Value network, company boundaries	Internal business/ Process	Value cluster	Channel
e-Knowledge Network Perspective	Implementation (resources needed); Capabilities (skills needed)	--	--	Infastructure Management III (resources/ assets)	Strategic resources (core competencies, strategic assets)	Innovation/ Learning future readiness	Resource system	Resource management; Information

customer loyalty in e-business (Chittaro & Ranon, 2002). Distribution involves traditional and Internet (as called e-channel or virtual e-chain) management and innovation (Manthou et al., 2004; Mascarenhas et al., 2002).

Another way to maximize profit, besides increasing revenue, is to reduce fixed and variable cost (Lee & Brandyberry, 2003). Traditionally, fixed cost refers to invariable selling and administrative expenses. In the context of e-business, fixed cost can include e-business system development and maintenance expenses, as well as other utility and management overhead. Variable cost measures the materials, money, and labor expenses involved in producing/importing and selling the product. In the context of e-business, labor expenses should include the effort spent on knowledge management (transmission, sharing, and innovation), building relationships, and education in e-era technology (Ash & Burn, 2001; Cash et al., 2004).

One indirect, but potentially effective, method to reduce cost is to shorten the sales cycle. In addition to product quality, price, and the e-marketing mix, the customer profile is an important determinant of the e-business sales cycle. This profile is a composite variable that reflects the customers' demographic characteristics, preferences, and behavior patterns. As noted by Lee and Brandyberry (2003), when compared with traditional customers, online customers tend to be less stable due to their "Logical," rather than "Physical," relationships.

Figure 2. Business model perspective of strategic e-business management



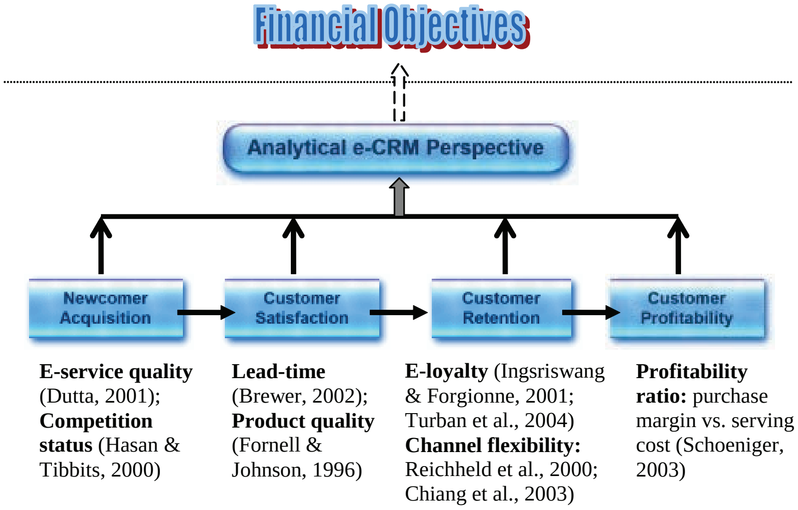
Supply: e-business capacity (Goldszmidt, Palma, & Sabata, 2001); e-supply chain efficacy (Golicic et al., 2002; Craighead & Shaw, 2003).
Demand: Customer retention - stickiness (Ingsriswang & Forgionne, 2001; Smith, 2003)
e-Marketing mix (see below).

Fixed cost: e-business system development and maintenance (Lee & Brandyberry, 2003).
Variable cost: material/labor input & training input--employ empowerment (Ash & Burn, 2001; Cash, Yoong, & Huff, 2004).

Dynamic pricing (Kelkar, Leukel, & SchmitzPrice, 2002)
Presentation style (Chittaro & Ranon, 2002)
e-Distribution effort (Mascarenhas, Kumaraswamy, Day, & Baveja, 2002; Manthou, Vlachopoulou, & Folinas, 2004)

Online customer profile: demographic characteristics, preferences and behavior patterns (Fang & Salvendy, 2003; Koppius, Speelman, Stulp, Verhoef, & Heck, 2005; Lee & Brandyberry, 2003)

Figure 3. e-CRM perspective of strategic e-business management



E-service quality (Dutta, 2001); **Competition status** (Hasan & Tibbits, 2000)

Lead-time (Brewer, 2002); **Product quality** (Fornell & Johnson, 1996)

E-loyalty (Ingsriswang & Forgionne, 2001; Turban et al., 2004) **Channel flexibility:** Reichheld et al., 2000; Chiang et al., 2003)

Profitability ratio: purchase margin vs. serving cost (Schoeniger, 2003)

Analytic e-CRM Perspective

Customers are at the core of all businesses. With the Internet, customers have realized the benefits of shopping online, including convenience, broader selection, competitive pricing, and greater access to critical business information (Chen et al., 2004). Relationships and collaborations are forged in e-business to enter new markets or enhance customer, supplier and business interactions (Damanpour, 2001). On the other hand, customers' involvement in online retailing is impeded by security and privacy concerns, download time, and other technology barriers, or unfamiliarity (Chen et al., 2004). Furthermore, customers can switch to other competitive URLs in seconds with minimal financial cost (Ingsriswang et al., 2001), which makes successful customer management especially vital in e-business (Ace, 2002).

Figure 3 depicts the e-CRM perspective. As indicated in the figure, the keys to achieve customer profitability are customer acquisition and customer retention, i.e., to continuously attract newcomers and retain loyal customers. Achieving customer satisfaction can turn newcomers into loyal customers. Representative decision factors in the e-CRM perspective, which have not been covered previously, are highlighted in Figure 4.

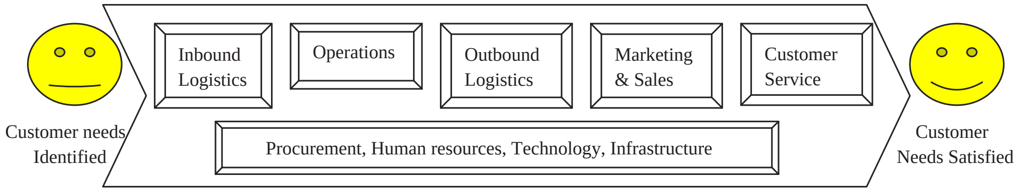
The success or failure of a customer acquisition campaign depends on precise, timely targeting that delivers valuable offers to prospects and keeps costs low. This targeting could involve finding previously untapped customers (for example, baby diapers for new parents) or competitors' customers (Berson, Smith, & Thearling, 1999). While acquisition costs vary widely among various businesses, optimized targeting with proper customer profile research and e-marketing mix strategy is consistently a top priority, as is e-service quality and competitive status. E-service quality involves network reliability and customer support (Dutta, 2001), while competition status represents the company's external relationship with the supplier, availability of other distribution channels, entry barriers, rivalry, and product substitutes (Kaplan et al., 1992; Hasan et al., 2000).

The next step is to ensure customer satisfaction with lead time, product quality, service quality, and competitive pricing (Kaplan et al., 1992). Lead time measures the time required for the company to meet its customers' needs, sometime referred to as "order-to-delivery cycle time" (Brewer, 2002). Quality measures the defect level of products as perceived and measured by the customer. A product with high quality and a high level of customization may increase the degree of customers' satisfaction (Fornell & Johnson, 1996). E-service quality and price also will greatly impact satisfaction.

However, satisfied customers are not necessarily loyal customers (Gale, 1997). Loyal customers, who repeat their purchases or visits persistently, are valuable business assets (Turban et al., 2004). According to Reichheld and Schefter (2000), e-loyalty is an economic necessity in the e-era. The idea is to develop and maintain long-term relationships with customers by creating superior customer value and satisfaction (Ingsriswang et al., 2001).

Goodwill, the favor or prestige that a business has acquired beyond the mere value of what it sells (Merriam-Webster online, 2005), reflects

Figure 4. A generic value chain (Adapted from Lewis, 2001)



the cumulative impact of marketing and customer satisfaction (Anderson & Fornell, 1994; Jennings & Robinson, 1996). Companies should determine their and use their core competencies to target the market (Smith, 2002). Channel flexibility refers to the convenience and availability of distribution channels besides the Internet. According to Reichheld et al (2000), the seamless integration of different channels can prove to be valuable. This finding has been verified by Chiang et al. (2003)'s, who determined that the e-channels could increase the e-business companies' profit indirectly through retail channels.

All customers are not created equal. If the company could properly measure the profitability of its customers, it can implement corresponding margin strategies to achieve higher customer and corporate profitability. Profitability can be measured at either the individual or segment level by identifying the customers' purchase to cost margin. Costs uniquely traceable to customers include customer transactional cost, customer service and support cost, packaging, delivery, and post sales costs. The ratios of the mix of customer purchase margin to the customer serving cost are thereby revealing when compared on an individual customers basis, as well as by segment or channel (Schoeniger, 2003).

Process Structure Perspective

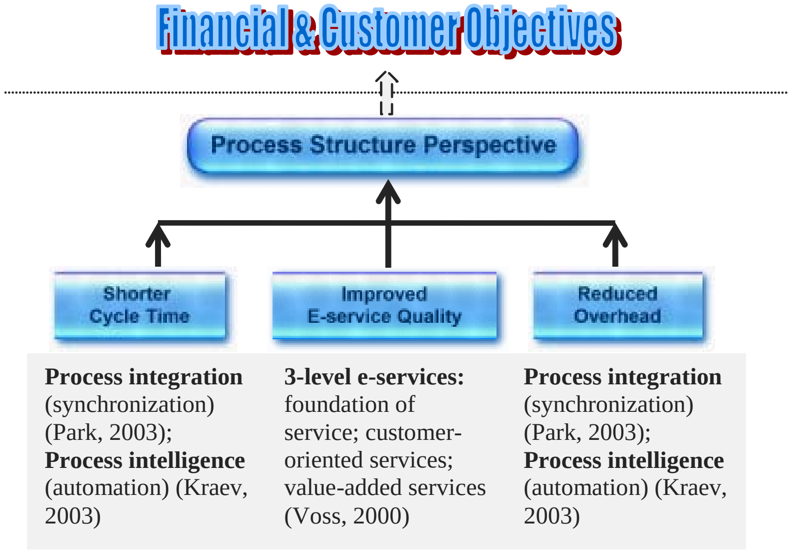
E-business should feature speed, flexibility and fluidity, sometimes described as agility (Introna, 2001; Metes, Gundry, & Bradish, 1998). Existing business processes must be seamlessly integrated with the new, electronic form of interaction with suppliers and customers. A generic value chain is illustrated in Figure 4, which offers an abstract description of the processes within any type of business (including e-business). To be feasible in e-business, the internal process view should consider the flexibility and intelligence of the process structure (Hasan et al., 2000).

For e-businesses to operate successfully there must be flexibility and scalability to accommodate continuous process changes, readiness to provide an up-to-the-minute and integrated view of the product, process and equipment, and capability to collect and store the results of historical and proactive analysis for future process innovation. Such process improvements can be achieved through intelligence and integration of business models and data with the Internet and with the systems of the company's trading partners. As summarized in Figure 5, improved effectiveness and efficiency in these core business processes will lead to faster cycle times, enhanced service quality, reduced overhead, and more competitive offerings.

Different from the customer-perspective sales cycle, the general cycle time measures the time needed by the business to plan and stock (inbound logistics), inventory and schedule (operations), lead time (order-to-delivery time), and invoice a particular product (outbound logistics). Accordingly, incremental costs are induced as the cycle lengthens. Effective process integration and intelligence can optimize this cycle, measurably reduce inventories and help offer exactly the products that the market demands at any given time. Wherever there are manual and sporadic tasks in the product cycle, there are chances for overhead costs, delays, and errors, all of which can all contribute to longer cycle times.

In the EBBSC framework, process integration is a composite variable that reflects the degree of problem critical data, information and knowledge sharing, and transmission across different departments and groups (from downstream to upstream and inbound to outbound). Process integration also incorporates the effectiveness of two or more identical (horizontal) or successive (vertical) stages in producing or distributing a particular product. Process intelligence represents the ability of the business processes to perceive and act in the surrounding environments, to respond appropriately to the prevailing circumstances in a dynamic

Figure 5. Process structure perspective for e-business strategy



business situation, to learn and to improve the process with prior experiences.

As emphasized in the e-CRM perspective, e-service is the glue that holds the e-business process together (Tschohl, 2001). According to Voss (2000), customer service generally involves three levels of service and overall e-service quality can be estimated by incorporating the quality indicators of the three levels of e-services.

- The first level, foundation of service in e-business, includes minimum necessary services, such as site responsiveness (e.g., how quickly and accurately the service is provided), site effectiveness (e.g., site interface friendliness and freshness), and order fulfillment. The e-business companies should monitor network performance and infrastructure to ensure basic customer service.
- The second level, customer-oriented services, involve: (1) informational capabilities: service and help information availability, perceived ease and actual convenience of finding the help needed, customer profile personalization, and interactive communication with service representatives, and (2) transactional capabilities: site security and privacy, order configuration, customization and tracking, complete support during the ordering process and after the purchase period.
- The last level, value-added services are extra services, such as location sensitive selling and billing or online training and education that add value to overall service quality. Some value-added services may stand alone from an operational perspective, while others add value to existing services. Overall, value-added services provide operational and administrative synergy between or among other levels of services.

Being agile and flexible, the virtual process of e-business replaces the traditional product inquiry and physical clearinghouse process and provides greater operating advantages that may lead to reduced overhead. As the cycle time is shortened through process integration and intelligence, overhead will be reduced accordingly. Process integration and intelligence is a significant advantage in achieving e-business focus and flexibility because, in many instances, these capabilities can replace the need for a well-defined organizational structure and often whole layers of staff.

E-Knowledge Network Perspective

Targets for success keep changing so that the company must make continual improvements to survive and succeed in the intensive global competition (Kaplan et al., 2001). Organizations operating in the new business environment should be adept at creation and application of new knowledge as well as ongoing renewal of existing knowledge archived in company databases (Malhotra, 2000; Soliman et al., 2001).

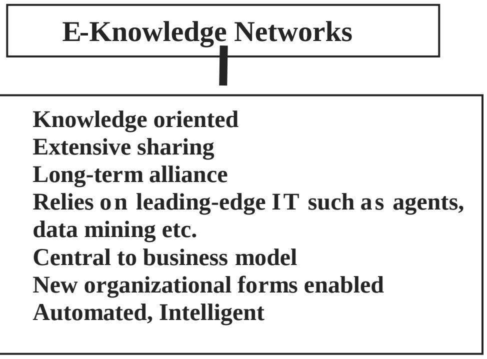
E-business knowledge (or "e-knowledge"), including knowledge about internal functions and processes, about customers and markets, and about strategic partners, can be created, shared, and managed more effectively by a combination of new organizational designs and the adoption of new technologies, such as data mining and intelligent agents. Organizations are now creating knowledge networks to facilitate improved communication of data, information, and knowledge, while improving coordination, decision making, and planning based on the Internet-driven "new economy" technologies that were unavailable until recently (Warkentin, Sugumaran, & Bapna, 2001).

Figure 6 highlights some of the characteristics of e-knowledge networks.

This enhanced e-knowledge innovation and management will lead to greater back-office efficiency, flexible adaptation to market changes, greater customer intimacy, improved strategic planning, improved decision making, rapid and flexible relationship management processes, and other organizational benefits. There are additional implications of staff proficiency, process integration, and process intelligence, as summarized in Figure 7.

Specific manager proficiency and employee skills are required to operate in the new competitive e-business environment. E-business managers are responsible for identifying the major factors involved in their business strategy, specifying the relationships between the factors, and generating long-term and short-term strategic e-business plans that will improve overall organizational performance. Similarly, employees should be provided with particular skills and proficiencies across different departments. For instance, customer service team is capable of assisting customers throughout their online purchase process in a timely and friendly manner to ensure customer satisfaction and retention. A technical support team is in charge of ensuring that the site runs properly and securely under all circumstances.

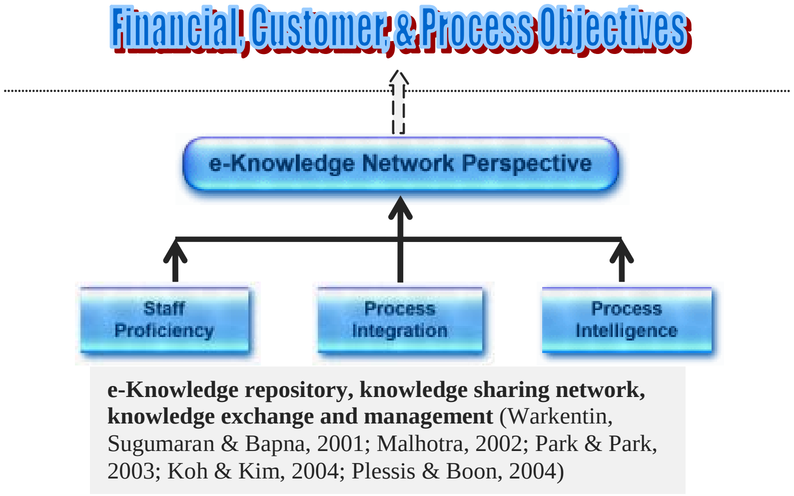
Figure 6. E-knowledge networks characteristics (Adapted from Warkentin et al. 2001)



The e-knowledge network offers a repository where new knowledge is created and collected, while existing knowledge, archived in data warehouses, is renewed and updated. Management and operational judgment, knowledge, and experiences are shared and managed to facilitate improved communication, coordination, decision making, and planning. Staff training can be utilized to improve employee skills and maintain currency with the technology shift.

Process integration enables a company to unify every aspect of its back-end infrastructure and increase responsiveness to inventory levels, customer demands, and delivery schedules by integrating disparate business processes, not only within an enterprise, but also across organizational boundaries. To achieve process integration in e-business, the communication infrastructure must be designed for a mission-critical environment,

Figure 7. E-knowledge network perspective of strategic e-business management



e-Knowledge repository, knowledge sharing network, knowledge exchange and management (Warkentin, Sugumaran & Bapna, 2001; Malhotra, 2002; Park & Park, 2003; Koh & Kim, 2004; Plessis & Boon, 2004)

scalable to increasing numbers of transactions and trading partners, and robust enough to integrate with the core business applications. E-knowledge innovation and management facilitates the integration process by creating e-knowledge networks that are characterized by automated exchange of rich knowledge by unattended computer systems, programmed to capture and evaluate knowledge with data mining algorithms, share it with strategic allies, and direct the operation of key interactive processes. Through e-knowledge networking, internal business data can be retrieved and shared across different departments and groups, and problem critical information and knowledge can be transmitted, integrated and processed from downstream to upstream as well as inbound to outbound.

The flattening of the organizational hierarchy also contributes to process integration, which leads to higher process efficiency, visibility and transparency. In contrast, traditional organization structures are hierarchical and functionally oriented (Chen & Ching, 2002). As a result, information is filtered and modified as it makes its way through different levels of management. Enabled by e-business capabilities, companies with a flattened organizational hierarchy have the built-in flexibility to move swiftly toward capturing new opportunities, react quickly to shifts in the environment, and respond promptly to the customers needs.

Process intelligence facilitates matches between the company's offering and target customers, competitors, and the current business by automating the decision and action processes and initiating real time analytics of sales and e-services as well as business notification and alerting (Park & Park, 2003). Such effort requires a wide range of process steps to be understood and represented, not only within an organization, but communicated to trading partners.

An e-knowledge network generates and stores immediate (real-time) knowledge about internal functions and processes, about customers and markets, about strategic partners, and about supply chain partners (suppliers, vendors, dealers, and distributors). Using the knowledge repository, the company can create new internal and external structures and relationships, which leads to further knowledge and continuous strategy improvements. Intelligent technology, which enables communication with trading partners across different platforms, can help represent, implement and track external business processes (contact agents of other companies, request information on merchandise/suppliers, and negotiate with them about purchase conditions) in a dynamic and flexible way (Park et al., 2003).

EBBSC SUMMARY AND ILLUSTRATION

Using the EBBSC components, we can develop the major measures and factors involved in the EBBSC framework. These measures and factors, which have been identified in each EBBSC perspective, are summarized in Table 5.

The major measures (Square) and the corresponding decision factors (Oval) and relationships (Arrow Lines) specified in the EBBSC framework are illustrated in Figure 8. This framework also forms the basis for specifying a precise and explicit functional model for strategic e-business management. At the conceptual level, it offers the e-business manager a big-picture perspective that is critical in generating effective e-business strategies. Aided by this framework, e-business companies can identify the major factors regarding the four e-business perspectives and specify the direct and indirect relationships among the various factors.

As an illustration, consider an e-business that seeks to acquire more customers in the next planning period. The manager first will locate the strategic measure of new customer acquisition in the framework and identify the relevant decision factors. As the EBBSC framework indicates, these factors include the customer profile, competition, the marketing mix, and e-service quality. Next, the manager can formulate a tentative strategy plan. In this case, the framework suggests that the company needs critical data and information regarding the prospective customer population and the competitors. Based on the collected information, management must decide on a specific marketing mix and e-service solution. Starting from the market mix or e-service quality components, the EBBSC framework suggests the steps to create the mix and quality plan. Having the priority of the strategic objective at each stage, the manager can plan and allocate the available budgets and resources more effectively to achieve these objectives.

DISCUSSION AND CONCLUSION

In this study, we have developed a balanced scorecard-based framework for strategic e-business management, which contributes to both theory and practice. From a theoretical standpoint, the balanced scorecard adaptation offers an innovative methodology to formulate and evaluate e-business strategy. The EBBSC framework also indicates that e-business strategy making will involve multiple decision criteria. Using this framework, the decision maker can establish an evaluation model for strategic e-business decision support. Figure 9, for example, shows such a multi-criteria e-business strategy evaluation model utilizing the strategic measures specified in the EBBSC framework. Based on the Analytic Hierarchy Process (AHP) concept (Forgionne, 1999), this EBBSC strategy evaluation model associates a hierarchy of evaluation measures relevant to the context of e-business strategy in an integrated fashion.

Using the hierarchy in Figure 9, the decision maker can make pairwise comparisons of decision criteria across the multiple dimensions. The AHP methodology then will convert the multiple measures into an overall scorecard value for each considered strategy. This AHP-based EBBSC evaluation model, then, will identify, in rank order, the most promising e-business strategies.

In practice, the EBBSC provides a means of identifying business opportunities and threats in both the internal and external environment, analyzing current business capabilities and resources to address the opportunities and threats, and generating effective e-business strategies that would improve the company's overall business

Table 5. Description of the measures & factors in the EBBSC framework

Factor (symbol)	Explanation	Factor (symbol)	Explanation
Profit (Profit)	The difference between the revenue and cost	Marketing-mix (M)	The company's effort on commercial processes involved in promoting/selling
Revenue (R)	Total income in a given period	Customer Acquisition (CA)	The number of new customers acquired in a given period
Cost (C)	The total expense (e.g. money, time, and labor) incurred in a given period	Customer Satisfaction (CS)	Measure of determination that a product meets a customer's expectations and needs
Price (P)	The amount of money needed to purchase the product	Customer Retention (CR)	Measure of customers revisit to the site and repeat purchases over a period of time
Purchases (PU)	The total quantity of product actually sold to customers	Customer Profitability (CP)	The ratio of the customer serving costs to the mix of customer purchase margin
Quantity Demanded (QD)	The total quantity customers are willing and able to purchase	Staff Proficiency (SP)	The efficiency of the company staff in providing the product and service
Quantity Supplied (QS)	The total quantity the company offers for a sale	E-service quality (EQ)	Measure of the company's e-service quality
Variable Cost (VC)	The portion of cost that varies in relation to the level of production activity	Process Integration (PIG)	The degree of the company's business process integration
Sales Cycle (SC)	The time between the point the product is listed and the point the product is sold	Process Intelligence (PIL)	The ability of the company's business process to respond to and improve its position in the business environment
Cycle Time (CT)	Time that elapses in conducting inbound operations, and outbound logistics	Knowledge Network Efficacy (KNE)	The company's investment in knowledge transmission, sharing, and innovation
Unit Cost (UC)	The cost per product	Capacity (CT)	The equipment, personnel, and technology capacity of the company
Fixed Cost (FC)	The portion of cost that is independent of the number of products produced/sold	Goodwill (G)	The company's accumulative prestige and perceived value in the market
Product (PD)	Measure of the product quality, positioning, and Internet branding etc.	Competition (CO)	Measure of the rivalry between the company and other businesses in the market
Presentation	The selection of product presentation and distribution formats	Channel Flexibility (CF)	The convenience and availability of distribution channels besides the Internet
Promotion (PM)	The company's expenditures on product promotion	Supply Chain Efficacy (SCE)	The effectiveness of the company in managing relationships with its suppliers
Profile (PF)	The target customers' average disposable income, needs or preferences index	Staff Qualification (SQ)	General rating of the company's staff skill level
Distribution Effort (DE)	The company's effort on distribution channel	Staff Training (ST)	The company's investment in staff training

performance and profitability. As illustrated in Figure 10, proper decision technology can deliver the EBBSC model, provide intelligent decision support to practitioners in overcoming analytical and technical barriers, and guide e-business managers towards an effective e-business strategy. The EBBSC also provides a stable point of reference for e-business companies to understand and manage e-business initiatives, enables e-business managers to plan and allocate resources (including tangible and intangible strategic assets) more effectively, and align strategic objectives with performance results.

As an innovative and exploratory framework for strategic e-business management, the EBBSC offers several opportunities for future endeavor.

Figure 8. An overview of the EBBSC framework

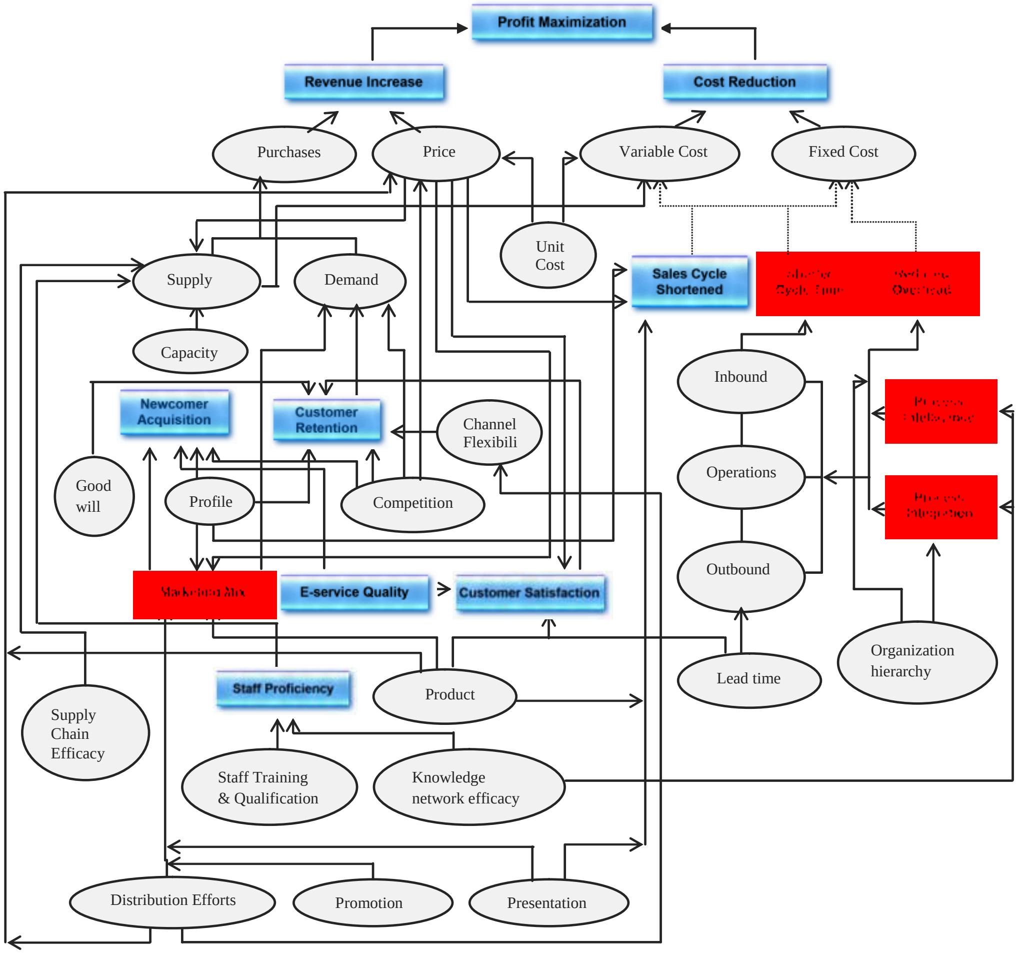


Figure 9. EBBSC strategy evaluation model

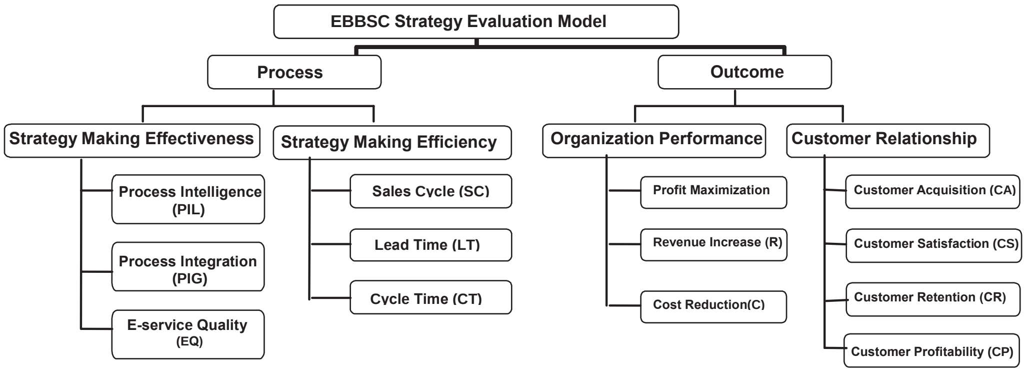

Figure 10. EBBSC mediated decision support architecture for e-business strategy

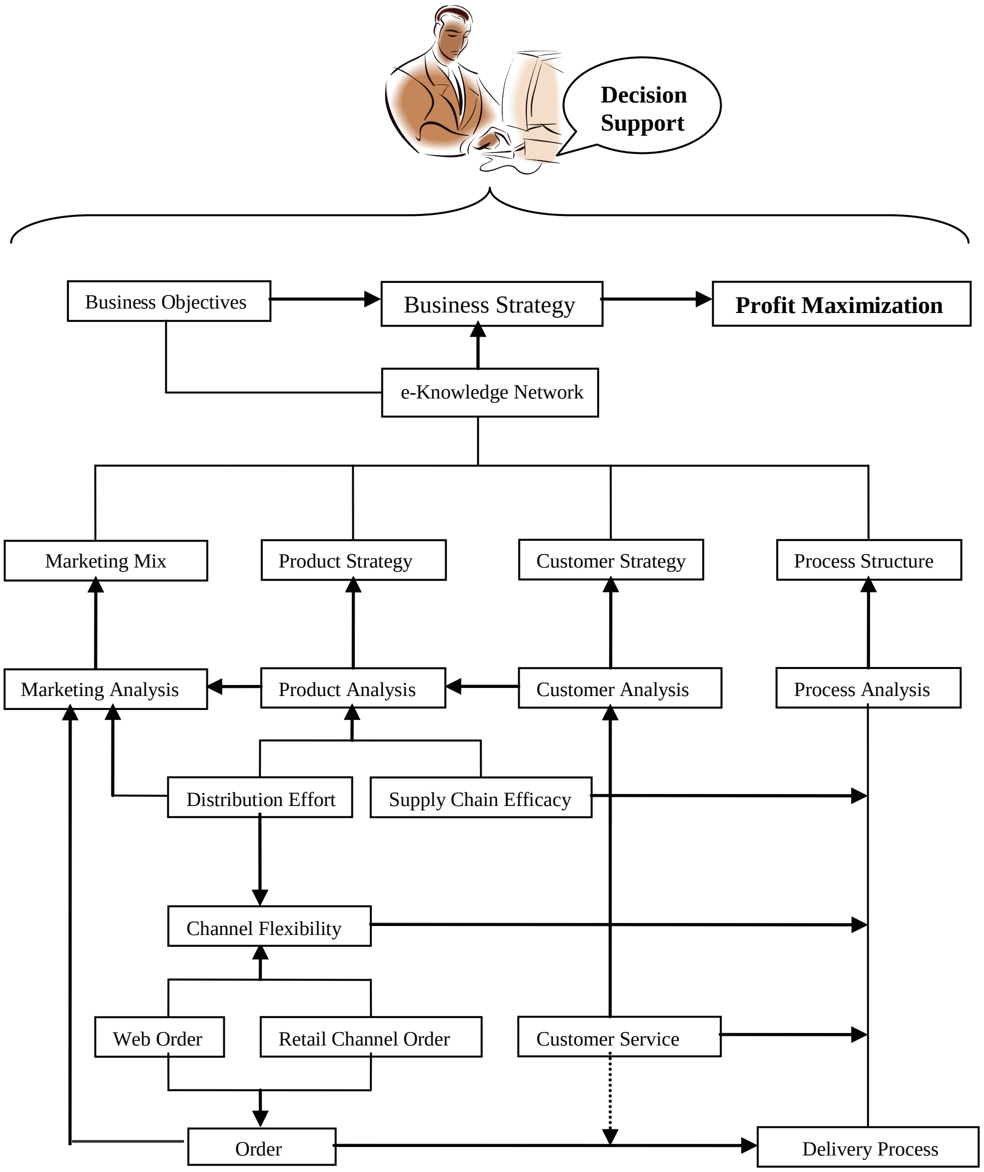

First, empirical research is needed to specify the measures, decision factors, and corresponding functional relationships in each e-business perspective. Another possible extension is to apply the EBBSC methodology to both profit driven and non-profit e-businesses.

To illustrate a potential non-profit application, consider an academic surgical organization. Under the business model perspective, instead of profit or revenue oriented indicators, specific measures would include management expenses, research grants, billings or collections, and days in receivables for outstanding invoices. Comparatively, the e-CRM perspective can be measured by patient satisfaction, number of outside referrals, invited lectures given or articles published in peer-reviewed journals. The process structure could include measures of operating room cases, consultations performed, clinic cancellations or length of stay. Finally, e-knowledge learning and growth could include measures of internal and external clinical program development or research development and faculty promotion. The specifications of the conceptual model will be determined by the specific application settings and the data sources selected to operationalize the model. Such empirical issues could possibly result in different versions of the operationalized model in practice, but the conceptual EBBSC framework remains feasible and applicable across different practice fields.

ACKNOWLEDGMENT

Chapter 4.5

Strategic Management in City Government:
Integrating Information Communication Technologies and Marketing in a Causal Model to Drive Stakeholder Satisfaction and Economic Development

Laura L. Matherly
Tarleton State University, Central Texas, USA

Maureen Jouett
Tarleton State University, Central Texas, USA

ABSTRACT

Integrating information communication technologies (ICTs) and marketing in strategic management of city government is critical to achieving stakeholder satisfaction and economic development. As a result of the rapid growth in computer networks and access to online services, the use of ICTs, for example, Internet and Intranet, as a communication and marketing platform can provide a city with a global advantage. City marketing focuses on promoting the attributes of a location to prospective stakeholders so that these individuals, businesses, and investors are attracted to visit, locate, or invest in the city. A causal model is presented where ICT is used to not only to deliver services to internal stakeholders, but also to market a city to external stakeholders. To be successful, managers need to be skilled in current technologies and marketing practices. Case study applications are discussed as well as the questions to address in future research to most effectively integrate ICTs and marketing in city management.

INTRODUCTION

Organizations are increasingly faced with the global challenges of international competition and as a result, the adoption of information communication technologies (ICT**)** as a marketing competency has become a strategic imperative (Gummesson, 2002; Lapierre & Medeiros, 2006; Brady, Fellenz & Brookes, 2008). City governments are utilizing emerging technologies and especially, ICTs, as a major catalyst to market and communicate with stakeholders to ultimately attain strategic objectives such as growth and economic expansion. The purpose of this chapter is to provide a model for the use of marketing and ICTs in strategic planning to create a distinctive competency and address the challenges that result in achieving strategic performance objectives. The causal model developed in this chapter proposes that ICT initiatives and investment in the ICT infrastructure can be used to improve internal stakeholder services and satisfaction as well as with a marketing plan to promote the attractiveness of the city image to external stakeholders. Marketing and ICTs are presented as activities in a strategic map of causal linkages: by developing and recruiting employees with the skill sets required to effectively integrate ICT initiatives and marketing plans that develop customer relationships and improve service quality, a city's image to both internal and external stakeholders will be enhanced. Excellent internal processes and service levels can advance community outcomes such as health, safety and welfare as well as a city's overall reputation which ultimately impact the attainment of strategic goals such as economic development.

First, a review of the developments in performance management, balanced scorecards, and strategic management is discussed with an eye toward developing a generic causal model for city management that starts with developing the employee and the information capital of the organization which in turn improves internal processes, services and eventually, stakeholder satisfaction. The strategic group map (Kaplan & Norton, 1996) was chosen as a framework for the model because it challenges strategic planners to go beyond measuring lagging performance indicators such as economic development and growth to specify the drivers of economic development and growth. For example, if a city's image drives economic growth and marketing positively impacts a city's image, by measuring and investing in marketing initiatives, corresponding improvements in image and then economic growth will occur.

The role of ICTs in contemporary marketing practices (CMP) over the last decade is examined as an effective solution to meet the challenges brought about by a connected, global economy and expanded and empowered customer base. Given the importance of technology in developing a strategic marketing plan, a number of ICT applications are presented. Several case study applications are discussed to illustrate the application and benefits of ICTs to city marketing. Last, the future role of ICTs in city government is examined by posing the fundamental issues in the form of research questions to be answered that will illuminate how to effectively integrate specific ICT and marketing practices into strategic management of city governments. The management mindset that is required to be successful and competitive, both in determining the strategic direction and implementing the technological changes required by the new marketplace is addressed.

PERFORMANCE MANAGEMENT AND A CITY STRATEGIC GROUP MAP

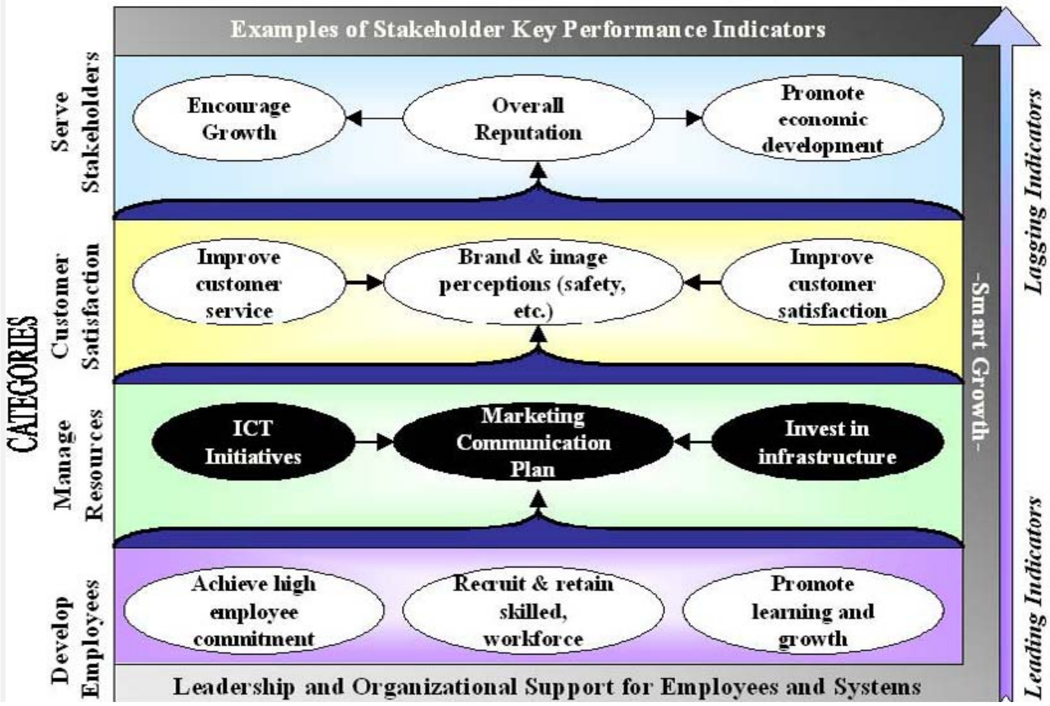
Over the last decade, developments in performance measurement have signaled the need for organizations to monitor performance dimensions that go beyond traditional financial measures to include measuring and improving those factors that ultimately impact financial performance such as stakeholder satisfaction.

In 1992, Kaplan and Norton introduced the balanced scorecard as an overall framework for establishing a performance measurement system that predicts financial results. They provided a framework for capturing metrics at the executive level based on four categories: (1) customer satisfaction, (2) financial performance, (3) internal processes and (4) employee innovation and growth. In brief, nonfinancial measures provided the balance needed to supplement financial measures and align employees with strategy. Although many of the balanced scorecard applications are in industry, the City of Charlotte, North Carolina applied the concepts to city management and developed a city scorecard (Syfert & Elliot, 1998 ; Eagle, 2004).

Kaplan and Norton (1996, p. 149) define strategy as "a set of hypotheses about cause and effect" and maintain that every measure should be identified in a chain of outcome measures and corresponding performance drivers of the outcome measures. They introduced the concept of strategy maps--there is a causal path among the four perspectives. Hence, the categories and measures within the categories are linked in a causal path of leading and lagging indicators. Essentially, improving employee innovation and growth (which includes technological and organizational capabilities) will result in continuous improvement of key internal processes. Improved internal processes that deliver value to the customer will lead to subsequent improvements in customer satisfaction, which in turn will result in improved financial performance. The value of using this approach is that managers are more likely to be successful in meeting/improving the performance of lagging indicators, such as economic growth, by identifying and verifying the factors that drive economic growth.

The four categories (and performance measures) in Kaplan and Norton's (1996; 2004) strategic group map are typically adapted or customized when applied to a particular organization. In Figure 1, an example of a strategy map

Figure 1. City strategic map



for city government is proposed that illustrates the central role that marketing and ICTs play as leading indicators to customer and stakeholder satisfaction. The model reads from the bottom up--the leading indicators at the base drive the next level of indicators until the uppermost level of stakeholder outcomes is reached. First, employee development is essential to drive effective resource management. Next, investment in ICT initiatives and infrastructure as part of a marketing communications plan helps manage resources efficiently as well as market a city. Using ICT as a marketing tool can improve branding/image perceptions, customer service and customer satisfaction. Enhancing a city's identity or image, services and customer satisfaction will ultimately impact key performance indicators such as overall reputation, economic development and growth. In the following sections, the major categories and factors within each category are discussed with an emphasis on the central role that ICT and marketing play in eventually producing positive stakeholder outcomes.

DEVELOP EMPLOYEES

The catalyst for successful resource management is a committed and skilled workforce which is supported by the organization's culture and leadership to continue to learn and grow (Matherly, 2007). Figure 1 is an example of a strategic group map for city management. The category at the bottom of the model includes three areas to address in order to develop employees; an institution needs to achieve a high level of employee commitment, recruit and retain a skilled workforce, and promote learning and growth of employees. Both Baldrige (2008) and Kaplan and Norton (1992) recognize the essential role that the people, i.e., employees and managers, play in driving process improvements and performance excellence. In a study of ICT deployment in marketing applications, Brady, Fellenz and Brookes (2008) conclude that there is a "need to study and expand the skill set of marketers into technological, managerial, and organizational areas to more fully enable the use of ICT within contemporary marketing practice" (p. 108). Not only do employees need the skills to work effectively within an organization's existing technology infrastructure, they also must be familiar with new technologies to expand ICT initiatives to create competitive advantage. Only by training and developing existing employees or recruiting and hiring employees/contractors with the required ICT skill set can a city effectively implement new applications and forms of ICT.

With the rapid changes in and complexity of ICTs, there is a corresponding increase in the information processing and analytical requirements of managers creating a challenge in integrating technology changes into strategic planning and marketing (Fisher, Raman & McClelland, 2000; Holland & Naude, 2004). Executives must choose technologies that are integrated with the needs of the organization *and* customers and manage any resistance and barriers to implementation (Leverick, Littler, Bruce & Wilson, 1998; McAfee, 2006). Without a sufficient skill set in technology, planners will be unable to take advantage of emerging opportunities and maximize the value of ICTs (Brady, 2003). The practical reality is that managers are being asked to understand, develop and implement ICT applications that efficiently and effectively market their services to stakeholders—the customer interface—as well as integrate the programs across operations. For example, an organization's ability to assimilate, store and retrieve new information and apply this learning affects successful customer relationship management (CRM). CRM systems capture and integrate customer data from across the city, consolidating the data, analyzing the data, and then distributing the results to various systems and stakeholders across the organization. Effective organizations are those that invest in both the technology infrastructure and organizational learning to support the building of their marketing intelligence (Chen & Ching, 2004). A learning organization that fosters employee commitment and growth, for example, by investing in training and development, will result in more effective and efficient resource management.

MANAGE RESOURCES

Employees who are committed to achieving a city's performance objectives and skilled in technology applications and marketing can drive the development of the appropriate technology infrastructure that can effectively market a city to stakeholders. In Figure 1, the ability of a city to manage resources effectively and positively impact customer satisfaction is determined by how effectively ICT initiatives are deployed which requires an investment in the ICT infrastructure. Further, the ICT infrastructure needs to be integrated into the marketing plan both to deliver services to internal stakeholders and to market the city to external stakeholders. ICTs provide greater access to information, dramatically increase the speed of transmitting information and allow for wide-spread broadcast and use of information. By providing services through an ICT interface, improvements in service, quality, accuracy and operations will result in a subsequent increase in customer satisfaction.

Marketing, through the effective use of ICTs, can improve a city's image, attract new businesses or help retain and expand existing businesses, as well as accentuate a city's attributes such as its workforce, talent pool and services offered. Similarly, an effective ICT marketing program can counteract negative images through the positive interaction of city employees with citizens and visitors. ICTs can enhance communication and improve relationships between the city and its citizens and help secure community support for changes in service delivery. For example, ICTs can be used to increase citizen participation in local government and through collaborative problem solving and communication help reverse an economic decline of an abandoned downtown area. Moreover, the potential for ICTs to alleviate poverty and promote economic growth in developing countries justifies greater attention and systematic analysis (Eggleston, Jensen & Zeckhauser, 2002).

Expand ICT Initiatives and Invest in the Technology Infrastructure

Expanding ICT initiatives and investing in the organization's technology infrastructure are essential to success and a growing assortment of technology tools are available for cities to employ. Technological devises and software are primarily related to obtaining and sending information at unprecedented speeds. Wireless networking affords a city with greater mobility and in many cases affords smaller cities the ability to maintain the same presence and competitive advantage that many larger cities have on the internet. The business community argues that wireless internet access is good for economic development and a handy tool for business travelers (Swope, 2007). Mobile devices and software allow remote connection to desktops and office networks for access to information. Electronic transfer of information is not only more efficient and timely but it can improve accuracy.

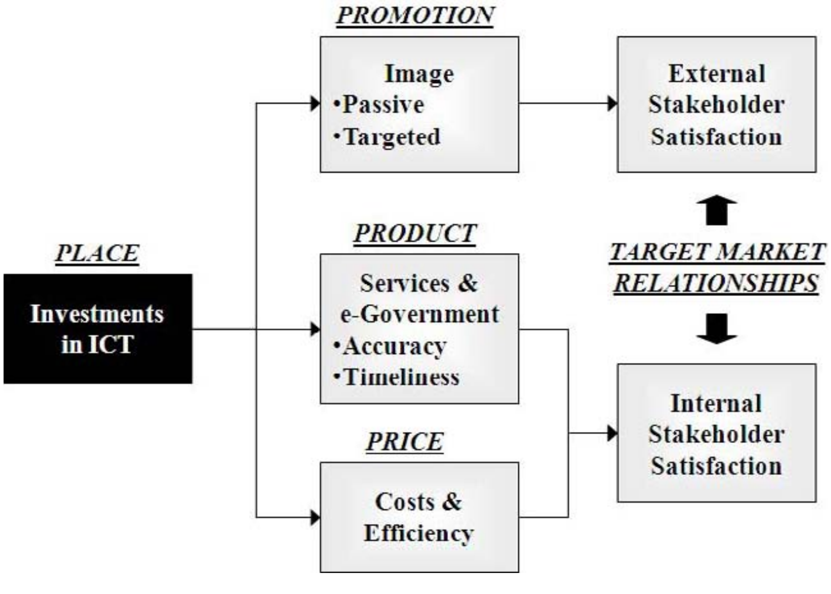
Develop and Implement City Marketing Plan

Marketing is recognized as a body of professional skills and techniques for bringing the producers of products and services together with people that need or can use them. A review of strategic group maps in peer reviewed journals as well as those reported in the public domain reveals that although hundreds of organizations have developed strategic group maps, a key factor absent in these applications is marketing as a leading indicator and driving force in developing community perceptions of the organization's image which ultimately impacts lagging indicators such as economic growth and financial performance. More and more, marketing principles are being applied to city management and city websites deliver brand information that can create value, a positive image, recognition and recall that attracts external stakeholder groups. The qualities which make a city unique create an identity or image that can be used to market a location (Erickson & Roberts, 1997). Based on a communication-based marketing model, Duncan and Moriarty (1998) point out the importance of managing consistent messages across all stakeholder groups so that communications are managed strategically to build brands and external relationships. Tschirhart (2008) demonstrates that while many city government websites deliver brand information, there are substantial inconsistencies in whether cities follow this recommended branding practice.

Marketing can play a central role in establishing a particular city as an attractive location and ICT is an effective and efficient method for communicating and facilitating a host of marketing activities. In Figure 2, the four P's (product, price, place and promotion) are integrated in a marketing and ICT model that emphasizes the importance of target market relationships. ICT is place, i.e., ICT is the mechanism/channel used to promote a favorable city image; conduct services (product); and improve operations and efficiency (price). Both internal and external stakeholders can be targeted by marketing communications efforts of cities. These stakeholders include the citizens, city council and mayor, city manager, department heads, employees, bonding agencies, investors, economic development prospects, visitors, shoppers, tourists and current businesses. Moreover, ICT can be designed to be interactive, e.g., by conducting services and communications online.

Having an excellent offering or product does not ensure that prospective buyers will know about it. ICTs are fast becoming the main medium for proactive, targeted marketing – they

Figure 2. Integrated marketing and ICT communication strategy



can be customized, personalized, shared, two-way, interactive and cost-effective. In Figure 2, targeted marketing can be used to improve the image of a city with external stakeholders. ICTs can facilitate marketing and the exchange of mutually beneficial information between a city and its stakeholders. The use of ICTs provides a viable resource to cities, facilitates competitive advantage and opens opportunities for future success. CRM systems can be used to organize, store and retrieve relevant information required for tailored, multi-channel marketing. Pinpoint marketing – getting the right message to the right people at the right time – and data mining capabilities are enhancing marketing efforts for seasonal activities so that previous users are solicited when similar activities are planned. Online community networks are natural marketing channels. Marketing packages can be quickly produced to prepare professional presentations that are available with user friendly software programs to effectively communicate a city's financial condition, for example, to bond rating agencies. Ease of access to financial information helps these agencies determine bond ratings that can lead to substantial monetary savings as investors evaluate the risk involved in purchasing city bond offerings.

Integrating ICTs with the Marketing Plan

Over the last decade, new directions for marketing and management have been identified in response to changes in factors that influence organizational success. Numerous researchers are calling for a multidisciplinary framework that integrates managing ICTs uses, forms and infrastructure with contemporary marketing practices (e.g., Achrol & Kotler, 1999; Coviello, Miller & Marcolin, 2001; Gommans, Krishnan & Scheffold, 2001; Brady, Saren & Tzokas, 2002; Brady, 2003; Brookes, Brodie, Coviello & Palmer, 2004; Chen & Ching, 2004; Barwise & Farley, 2005; Brodie, Coviello & Winklhofer, 2008). Gummesson (2002) defines the new economy as a network society that focuses on services, emerging customer roles, information technology, globalization and alliances between countries and these forces have ushered in a shift from the traditional marketing paradigm (the four P's-product, price, place and promotion) to relationship marketing and interactive marketing (Webster, 1996; Deighton, 1996; Webster, 1998; Day & Montgomery, 1999; Webster, 2005). Relationship marketing is a necessary perspective requiring a new mindset to address the networks and interactions that are embedded in organizations, markets and society. The network organization includes all stakeholders that interact with the organization—both intra and internet interactions. Similarly, in a survey of marketing research professionals, Struse (2000) identified the top influences of the 21st century as the internet, globalization of business, culture and research and one-to-one (relationship) segmented marketing. Increasingly, technological expertise and investment will be required as part of strategic planning and marketing.

Generally, ICTs can be used as a marketing communication tool to promote a city's image in either a passive or targeted mode (see Figure 2). In the passive form, they can provide: citizen access to information, government functions and services; locations and directions to parks and community centers; calendars of city-sponsored events and activities; access to property information and citizen services; job postings; phone and staff directories; meeting notices; statistics about the city; and tourist information. Stakeholders recognize that the Web is a good place to conduct a site search (Bastain, 2007). Having information readily available and accessible can provide a competitive advantage as a city can showcase strengths and opportunities to potential stakeholders. For example, having accurate, referenced data allows businesses and cities to conduct systematic and realistic evaluations of prospective locations. Increased levels of information access enable a city to differentiate incentive packages to increase competitiveness and improve success rates in attracting new residents and businesses. Stakeholders can conduct research using community and regional websites as primary information sources and avoid the high costs of external consultants (Bastain, 2007).

E-government is the application of the Internet and related technologies to digitally enable government and public sector agencies' relationships with citizens, businesses, and other arms of government. In addition to improving the delivery of government services, e-government can make government operations more efficient and also empower citizens by giving them easier access to information and the ability to network electronically with other citizens. Governments use internet technology across many operations, agencies and levels to deliver information and services to citizens, employees, and businesses with which they work (Laudon & Laudon, 2006). The Organization for Economic Co-operation and Development (OECD) recognizes e-government as a major enabler of good government practices (OECD, 2003). The OECD's charter is to promote policies designed to achieve high economic growth and expansion for over 30 member countries and recognizes that e-government helps improve efficiency and services as well as achieve policy outcomes and economic objectives. To illustrate, ICTs can be transactional providing for: license renewal and payment; remittance of parking citations and court fines; registration for programs and other functions; interactive job applications; online permits, business licenses, court documents; sales tax collection; distance learning; web casting of city/county meetings; communications with local leaders; and links to other key sites (airport, transportation, hotels). ICT and access to digital democracy can enhance the community's democratic participation in public affairs; for example, with e-voting and e-ballots, and citizens can express and exchange views with elected representatives (Bozinis, 2007).

ICTs can be used to facilitate compliance with governmental regulations. For example, in some countries, citizens are entitled to information about the affairs of government and the official acts of public officials and employees. Interactive technology expedites the delivery of information, and provides a conduit for continuous feedback that can significantly impact responsiveness to stakeholders. Timeliness of information and availability allows cities to respond quickly to community needs. However, this requires the monitoring and coordination of numerous communications from multiple media.

In summary, ICTs can be used to communicate service information to internal stakeholders, improve operations and efficiency and promote city programs that advance community well being, e.g., health, safety and welfare. The success of e-government in the provision and delivery of public goods and services as well as marketing communications is well documented (e.g., Mellor, 2006; Kim, 2007; Halaris, Magoutas, Papadomichelaki & Mentzas, 2007). In order to implement ICT changes effectively and efficiently, Gummesson (2002) stresses the importance of focusing on internal networks and interactions. ICTs allow for employee interaction and shared information that can improve communications, operations and efficiency. On a global level and especially where stakeholders are geographically dispersed, applications such as video communication technology are more cost efficient and timely than face-to-face interactions. Moreover, interactive technology provides a mechanism for supplying information and interfacing with stakeholders on a personal basis such as after hour's contact which is especially effective at facilitating transactions and dealings across international time zones. ICTs expedite the communication and exchange of information which can facilitate consensus building and support for decisions and plans, for example, to invest or locate in a given community (West & Berman, 2001).

CUSTOMER SATISFACTION

The reputation of an organization, defined as the set of attitudes and beliefs that an individual or market holds about an institution, can provide a competitive advantage that enhances an institution's long-term ability to create value (Goldman, Gates & Brewer, 2001; Suh & Amine, 2007). In Figure 1, customer satisfaction results from how well resources are managed, i.e., integrating ICTs and marketing applications will (1) improve operations and efficiency, (2) promote the city image, brand identity and relationships, and (3) improve service and quality. Since ICTs can provide immediate access to a wealth of information and allow for a tailored response to inquiries, cities can improve services and lower costs, cultivate direct relationships and further facilitate customized communication. To promote image and brand identity in order to remain competitive in a rapidly changing global environment, city managers can use ICT to communicate, market and interface with stakeholder groups. City managers and elected officials typically set specific objectives to focus their marketing, financial and operational efforts. These activities include: establishing the image a community seeks to portray; target marketing to national and international investors; providing data for global economic development opportunities; promoting city activities; and enhancing city services.

Research in marketing points to the pivotal role that image marketing targeted to identified market segments has in impacting economic development and growth (Suh & Amine, 2007). An organization's reputation is an important intangible resource, can provide a competitive advantage and is particularly important in global markets (Gardberg & Fombrun, 2002). How stakeholders develop their image of an organization is based on the information they receive (Schuler, 2004) and an effective and efficient vehicle for communicating and facilitating image marketing is the use of ICTs.

Two-way marketing and communications techniques in local government can establish stronger links between citizens and government, build community, and improve the local business climate, while boosting a municipality's image and civic pride (Kellogg & Lillquist, 1999). This can also provide cities with a competitive advantage and opportunities for an increased rate of return on marketing investments. Cities that capture and analyze the demographics of their communities can use the information to market to potential retail and economic development stakeholders, i.e., targeted promotions. For example, education, occupation and income are all measures of purchasing power, but they also reflect other attributes that are vital to economic development, such as the labor pool and intellectual capital. Since it is important to recognize that all businesses are not equally interested in all segments or demographic information, cities should design strategies that will best serve their different target markets. Providing regular demographic updates that are available to requestors in a downloadable format gives a city the opportunity to provide data, analysis and reports to prospective investors.

Providing easy access to municipal government information that can be used, for example, to estimate traffic flow and demand, can enhance the bottom line for private business. Sharing and showcasing the creative tools and innovations local governments are using results in more effective communication with citizens, businesses, visitors and other audiences. To illustrate, Geographic Information Systems (GIS) are tools for storing, retrieving and manipulating data to solve complex problems, e.g., operations such as the school districts can display a map with features associated with data. By selecting a given school, test scores, student demographics and financial expenditures are available. Similarly, police departments can profile crime statistics and characteristics by geographic areas which can help lower crime rates. Hence, using GIS results in more efficient and effective responses to community needs (Nedovic-Budic & Godschalk, 1996; Brown & Brudney, 1998).

The accumulation and circulation of community information in electronic databases can have a broad impact on city marketing and brand identity. By compiling a city's consumer characteristics, potential customers or prospects can be selectively targeted with promotional material through various media. This information is valuable to marketers and retail decision makers. Optimal selection of locations for stores and showrooms or franchises, regional shopping malls, etc., is facilitated through the use of this information. Target marketing to potential stakeholders offers an opportunity for city growth and economic development.

Websites with up-to-date and salient information will attract more traffic from location consultants and companies seeking site locations. Additionally, cities can target the distribution of information to increase marketing effectiveness and reduce media planning expense by resource allocation in areas that provide the greatest rates of return. Cities can focus their marketing efforts to the economic development segments they are interested in developing, e.g., industry, investors, etc. Software is available to track information requests and management can use this tracking technology to further enhance their web-based information offerings.

Some of the additional benefits of e-government are that it: is always open (i.e., 24-hour city hall); expedites transactions; reduces costs; improves citizen and business satisfaction; improves security application and accessibility; allows language options; and facilitates greater citizen participation (Shark, 2007). Also, the advantages of ICTs include timely compilation and dissemination of information and increased efficiency, e.g., lower transaction costs. ICTs facilitate participatory democracy/public decision making and enable wide, efficient and transparent participation between citizens and organizations to arrive at better and faster decisions through negotiation (Benyoucef & Verrons, 2008; Kim 2008). Such proactive problem solving helps cities to compete in an increasingly changing and global environment.

Presently, city administrators and leaders are leveraging resources and forming partnerships to expand and improve services, communications and infrastructures. They are striving to make their communities more attractive places to live, work or vacation – places where people want to raise children and perhaps retire (Kellogg & Lillquist, 1999). Cities must perform cost/benefit analyses to offer incentives that will contribute to the long-term success of the community. Successful implementation of ICTs can result in the acquisition and delivery of community information as well as individual consumer information. This information can then facilitate the design of new effective marketing strategies. Investing in ICT initiatives that result in better efficiency and cost savings ensures a city's ability to remain competitive. To illustrate, with rising fuel costs, there are significant cost savings in making data accessible and coordinating interactions such as telecommunications and video conferencing that do not require stakeholders to travel and be available on site.

Cities employing ICTs can create a competitive advantage when they are able to integrate information regarding factors such as building permits issued, market characteristics, constituent data and infrastructure condition, within a jurisdiction. Tracking building permits issued provides a competitive advantage for cities as they are an indicator of the economic vitality of a city, reflecting the amount of private investment being made in the local community. This is advantageous to a city given that bond agencies desire non-governmental investment in the local community. Examining trends in long-term growth helps prospective businesses/investors determine the likelihood that their investments will be profitable.

By improving operations, service and quality, community (internal customers) satisfaction will increase. In addition, by integrating ICT and marketing initiatives to proactively promote the city's image and build customer relations, improvements in external stakeholders will result. Cities that can more effectively promote the qualities of their locale to prospective stakeholders seeking information for tourism, relocation, economic development, etc., have a competitive advantage over other cities in attracting visitors, residents, and investors.

STAKEHOLDER OUTCOMES

In Figure 1, the final, top category is stakeholder outcomes and includes lagging performance indicators that are a result of improvements in customer satisfaction. In brief, if a city promotes its image and brand identity, builds relationships with customers and has high levels of customer service, its overall reputation will be enhanced which will also encourage economic growth and development as well as advance community outcomes such as health, safety and welfare.

The role of economic development is to increase the per capita income of a city's residents. For example, community information about activities, attractions and events can be communicated through ICTs resulting in increased tourism which brings in financial resources vital to community prosperity. Local government communications can encourage citizen responsibility, create citizen ownership and support and empower people to solve problems on their own, without having to rely solely on government (Kellogg & Lillquist, 1999).

More and more, stakeholders are sophisticated participants requiring substantial flows of information from a more organized but complex market; therefore, ICTs are essential for attracting and retaining business activity in an intensely competitive market (Perryman, 2006). The ultimate goal is for cities to meet their stakeholder needs, to provide information to prospects and to improve overall productivity. Cities seek to respond to an increasing demand from users for access to information that does not require the use of intermediaries. ICTs allow for service and resource comparisons with other jurisdictions which are increasingly sought after by prospective investors and economic developers on a regional, national and global basis. User-friendly interactive software can eliminate the need for users to have extensive technical knowledge in order to access information.

Further, cities can partner in a collaborative environment with other stakeholders to support common goals of economic growth and development and enhance global competitiveness. By leveraging critical expertise and financial resources, the community benefits. ICTs can facilitate the development of complementary interests between cities and private corporations to support city marketing. Government agencies may realize the commercial value of the data that is gathered for the purpose of public administration and offer that data to provide economic development opportunities in their communities. ICTs are changing the speed and efficiency of many industries, including cities. ICTs enable cities to personalize marketing media to individual organizations seeking to invest/relocate to a city.

Investing in the technology infrastructure can improve a city's services and operations and, therefore, enable it to effectively meet important stakeholder outcomes such as advancing health, safety and welfare. To illustrate, in the police and emergency areas, systems that monitor key performance indicators can significantly improve services such as response time. Computer assisted dispatch and mobile data terminals combined with global positioning systems enable reduced response times by providing the geographic information and route in the field. Similarly, field reporting systems that allow officers to generate reports on offenses and incidents real time improve description accuracy and efficiency.

The strategy map example developed in Figure 1 is a strategic tool that provides an illustration of how city planners can drive improvements in key performance indicators. Developing a strategic group map is part of strategic management and should reflect a city's mission, vision and values and be based on an analysis of the internal and external environment (strengths, weaknesses, opportunities and threats) as well as key success factors for a given city (Matherly, El-Saidi & Martin, 2008) . For instance, the vision articulates the image a city seeks to attain in the future and a community survey could determine what the overall image/reputation of the city is with key stakeholders. Collecting and analyzing data on each of the performance indicators in each category will reveal whether the causal paths are correct. For example, the implementation of specific ICT applications and marketing initiatives should result in improved operations. Improvements in operations, such as timelier turnaround for service and accuracy in transactions, are predicted to result in a better reputation and image for a city with internal stakeholders. Similarly, investments in customer relationship management and external marketing should result in improvements in external stakeholder reputation and therefore, more targeted economic development.

CASE STUDY APPLICATIONS

There are numerous examples of successful applications of ICTs in city management and marketing. In Killeen, Texas, U.S.A., a city of 110,000+ in central Texas, over 89% of the population uses ICTs. Citizens perform a myriad of activities on the city's website such as:

- obtain permits and licenses
- view council meetings or review past minutes
- check city documents and/or regulations
- obtain police accident reports
- verify book availability at the library
- view pets available for adoption
- look up and pay their utility bills
- obtain demographic information
- check airline flight schedule/status
- check for upcoming events
- register for park and recreation events
- obtain records requests

Using CRM, the city can track and evaluate the effectiveness of solicitation campaigns. By integrating ICT and marketing applications, the CRM system provides more effective outreach, tourism, and recruiting campaigns, resulting in targeted economic development. GIS capabilities allow citizens to determine the location of utilities, schools, churches, etc. Other forms of ICT include a government television channel, automated telephone systems, email and mass email services, text messaging and internet streaming. Websites bring a host of information to the citizens, promote city activities, enhance citizen involvement, aid in the adoption of pets using online files and result in greater citizen participation in city programs.

Thousands of internal and external users access web-based services daily affording the city new opportunities to market itself. This marketing outreach would not have been possible before the advent of ICTs. GIS fosters collaboration among service providers. Any street address can be displayed in GIS including work orders, building permits, code enforcement cases, occupational licenses and garage sales. New development websites target developers, homebuilders and prospective property buyers. These websites become portals of information for prospects and display sites for development review files including, for example, subdivision master plans, plats and commercial site plans. They give the city a competitive advantage by saving customers a trip to city hall.

The city of Charlotte, North Carolina uses the balanced scorecard and strategic group maps to facilitate communication and strategic planning as well as drive improvements in key performance indicators (Kaplan, 1999). One of the objectives on the city's corporate balanced scorecard is to promote growth in targeted types of business. By using GIS, the police department was able to improve services and reduce the crime rate, i.e., advance the health, safety and welfare of the community and encourage economic growth. The ICT application facilitated the mobilization of municipal resources to address specific local problems and to track the condition of neighborhoods. Ultimately, the police department was able to determine the reasons for higher incidents of crime in targeted areas. Computer aided dispatching (CAD) and the use of lap-top computers enabled police to query information while traveling to their destination or before questioning the driver of a car stopped for a traffic violation.

The National League of Cities (NLC) of the United States (2007) cites several examples of stakeholder benefits from ICTs in its highlighted city practices. Albany, New York has an interactive map of the downtown area on its web site with links that provide more information about Albany such as investment opportunities, living in Albany, current news about Albany as well as links to City of Albany resources, economic development, government, media, professional affiliations and travel and tourism. The Downtown Albany Business Relocation & Development Package provides comprehensive information for stakeholders who want to invest in the future downtown area. Topics include: Empire Zone Benefits, Tech Valley Investments, Quality of Life, Parking/Transportation, Market Data, Financing Programs, Headlines/Testimonials, Entertainment District, Downtown Living, and Downtown Development. Clay County, Kansas, seven cities, and a water conservation district collaborated to create a suite of web sites with a shared events database. The web sites provide expanded opportunities for marketing and economic growth. Rock Hill Rocks is a sports marketing campaign to showcase the city of Rock Hill, South Carolina, to promote its world-class venues and to attract visitors from across the country. The campaign includes a sports web site and sports marketing brochure. Adel, Georgia invested in the technology infrastructure to provide high-speed wireless Internet services to its citizens. The city used the existence of the service, as well as its reputation for having a high level of service, as a marketing tool to attract new businesses and encourage economic growth.

Additionally, Fort Wayne, Indiana implemented lean manufacturing and six sigma (quality improvement) by bringing business applications and philosophies to city management (George, 2003). Claiming that providing excellent services to its citizens is part of "e-City," the city launched a total of 60 projects over a 3 year period that saved almost $3 million. Fort Wayne's free wireless network covers 85 percent of its citizens, including 87 schools, 2000 teachers, 54,000 students, and all libraries and airports. The broadband network facilitates online learning for teacher training and makes it easier for parents and teachers to communicate. Innovative programs undertaken include virtual diabetes diagnosis with retinal scans and the "Net Literacy" program, in which young people teach seniors about computers.

The NLC in 2008 provides additional examples of creative ICT and marketing applications that resulted in improvement in strategic performance indicators such as economic growth--examples from Colorado, Texas and California are discussed in the following paragraphs. Englewood, Colorado's Citywide Computer Coaching Network is a cost-effective approach for developing employees and meeting the internal training needs of city employees. Computer training is delivered by peer-trainers through traditional classroom instruction, brown bag sessions, and one-on-one coaching. Coaches are not technology professionals, but city employees who volunteer their time to teach the practical skills they use on an everyday basis. By leveraging the knowledge and skills of internal resources, the City is able to deliver effective training at a fraction of the cost typically associated with technical training. This unique approach to internal training has dramatically reduced the costs associated with technical training because expenses are limited only to the costs of copying handouts and materials.

In response to a low unemployment rate and surplus of new jobs and companies, Austin, Texas shifted the focus of its economic development strategy from attracting new businesses (a lagging indicator) to recruiting and training workers (a leading indicator). AustinAtWork.com is an online recruitment tool which gives a job applicant Web access to search for jobs and submit a confidential skills profile. Job postings and profiles are matched based on pertinent criteria, and both employer and job seeker are notified. The software also allows employers to conduct on-line interviews and skill testing with job candidates. In its first year, over 1,000 jobs were posted and over 20,000 candidates (15 percent from outside the area) visited AustinAtWork.com.

Sunnyvale, California's Patent and Depository Library, which had been in operation since 1963, was outmoded and expensive to operate. To maintain and update the service, the city partnered with the U.S. Patent and Trademark Office to create the Sunnyvale Center for Innovation, Invention and Ideas (SCI3). The Center (1) assists entrepreneurs and start-up businesses to use new technologies and (2) helps established firms maintain their competitiveness through better access to technological information which increased the number of technological jobs in the region (economic growth). SCI3 uses new technology to provide timely, accurate, and cost-effective patent, trademark and intellectual property information. It also offers direct on-line image access to the patent database, and has video conference capabilities.

Littleton, Colorado's New Economy Project uses the idea of "economic gardening," or growing jobs locally by creating a nurturing environment for entrepreneurs. The program provides sophisticated information services as well as tracking of best ideas, best practices, and best technology of select high growth companies. Some examples of services are tracking construction bids for architects, developing profiles for multimedia companies on their competitors, and finding investors for foreign companies. In addition, the city subscribes to GIS and database research services, keeping track of statistics on local businesses, running focus groups, and monitoring legislation, new product releases and trends in order to share marketing and other information with businesses. The project also seeks to increase networks and connections between industry, research facilities, universities, competitors, suppliers, and customers. As part of the New Economy Project, the city sponsors the "econ-dev" Internet mail list of 300 economic developers worldwide interested in economic gardening. The investments in the technology infrastructure significantly led to more growth in the region.

The Glasgow City Marketing Bureau has been using leading-edge technology to promote Glasgow nationally and internationally. The prestigious Institute of Electrical and Electronic Engineers (IEEE) International Conference on Communications was broadcast live on Glasgow's Convention Bureau Website and viewed by more than 400 technology enthusiasts from around the world. The number of monthly page views on www.seeglasgow.com has grown from 800,000 to 1.8 million in 2007 (Glasgow, 2007).

The OECD (2003) provides numerous examples of international case study applications. Germany has implemented e-government, and in order to facilitate the smooth flow of information between citizens, business and the federal government has developed uniform, government wide standards, procedures and architecture for e-government applications. Given the complexity and coordination challenges across agencies, they recognized the importance of using standard procedures for a multitude of electronic services. Italy provides e-literacy training aimed at providing managers with the skills necessary to meet the organizational needs relating to e-government and innovation plans. IT literacy and technical skills are necessary to implement e-government, which results in better government. Delays in implementing new technologies will penalize economic development in a competitive, global and rapidly changing market.

These case study applications represent only a small portion of successful implementations of ICT and marketing initiatives but depict the importance and potential of marrying technology with marketing to improve internal processes, promote a more favorable image and meet stakeholder expectations. The effectiveness of specific ICT and marketing initiatives may vary depending on the municipality. So as to achieve improvements in lagging strategic performance indicators, each city should hypothesize and verify the major categories and variables in a strategic group map. By integrating the appropriate ICT and marketing initiatives in a causal path, a city will be better positioned to meet their performance excellence targets.

RESEARCH ON THE FUTURE ROLE OF ICTS AND CITY MARKETING

In the new electronic marketplace, selecting the appropriate technology requires taking a calculated risk and success is contingent on senior management support. Competitive advantage comes from integrating and aligning ICTs with the overall strategy and marketing plan—and doing so better and faster than the competition. However, implementing ICT initiatives can be expensive and difficult when there are project cost overruns and service failures (OECD, 2003). Descriptive research can determine what ICT and marketing applications are used most frequently across different municipalities. For example, a survey conducted in Mecklenburg County, North Carolina indicated that 44% of respondents in a community survey had accessed the County's website and were familiar with e-government services (2007). For those respondents who had used e-government services in the previous twelve months, the survey assessed their experience in four areas: convenience, navigation, accuracy and up-to-date information, and the likeliness to use the service again. Overall ratings averaged ninety percent customer satisfaction (Mecklenburg Community Survey, 2007).

Whether a city is successful in driving positive stakeholder outcomes needs to be verified by collecting data/research on the factors identified in the strategic group map. Causal research should investigate which applications are "best practices" and drive improvements in lagging indicators such as operations, service, or image and in the end, economic growth, e.g., those specified in the strategic group map in Figure 1. Research that uses path analysis which allows variables to act as both independent and dependent variables will be required to test a given strategic group map model (Byrne, 2001). For example, in a study on city management of cities > 50,000, West and Berman (2001) used a nonrecursive structure model and found that the use information technology was a significant predictor of management practices (e.g., management that promoted openness, support and risk taking) which, in turn, increased organizational effectiveness. However, controlling for management practices, information technology was not positively related to organizational effectiveness, nor was there a direct relationship between management practices and information technology.

Some fundamental issues to guide future descriptive and causal research posed as thought-provoking questions follow:

1. How do different cities use ICTs to improve service and market/ communicate their image? What are the most frequently used forms of ICTs for internal services/operations and external marketing?
2. What do we really know about how stakeholders make choices? How suitable is a city's website for meeting the divergent needs and wants of multiple stakeholders?
3. What do target stakeholders want from the city and an ICT? Working back from the customer, how well does the current system meet those needs?
4. How well does a given city's ICT capability compare to rivals—both now and in the future? Who are the "best in class" organizations worth benchmarking against?
5. What are the most effective ways for cities to reach and serve their markets? How effective are different uses and forms of ICTs in ultimately affecting stakeholder outcomes? What are the implications for technical expertise requirements and education?
6. How do stakeholders, e.g., potential investors, use information from the website? Can exchanges that create mutual value expand global and long-term stakeholder relationships that benefit the city? What is really known about traffic on the internet and it's potential value to the organization?
7. Who is accessing the city's website? How can that information be used to develop interactive relationships with stakeholders?
8. What specialist expertise and knowledge is necessary to incorporate rapid developments in ICTs? How are processes and services coordinated and aligned with shifting market requirements? How can an organization effectively adapt to changing customers, relationships, and markets?
9. What is the added value of and return on ICT applications? What determines the success or failure of an ICT initiative?
10. Do managers have the education and expertise to effectively integrate ICTs in strategic planning and marketing? How can this intellectual capital be increased?
11. How can stakeholder needs and priorities be incorporated into the latest communications, networking and interactive software and hardware?

CONCLUSION

The overall benefits for a city in integrating the use of ICTs and marketing as part of a strategic plan are effective direction of scarce resources to key business drivers that impact stakeholder satisfaction. In general, a strategy map provides a process for the city to articulate and execute its mission with regard to its key stakeholders by identification of key issues and focus on priorities, strategic activities, budgets and projects. By linking key performance indicators such as marketing and ICT initiatives to strategic areas of focus, management can provide the impetus for proactive, focused process improvement in internal processes and ultimately, stakeholder satisfaction. Future studies should examine the impact of investment in marketing and ICT initiatives on brand and image perceptions of a city. The results of stakeholder surveys on customer service, satisfaction and perceptions of the city identity are key performance indicators that can be reported on city scorecards.

Once the primary goals of a marketing plan are established, ICTs can be used to help improve a city's image and positively position a city in the evaluation of visitors, residents and businesses. Organizations will need an internet strategy and expertise to prosper in the new environment. It is incumbent upon management to ascertain if the objective and value are cost effective or to find the most effective communication mix at the least possible cost (Kerin and Peterson, 2007). The ability of the internet and ICT to disseminate large amounts of information to large numbers of stakeholders in an effective and efficient manner across the globe often results in a high value/cost ratio or a reasonable return for the investment.

Cities and countries differ in the extent of access to ICTs—wealthier countries have more investments in technology and are more accessible to external marketing communications (Shih, Kraemer & Dedrick, 2008). Improvements in a country's ICT infrastructure, human capital, institutional environment, e.g., economic freedoms and entrepreneurial activities determine the readiness of an emerging market to adopt the ICTs. Known as the digital divide that separates countries by the extent of access to ICTs (Gregorio, Kassicieh & De Gouvea Neto, 2005), cities on the less developed side of ICTs may find it difficult to market their cities on a regional or global basis while cities on the more developed side may be able to utilize first mover advantages that result in early adoption and improvement of key performance indicators such as economic growth. Recognizing the challenge of global connectivity and regional differences in ICT services, the International Telecommunication Union and European Commission committed to (1) support the development of human and organizational learning capital in technology, (2) standardize market and information policies across regions as well as (3) build the technology infrastructure for Africa, Asia-Pacific and the Caribbean (2008).

The development of ICTs in city management has profound effects on image marketing, communication and services while opening the paths to improve customer relationship management on an international scale. Successful deployment of ICT initiatives and investments in the technology infrastructure requires integration across organizational functions and relationships so that an organization's strategic approach reflects what is valued by the stakeholders.

Chapter 4.6

Managing Executive Information Systems for Strategic Intelligence in South Africa and Spain

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

José L. Roldán
University of Seville, Spain

ABSTRACT

Strategically important information for executive decision-making is often not readily available since it may be scattered in an organization's internal and external environments. An executive information system (EIS) is a computer-based technology designed in response to specific needs of executives and for decision-making. Executives having the "right" information for strategic decision-making is considered critical for strategic intelligence (SQ). SQ is the ability to interpret cues and develop appropriate strategies for addressing the future impact of these cues. In order to gauge the current situation in respect of information in an EIS and for managing future EIS development, the authors research EIS in organizations in two selected countries: South Africa and Spain. From their EIS study, parallelisms and differences are identified and implications for SQ are discussed. Some practical implications for future EIS development are given. The authors suggest these should be considered so that SQ for executive decision-making is facilitated.

INTRODUCTION

The focus of this chapter is twofold: (1) to discuss executive information systems (EIS) for strategic intelligence (SQ); and (2) to present EIS research from studies in South Africa and Spain and to discuss the SQ implications thereof when considering future EIS development in these countries.

This chapter is organized as follows: The concepts of strategic information and executive information systems (EIS) introduced. Executives having the "right" information for strategic decision-making is considered critical for SQ. A survey of EIS in organizations in South Africa and Spain is undertaken to identify the nature and sources of information included in these surveyed organization's EIS. The implications of this information for SQ for executive decision-making is then discussed. Some future EIS trends are noted and a conclusion is given.

Organizations use a wide range of technologies and products to help users make better business decisions. Strategic decision-making is often the result of collaborative processes. Strategically important information for executive management decision-making is often not readily available since it may be scattered in an organization's internal and external environments. Strategic information systems (IS) provide or help to provide, strategic advantage to an organization (Turban, McLean & Wetherbe, 2004). An increasing number of organizations are recognising the strategic significance of their information technology (IT) resources (Maier, Rainer, & Snyder, 1997).

An EIS is a computer-based technology designed in response to the specific needs of executives and for making both strategic and tactical decisions. An EIS is used by executives to extract, filter, compress, and track critical data and to allow seamless access to complex multidimensional models so that they can see their business at a glance. This facilitates executives making strategic and tactical decisions thereby leading to strategic excellence for their organizations. EIS have been successfully implemented in many organizations and in many countries.

SQ is defined as "*the ability to interpret cues and develop appropriate strategies for addressing the future impact of these cues*" (Service, 2006, p. 61). SQ systems are IS designed to provide information about competitors and the competitive market environment which can be helpful in making strategic management decisions (Mockler, 1992). The notion of SQ leads to strategic excellence (Service, 2006). Strategy is a journey of planning, implementing, evaluating and adjusting while paying attention and focus on the "right" things. Strategy does not deal with future decisions—it deals with decisions for the future. Executives must progress from strategic planning, to strategic thinking to strategic leadership through developing better SQ. In the past, strategy has been too much of a mechanical process and should shift away from a process-centered to a people-centered approach of thinking. However, it is somewhat harder for executives who are process-centered analyzers rather than people-centered synthesizers, who focus on the present rather than the future, to develop SQ. The first step is for executives to recognize that SQ exists and its importance for their organizations. One approach for accomplishing this is through scanning of the external IT environment.

Scanning is the behavior executives perform when they are browsing through data in order to understand trends or sharpen their general understanding of the organization (Vandenbosch & Huff, 1997). Empirical evidence suggests that a significant portion of executive time is spent scanning for information. Environmental scanning acquires data from the external environment for use in problem definition and decision-making.

An effective way to evaluate the success of an EIS is to obtain opinions from the executive users (Jirarchiefpattana, Arnott, & O'Donnell, 1996). Since managing EIS is important for organizations, the objective of this chapter is to present the empirical results of quantitative surveys on EIS in a sample of organizations in South Africa and Spain. Such results may serve to underpin managing future EIS development with a need to focus on strategically important information from internal and external environments for SQ. It remains the challenge for IS professionals to design IS to support and enhance the strategic scanning behaviors of executives in complex and turbulent environments. Information is the fuel for planning and "strategizing." Strategic focus on the "right" things, leads to developing a better SQ for executives; executives become better strategists and thereby provide strategic advantage to their organization. Most EIS facilitate search and scanning behaviors for executives.

In the next section, the background to strategic information (including strategic information systems) and executive information systems (EIS) are introduced. Thereafter EIS development, some EIS issues, Web-based systems and the right information are discussed.

BACKGROUND TO STRATEGIC INFORMATION AND EXECUTIVE INFORMATION SYSTEMS

Concepts of Strategic Information and Strategic Information Systems

Information is data that have been organized so that it has meaning and value to the recipient. The recipient (e.g., an executive) interprets the meaning and draws conclusions and implications from the data. Data items are typically processed into information by means of an IS application. Strategic information refers to the long-term nature of the processed data and to the significant magnitude of advantage it is expected to give to the organization. Strategically important information (intelligence) for executives is often not readily available and furthermore it is scattered in an organization's internal environments.

From the literature, there appears to be two types of strategic scanning information that can be identified for executives:

- **Accommodation information:** This is general surveillance information which is not necessarily coupled with a specific threat or opportunity to an organization; and
- **Assimilation information:** This is more specific and likely to be coupled to identifying strategic threats and opportunities to an organization.

Strategic IS (SIS) are systems that facilitate an organization gaining a competitive advantage through their contribution to the strategic goals of an organization. SIS is characterised by their ability to significantly change the manner in which business is conducted in order to give it an organizational strategic advantage. Any IS that changes the goals, products, processes or environmental relationships to help an organization gain competitive advantage (or reduce competitive disadvantage) is a SIS. An EIS is an example of a SIS.

Executive Information Systems (EIS)

EIS have experienced significant expansion since the 1990's as a result of facilitating internal and external pressures. In 1977 the first paper "Building EIS, A Utility for Decisions" by D. R. Nash appeared in the *DataBase* journal (Nash, 1977). Watson, Rainer, and Koh (1991) then set a landmark in the study of EIS practices by describing a useful framework for EIS development which encompasses three elements: (1) a structural perspective of the elements and their interaction; (2) the development process; and (3) the dialogue between the user and the system.

Following there, from several contributions in the literature show that a general view on EIS usage in different countries can be found (Allison, 1996; Fitzgerald, 1992; Kirlidog, 1997; Liang and Hung, 1997; Nord and Nord, 1995, 1996; Park, Min, Lim, & Chun, 1997; Pervan, 1992; Pervan and Phua, 1997; Thodenius, 1995, 1996; Watson, Rainer, & Frolick, 1992; Watson, Watson, Singh, & Holmes, 1995). Several other contributions show a general view on EIS use in different countries for example South Korea, Spain, Sweden, Turkey, United Kingdom, and the United States of America. While our EIS study in this chapter adopts a comparative approach and which is not frequent in EIS literature, comparative EIS studies by Park et al. (1997) and Xu, Lehaney, Clarke, and Duan (2003) do exist.

EIS grew out of the development of IS to be used directly by executives and used to augment the supply of information by subordinates. EIS is the only known mature IS dedicated to business executives (Tao, Ho & Yeh, 2001). Definitions of EIS are varied and all identify the need for information that supports decisions about the business as the most important reason for the existence of EIS. In this chapter EIS is defined as a computer-based system intended to facilitate and support the information and decision-making needs of executives by providing easy access to internal and external information relevant to meeting the strategic goals of the organization. While a definition is useful, a richer understanding is provided by describing the capabilities and characteristics of EIS.

Earlier studies described EIS capabilities which are focused on providing information which serves executive needs. Srivihok (1998) reports that these capabilities are concerned with both the quality of the system (e.g., user friendliness) and information quality (e.g., relevance). Sprague and Watson (1996) identify the following capabilities or characteristics of EIS:

- Tailored to individual executive users
- Extract, filter, compress, and track critical data
- Provide online status access, trend analysis, exception reporting, and “drill down”
- Access and integrate a broad range of internal and external data
- User-friendly and require little or no training to use
- Used directly by executives without intermediaries
- Present graphical, tabular and/or textual information

Other researchers suggest additional capabilities and characteristics of EIS:

- Flexible and adaptable (Carlsson & Widmeyer, 1990)
- Should contain tactical or strategic information that executives do not currently receive (Burkan, 1991)
- Facilitate executives’ activities in management such as scanning (see, for example, Frolick, Parzinger, Rainer & Ramarapu (1997) for a discussion on environmental scanning), communication and delegating (Westland & Walls, 1991)
- Make executive work more effective and efficient (Friend, 1992)
- Assist upper management to make more effective decisions (Warmouth & Yen, 1992; Chi & Turban, 1995)
- Incorporate an historical “data cube” and soft information (Mallach, 1994). A data cube is a structure in which data is organized at the core of a multidimensional online analytical processing (OLAP) system and soft information includes opinions, ideas, predictions, attitudes, plans, and so forth (Watson, O’Hara, Harp, & Kelly, 1996)
- Provide support for electronic communications (Rainer & Watson, 1995a)
- Enhanced relational and multidimensional analysis and presentation, friendly data access, user-friendly graphical interfaces, imaging, hypertext, Intranet access, Internet access, and modeling (Turban, McLean, & Wetherbe, 1999)

EIS may include analysis support, communications, office automation, and intelligent support (Turban, Rainer & Potter, 2005). From this data, executives are able to glean cues which may be used towards achieving SQ in an organization. It is therefore important that EIS are developed to facilitate information cues for executives. EIS development is now discussed.

EIS Development

Decision-making is recognized as one of the most important roles of executives. Executives are facing a business environment characterised by escalating complexity and turbulence. Given this environment, there is a need to have a clear understanding of the terms "complexity" and "turbulence" when developing EIS. These two terms are now discussed.

- **Complexity** generally refers to a large number of variables (many of which are perceived to be uncontrollable) making up a system. Complexity is defined as the degree to which an innovation is perceived as relatively difficult to understand and use. Unstable environments create strategic uncertainty for executives.
- **Turbulence** implies complexity with a high degree of change or dynamism added. Ansoff and McDonnell (1990) suggest that four characteristics contribute to the turbulence of the environment:
    - **Complexity** (the variety of factors that management must consider when making decisions)
    - **Novelty** (the discontinuity of successive challenges that an organization encounters in the environment)
    - **Rapidity of change** (the ratio of the speed of evolution of changes to the speed of the organization's change)
    - **Visibility of the future** (the predictability of information about the future, available at the decision time). The characteristics of information in a turbulent environment are complicated, novel, dynamic, or ambiguous (Wang & Chan, 1995)

Strategic uncertainty caused by business environment turbulence leads to increased demand for strategic information. Forsdick (1995) found that the overwhelming consensus of executives surveyed was that complexity implied a lack of understanding of the factors impacting on their organizations and that complexity was increasing over time. This researcher reports that approximately half the respondents in his survey saw turbulence as referring to the rate of change in uncontrollable external variables. Despite the availability of comprehensive reports and databases, executives take decisions based on their interactions with others who they think are knowledgeable about issues.

EIS development in organizations usually follows an evolving (or adaptive) approach instead of the traditional linear systems development life cycle. The initial application of the EIS should be small so that EIS developers can deliver a system quickly. A portion of the EIS is quickly constructed, then tested, improved and enlarged in steps. What makes EIS development particularly interesting and challenging is the unique combination of considerations that affect the effort. Watson et al. (1995) suggest three factors which are particularly relevant:

- An organization's senior executives are seldom hands-on computer users as they "*probably are of an age to have missed the computer revolution*" and may question the need for them now.
- Executives perform highly unstructured work that is difficult for them to describe with sufficient precision to identify information requirements.
- An EIS is typically a new type of application for systems analysts and often requires learning and using new technology and understanding managerial work.

From the above, it is evident that EIS development is a complex task which requires a large investment of time and money.

Some EIS Issues, Web-Based Systems and the "Right" Information Issues

It is critical that when an IS is defined it meets specific executive or manager information requirements. This is particularly true in EIS development. In the development of an EIS in an organization, one issue that should be considered is flexibility (Barrow, 1990; Srivihok, 1998). Salmeron (2002) reports that if this were not so, EIS would soon become a useless tool which would only deal with outdated problems and would therefore not contribute to decision-making. Without new or updated information, executives will be unable to ascertain whether their views of the environment and their organization's position within it remain appropriate. With the correct problem formulation, information assists executives establish options and select courses for action. Without the "right" information cues, executives may develop inappropriate strategies for addressing the future impact of these cues. SQ will therefore not be manifested.

Another issue is that EIS are high-risk information technology (IT) investments. Remenyi and Lubbe (1998) indicate that there is an increasing amount of IT investment and substantial evidence of IS failures in organizations. EIS has become a significant area of business computing and there are increasing amounts of money being invested by organizations in EIS development projects. Since EIS are highly flexible tools and since executives may behave in various ways to retrieve information from them, managing their successful development becomes that much more critical. Executives need to receive the "right" information cues from their organization's EIS.

A third issue is that EIS should be flexible to support different classes of business data: external, internal, structured, and unstructured. Examples of external data are from customer relationship management systems (systems intended to support customers) or news items (from external data sources). Enterprise resource planning (ERP) systems capture operational (internal) data in a structured format—SAP® is an example of an ERP system. Business processes represent internal data. Structured and unstructured data may be found in e-mails and Web sites. Web sites deal with both external (e.g., extranet) and internal (e.g., intranet) data sources. For example, EIS provide executives with access to external information such as news, regulations, trade journals, and competitive analysis. Some executives use their EIS to scan broadly across a wide variety of information external to the organization's databases (Vandenbosch & Huff, 1997). Organizational scanning activities can therefore be placed on a continuum from irregular to continuous scanning.

EIS products as a standalone application have started to disappear. Nowadays they tend to be included in larger IS or as a module integrated in ERP systems (e.g., SAP®). Furthermore there is a blurring of management IS (MIS), decision support systems (DSS) and EIS to business intelligence (IS) systems. According to Negash (2004) "*BI systems combine data gathering, data storage, and knowledge management with analytical tools to present complex internal and competitive information to planners and decision makers*" (p. 178). A key driver behind the uptake of BI solutions is the need to remove a degree of the uncertainty from an organizational business process and replace it with genuine intelligence. According to Cook and Cook (2000), the Achilles heel of BI software is its inability to integrate unstructured data into its data warehouses or relational data bases, its modelling and analysis applications and its reporting functions. In BI, intelligence is often defined as the discovery and exploration of hidden, inherent, and decision-relevant contexts in large amounts of business and economic data.

One problem with EIS development is that there may be technical issues to deal with, such as integrating EIS with an organization's existing business systems for access to internal, structured and unstructured data.

Another problem is that there are issues of trust and credibility of information that can be found in an EIS which mitigates against intensive executive reliance on IS. For example, if an executive is not receptive to new and unexpected accommodation or assimilation information; or if new information does not emerge during the scanning process, creative insights and improved decision-making may not arise. This may then result in an executive not paying attention and focus on the "right" things.

Web-Based Systems

With the emergence of global IT, existing paradigms are being altered which are spawning new considerations for successful IT development. Web-based technologies are causing a revisit to existing IT development models, including EIS. The Web is "a perfect medium" for deploying decision support and EIS capabilities on a global basis (Turban et al., 1999). Organizational success in accomplishing strategies is a function of how one arranges, develops, changes or uses an organization's systems. These systems, for SQ, should extend beyond automated MIS, IS and IT to include all (including Web-based) organizationally related systems. This is evident from the business environment since "the relevant physical and social factors outside the boundary of an organization that are taken into consideration during organizational decision-making" (Daft, Sormunen, & Parks, 1988).

The "Right" Information
