Library of Congress Cataloging-in-Publication Data

Strategic information systems : concepts, methodologies, tools, and
applications / M. Gordon Hunter, editor.
v. cm.
Includes bibliographical references and index.
Summary: "This 4-volume set provides a compendium of comprehensive advanced
research articles written by an international collaboration of experts
involved with the strategic use of information systems"--Provided by
publisher.
ISBN 978-1-60566-677-8 (hardcover) -- ISBN 978-1-60566-678-5 (ebook) 1.
Management information systems. 2. Information technology--Management. 3.
Strategic planning. 4. Management information systems. I. Hunter, M. Gordon.
HD30.213.S774 2010

Additional Research Collections found in the "Contemporary Research in Information Science and Technology" Book Series

Data Mining and Warehousing: Concepts, Methodologies, Tools, and Applications
John Wang, Montclair University, USA • 6-volume set • ISBN 978-1-60566-056-1

Electronic Business: Concepts, Methodologies, Tools, and Applications
In Lee, Western Illinois University • 4-volume set • ISBN 978-1-59904-943-4

Electronic Commerce: Concepts, Methodologies, Tools, and Applications
S. Ann Becker, Florida Institute of Technology, USA • 4-volume set • ISBN 978-1-59904-943-4

Electronic Government: Concepts, Methodologies, Tools, and Applications
Ari-Veikko Anttiroiko, University of Tampere, Finland • 6-volume set • ISBN 978-1-59904-947-2

Knowledge Management: Concepts, Methodologies, Tools, and Applications
Murray E. Jennex, San Diego State University, USA • 6-volume set • ISBN 978-1-59904-933-5

Information Communication Technologies: Concepts, Methodologies, Tools, and Applications
Craig Van Slyke, University of Central Florida, USA • 6-volume set • ISBN 978-1-59904-949-6

Intelligent Information Technologies: Concepts, Methodologies, Tools, and Applications
Vijayan Sugumaran, Oakland University, USA • 4-volume set • ISBN 978-1-59904-941-0

Information Security and Ethics: Concepts, Methodologies, Tools, and Applications
Hamid Nemati, The University of North Carolina at Greensboro, USA • 6-volume set • ISBN 978-1-59904-937-3

Medical Informatics: Concepts, Methodologies, Tools, and Applications
Joseph Tan, Wayne State University, USA • 4-volume set • ISBN 978-1-60566-050-9

Mobile Computing: Concepts, Methodologies, Tools, and Applications
David Taniar, Monash University, Australia • 6-volume set • ISBN 978-1-60566-054-7

Multimedia Technologies: Concepts, Methodologies, Tools, and Applications
Syed Mahbubur Rahman, Minnesota State University, Mankato, USA • 3-volume set • ISBN 978-1-60566-054-7

Virtual Technologies: Concepts, Methodologies, Tools, and Applications
Jerzy Kisielnicki, Warsaw University, Poland • 3-volume set • ISBN 978-1-59904-955-7

Contents

Volume I

Section I. Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of strategic information systems. Chapters found within these pages provide an excellent framework in which to position strategic information systems within the field of information science and technology. Individual contributions provide overviews of strategic intelligence, strategic decision making, and decision support systems, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of strategic information systems.

Section II. Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of strategic information systems. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful management information systems, data warehouses, and decision support systems are discussed.

Volume II

Section III. Tools and Technologies

This section presents extensive coverage of the technology that informs and impacts strategic information systems. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support the emergence and advancement of strategic information systems. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Section IV. Utilization and Application

This section introduces and discusses the utilization and application of strategic information systems. These particular selections highlight, among other topics, optimizing the relationship between business and information technology, applications of decision making and support systems, and the ways in which strategic intelligence has been applied in society. Contributions included in this section provide excellent coverage of today's strategic environment and insight into how strategic information systems impact the fabric of our present-day global village.

Volume III

Section V. Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of strategic information systems around the world. Chapters included in this section analyze organizational knowledge management, e-collaboration, and group decision support systems. The inquiries and methods presented in this section offer insight into the implications of strategic information systems at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Section VI. Managerial Impact

This section presents contemporary coverage of the managerial implications of strategic information systems. Particular contributions address firm performance as it relates to IT strategy, the nature of knowledge in the IT workforce, and the effectiveness of strategic implementation. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how strategic information systems can inform their practices and behavior.

Volume IV

Section VII. Critical Issues

This section addresses conceptual and theoretical issues related to the field of strategic information systems, which include failures and successes in system implementation. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters also address service quality in supply chain management, petri nets, and privacy and security in customer relationship management. Overall, contributions within this section ask unique, often theoretical questions related to the study of strategic information systems and, more often than not, conclude that solutions are both numerous and contradictory.

Section VIII. Emerging Trends

This section highlights research potential within the field of strategic information systems while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight advancements in enterprise resource planning, strategic technology planning, and strategic decision making for Green IT. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Preface

Over the past decade, the strategic use of information systems has played an invaluable role in the explosion of information technology. However, adopting a strategic information system is rarely successful without the necessary care and attention. In today's fast-paced, on demand economy, implementation of information systems is a high risk, high reward decision. The impact of a thorough understanding of all vital aspects, ranging from specific mechanics of a system to the theoretical impact and future development, cannot be underestimated when investing in an information system.

Now, with the widespread use of strategic information systems and the efficiency expected by consumers in many industries, there is a call for greater research and development and for efficient systems in an ever widening spectrum of business, governments, and education. To keep up with the demand for newer and better systems, practitioners and researchers must keep abreast of the current research.

In order to provide the most comprehensive, in-depth, and recent coverage of all issues related to the development of cutting-edge strategic information systems, as well as to offer a single reference source on all conceptual, methodological, technical and managerial issues, as well as the opportunities, future challenges and emerging trends related to the development of strategic information systems, Information Science Reference is pleased to offer a four -volume reference collection on this rapidly growing discipline, in order to empower students, researchers, academicians, and practitioners with a comprehensive understanding of the most critical areas within this field of study.

Entitled "Strategic Information Systems: Concepts, Methodologies, Tools, and Applications," this collection is organized in eight distinct sections, providing the most wide-ranging coverage of topics such as: 1) Fundamental Concepts and Theories; 2) Development and Design Methodologies; 3) Tools and Technologies; 4) Utilization and Application; 5) Organizational and Social Implications; 6) Managerial Impact; 7) Critical Issues; and 8) Emerging Trends. The following provides a summary of what is covered in each section of this multi -volume reference collection:

Section 1, **Fundamental Concepts and Theories**, lays a foundation for the extensive research in the following sections. It begins with "The Nature of Strategic Intelligence, Current Practice and Solutions,“ by Mark Xu and Roland Kaye which complements the essential theories in "Strategic Alignment Between Business and Information Technology," by Fernando José Barbin Laurindo, Marly Monteiro de Carvalho and Tamio Shimizu. "Decision Support Systems," by John Wang and David J. Radosevich also provides an important perspective into how DSSs have changed the way business view information technology. Another consideration is discussed in "The Evaluation of Decision-Making Support Systems' Functionality," by Giusseppi Forgionne and Stephen Russell. This chapter includes an important discussion of how to best quantify and assess decision making systems. This section also includes chapters on the concepts underlying the effect of strategic systems with chapters like "Strategic Decision Making in

Global Supply Networks" by Ozlem Arisoy and Bopaya Bidanda, "Leveraging Supply Chain Management in the Digital Economy" by Mahesh S. Raisinghani, and "Information and Knowledge Perspectives in Systems Engineering and Management for Innovation and Productivity Through Enterprise Resource Planning" by Stephen V. Stephenson and Andrew P. Sage. These chapters provide a basis for further research and innovation.

Section 2, **Development and Design Methodologies**, illustrates the fundamental nature of the development stage. Selections such as "Strategic Technology Engineering Planning" by practitioners Tony C. Shan and Winnie W. Hua, "Design Science: A Case Study in Information Systems Re-Engineering" by Raul Valverde, Mark Toleman, and Aileen Cater-Steel, and "Design and Development of a Quality Management Information System," by M. Sakthive, S. R. Devadasan, S. Ragu Raman and S. Sriram, introduce the reader to all of the various facets of developing strategic systems that can ensure success or cripple a project from the start. Other chapters like "Data Warehouse Design to Support Customer Relationship Management Analysis" by Colleen Cunningham and Il-Yeol Song, "Designing Clinical Decision Support Systems in Health Care: A Systemic View" by Wullianallur Raghupathi, and "A Framework for a Scenario Driven Decision Support Systems Generator," by M. Daud Ahmed and David Sundaram provide specific examples of these critical underpinnings. "Challenges in Developing a Knowledge Management Strategy: A Case Study of the Air Force Materiel Command," by Summer E. Bartczak, Jason M. Turner and Ellen C. England, and "A Methodology for Developing Integrated Supply Chain Management System," by Yi-chen Lan and Bhuvan Unhelkar complete this section's treatment of current design and development research.

The chapter "Intelligent Agents in Decision Support Systems" by Gloria E. Phillips-Wren begins the next section, **Tools and Technologies**, with a discussion of how web-based, distributed systems can combine with artificial intelligence techniques to aid decision makers. "Agents and Multi-Agent Systems in Supply Chain Management: An Overview" by Pericles A. Mitkas and Paraskevi Nikolaidou charts the current advances in applying multi-agent systems to supply chain management and is complimented by chapters such as "Beyond Intelligent Agents: E-sensors for Supporting Supply Chain Collaboration and Preventing the Bullwhip Effect" by Walter Rodriguez, Janusz Zalewski and Elias Kirche, "Intelligent Supply Chain Management with Automatic Identification Technology" by Dong Li, Xiaojun Wang, Kinchung Liu, and Dennis Kehoe, and "Supply Chain Management and Portal Technology" by Scott Paquette. Supply chain management is not the only sector affected by the research in this section. Chapters like "An Ontology-Based Intelligent System Model for Semantic Information Processing," by Mark Xu, Vincent Ong, and Yanqing Duan, "A Knowledge Integration Approach for Organizational Decision Support" by Kee-Young Kwahk, Hee-Woong Kim and Hock Chuan Chan, and "Mobile Technologies in the New Zealand Real-Estate Industry," by Eusebio Scornavacca and Federico Herrera, provide perspective into the current tools that are setting trends reaching across many different industries.

Section 4, **Utilization and Application,** introduces research conducted on what is often the crux of any innovation. The actual worth of a system is in its proper use, and chapters like "I-Fit: Optimizing the Fit between Business and IT" by Alea Fairchild, Alea Fairchild, Piet Ribbers, Erik van Geel and Geert Snijder, "Managing Executive Information Systems for Strategic Intelligence in South Africa and Spain" by Udo Richard Averweg and José L. Roldán, and "An Application of Multi-Criteria Decision-Making Model for Strategic Outsourcing for Effective Supply-Chain Linkages" by N. K. Kwak and Chang Won Lee chronicle how best to ensure proper application. This is never more important than in healthcare, discussed in "Nonparametric Decision Support Systems in Medical Diagnosis: Modeling Pulmonary Embolism" by Steven Walczak, Bradley B. Brimhall and Jerry B. Lefkowitz, and "Decision Making by

Emergency Room Physicians and Residents: Implications for the Design of Clinical Decision Support Systems," by Michael J. Hine, Ken J. Farion, Wojtek Michalowski, and Szymon Wilk, and "Decision Support Systems for Cardiovascular Diseases Based on Data Mining and Fuzzy Modelling" by Markos G. Tsipouras, Themis P. Exarchos, Dimitrios I. Fotiadis, Aris Bechlioulis and Katerina K. Naka. In these chapters, and in this entire section, the reader is given a clear understanding of the dynamics involved in applying and using decision support systems.

Understanding and quantifying implementation strategies is an important part of applying strategic systems, but also necessary for understanding the issues created by these systems. Section 5, **Organizational and Social Implications,** presents ways that strategic systems affect the preexisting "human systems." "Supporting Distributed Groups with Group Support Systems: A Study of the Effect of Group Leaders and Communication Modes on Group Performance" by Youngjin Kim, and "Supporting Structured Group Decision Making Through System-Directed User Guidance: An Experimental Study" by Harold J. Lagroue III, both consider how to aid group decision making. Other chapters, including "E-Collaboration Using Group Decision Support Systems in Virtual Meetings" by Jamie S. Switzer and Jackie L. Hartman, "K-link+: A P2P Semantic Virtual Office for Organizational Knowledge Management" by Carlo Mastroianni, Giuseppe Pirrò and Domenico Talia, and "Organizational Culture for Knowledge Management Systems: A Study of Corporate Users" by Andrew P. Ciganek, En Mao and Mark Srite, broach the topic of organizational management. "Organizational Readiness Assessment for Knowledge Management" by Kaveh Mohammadi, Amir Khanlari, and Babak Sohrabi and "Strategic Alliance Capability: Bridging the Individual Back into Inter-Organizational Collaboration" by Christiane Prange, look at two specific issues in organizations, discussing how these systems can affect and enable knowledge management. Lastly, this section includes a look at a number of contexts through chapters such as "SHRM Portals in the 21st Century Organisation" by Beverley Lloyd-Walker and Jan Soutar, "Ethnographic Discovery of Adverse Events in Patient Online Discussions: Customer Relationship Management" by Roy Rada, "The Factors Influence Suppliers Satisfaction of Green Supply Chain Management Systems in Taiwan," by Hsiu-Chia Ko, Fan-Chuan Tseng, Chun-Po Yin and Li-Chun Huang, and "The Strategic Implications of E-Network Integration and Transformation Paths for Synchronizing Supply Chains," by Minjoon Jun and Shaohan Cai.

The next section, Section 6, **Managerial Impact,** delves into the concerns created by and solved by humans managing these systems. The first chapter "IT-Enabled Strategy: Implications for Firm Performance?" by Paul L. Drnevich discusses some of the opportunities that information systems offer to enhance performance, as well as identifying potential pitfalls. "Building the IT Workforce of the Future: The Demand for More Complex, Abstract, and Strategic Knowledge" by Deborah J. Armstrong, H. James Nelson, Kay M. Nelson, and V.K. Narayanan builds on this discussion by exploring the necessary mindsets required by a fully modern business. One of these shifts is the subject of "Managing Knowledge Capabilities for Strategy Implementation Effectiveness" by Sineenad Paisittanand, L. A. Digman and Sang M. Lee, in which the authors researched the effect of knowledge process capabilities on strategy implementation effectiveness. Also included in this section are chapters addressing topics related to customer relationship management, human resources, and financial management, presenting the complete, empirical view of how strategic systems affect the modern management of resources.

Section 7, **Critical Issues,** highlights the reasons for failure and success of system implementation and utilization. The following chapters are an important reference for both researchers and practitioners, featuring case studies and recent developments. The selections "Information System Development Failure and Complexity: A Case Study," by Abou Bakar Nauman, Romana Aziz and A.F.M. Ishaq, "Empirical

Assessment of Factors Influencing Success of Enterprise Resource Planning Implementations” by Fiona Fui-Hoon Nah, Zahidul Islam, and Mathew Tan, and “A Strategic Framework for Managing Failure in JIT Supply Chains” by Jaydeep Balakrishnan, Frances Bowen, and Astrid L.H. Eckstein provide case studies and examples from functioning business and organizations. These selections give real-time problems and solutions that are invaluable when it is necessary to avoid any pitfalls. Chapters like “Information Feedback Approach for Maintaining Service Quality in Supply Chain Management,” by R. Manjunath, “Towards Stable Model Bases for Causal Strategic Decision Support Systems” by Christian Hillbrand, and “Supporting Demand Supply Network Optimization with Petri Nets” by Teemu Tynjala, explore how to approach and solve problems that develop from using strategic information systems. This section also includes chapters addressing more delicate ethical issues, as in “Security Policies and Procedures” by Yvette Ghormley and “Privacy and Security in the Age of Electronic Customer Relationship Management” by Nicholas C. Romano, Jr and Jerry Fjermestad.

Lastly, Section 8, **Emerging Trends**, provides an exciting view of the cutting-edge research currently being conducted. “Enterprise Resource Planning (ERP): Past, Present and Future” by Ronald E. McGaughey and Angappa Gunasekaran is an excellent overview of the present and an insightful look into the future areas of development. Ashley Davis’s contribution, “Enterprise Resource Planning Under Open Source Software,” explores the possibilities and critical factors offered by open source software. The expansion of strategic information systems is the subject of such chapters like “The Dynamics and Rationality of Collective Behavior within a Global Information System” by Jacek Unold, “Toward an Interdisciplinary Engineering and Management of Complex IT-Intensive Organizational Systems: A Systems View” by Manuel Mora, Ovsei Gelman, Moti Frank, David B. Paradice, Francisco Cervantes and Guisseppi A. Forgionne, “Strategic Technology Planning for the Techno-Global Economy: Cities in the Market” by Al D. McCready, and “Enhancing Decision Support Systems with Spatial Capabilities,” by Marcus Costa Sampaio, Cláudio de Souza Baptista, André Gomes de Sousa, and Fabiana Ferreira do Nascimento. Innovation is also taking place where strategic systems are common as shown in “Strategic Decisions for Green Electricity Marketing: Learning from Past Experiences” by Marta Pérez-Plaza and Pedro Linares, “The Future of Supply Chain Management: Shifting from Logistics Driven to a Customer Driven Model” by Ketan Vanjara, and “System Dynamics Modeling for Strategic Management of Green Supply Chain,” by Ying Su, Zhanming Jin, and Lei Yang. This section forms an invaluable aid for spurring on further research and creating new applications to aid all areas of future societies.

Although the contents of this multi-volume book are organized within the preceding eight sections which offer a progression of coverage of important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore, to ensure that the scholar, researcher, and educator have access to the entire contents of this multi-volume set, as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited, multi-user electronic access to the online aggregated database of this collection for the life of the edition free of charge when a library purchases a print copy. In addition to providing content not included within the print version, this aggregated database is also continually updated to ensure that the most current research is available to those interested in strategic information systems.

Strategic information systems will undoubtedly continue to become increasingly important to all facets of life in a modern society. Therefore, a complete understanding of the concepts and research offered in this book will be instrumental to the achievement of any structured goal whether in business, government, education or even daily life. Although strategic information systems promise to effectively manage all facets of an organization, experience has proved that only through careful and responsive implementation can these promises be fulfilled completely. These volumes are the building blocks to reach the desired functionality.

The diverse and comprehensive coverage of strategic information systems in this four-volume, authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamentals while also fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of strategic information systems.

Strategic Information Systems:
An Overview

M. Gordon Hunter
University of Lethbridge, Canada

ABSTRACT

This introductory chapter presents an overview of the field of Strategic Information Systems. To begin, the concepts of strategy and information systems are introduced to provide a context for the subsequent discussion. Then themes are identified via a review of existing literature. This review provides further context within which implications for the future are proffered. The chapter concludes with a call to researchers to further investigate this varied and intriguing field of study.

INTRODUCTION

What is the field of study called "Strategic Information Systems" about? Is it about information systems that are strategic? Is it about information systems that support strategy? Is it about how strategy and information systems should be aligned? The answer to these three questions is "yes". This chapter accepts the above myriad of interpretations of strategic information systems and presents a review of the many varied concepts and issues.

A perspective on the interpretation of these terms is that information technology may be used to represent the components of infrastructure, such as hardware and telecommunications. Then, the term information system (which would encompass these infrastructure components) also includes the processes, both manual and automated, which support business operations and eventually, in relation to the organization's strategic direction, contributes to competitive advantage. However, in this chapter information systems and information technology will be used interchangeably, mainly because their use throughout the literature reviewed here is not entirely consistent. That is, in this discussion they will mean the same thing. In general, information systems (and in this chapter information technology) exist to gather data and transform that data into information to support decision making within an organization. These decisions may be made at various levels within the organization. However, the eventual consequence of management decisions will relate to the overall business strategy. Thus, the information systems must provide support for the strategic direction of the organization.

So, whether the information system is strategic or that it supports strategic initiatives it is an important consequence that information systems be aligned with the adopted strategy of the organization.

A REVIEW OF THE EXISTING LITERATURE

The available literature provides a plethora of concepts and themes related to strategic information systems. This section of the chapter will first present a discussion of general concepts which provide a context for strategic information systems. The next part of the chapter will then focus upon themes which emerge from the literature. The research reported here relates to perspectives of overall approaches to strategic information systems. Specific applications are finally presented at the end of this section.

Concepts

The concepts discussed in this section describe various contexts within which information systems functions in relation to strategic initiatives. To begin, the case is made for evaluating information systems relating to their use in infrastructure and business processes. Next, competitive advantage will be facilitated through management of information resulting from information systems that appropriately reflect current business processes. A consideration for aspects beyond financial measures is introduced by the concepts of the Balanced Scorecard. Finally, alignment of information systems and strategy is discussed through the concepts of Six Sigma, Business Architecture, and the generic business model.

Any investment decision by an organization is usually accompanied by a calculation estimating the expected return to be gained. Investments in information systems have been subject to a similar evaluation approach. However, there seems to be issues which are related to information system implementation evaluation. (Brynjolfsson, 1993). With regards to the overall implementation of information systems there is an unclear delay in the period of potential payback from the initial investment. Further, current wisdom suggests that perhaps there should be a consideration for the differentiation between infrastructure investments and those meant to support and facilitate business processes (King, 2007). The infrastructure investments should be considered “table stakes” and are similar to other infrastructure items such as telephones and lighting. So, these investments should simply be considered a necessary part of being in the game. They should provide a minimum level of service in order to be considered successful. The investments in information systems which are related to facilitating business processes should most certainly be evaluated. Indeed, these investments will have important affects on performance and will eventually contribute to the organization’s competitive advantage. This is the perspective that should be taken by the decision makers.

Kadiyala and Kleiner (2005) investigated competitive advantage and present an overview of new developments in information systems. They suggest that information systems have an impact on the competitive advantage of the organization at the strategic level. The use of information systems will support better decision making and improved customer service. Better management of information will result in increased productivity. Overall, more certain strategic decisions will result in competitive advantage. Further, competitive advantage will be facilitated by the existence of current information systems. This means that the information system should reflect the current status of business processes.

The Balanced Scorecard (Kaplan and Norton, 1992) approach to performance measurement incorporates both financial and non-financial measures. The Balanced Scorecard includes four perspectives relating to customers, business processes, learning and innovation, and financial. The use of the balanced Scorecard approach results in a change of focus from achieving business objectives to identifying the information necessary to measure performance. Further, Epstein and Rejc (2005) propose to incorporate the Balanced Scorecard approach when evaluating information systems investments. They suggest this improved rigor will support the justification and evaluation of information system initiatives. Thus, based upon the four perspectives of the original Balanced Scorecard Epstein and Rejc (2005) propose that organizations must develop specific information systems related measurements. It is important, they note, that these measures be aligned with the overall corporate objectives. They conclude by suggesting a method for determining the appropriate measures for a specific organization. Also, the use of the Balanced Scorecard approach for the evaluation of information systems performance is also proposed by Huang and Hu (2007). They propose that through employing this approach alignment may be achieved between business strategy and the necessary information systems processes. They suggest that alignment is not a process but a mindset. Thus, alignment will drive the design, management, and execution of the information system function in concert with the strategic goals of the business. Finally, Hanafizadeh et al (2008) propose the use of the Balanced Scorecard to initially identify strategic business processes and then to ensure alignment of information systems investments with the strategic goals of the business.

The concept of alignment is also presented here through a discussion of the concepts related to Six Sigma, Business Architecture, and generic business model.

Six Sigma is a comprehensive system which contributes to improved business performance (Pande et al, 2000). The value of the method is that its use improves competitive advantage and supports a move to overall business excellence (Lawton, 2004). The Six Sigma application to information systems represents an important strategic initiative (Hsieh et al, 2007). The application of the method to process improvement projects facilitates alignment with the corporate strategic plan.

The Business Architecture concept (Versteeg and Bouwman, 2006) places responsibility over economic activities, or business domains, within an organization. A business domain is a function over which meaningful control may be implemented through appropriate business processes. The establishment of a Business Architecture will facilitate understanding of the business strategy and how the business processes relate to the strategy. In turn, direction will be taken in the design of information systems which will support the business strategy.

Hedman and Kalling (2003) describe components of a generic business model which may be employed to demonstrate the relationship between the business and information systems and to show how information systems relate to the broader business context.

The various concepts presented above serve to outline a number of perspectives regarding the context of information systems and their relationship with business strategy. In general, a strategic goal may be identified to establish and maintain competitive advantage. An important component of this initiative is the information system. The concepts outlined here suggest that alignment of information systems and strategic initiatives will facilitate improved performance and ultimately make a positive contribution to competitive advantage.

Themes

The themes which emerged from the literature about information systems and strategy relate to perspectives on the dynamic environments of both information systems and strategy; about knowledge sharing and knowledge management; and about the generic approach to business process improvement. These themes are presented in the context of ensuring information systems represent necessary business processes and are aligned with business strategy to ensure a positive contribution to competitive advantage.

The environment of both information systems and strategy is dynamic and continually changing. Beeson et al (2002) present a communication and decision making framework to facilitate responding to changing circumstances. This framework supports the linkage of business strategy with information systems development. Further, a close alignment of information systems and the strategy of the business are difficult to attain (Boddy and Paton, 2005). The environment of both information systems and the business is dynamic. While alignment will facilitate competitive advantage, a contingent approach will be necessary. Thus, Boddy and Paton (2005) suggest the use of semi-structures which entails a separate business unit to function in a temporary decentralized form. This autonomous and innovative business unit may be employed to counter the demands of stability for the existing business. In relation to information systems, then it is incumbent upon management to decide which projects reinforce stability and which foster innovation. Also, enterprise agility involves the ability to respond rapidly to environmental change (Overby et al, 2006). Thus an agile business will perform well in changing environments. Effective use of information systems will facilitate enterprise agility. Information systems should be used for both sensing and responding to rapidly changing environments.

Knowledge sharing facilitates strategic planning (Pai, 2006). Knowledge sharing may be enhanced by such organization structures as steering committees and strategic planning teams specifically related to information systems implementation. Knowledge sharing and transfer may be facilitated by such information systems as groupware and web-based applications (Lee and Bai, 2003). Also, knowledge sharing requires activities related to both knowledge contribution and knowledge seeking (Bock et al, 2006). In order to facilitate both contribution and seeking collaborative norms must be established within the business which promotes both of these activities. Knowledge management systems in general and specific systems such as SharePoint provide the platform for knowledge sharing. Further, knowledge sharing is also facilitated through the establishment of electronic knowledge repositories such as expert knowledge, lessons learned databases, and project web sites. (Fulk et al, 2004). Thus, the idea of Knowledge Management attempts to provide sustainable competitive advantage through the development of a strategy for effectively employing knowledge across a business (Barber et al, 2006). Knowledge management is more about connection rather than collections (Dougherty, 1999). That is, the management of corporate knowledge should focus on its transfer among appropriate individuals within the company. It is not sufficient to just gather data. It is necessary to ensure those who need the information are connected in a way that knowledge may be shared. The connection processes can be managed through the use of information systems.

The idea of attempting to improve businesses processes is not new. However, relating the improvement of business processes through appropriate use of information systems is relatively recent. Not too long ago, Hammer and Champy (1993) defined Business Process Reengineering (BPR) as follows:

The fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical contemporary measures of performance, such as cost, quality, service, and speed.

However, according to Ackermann et al (1999) the focus in practice regarding BPR has been on efficiencies such as cost reduction. This focus may be the result of assessing BPR initiatives based upon the bottom line. Thus, Ackermann et al (1999) propose a customer focus which will result in more of a consideration for the effective renewal of business processes.

Wheeler (2002) has proposed a net-enabled business innovation cycle (NEBIC) as a way to determine and evaluate a business' capability to employ digital networks to improve performance through increasing customer value. Hackbarth and Kettinger (2004) have employed NEBIC to evaluate how businesses use technology to support strategy. They determined that businesses follow one of two paths. One path, an incremental strategy employs a gradual approach to business process improvement. The second path, a leapfrogging strategy entails an approach of rapidly exploiting technology to achieve business innovation. When the external business environment is very competitive and the business experiences pressure to respond to market opportunities the second approach, leapfrogging is what firms tend to adopt.

Applications

While many information systems applications may contribute to the strategic initiatives of an organization, this section focuses on enterprise-wide systems which are able to provide a cross functional perspective on business operations and consequently make a contribution to competitive advantage. Thus, to begin, Enterprise Resource Planning (ERP) systems are discussed. Then the major modules within an ERP system are presented. These modules include, Customer Relationship Management (CRM), Supply Chain Management (SCM), and Human Resource Management (HRM). It is noted that these major modules facilitate a strategic emphasis on customers, suppliers, and employees.

Enterprise Resource Planning (ERP)

An Enterprise Resource Planning information system is an, *"information system that supports and integrates all facets of the business…"* (Jessup et al, 2008, p. 414)

It has been determined that 42% of corporate level information systems projects are terminated before completion (Wysocki, 1998). Further, projects involving business process re-engineering technology fail to meet their objectives in over 50% of the documented cases (Stewart, 1993; Roth and Marucheck, 1994; and Rohleder and Silver, 1997). More recently, Ettlie et al (2005) found that the potentially most hazardous information systems projects relate to the purchase and implementation of enterprise systems. They suggest the predictors of positive adoption performance are leadership (introducing learning to the workplace); business processes (adoption of new technology will change the business processes); and acquisition strategy (through the concepts of transaction cost economics potential benefits for adoption may be identified). Thus, ERP systems are both high risk and high reward.

Huq et al (2006) investigated the change management activities of three companies to understand the influence of the use of business process reengineering (BPR) techniques on the ERP endeavor. The authors found that the organizations experienced changes in their structure, organizational culture and management processes as a function of using BPR techniques to support the ERP implementation. Six change management issues:

- Leadership
- barriers to change
- communications
- implementation of change and control
- culture
- change review are important factors of consideration when implementing change

Cotteleer et al. (2006) investigated the degree to which changes in process dynamics affect operational performance. Using longitudinal case study data, the authors found that order fulfillment lead-time, a key performance indicator, demonstrated improvement after ERP system implementation. This suggests that performance enhancements do arise from the implementation of new ERP technologies.

Al-Mashari et al. (2003) developed a taxonomy of ERP critical factors to demonstrate the interrelationship between the uses of technology to support business strategies. In their taxonomy, the authors assert that ERP implementations occur in three stages (setting-up, implementation, and evaluation) with 12 factors of importance across these stages. The taxonomy highlights that ERP benefits are achieved when the implementation approach and the performance measures of the business are closely aligned. The authors suggest that leadership and commitment are the two key elements of ERP success.

Welch and Kordysh (2007) outline a number of aspects that contribute to successful ERP implementation and use. The key aspect relates to harmonization of business processes with the ERP system processes. Information system acquisitions must respond to business needs and consequently support strategic initiatives. Enterprise-wide information systems link the systems and the strategic objectives of the business (Ndede-Amadi, 2004).

Customer Relationship Management (CRM)

A Customer Relationship Management information system supports the, "…*interaction between the firm and its customers.*" (Jessup et al, 2008, p. 412).

Valos et al (2007) reviewed CRM through the lens of Porter's (1980) three generic marketing strategies. The strategies relate to the approach a business takes when dealing with markets and includes product differentiators, cost leaders, and product focus. In all cases, while CRM may be employed in different ways this specific information systems application does contribute positively to the strategy of the business.

Successful CRM systems (Yu, 2001) have common characteristics related to corporate culture (senior management support through major financial commitment); and an emphasis on technology improvement (including alignment between information systems and marketing).

An extension of CRM is electronic customer relationship management (eCRM). This approach employs technology to facilitate the gathering of data and interacting with customers. This strategic initiative has met with success by those companies investigated by Chen and Chen (2004). They determined that success factors for eCRM implementation and use related to similar aspects of successful generic information systems implementation. These factors include leadership; perceived usefulness; alignment; integration; and culture.

Lin et al (2006) support earlier work that suggests eCRM is an important strategy for business. They employ a modified version of Grant's (2003) strategic alignment model to evaluate the strategic impact of eCRM.

Nguyen et al (2007) suggest that a CRM system is not just another information tool. If applied properly, CRM programs can contribute exceptional economic value to the company as well as competitive advantage. They differentiate between CRM, eCRM, and mCRM based upon the use of current and leading edge technology. Implementation issues however relate to those commonly encountered in the implementation of generic CRM initiatives.

Supply Chain Management (SCM)

A Supply Chain Management information system manages the, "… *network of suppliers and subsuppliers that a company interacts with*." (Jessup et al, 2008, p. 421).

Lin and Tseng (2006) demonstrate the strategic importance of integrating operations with suppliers and customers through a supply chain management system. Supply chain management entails the business relationships between suppliers and the company. As more advanced technology is employed in this management process operations become more integrated between the company and the suppliers.

Human Resource Management (HRM)

A Human Resource Management information system provides technological support for the effective management of employees. (Haag et al, 2008).

The practice of Human Resource Management and the use of information systems can contribute to strategic initiatives (Ferratt et al, 2005) of the business. The strategic HRM literature offers three perspectives in this contribution. One perspective, the universalistic approach (Pfeffer, 1998), suggests that "best practices" exist which may be applied across organizations regardless of context. Another perspective, the contingency approach (Youndt et al, 1996) argues that business strategy affects HRM practice. The third perspective, the configurational approach (Doty and Glick, 1994) suggests that patterns of HRM practices exist and they are synergistic sets of practices that are complementary with the strategy of the business. This latter perspective provides the richest link between HRM practice and business strategy because of its incorporation of complex patterns of operation (Ferratt et al, 2005).

Byrd et al (2004) investigated the skill and experience of information technology personnel and the consequent affect on the competitive advantage of the business. They determined that a high level of knowledge and skill on the part of information technology personnel contributed to business competitive advantage.

Mayfield et al (2003) developed a comprehensive model representing the functions of human resource information systems. They determined that these systems are an essential factor in competent, learning organizations. As a consequence, the use of these systems leads to competitive advantage.

IMPLICATIONS FOR THE FUTURE

King (2007) suggests that organizations should focus on their core competencies and outsource other activities to specialist companies. This means that for the information technology organization it is important to identify the necessary core competencies, and retain them within the organization, to support the strategic initiatives of the business.

As Hoving (2007) suggests,

> *The challenges of IT leadership continue to increase. IT leaders need many talents to succeed: 1) innate knowledge of the technologies and natural intuition to know which ones are going to pay off; 2) business acumen and the fortitude to demand measurable returns; 3) the ability to manage a diverse set of internal and external resources within an ever changing set of value propositions; and most import; 4) the IT leader … has to be an executer with a keen sense of what it takes to get the right things done.* (Hoving, 2007, p. 153)

Hunter (2007) in his review of Chief Information Officer (CIO) management experiences suggests,

> *The future entails some exciting times for the CIO. For their business unit the CIO will be investigating the implementation of standards in the performance of duties. Staffing will continue to be an issue. Finding individuals with the necessary skills and ensuring they retain those necessary skills will require continual vigilance as business requirements evolve. Further, as the CIO is recognized within the com-*

pany as a fully fledged member of the senior management team there will be more of a requirement to contribute to the overall goals and direction of the company. The contribution to be made by the CIO and the information systems function will be in the appropriate application of technology in support of the company goals. It will still remain the purview of the CIO and the information systems function to be the source for ideas on the application of new technology. Again, it will be incumbent upon this area to show leadership in the appropriate use of any new and emerging technologies. (Hunter, 2007, p. 245)

CONCLUSION

This chapter has presented an overview of strategic information systems. It is important that information systems be aligned with the strategy adopted by the organization. An information system may be strategic itself or it may simply support strategic initiatives. In any case it is incumbent upon senior management to recognize the vital role played by information systems in relation to the strategic initiatives of the organization.

Information systems must be aligned with and function within the context of strategic initiatives. While post-implementation evaluation of information systems should be conducted, it may be prudent to incorporate non-financial measures into the assessment. Infrastructure components are necessary and should be evaluated based upon required service levels. The implementation of information systems to support business functions may be assessed using traditional financial measures. However, other criteria should also be adopted. These criteria could relate to intangibles such as better customer service; or improved decision making. Another consideration is the assessment of how the information system contributes to competitive advantage.

The current business environment is continually changing. Thus, information systems must be capable of responding dynamically to an elusive strategic target. As the business environment changes so too must the processes that support the business functions. Thus, information systems may be employed to facilitate continuous business process improvement. But information systems must go beyond simply processing data into information, and must facilitate the sharing and management of knowledge.

Further, alignment is the cornerstone of the relationship between information systems and strategy. Information systems must respond to and support the strategic initiatives of the organization.

Finally, this area of strategic information systems is a rich field for investigations. Researchers are encouraged to bring their expertise to the exploration of this topic. As shown above this is a dynamic environment for both information systems and strategic business initiatives. This ever changing field of study contains a plethora of new and interesting topics to investigate.

Section I

Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of strategic information systems. Chapters found within these pages provide an excellent framework in which to position strategic information systems within the field of information science and technology. Individual contributions provide overviews of strategic intelligence, strategic decision making, and decision support systems, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of strategic information systems.

Chapter 1.1

The Nature of Strategic Intelligence, Current Practice and Solutions

Mark Xu
University of Portsmouth, UK

Roland Kaye
University of East Anglia, UK

ABSTRACT

This chapter discusses the nature of strategic intelligence and the challenges of systematically scanning and processing strategic information. It reveals that strategic intelligence practice concentrates on competitive intelligence gathering, non-competitive related intelligence have not yet been systematically scanned and processed. Much of the intelligence is collected through informal and manual based systems. Turning data into analyzed, meaningful intelligence for action is limited to a few industry leaders. The chapter proposed a corporate intelligence solution, which comprises of three key intelligence functions, namely organizational-wide intelligence scanning, knowledge enriched intelligent refining, and specialist support. A corporate radar system (CRS) for external environment scanning, which is a part of the organizational-wide intelligence scanning process is explored in light of latest technology development. Implementation issues are discussed. The chapter develops insight of strategic intelligence, and the solution could significantly enhance a manager's and a company's sensibility and capability in dealing with external opportunities and threats.

INTRODUCTION

As the business environment becomes more turbulent and competition becomes fiercer, developing foresight about future opportunities and threats, and reacting quickly to the opportunities and threats, becomes a core competency of a wining organization. Companies that can generate competitive intelligence are leaders in their industry (Desouza, 2001). However the increasing demand for strategic information has not been satisfied by the explosive growth in data available. This is reflected in two facets: firstly, computer-based information systems are inadequately implemented at the corporate level for strategic information delivery; secondly, senior managers who go online always feel overwhelmed with the glut of data instead of meaningful, actionable information. Research which applies computing technology to support strategic management activities concentrates on the development and the implementation of computer-based systems for decision support. Systems such as decision support system (DSS), executive information systems (EIS), or executive support systems (ESS) are examples. Strategic management process however is more than an activity of making decisions (Simon, 1965), the process begins with strategic information acquisition, formulating strategic problems, reasoning strategic alternatives, and finally making a decision. There is a distinction between supporting managers with strategic information and supporting making decisions. Information systems tend to emphasize decision-making support more than strategic information support. Senior managers' information acquisition processes have not been adequately addressed in the context of information systems development, except the field of competitive intelligence (Cobb, 2003; Pelsmacker et al., 2005; Patton & McKenna, 2005; Sauter, 2005) and Web-based information searching systems (Chen, Chau, & Zeng, 2002). Supporting strategic intelligence activity with information technology is an area remaining largely unexplored. This chapter aims to address the nature of strategic intelligence and the challenges, and to explore the possible solutions towards improving organizational strategic intelligence process.

DEFINITIONS OF STRATEGIC INTELLIGENCE

The term of strategic intelligence is often used interchangeably with other terms: data, information, intelligence, and knowledge. There seems to be no generally agreed definitions towards these terms, but they are different in the context of this chapter as follows:

Data is the raw material of organizational life; it consists of disconnected numbers, words, symbols relating to the events, and processes of a business. Data on its own can serve little useful purpose.

Information comes from data that has been processed to make it useful in management decision-making. Intelligence in most cases is referred to competitors' information (CI), or competitive intelligence or the totality of external information (Baatz, 1994). Competitor intelligence has often been regarded as a process of collecting and processing competitors' information following a CI cycle, which includes identifying the strategic needs of a business, systematically collecting relevant information on competitors, and processing the data into actionable knowledge about competitors' strategic capabilities, position, performance, and intentions. However, the boundary of competitor's intelligence has always been extended to include not only competitor's information, but also market and environment information for strategic decision. For example, Tyson (1990) defines competitor intelligence as an analytical process that transforms raw data into relevant, accurate, and usable strategic knowledge, more specifically, it includes:

- Information about a competitor's current position, historical performance, capabilities, and intentions.
- Information about the driving forces within the marketplace.
- Information about specific products and technology.
- Information external to the marketplace, such as economic, regulatory, political, and demographic influences that have an impact on the market.

Baatz (1994) refer the term “corporate intelligence” to the collection and analysis of information on markets, technologies, customers and competitors, as well as socio-economic and external political trends. Another term, business intelligence (BI) has been prevalent in the IT industry. Business intelligence is a process that its input is raw data; the data then is evaluated for usefulness to a relevant and reasonably reliable body of information; the analyzed, digested, and interpreted information thus becomes intelligence. The term “strategic intelligence” used in this chapter means strategically significant information to senior managers that is scanned, analyzed, digested, and is meaningful that could affects senior managers’ beliefs, commitments, and actions. The entire process of turning original data from both external and internal environment into intelligence is referred to intelligence activity.

Data, information and intelligence are closely linked to knowledge. Knowledge refers to totality of information related to policy, problem or issue whether it is quantitative or qualitative, data or opinions, judgements, news or concepts. According to Nonaka and Takeuchi (1995), knowledge is “justified true belief”; it is a dynamic human process of justifying personal belief towards the “true.” Information provides a new point of view for interpreting events or objects, which makes visible previously invisible meanings or shed light on unexpected connections. Thus, information is a necessary medium or material for eliciting and constructing knowledge. Information affects knowledge by adding something to it or restructuring it. Nonaka and Takeuchi (1995) further point out that information is a flow of messages, while knowledge is created by that very flow of information, anchored in the beliefs and commitment of its holder.

THE NATURE OF STRATEGIC INTELLIGENCE AND CHALLENGES

Strategically significant information is not a piece of static information that is readily available from certain sources. It is often derived from a sense making process that requires managerial knowledge and judgement. Strategically significant information can be viewed from different perspectives.

Internal vs. External Orientation

Strategic information has an internal or external orientation. Aguilar (1967) suggests two types of strategic information: *External strategic information* is information about events or relationships in a company’s external environment that may change the company’s current direction and strategy. *Internal strategic information* is information about a company’s capacity and performance that significantly affect a company’s strategic implementation. Because strategic decision is primarily concerned with external problems of a firm, the external orientation of strategic information has been emphasized by many researchers. Mintzberg (1973) reports that managers demonstrate a thirst for external information. This is supported by Macdonald (1995), who argues that change in an organization is seen as a process in which the acquisition of external information is critical. Yet, empirical research supporting this notion is limited. In contrast, Daft, Sormunen, and Parks (1988), reveals that senior managers rely as much on internal discussions and internal reports as they did on external media or personal contacts, senior mangers use internal and external source about equally. This view is reinforced by D’Aveni and MacMillan (1990) who found that managers of successful companies pay equal attention to both internal and external environments of their companies, but only during times of crisis, these managers focus more heavily on the external environment, which suggests that there may be a linkage between external information needs and the extent of environmental stability.

We anchor the view on internal-external orientation of strategic information (Xu & Kaye, 1995) by drawing an analogy between a manager navigating his company and driving a car, that is, managers cope with external changes by adjustments to the internal controls. Internal information is vital for controlling the operation, but cannot determine the direction of navigation. External information is of strategic importance, since strategic decisions are primarily long term with a balance towards external focus, whereas operational decisions are primarily short term and have an internal focus. External information is more dynamic and uncertain than internal information, and appears more difficult and costly to obtain than internal information. This poses a challenge of obtaining strategic intelligence from external environment.

Historical vs. Current, Future Orientation

Strategic information is also associated with its historical and future dimension. Information needed for performing routine tasks of daily operation and for short-range decisions will be different from information needed for long-range analysis and planning. Long term planning requires information about the past as well as projections of future conditions. Research (McNichol, 1993) suggests that senior managers demand more future and current information than historical information. This confirms Mintzberg's (1973) argument that managers indicate strong preferences for current information, much of which is necessarily unsubstantiated, and for information on events rather than on trends. Historical, aggregated information from the traditional formal information system provides little help in the performance of manager's monitoring role. Mintzberg's (1973) summarize the information that executives received into five categories:

- **Internal operations:** Information on the process of operations in an organization, and on events that take place related to these operations, comes from regular reports, ad-hoc input from subordinates, observations from touring the organization.
- **External events:** Information concerning clients, personal contacts, competitors, associates, and suppliers, as well as information on market changes, political moves, and developments in technology.
- **Analysis:** Executives receive analytical reports of various issues, solicited and unsolicited, come from various sources.
- **Ideas and trends:** Chief executives develop a better understanding of the trends in the environment, and to learn about new ideas by using a number of means such as attending conferences, glancing at trade organization's reports, contacting with subordinates, paying attention to unsolicited letters from clients.
- **Presses:** In addition to the usual types of information, chief executives receive information in the form of presses of various kinds, that is, from subordinates, clients, directors or the public, with which the chief executives must allocate their time and efforts to deal with.

The issue concerned here is the right balance between receiving historical, current and future oriented information by executives.

Raw Data vs. Filtered, Refined Information

Contradictory views exist towards if executives prefer analyzed information over factual raw data. Bernhardt (1994) argues that managers prefer analyzed information to detailed raw data, as analyzed information adds meaning and makes sense of the data. He believes that managers do not need lorry loads of facts or information; they need an analytical intelligence product, delivered on time, and in a format that can be easily and quickly assimilated. The analytical intelligence product shall be factual, meaningful, and actionable information. It has been revealed (Taylor, 1996) that current information systems produce sheer volume of data but little meaningful information to senior managers. Increasingly providing senior managers direct access to operational data and leaving them to their own devices is a disservice to the organization, as it creates the problem of "data deluge" and the frustrations that arise from time wasted in trying to assemble meaningful information from raw data. Data deluge and information meaningless runs the risk of compromising the advances of colourful, graphic design of an EIS. Even with graphic-interface, high-speed communications, and data-warehousing technology, it is extremely difficult for a decision maker to review thousands of products, hundreds of categories. When adding the task of looking outside, at the world of the competitors, suppliers, customers, and the environment, identifying critical changes becomes a daunting task. Finding the problem becomes the real problem, that is, data can be too much for an executive to spot trends, patterns, and exceptions in detailed data. Thus data may need to be refined in order to be useful. Wright, Pickton, and Callow (2002) reveals that the most common problems in disseminating intelligence is making the information and structure relevant to the audience while being brief yet useful. Wyllie (1993) defines information refining as a social-technological process that enables intelligent human beings to extract and organize systematically the key items of knowledge kept in any given choice of information sources. The purpose of the process is to enable people from executives downwards to be better and more widely informed, while at the same time, reducing the amount of time they have to spend to keep up with headlines on media. The result of the refining process should be to bring about better, more informed decisions.

However, managers' demand for refined information has been questioned. Edwards and Peppard (1993) argue that refined information that reaches the top management team is likely to be distorted. The distortion may not be conscious, but due to the assumptions and knowledge used in handling the information, bring to bear on it. This suspicion is in line with the notion (Daft et al., 1988) that as strategic uncertainty increase, senior managers will want to form their own impression through direct contact with key environmental sources to ensure that data is undiluted and does not suffer from the loss of meaning associated with passing information through intermediaries. Mintzberg (1980) observed that managers clearly prefer to have information in the form of concrete stimuli or triggers, not general aggregations, and wish to hear specific events, ideas and the problems.

The issue concerned is whether strategic intelligence is more likely to be derived from refined data other than from data in its raw fashion. However, the debate is continuing but inconclusive.

Formal vs. Informal Systems

Strategic intelligence may be gathered from formal or informal systems. A formal system for information acquisition is defined as one with a set of procedure to follow, and is systematically used in regular basis, for example, the competitive intelligence cycle. An informal system is in contrast to the formal system that managers do not trace a map route from beginning to the end, and is intuitively used in ad hoc basis. Research suggests that managers often ignore formal systems, and in favour of informal systems for strategic significant information. Mintzberg (1980) argues that as a result of the distinct characteristics in information acquisition, managers often ignore the formal information system, as it takes time to process information. Managers therefore develop their own contacts and establish special communication channels to obtain information. Managers spend most of their time gathering information through less formal systems.

Empirical studies support the speculation that CEOs obtain most information through informal, irregular, human systems. In a study of executives of British Airways, Cottrell and Rapley (1991) found that the majority of executives spend their time in face-to-face or verbal contact (telephone or intercom) with peers and subordinates both inside and outside the organization. Most of the information is received in an unstructured way. Executives spend little of their time in reading or looking at highly structured information in reports or on computer screen.

The tendency towards using informal system by executives for intelligence poses a challenge to developing computer-based intelligence system that has often been regarded as a formal system.

Solicited vs. Unsolicited Intelligence

The terms "solicited searching" and "unsolicited searching" are rooted in social cognition theory regarding whether information scanning is directed by managers' intention or not (Kiesler & Sproull, 1982). In directed search, managers have intentions or objectives, exert efforts to scan information; in undirected search, managers follow perceptual process, which is relatively unaffected by intention and efforts. Aguilar (1967) used the term to appraise the effectiveness of managers' information scanning process, and managers' behavior in information acquisition: that is, whether the scanning is active or passive. If managers obtain most of their information on a solicited basis, their performance could be questioned on the grounds that they are not sensitive enough to valuable information other than what they actively seeking. In other words, solicited information may limited a manager's vision as the manager only knows what the manager wants to know, but not what is needed to know.

Managers appear obtaining more unsolicited information than solicited information. Information from outside sources tends to be largely unsolicited, whereas information from inside sources is largely solicited. This tends to suggest that unexpected information is more likely to be regarded as strategic intelligence than solicited information. If this speculation is substantiated, there shall be a system to proactively feed managers with unexpected intelligence.

Information Specialist Support vs. Managers' Own Scanning

Senior managers may need specialist to support them in information acquisition and processing, because managers' information acquisition pattern tends to be informal and in ad-hoc basis. Schmitz, Armstrong, and Little (1992) revealed that senior managers often lack time which will not allow them the luxury to sit at a terminal and deal with their information needs. They argue that it is still remains primarily the work of staff members to access and decipher the necessary information for senior managers. Langley (1996) cited a managing director, saying "technology on its own could not add value without the input of people who understood the business problems and the meaning of the data." As more information is collected from external environment, information processing becomes more complex, this necessitates the selection of personnel with analytical skills to work with such complex information (Ramaswami, Nilakanta, & Flynn, 1992). Frolick (1994) has taken this view forward and argues that executives need information specialists to support them using EIS. He describes that EIS is no longer for executive use only, rather, many other organizational non-executive personnel use it. For example, the middle level managers who spend a great deal of their time preparing report for executive consumption. The support-staff members include such individuals as the executive's secretaries. Information system does not require hands-on use by executives themselves. The executives would delegate the use of EIS to these individuals and have them bring back printed reports or conveying the message to them by daily summaries, presentations, exception reports, and so forth. EIS increasingly designed to be used by most, if not all, knowledge workers. This raises a critical question as to whether strategic intelligence should be processed by intelligence specialists or solely by executives' themselves?

EMPIRICAL STUDIES ON COMPETITIVE INTELLIGENCE IN PRACTICE

Many empirical studies related to strategic intelligence concentrate on competitive intelligence. Wright, et al (2002) conducted a study to examine how UK companies conduct competitive intelligence through questionnaire and interviews. The study examined the attitude of gathering competitive intelligence, strategies for intelligence gathering, use of intelligence and organizational locations of the intelligence function. Two types of intelligence gathering are identified: (a) easy gathering—firms use general publications and or specific industry periodicals and consider these constitute exhaustive information, and (b) hunter gathering—in additional to easy gathering, companies conduct own primary research on competitors. CI function within an organization are either in ad-hoc location—no dedicated CI unit within the organizational structure, and intelligence activities are undertook on ad hoc basis, typically, by the marketing or sales department, or in designated locations—specific CI function established within the organization with staff working full-time on monitoring competitors and competitive environments. Pelsmacker, et al. (2005) report through a comparative study of CI practice between South Africa and Belgium that companies in both countries are not well equipped with and not active to conduct effective CI, especially in the areas of planning, process and structure, data collection, data analysis, and skills development. CI-activities are not organized in a separate department, and if they are, are mostly done in the marketing and sales department. Sugasawa (2004) adds further evidence by showing that there is a strong interest in CI in Japan, but Japanese companies do not apply any specific analytical methodology to analyze intelligence. Dissemination of intelligence was primarily in written form rather than by electronic means. Computer-based systems are mainly used for intelligence storing and extracting.

In addition to ethic, lawful intelligence gathering by organizations, Crane (2004) suggests that many tactics are currently being used to gather industry espionage. The tactics take forms from clearly illegal, such as installing tapping device, stealing information, to rather more grey areas, this includes searching through a competitor's rubbish, hiring private detectives to track competitor's staff, infiltrating competitor organization with industrial spies, covert surveillance through spy camera, contacting competitors in a fake guise such as a potential customer or supplier, interviewing competitors' employees for a bogus job vacancy, and pressing the customers or suppliers of competitors to reveal sensitive information about their operations. Other means include conventional market research and competitor benchmarking through market scanning, industry profiling, debriefing of managers recruited from competitors.

An earlier study on competitive intelligence systems in the UK was conducted and reported by Brittin's (1991), which shed light on how companies gather and use competitive intelligence. As the findings tend to be comprehensive in terms of the CI cycle, the results are revisited and presented in Table 1.

Brittin's (1991) study reveals that competitor intelligence systems were primarily manual-based in practice. Intelligence gathering relies on managers, data analysts, and sales force. Most intel-

Table 1. Competitor intelligence systems (Source: Brittin, 1991)

	Competitors monitored / Kind of Information	Information sources used	CI Systems	Data analysis	Output / dissemination
Case 1 **A large financial institution**	25 ~ 30 competitors ❶ Financial performance, ❷ specific competitive activities.	Companies house, Stock Exchange, Broker's report, Press Cutting Services, Electronic sources, Consultant, Meetings, Dinner party circuit.	Personnel in the Research Department (manual-based)	Manual-based data analysis and evaluation by the Data Analysts. Hypertext system in Apple Mac is used to store data.	Information disseminating project is to be developed in the form of briefing papers.
Case 2 **A distribution company**	10 competitors 90% ~ 50% external information	Trade and Business Press, Online services (e.g., Dialog, data-Star), Sales force monthly report, Competitor's trade literature, Consult and employees.	Manual-based system by the Marketing Intelligence Manager and one assistant	Use SWOT analysis, but a lot digging and guess work. No computerized database, Data stored in filing cabinet.	❶ Monthly bulletin to managers with analysis. ❷ A spin-off publication for public consumption. ❸ Twice yearly report for managing director. ❹ Ad hoc reports
Case 3 **An engineering company**	About 300 competitors ❶ All aspect of competitor activity ❷ Market information	Published information, Trade journals, statutory company accounts, customers, employees.	Computer-based system in Business information unit	PC-based European competitor database, Mainframe MIS, Computerized data summarizing, and manual-based qualitative data analysis	Newsletters (including solicited and unsolicited information of competitors)
Case 4 **A chemicals company**	500 on a regular basis ❶ Competitors and ❷ Competitive products ❸ Environment	Newspapers, journals, on-line databases (e.g., Dialog) business associations, FT Business Resource Centre Imp/exp. statistics, products literature	Computer aided system in Corporate Information Department	Abstracts have been put into full-text database. Others in filing cabinet. Data is not analysed	❶Daily press scanning report ❷Specific information bulletins ❸Commercial business news bulletin for senior management ❹Ad hoc inquiry reports in various format.
Case 5 **An automotive company**	About 10 competitors ❶ Competitor's strategic intention, ❷ 90% ~95% external information	News-type databases covering the industry, company reports, press releases, promotional materials, trade show	Manual-oriented system in Business Planning Department	Data is analysed, interpreted A lot of intelligent guesswork, but limited data modelling and statistics	Presentations (90%) -computer slides, and hard copies.

ligence is collected from sources both inside and outside the organization. In terms of processing intelligence, very little sophisticated data analysis techniques are used; much of the data analysis is based on intelligent guesswork. Collected data was frequently sent to managers without any degree of analysis and interpretation. Sugasawa (2004) who reported intelligence practice in Japan confirmed a lack of sophisticated intelligence analysis.

Case Study: An Insurance PLC

Bata Insurance Group Plc[1] is a worldwide insurance group operating in many countries with over 100 subsidiaries. In the UK the operating companies are divided by product and includes Beta General Insurance UK Ltd., Beta Life Insurance UK Ltd., Beta Insurance International Ltd., Beta Investment Ltd. The Group Holding Company comprises of several functional departments for example, Legal & Secretarial, Financial Control & Planning, Corporate Relations, International Division, and Strategic Research. The data were collected through action research by the author who participated in a CRM "Client Relationship Management" project in one of the operating companies. The Information Manager of the Group Holdings Company revealed the group's information searching systems for strategic intelligence. Table 2 presents the intelligence searching systems used by the group companies.

The major sources used to scan intelligence include:

- Use the city Business Library and the British Library Business Reference for research projects, and directories and handbooks such as Evandale's London Insurance Market Directory.
- **Subscription for newspapers and industry publications for manager's general information and background reading:** These include daily, weekly and monthly publications such as The FT, The Economist, DYP Newsletters-Europe, DYP Newsletters-Reinsurance, Best's Review—Property/

Table 2. Strategic intelligence systems

The Companies	The Intelligence Searching and Coverage
Beta Insurance Holding Plc	▪ Comparison of main UK competitors from financial results, share price tracking, and press releases ▪ Financial analysis of reinsurance companies from company reports and accounts ▪ Monitoring UK composite insurers from city analyst's reports and a press cutting service
Beta General Insurance UK Ltd.	▪ Press cutting services ▪ PC-based marketing intelligence system, searching extracts from publications (ESMERK) ▪ Data monitor reports on financial services ▪ Networking with competitors
Beta Life Insurance UK Ltd.	▪ Press cuttings ▪ Use of published surveys ▪ Market research association (external)
Beta Insurance International Ltd.	▪ AM Best's on CD ROM ▪ On-line news information services ▪ Competitors financial data ▪ "Soft" information database
Bata Investment Ltd.	▪ Datastream online services ▪ Bloombergs ▪ Contact with external analysts ▪ Track statistics on competitors

Casualty, Best's Review - Life/Health, Insurance Times, FT World Insurance Report, and so forth.

- **Subscription for CD-ROM and online business database:** For example, Datastream
- **Company reports and accounts** collected from city library, Insurance association
- **Economic reports** from banks, stockbrokers, and reports by analysts on the insurance industry
- **Other free publications received by directors and executive staff:** For example, "Insurance Today" (where the advertisements are paying for the copy), giving details of the UK market products and developments. "European Insurance Bulletin" which can keep top management abreast of happenings.
- **The Association of British Insurers (ABI) and the Chartered Insurance Institute (CII) that provide services on insurance statistics, references, and articles on specific topic**
- **Ad hoc intelligence collection by company managers and staff members:** One department of the company also analyzes the financial results of reinsurance companies, periodically reminds the users of the service throughout the group that any "market intelligence" news on reinsurance company being vetted be passed to them. Overseas managers on their UK visits are also asked to set up meetings with them to discuss the local market situation.
- **Computer-based market intelligence system:** Staff throughout the regions is asked to pass on any piece of news they hear about competitors or brokers to central co-ordinators. The database in the UK head office containing news items on competitors, articles from trade magazines, advertisements, and inter-company meetings is being made available over the network to the different areas.

It is reported that most members of the staff do not have the time to read and absorb all the information that is available. Therefore the information service workers look through most publications, mark up the articles of interest for cutting out, and file the data for any enquiry. This service is centralized to serve the whole group. On the other hand, some group executives (e.g., executives for overseas life operations) have made very little use of the research material available to them, as they had good personal contacts with a large number of people in other parts of the group. They naturally adapt at personnel networks for information gathering.

DISCUSSION

The empirical evidence suggests that external intelligence—primarily competitive intelligence and market/industry intelligence as reviewed above, has been addressed by many companies engaged in CI activities. A manager from Bata Group comments that "In today's rapidly changing business world the need for timely and accurate market intelligence will increase. We need to know what our competitors are doing almost before they do." The sources used for intelligence gathering are heterogeneous, but most intelligence tends to be gathered from public domain. Managers' intelligence needs are often fulfilled by using a broad range of approaches, which are characterized as manual-based and unsystematic tendencies. The current intelligence practice exhibits the following deficiencies:

- **Manual based:** Competitive intelligence is collected mainly by managers and information workers from various publications and general information sources. The current method of press cutting and searching is labour intensive. Computer-based intelligence systems are limited to data storage, retrieval, and CD-ROM/online database searching.

- **Intelligence scanning is ad hoc and the process is functionally divided:** Most organizations scanned intelligence irregularly. Scanning is commonly conducted by sales force, and relies on managers' own personal networks. Cobb (2003) argues established organizational CI processes often suffer from holes in data or data integrity causing errors in the interpretation of that data for intelligence purpose, and suggests that scanning activity will be accomplished by a separate, distinct department, unit, or individual that reports directly to the executives in the organization.
- **Lack of Filtering, Refining and Sense Making of Intelligence:** As revealed from the empirical studies, data scanned is not often filtered, processed, and interpreted into meaningful intelligence in required form before reaching the managers, and there is a lack of sophisticated intelligence analysis tools. This affirms Maier et al.'s (1997) assertion that the most common problem in the dissemination phase is making the information and structure relevant to the audience while being brief yet useful. Without data refining, providing increased data access and search facilities to senior managers can exacerbate the problem of data overload. However, filter and interpret intelligence through a systematic system faces great challenges, on the one hand, recognizing which data is of strategic importance needs management knowledge and judgement. Human cognition and intuition process often dominate interpreting, reasoning, and learning that are subtle. On the other hand, technology in semantic data searching, machine learning is limited to structured data analysis, but not to dynamic strategic intelligence. Even with intelligent system and knowledge based expert system, letting computers represent a great deal of human knowledge for data interpretation is still a challenge, since knowledge may not exist in a visible, explicit form for acquisition.

THE SOLUTIONS

Organization-Wide Intelligence Scanning

The way to avoid ad hoc intelligence scanning is to have systematic and organization-wide scanning systems. It is believed that systematic scanning of business environment for strategic information can improve the completeness and quality of strategic intelligence. Huber (1990) assert that the use of computer-assisted information processing and communication technologies will lead to more rapid and more accurate identification of problems and opportunities; and the use of computer-assisted information storage and acquisition technologies will lead to organizational intelligence that is more accurate, comprehensive, timely, and available. Environmental scanning: as defined by Maier, Rainer, and Snyder (1997) is a basic process of any organization, acquires data from the external environment to be used in problem definition and decision-making. The environment consists of all those events, happenings, or factors with a present or future influence on the organization that, at the same time, lies outside the organization's immediate control. The primary purpose of environment scanning is to provide a comprehensive view or understanding of the current and future condition of the five environmental constituents: social, economic, political regulatory, and technological. Scanning invokes a process of externalization, causing the company to expand the focus of decision-making to include the perspectives of outsiders, for example, present and prospective competitors, customers, regulators, stakeholders, and the perspectives of economic condition, political climate, technology development, social and cultural changes. An information scanning mechanism could ensure systematically collection of relevant, important information from various sources available both inside and outside a company.

The current practice of intelligence gathering significantly relies on managers and sales forces. This runs the risk of missing significant intelligence being noticed due to time constraints and limited capabilities of individual managers, and the narrow focus of sales and marketing staff. To maximize the effectiveness and efficiency of environmental scanning, organization-wide intelligence scanning is desirable and possible. Because organization members have wide contacts with a variety of external entities, also they work closely in the front-line to interface with company's customers, hence, a variety of intelligence can be gathered for the attention of senior managers. Organization-wide intelligence scanning should focus on scanning external environment for intelligence. The scanning function can be performed through formal, informal intelligence collecting/reporting systems or third party agency, which are suggested as below:

Intelligence Scanning Through Informal Systems

The informal systems for organization-wide intelligence scanning can include, for example:

- **Sales force report:** Companies can ask their field sales forces to gather up intelligence about competitors, suppliers, and customers, as well as market intelligence.
- **Business trip report:** Business trip report by managers who visited foreign markets. The managers are briefed before the trip by a member of the corporate business intelligence unit, and on their return report back with findings related to the issues and questions raised at the briefing.
- **Intelligence gathering box and online intelligence forum:** Every employee may have something to contribute in terms of competitive intelligence. A company should encourage its staff to contribute information on market, competitors, ideas and suggestions or even rumour, gossip and office grapevines by using an intelligence box or an online forum where valuable intelligence can be collected and rewarded.
- **Friday round tables:** A company can organize a series of round-table meetings in various locations, where a particular topic related to intelligence gathering is discussed. With the aid of a knowledge team facilitator, knowledge for intelligence scanning/processing is articulated, captured.

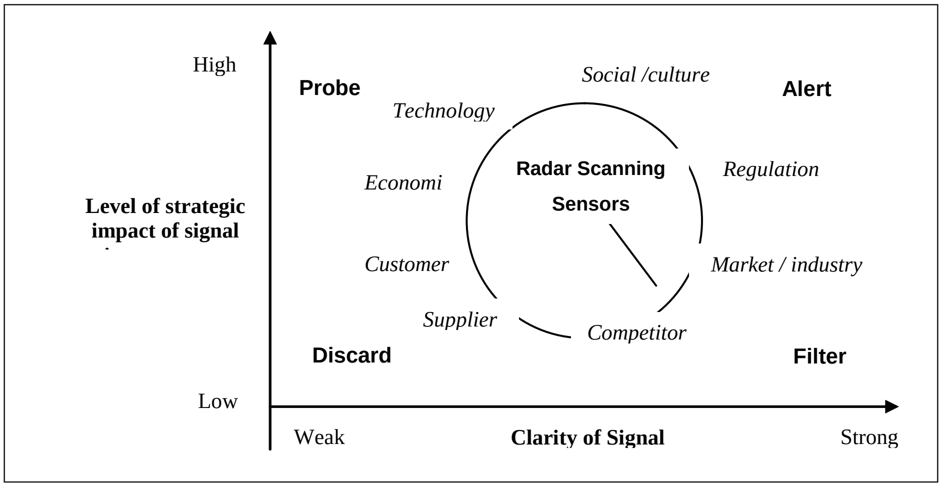
Structured Intelligence Scanning: A Corporate Radar System

Formal methods are needed to systematically collect external information. A company's intelligence centre, and intelligence workers have the responsibilities to fulfil intelligence scanning and analyzing tasks. In addition, computer assisted system shall be considered to enhance intelligence scanning. Business organizations could develop a radar-type system (or function) to continuously but selectively detect significant signals from environment sectors. A corporate radar system for strategic information scanning is depicted in Figure 1.

The radar scanning system works according to two main criteria: the clarity of the signals detected from the environment and the level of strategic significance of the signals. Center to the scanning is the sensor that continually detects all signals emerged from the business environment. Each signal detected will be handled by four distinctive and related processors according to the nature of the signal, i.e.

- **An alert:** If the signal detected is strategically important, and the signal is with strong clarity, that is, message is clearly stated and from reliable sources, the signal will be

Figure 1. A corporate radar system for environment scanning



alerted immediately as hot intelligence to executives.

- **A filter:** If many signals being detected but not all of them are of strategic importance, for example, information regularly received by the company from its environment, the signals have to be selected from a potentially large mass of data, and filtered for relevance. Because most of the signals are less important to derive strategic information, the filter function thus is vital to screen out irrelevant information and to eliminate information overload.
- **A probe:** The radar system may detect a weak signal but it may have potential strategic impact on the organization, the signal thus must be probed and amplified. Information as such is often less structured and not easily to obtain. Much of this type of signal may fall into the "soft" information category, that is, opinions, predictions, hearsay, ideas, rumours, and gossips. The vague signal needs to be verified, and amplified in order to assess its potential impact on the strategic direction of the organization.
- **A discard mechanism:** This is needed to handle large amount of weak signals that are not strategically important or relevant to the organization.

The aforementioned radar sensor, alert, filter, probe, and discard functions can be a computerized or a manual based system. Whatever it is, knowledge needs to be embedded within the system to underpin the operation of the radar system.

It is worthy to note that the environmental sectors for radar scanning may vary from one industry to another. We examined this in a previous study (Xu, Kaye, & Duan, 2003) that the significance of environmental sectors for scanning is industry specific. For example, in the computer industry, customer, competitor, market/industry, and technology sectors are more strategically important than other variables, showing that these sectors have high strategic impact signals. Thus the focus of radar scanning may need to be adjusted to target these environmental sectors. Stoffels (1994) addresses that "the strength of signals is related to the uncertainty of environment, that is, weaker signals are associated the remote environment, and strong signals with the task environment. The environment scanning effort is much required in the remote environment as the visibility of the future diminishes with increasing turbulence, and predictability deteriorates accordingly."

Using Third Parties to Carry Out Intelligence Gathering

A company may choose to use third parties to conduct intelligence scanning. External intelligence firms can be helpful in gathering and analyzing certain information. They can assist in synthesizing monthly intelligence, performing difficult information gathering tasks, and training employees. The third-party status also helps break down any political barriers that may exist within an organization. In this way the third party serves as a catalyst in the process. Tan, Teo, Tan, and Wei (1998) support this notion by asserting that use of external consultants results in effectiveness of environmental scanning. They explained that besides providing and interpreting information, external consultants have helped to equip organization with the knowledge and skills for doing environmental scanning on the Internet. These services include conducting courses on the use of Internet tools and compiling links to potentially useful information sources.

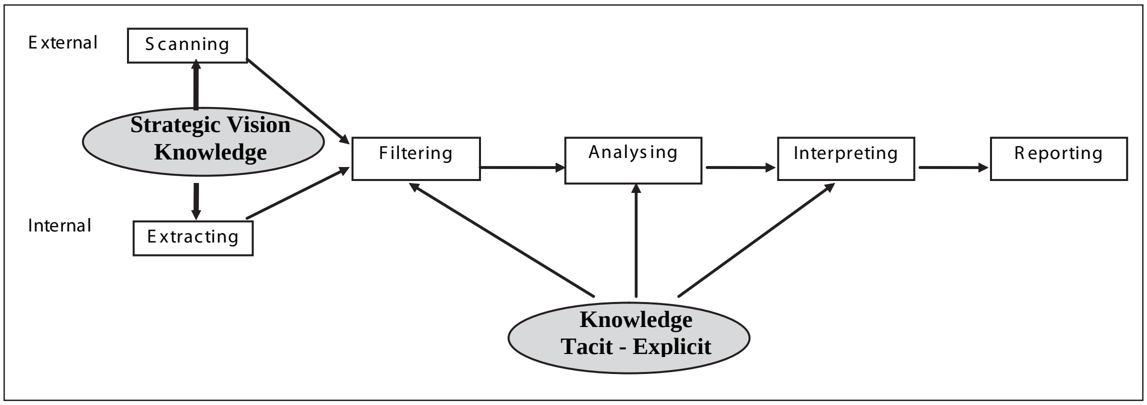
Organization-wide intelligence scanning is envisaged to enhance external intelligence scanning. However, systematically scanning the entire environment is both costly and inappropriate. A manager is interested in the environment that influences his decisions, hence, environmental scanning needs to be selective, yet ensure that sufficient variety is maintained to avoid missing important signals. Auster and Choo (1995) suggest that selecting which environment for scanning is effected by a variety of influential factors, for example, the turbulence of the environment, the difference of industry sectors, or the company's competition strategy. It can be argued from this study that for effective organization-wide intelligence scanning, making knowledge about which environment to scan explicit is vital.

Knowledge-Enriched Intelligence Filtering and Refining

In order to produce analytical intelligence product—meaningful and digestible information, it is vital to filter out irrelevant data and to refine data into meaningful intelligence. The current process of intelligence analysis is a human centred, knowledge intensive process, that is, relies on managers themselves and their knowledge and judgement. Thus the solution to refine intelligence must incorporate managerial knowledge used for intelligence scanning and analysis. Figure 2 shows the intelligence process by highlighting the knowledge enriched filtering and refining function.

As highlighted in the diagram, the intelligence scanning and refining (filtering-analyzing-inter-

Figure 2. Intelligence process with scanning, refining, and supporting function



preting) process should embed strategic vision and human knowledge. This can be achieved by:

- **Using intelligent agent-based system that uses knowledge base, case based reasoning, machine learning, or user feedback and interaction to semantic scanning and analysing intelligence according to user profile:** For example, intelligent agents could base on past information search activities and predefined information needs in "*user profiles*", which is generated by a learning agent, or defined by the user. The user profile can consist of executive's personal profile, executive's information needs and interests, executive roles, and organizational environment profile, which enable software agents to perform domain-specific acquisition, synthesis and interpretation of information. As a result, information processing becomes more personalized to the executive.
- **Creating a knowledge creation and sharing field/culture to turn tacit knowledge into explicit form so that employees**, particularly intelligence staff can be guided to detect and make sense of strategic significant information.

It is envisaged that computer based knowledge enriched intelligence scanning, refining can selectively and systematically scan and categorize, prioritize, and analyze large amounts of data on a continuous basis. Analyzed intelligence will report to, or alert managers to enlarge managers' vision on strategic issues by providing consistent, routine surveillance of a wide range and a variety of data that would not be possible with current management reporting techniques.

Knowledge Workers/Intelligence Specialist Support

Although computer-based intelligence system (scanning, refining) may be developed, it is evident that many senior managers may not wish to use such systems to acquire strategic intelligence due to the nature of managerial work. The advanced systems may be better used by intelligence specialists/knowledge workers, so that analyzed intelligence can be delivered to the senior managers by the specialists. If managers' information requirements can be predefined, the specialist will search necessary databases and the external environment to locate the information as required. If however, managers do not solicit information, the intelligence specialist can continually scan the external environment and proactively report significant intelligence (most of them probably are unexpected) to the senior managers via written or verbal communication channels. Less important information is consolidated, synthesized, and digested to a brief level that managers receive on regular basis. With the support of intelligence specialists, both internal and external data can be systematically scanned, filtered, synthesized, and reported in both regular and ad hoc basis through formal and informal systems.

The challenge however is that intelligence specialists need to possess managerial knowledge and similar judgement that managers use to acquire information. This relies on knowledge sharing. In addition, intelligence specialists need to have rich knowledge of information sources and skills in exploiting, evaluating, and interpreting information.

IMPLEMENTATION

Implementation of the above solution will inevitably require a change of vision, intelligence process, organizational structure and culture. Managers need to develop a strategic vision in order to give a company's intelligence activity a sense of direction. The purpose is to give corporate members a mental map of the world they live in and to provide a general direction as to what kind of intelligence they ought to seek and report. A strategic vision created by senior management helps foster a high degree of personal commitment from middle managers and front-line workers.

A common problem in establishing intelligence functions might be that most companies prefer not to devote resources to such a function until it can prove that the function is necessary and will succeed. Therefore, a visionary leadership is needed, who can perceive the benefits of strategic intelligence and provides support for developing the intelligence function.

What remains critical is how managerial knowledge can be elicited to underpin the radar scanning system, and the refining system. The knowledge spiral model (Nonaka & Takeuchi 1995)—sharing knowledge through socialization could facilitate the process of sharing experiences and turning tacit knowledge to explicit knowledge, for example, in the form of an intelligence gathering event, briefing, club, online discussion forum.

There is probably no one structure that can fit a variety of different organizations. The variety very much depends on the size of the firm, the type of the business, the degree of centralization or decentralization of its activities and decision-making. It is perfectly possible that a centralized intelligence function is established to coordinate organizational-wide intelligence activities and to operate the corporate radar system. This can overcome the data integrity problem that often resulted from functionally divided organizational CI processes.

In accordance with structural change, a knowledge creating and intelligence gathering culture need to be created. Organization-wide intelligence gathering relies on every member's commitment to intelligence activity. Environmental scanning is an essential behavior attribute of culture because scanning provides the first step in a chain that culminates in organizational actions (Saxby, 2002). The briefing on intelligence gathering, incentives, the informal networks form an intelligence culture. Senior managers must continually reinforce the desired culture traits through their own behavior.

CONCLUSION

This chapter reviewed the nature of strategic intelligence and highlighted the challenges of systematically managing strategic intelligence. Strategic intelligence is not a static piece of information that can be easily obtained. What constitutes strategic intelligence is subject to managerial judgement and sense making that requires managerial knowledge. The current process of intelligence activity is either divided by organizational function, or is ad hoc relying on individual manager. Intelligence gather is primarily concentrated on competitive intelligence. Computerized system has played limited role in intelligence scanning and analysis. There is a lack of systematic intelligence scanning, analyzing and intelligence support, and culture.

The solution proposed to improve strategic intelligence activity addresses three significant intelligence functions that constitute a systematic intelligence process. The organization-wide scanning and the corporate radar system will ensure continuous monitoring and scanning of all signals from the market, competitors, and customers, and the far environment. The refining function is enriched with managerial knowledge so as to filter out irrelevant information and ensure meaningful intelligence is reached executives. Intelligence specialists as an organization's knowledge workers will provide complementary support for executives who are not inclined to use formal intelligence systems.

Managing strategic intelligence cannot be subject to sole technical solutions. Enabling technology to assist managers in their intelligence scanning and analysis activities is a challenging task. Therefore, effective managing strategic intelligence will rely much on an organizational approach including illustration of organizational vision, sharing tacit knowledge, establishing an intelligence culture and redesigning the process of intelligence gathering, analysis, and dissemination.

Chapter 1.2

Strategic Alignment Between Business and Information Technology

Fernando José Barbin Laurindo
University of São Paolo, Brazil

Marly Monteiro de Carvalho

Tamio Shimizu
University of São Paolo, Brazil

INTRODUCTION

Information technology (IT) has assumed an important position in the strategic function of the leading companies in the competitive markets (Porter, 2001). Particularly, e-commerce and e-business have been highlighted among IT applications (Porter, 2001). Two basic points of view can be used for understanding IT's role: the acquisition of a competitive advantage at the value chain, and the creation and enhancement of core competencies (Porter & Millar, 1985; Duhan, Levy, & Powell, 2001).

Several problems have been discussed concerned with IT project results in effectiveness of their management. Effectiveness, in the context of this article, is the measurement of the capacity of the outputs of an information system or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive (Shimizu, Carvalho, & Laurindo, 2006).

There is a general consensus about the difficulty of finding evidence of returns over the investments in IT (the "productivity paradox"), even though this problem can be satisfactorily explained (Farrell, 2003). Carr (2005) defends the idea that IT in itself has no more strategic value, since it is so widely disseminated that it could not be a source of strategic differentiation anymore.

In order to better use these investments, organizations should evaluate IT effectiveness, which allows the strategic alignment of objectives of implemented IT applications and their results with the company business vision (Shpilberg, Berez, Puryear, & Shah, 2007; Laurindo & Moraes, 2006). Besides, it must be highlighted that if IT applications are associated with changes in business processes, it is possible to notice greater impacts in business performance (Farrell, 2003).

According to Benko and McFarlan (2003), three aspects must be taken into account about IT strategic alignment: IT projects portfolio, business objectives, and the constantly changing situation of business environment.

Thus, the comparison and evaluation of business and IT strategies and between business and IT structures must be a continuous process, since the company situation is constantly changing to meet market realities and dynamics.

THEORETICAL BACKGROUND

Finding Strategic IT Applications

The discussion about the strategic impact of IT applications started in the 1970s, when technology began to provide more powerful alternatives not only for solving companies' problems but also for increasing their business competitiveness (Shimizu et al., 2006).

One of the first important proposals for studying the strategic role of IT was that of *critical success factors* (CSFs), which is still a widespread method used for linking IT applications to business goals, and for planning and prioritizing information systems projects. This method was proposed by Rockart (1979) and states that the information systems, especially executive and management information systems, are based on the current needs of the top executives. These information needs should focus on the CSFs.

Rockart defines CSFs as the areas where satisfactory results "ensure successful competitive performance for the organization." This author states that CSFs' prime sources are the structure of the industry, business (or competitive) strategy, industry position, geographic location, environment, and temporal factors.

Basically, the CSF method includes the analysis of the structure of the particular industry and the business strategy, and the goals of the organization and its competitors. This analysis is followed by two or three sessions of interviews with the executives, in order to identify the critical success factors related to business goals, define respective measures (quantitative or qualitative) for the CSFs, and define information systems for controlling CSFs and their measures (Shimizu et al., 2006).

For Rockart, this process can be useful at each level of the company and should be repeated periodically, since CSFs can change through the time and also can differ from one individual executive to another.

The CSF method had an important impact on managerial and strategic planning practices, even though it was primarily conceived for information systems design, especially management and executive information systems.

Besides the utilization in information systems planning and information systems project management, it has been used in strategic planning and strategy implementation, management of change, and as a competitive analysis technique.

Furthermore, the continuous measurement of CSFs allows companies to identify strengths and weaknesses in their core areas, processes, and functions (Rockart, 1979).

More details of the process of implementation of the CSF method can be found in Rockart and Crescenzi (1984).

Understanding IT Strategic Role in Companies

McFarlan (1984) proposed the Strategic Grid that analyzes the impacts of IT-existent applications (present) and of an applications portfolio (future), defining four boxes, each one representing one possible role for IT in the enterprise: "Support," "Factory," "Turnaround," and "Strategic" (see Figure 1).

- *Support:* IT has little influence in present and future company strategies.
- *Factory:* Existent IT applications are important for the company's operations success, but there is no new strategic IT application planned for the future.
- *Turnaround:* IT is changing from one situation of little importance ("support" box) to a more important situation in business strategy.
- *Strategic:* IT is very important in business strategy in the present, and new planned applications will maintain this strategic importance of IT in the future.

In order to assess the strategic impact of IT, McFarlan proposed the analysis of five basic questions about IT applications, related to the competitive forces (Porter, 2008):

Can IT applications:
- build barriers to the entry of new competitors in the industry?
- build switching costs for suppliers?
- change the basis of competition?
- change the balance of power in supplier relationships?
- create new products?

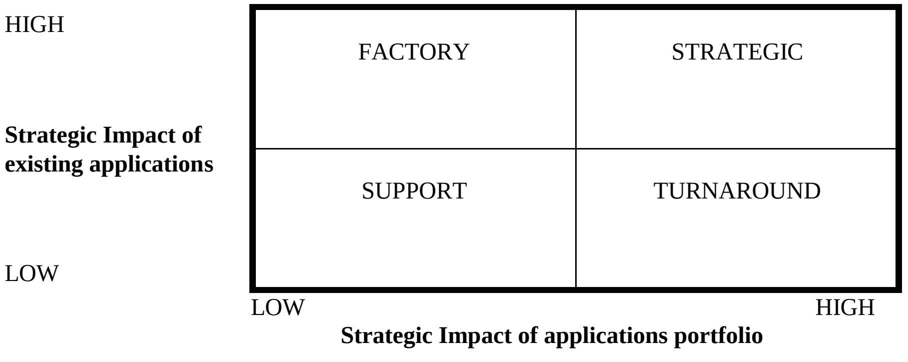
These questions should be answered considering both present and planned future situations.

Thus, IT may present a smaller or greater importance, according to the kind of company and industry operations. In a traditional manufacturing company, IT supports the operations, since the enterprise would keep on operating even when it could not count on its information systems. However, IT is strategic in a bank for business operations, since it is a source of competitive advantage and a bank cannot operate without its computerized IS.

Nolan and McFarlan (2005) have updated the Strategic Grid, changing the two "axes" for "Need for Reliable IT" (instead of "Present Impact") and "Need for New IT" (instead of "Future Impact"). These authors stated that companies in "Support" and "Factory" quadrants adopt a *defensive* approach regarding IT. On the other hand, companies classified in "Turnaround" and "Strategic" quadrants can be considered *offensive* in IT use. They also indicated the right policies in IT governance (Weil & Ross, 2005) for the board of directors' use in each of the four situations of the Strategic Grid.

Porter and Miller (1985) highlight the concepts of the value chain (activities inside the company linked by connections and which have one physical component and another of information processing) and value systems (the set of value chains of an industry from the suppliers to the final consumer).

Figure 1. Strategic grid of impacts of IT applications (McFarlan, 1984)



IT permeates the chains of value, changing the way of executing activities of value and also the nature of the connections among them and, therefore, IT can affect competition:

- by changing the structure of the sector since it has the ability to influence each of the five forces of competition (Porter, 2008);
- by creating new competitive advantages, reducing costs, increasing differentiation, and altering the scope of competition scope; and
- by generating completely new business.

The potential that IT has to make these changes varies according to the characteristics of the process (value chain) and of the product, regarding information needs. The "Information Intensity Matrix" considers the value chain and analyzes "how much" information is contained in the process and the product (see Figure 2). In companies whose products and processes contain a lot of information, information technology will be very important (Porter & Miller, 1985).

In their original article, Porter and Millar did not cite an example for "high information content in the product" or "low information intensity in the process" in the Information Intensity Matrix. However, for Duhan et al. (2001), this would be the case of educational and law firms, for consulting firms would also fit in this same quadrant.

Further according Duhan et al. (2001), an analysis of the value chain would be impaired in the case of knowledge-based companies (such as consulting firms) where it is hard to identify the value that is aggregated to each activity. In these situations, the authors propose that using the essential competencies would be more appropriate to plan the strategic use of information systems.

Henderson and Venkatraman (1993) proposed the "Strategic Alignment Model" that analyzes and emphasizes the strategic importance of IT in the enterprises. This model is based on both internal (company) and external (market) factors.

The authors emphasize that strategy should consider both internal and external domains of the company. Internal domain concerns administrative structure of the company; external domain concerns the market and the respective decisions of the company. Thus, according to this model, four factors (that the authors called domains) should be considered for planning IT:

1. business strategy,
2. IT strategy,
3. organizational infrastructure and processes, and
4. IS infrastructure and processes.

The Strategic Alignment Model brings the premise that the effective management of IT

Figure 2. Information intensity matrix (adapted from Porter & Millar, 1985)

INFORMATION CONTAINED IN THE PRODUCT

INFORMATION INTENSITY IN THE VALUE CHAIN (PROCESS)	LOW	HIGH
HIGH	*Ex: OIL REFINERY*	*Ex: BANKS, PRESS, AIRLINE COMPANIES, TELECOM*
LOW	*Ex: CEMENT*	

demands a balance among the decisions about those four domains above.

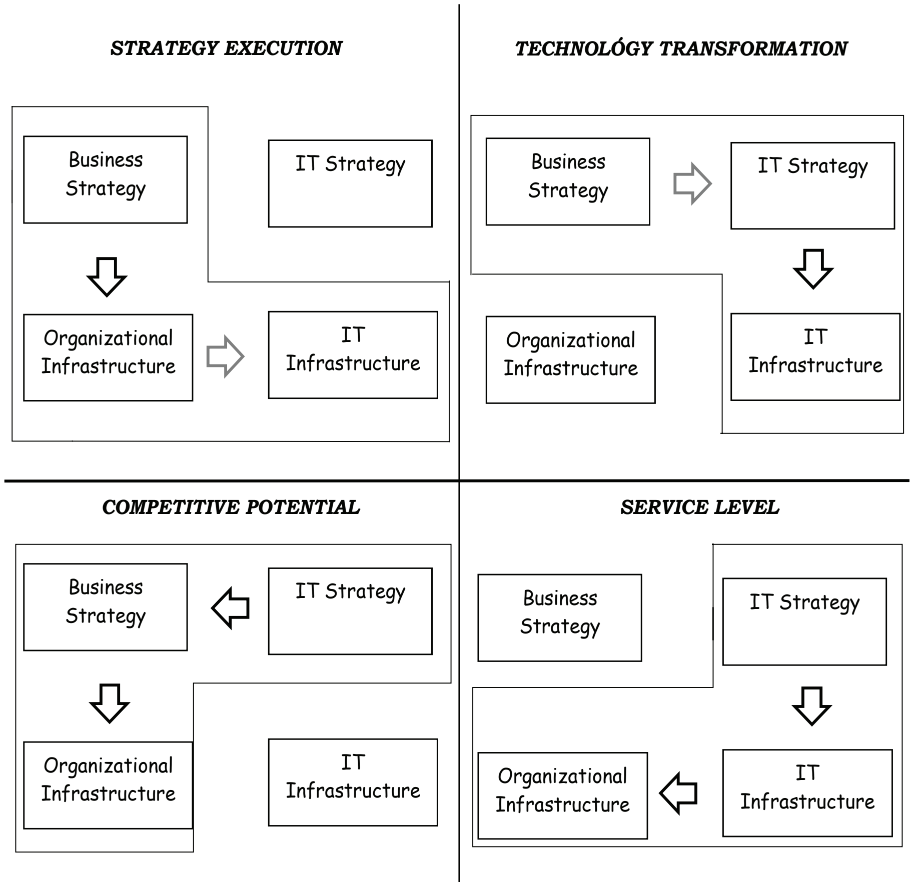
According to Henderson and Venkatraman, there are four main perspectives of Strategic Alignment, through the combination of the four factors, starting from business strategy or from IT strategy, as shown in Figure 3.

One important innovation of this model is that IT strategy could come first and change business strategy, instead of the usually general belief that business strategy comes before IT planning. This planning should be a continuous process, since external factors are in a permanent changing situation. If the company does not follow these changes, it will be in serious disadvantage in the fiercely competitive market. This is particularly true when a new technology is adopted by almost all companies in an industry, passing from a competitive advantage for those that have it to a disadvantage to those that do not use it. Thus, in this sense, the strategic alignment differs from the classic vision of the strategic plan, which does not present the same dynamic approach.

After the proposal of the four perspectives above, Luftman (1996) described four new perspectives that start in the infrastructure domains, instead of the strategies domains:

- *Organizational IT Infrastructure Perspective:*
  Organizational infrastructure → IT infrastructure → IT strategy
- *IT infrastructure Perspective:*
  IT infrastructure → IT strategy → Business strategy

Figure 3. Perspectives of strategic alignment (adapted from Henderson & Venkatraman, 1993)



- *IT Organizational Infrastructure Perspective:*
  IT infrastructure → Organizational infrastructure → Business strategy
- *Organizational Infrastructure Perspective:*
  Organizational infrastructure → Business strategy → IT strategy

Luftman (1996) also proposed that in some situations a fusion of two perspectives might occur. In these cases, two perspectives can be simultaneously assessed and impact the same domain: *IT Infrastructure Fusion, Organizational Infrastructure Fusion, Business Strategy Fusion, IT Strategy Fusion.*

Research has been developed in order to find the enablers of Strategic Alignment. Luftman (2001) listed five of them: senior executive support for IT; IT involved in strategy development; IT understands the business, business-IT partnership; well-prioritized IT projects; and IT demonstrates leadership. The absence or poor performance of these same factors are considered inhibitors of Strategic Alignment.

Some authors, like Ciborra (2004), state the strategic success of IT applications might be achieved through a tentative approach, rather than structured methods of strategic IT planning. These authors argue that frequently the drivers of strategic IT applications are efficiency issues, instead of a result of a strategic IT plan. Some important and well-known successful information systems, with clear strategic impacts, do not present evidence of being previously planned, which seems to be in agreement with this kind of thinking (Eardley, Lewis, Avison, & Powell, 1996).

EFFICIENCY AND EFFECTIVENESS: DIAGNOSING THE ROLE OF IT IN COMPANIES

In this article the importance of focusing on the effectiveness of IT utilization has been emphasized, since frequently analysis is done only from the point of view of efficiency. However, this does not mean that being efficient is not positive; it means that one needs to be efficient in certain areas. In other words, once effectiveness is achieved, increased efficiency can result in important gains and there are many models that help to analyze and improve IT efficiency.

Figure 4 contains a proposed diagram for viewing the situations related to efficiency and effectiveness in the use of IT.

When companies demonstrate low efficiency and high effectiveness, they are in "Chaos"—in a critical situation. The first move to get out of this situation should be to aim at increased effectiveness, to align the IT strategy with the business strategy. If the company has low effectiveness, but high efficiency in the use of IT, it means that it should redirect its efforts, change the focus of its activities, in order to use its good capacity where it can add value to the company's competitiveness.

Figure 4. Efficiency vs. effectiveness in IT applications (adapted from Shimizu et al., 2006)

		EFFECTIVENESS	
		LOW	HIGH
EFFICIENCY	HIGH	*NEED FOR A CHANGE OF FOCUS*	*"ÉDEN" (IDEAL SITUATION)*
	LOW	*"CHAOS"*	*OPPORTUNITY TO IMPROVE PROCESSES*

In the case of a company with high effectiveness, but low efficiency in IT utilization, it is necessary to work to improve its processes, with a view to exploiting to the maximum the focus that is already on the right things, and which can contribute to the success of the company's strategy. Finally, a company that is efficient and effective in the use of IT will arrive in "Eden," the ideal situation, which should be the goal for all.

CONCLUSION

At present there are a series of applications that have captivated the attention of many and have opened up new possibilities. Both Knowledge Management and Customer Relationship Management have been closely associated to IT. In fact, without IT these concepts could hardly have been effectively used in companies. In this sense, one important example is the growing use of business intelligence applications.

Despite the failure of many virtual enterprises (the so-called "dot.coms"), e-business and e-commerce applications seems to have reached a new maturity level, especially B2B (business-to-business—the connection between companies via the Internet).

There are various success stories, and large companies are increasingly investing in this success. According to Porter (2001), the Internet is the IT tool that, up to the present, has shown the greatest potential of being a source of obtaining or stressing strategic advantages. Therefore, an appropriate analysis and evaluation of IT effectiveness can take on a fundamental role, enabling it to really become a powerful tool for competitiveness.

The concepts described above show the importance of a broad view for analyzing IT strategic alignment. Each of the described models (CSF, Strategic Grid, Information Intensity Matrix, and Strategic Alignment) focuses on specific aspect of this issue.

These widespread known models, in fact, have complementary characteristics, and concomitant use of them allows a better comprehension of the role of IT in an organization.

On the other hand, even the use of the three models does not solve the complexity of IT alignment in organizations. As highlighted by several authors, sometimes a tentative and evolutionary approach can be successfully adopted, in circumstances that structured methods do not work properly. By this continuous focus in the IT strategic alignment, the problems of the "productivity paradox" would be overcome.

Further studies would be necessary for a better and deeper understanding of the importance of IT effectiveness for the success of competitive companies. However, this chapter intended to help find a way for this understanding and to provide some tools.

KEY TERMS

Competitive Forces: According to Porter (2008), the state of the competition in a particular industry depends on five basic forces: new competitors, bargaining power of suppliers, bargaining power of customers, rivalry among current competitors, and substitute products or services.

Critical Success Factor (CSF): One of the areas where satisfactory results "ensure successful competitive performance for the organization," according to Rockart (1979).

Effectiveness: In the context of IT, the measurement of the capacity of the outputs of an information system or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive. In other words, effectiveness can be understood as the ability of "do the right thing."

Productivity Paradox: The discussion about the lack of evidence about the return of investments on IT in the economy productivity indicators.

Strategic Alignment: The IT Strategic Alignment Model was proposed by Henderson and Venkatraman (1993) and consists of a framework for studying IT impacts on business and understanding how these impacts influence IT organization and strategy, as well as how it enables analysis of the market availabilities of new information technologies.

Strategic Grid: Nolan and McFarlan (2005) and McFarlan (1984) proposed the Strategic Grid, which allows the visualization of the relationship between IT strategy and business strategy and operations. This model analyzes the impacts of IT-existent applications (present) and of an applications portfolio (future), defining four boxes, each one representing one possible role for IT in the enterprise: "Support," "Factory," "Turnaround," and "Strategic."

Value Chain: According to Porter and Millar (1985), the set of technologically and economically distinct activities a company performs in order to do business.

Chapter 1.3

The Interplay of Strategic Management and Information Technology

Zaiyong Tang
Louisiana Tech University, USA

Bruce Walters
Louisiana Tech University, USA

ABSTRACT

The authors trace historical developments in the fields of information technology (IT) and strategic management. IT's evolution from the mainframe era to the Internet era has been accompanied by a shift in the strategic emphasis of IT. In the early days, IT's contribution to the organization was largely information provision, monitoring and control. Current research at the intersection of IT and strategic management increasingly highlights the impact of IT in terms of informing strategic decisions and enabling information flow vis-à-vis all manner of organizational processes. We believe these fields are ripe for research focusing on their complementary impact on organizational performance.

INTRODUCTION

We live in an age in which the value of information and knowledge has far surpassed that of physical goods. Information resources have become a key differentiator of successful businesses. Information technology (IT) and information systems (IS) are now integrated in almost every aspect of business, from planning to analysis and design, operations management and strategic decision making. Even for those businesses not in information industries, information plays a vital role in supporting their business functions, from routine operations to strategizing. John Naisbitt (1982) theorized that information would be the driving force for organizations. Companies that manage information well are more likely to maintain a competitive advantage against their peers. Because information has become a major force in driving business activities, Evans and Wurster (2000) proclaimed that every business is in the information business.

IT and IS have experienced dramatic changes in the last few decades. Their major role in business has shifted from tools to support "back-office" operations to an integrated part of business strategies and the maintenance of core competencies. Strategic management, as the process of business strategy formulation and strategy implementation, is concerned with establishing goals and directions, and developing and carrying out plans to achieve those goals. As organizations evolve, so do their strategies and strategic management practices. In recent years, IT has become increasingly important in strategic management. IT and IT-enabled systems are now indispensable in supporting business strategies. In this chapter, we examine the evolution of information technology and strategic management, and their interplay in the last 50 years. We start with a review of major theories and development in both strategic management and IT, and then explore how IT has become an enabler for strategic management. We also discuss research issues in IT-enabled strategic management, and suggest future directions in this cross-disciplinary research field.

STRATEGIC MANAGEMENT

Strategic management is concerned with managerial decisions and actions that determine the long-term prosperity of the organization. An organization must have a clear strategy and its strategy must be carefully developed and implemented to match its resources and environment in the pursuit of its organizational goals. Two meanings behind the often-used term "strategy," as Lowell Steele (1989) pointed out, are the ideational content of strategy and the process of formulating strategy. The former refers to the array of options that one uses to compete and survive, and the latter refers to the planning that leads to the construction of the strategic plan. Thus, IT-enabled strategic management must address the role IT plays in strategy content options and priorities, strategy formulation processes and strategy implementation processes. Strategic management focuses on identifying the direction of an organization, and designing and instituting major changes needed to gear the organization towards moving in the established direction.

Early research in strategic management started in the 1950s, with leading researchers such as Peter Drucker, Alfred Chandler and Philip Selznick. Drucker (1954) pioneered the theory of management by objectives (MBO). He is also one of the first to recognize the dramatic changes IT brought to management. He predicted in the 1960s the rise of knowledge workers in the information age (Drucker, 1968). Alfred Chandler (1962) recognized the importance of a corporate-level strategy that gives a business its structure and direction; as he put it, "structure follows strategy." Philip Selznick (1957) established the ground work of matching a company's internal attributes with external factors.

In the 1970s, theories of strategic management primarily focused on growth, market share and portfolio analysis. A long-term study aimed at understanding the Profit Impact of Marketing Strategies (PIMS) was carried out from the 1960s to the 1970s. The study concluded that a company's rate of profit is positively correlated with its market share. This is a result of economies of scale (Buzzell & Gale, 1987). As companies pursued larger market share, a number of growth strategies—such as horizontal integration, vertical integration, diversification, franchises, mergers and acquisitions, and joint ventures—were developed. As will be discussed later, those strategies are even more widely used today, with the facilitation of information and networking technologies.

Another shifting of strategic focus occurring in the 1970s was the move from sales orientation towards customer orientation. Researchers such as Theodore Levitt (1983) argued that businesses should start with the customer proposition. The right approach is to find out how to create value for customers and then make the products and services that meet the needs of the customers, rather than trying to sell to customers once the products are created.

In the 1980s, strategic management theories were largely geared towards gaining competitive advantages. Michael Porter (1980, 1987) proposed a number of very influential strategic analysis models, such as the five-forces model of competition, the value chain and generic competitive strategies. Porter suggested that businesses need to choose either a strategy of cost leadership (with lowest cost), product differentiation or market focus. Research has demonstrated that both market share leaders and niche market players may obtain high financial returns while most companies without a coherent strategy did not (e.g., Levinson, 1984). Adopting one of Porter's generic strategies helps a company to avoid the so-called "stuck-in-the-middle" problem. Many of Porter's ideas have been implemented in modern corporate strategic management frameworks. Strategic IS applications, such as supply chain management, are based on efficient value chain management and forming strategic alliances to maintain competitive advantages.

Lester (1989) suggested that companies sustain their strategic positions in the market by following seven best practices: continuously improving products and services, breaking down barriers between functional areas, flattening organizational hierarchies, strengthening relationships with customers and suppliers, effectively using technology, having a global orientation and enhancing human resource quality. Various information technologies have been used to support those best practices.

Hamel and Prahalad (1990) popularized the idea of core competencies. They argued that companies should devote their resources to a few things that they can do better than the competition, and relegate non-core business operations to business partners. This laid the foundation for outsourcing, which has gained in popularity since the late 1990s. The wide spread of information and network technologies has reduced the time and geographic barriers of outsourcing business functions to other companies.

Reengineering, also known as business process redesign, calls for fundamental changes in the way business is carried out. Traditional companies are organized around functional business areas, which often leads to limited communication and cooperation, as well as redundancy due to functional overlap. Hammer and Champy's book, *Reengineering the Corporation*, makes a convincing case for restructuring business resources around whole business processes rather than functional tasks (Hammer & Champy, 1993). IT and IS have become both an impetus and a facilitator for reengineering projects.

In the 1990s, researchers increasingly recognized the importance of customer relationship management (e.g., Gronroos, 1994; Sewell & Brown, 1990). Computer and network technologies have played a key role in making customer relationship management efficient and effective. Along the line of improving value to the customers, mass customization provides competitive advantages (Pine & Gilmore, 1997). Reaching and custom-serving individual customers are only feasible with the proliferation of information and communication technologies.

Peter Senge (1990), in his book, *The Fifth Discipline,* popularized the concept of the learning organization. The rationale in creating a learning organization is that the business environment has become more dynamic and complex. Companies must have the ability to learn continuously and adapt to the changing environment. People in a learning organization need to continuously expand their capacity to become more productive or to maintain their level of competency.

The Greek philosopher Heraclitus said nothing is constant but change. Indeed, Toffler (1970) has recognized that not only is Heraclitus still right, but the rate of change is accelerating. Hamel (2000) believes that all strategies decay over time; thus, organizations need to reexamine their strategies and strategic management practices. Moncrieff (1999) argues that strategic management is a dynamic process. Strategy is partially deliberate and partially unplanned. Recently, many researchers have recognized that organizations are complex adaptive systems in which multiple agents set their own goals, share information, collaborate and interact with one another (Axelrod & Cohen, 1999; Dudik, 2000; Landsbergen, 2005). Two foreseeable trends are: 1) more IT-enabled interactions among human agents in the complex adaptive systems, and 2) agent activities moving from purely human interaction to interactions involving artificial intelligent agents.

THE EVOLUTION OF IT

IT can be defined as technology applied to the creation, management and use of information. Any technology that deals with information gathering, processing, storing and dissemination is considered IT. Earlier examples of IT include pigeon carriers and sending messages by fire and smoke. By definition, IT does not have to be computer-based. However, practically speaking, today's IT is largely built on computer hardware and software applications. Thus, in the following, while we review IT development in the past, we focus on computing-related technologies.

An early and relatively sophisticated computing device was the abacus, invented around 500 B.C. in Egypt. Blaise Pascal invented the first mechanical calculating machine for adding and subtracting in 1642. A milestone in computing machine development was Charles Babbage's difference machine that could perform trigonometric and logarithmic operations. The first electronic computer, ENIAC (electronic numerical integrator and calculator), was developed in 1946. Commercially available computers began in the early 1950s, with IBM as the leading vendor.

One of the milestones in the computer industry was the arrival of the IBM System/360 in 1964. The System/360 was a family of computers running the same operating systems and using the same peripherals. Thus, companies could start with a less capable model and expand the capacity with more powerful models without the need to replace system software and peripheral components. Easy adoption through inter-changeability of hardware and software prompted significant growth of computer system usage in business in the 1960s and 1970s (with later models, such as the System/370). IBM first started unbundling software from hardware by selling software separate from its computer in 1969. That set the stage for the launch of an independent software industry. The fast growth of packaged software applications, in turn, prompted the growth of computer hardware.

The next major event in the computer industry was the birth of personal computers (PCs) in the mid-1970s. Intel introduced the first semiconductor microchip (the Intel 4004) in 1971. However, PCs were not widespread until the early 1980s, when IBM launched its standardized PC (known as the IBM PC). The IBM PC became "Machine of the Year," taking the place of traditional "Man of the Year" on the cover of *Time Magazine* in 1983. Other computer vendors jumped on the IBM PC bandwagon by producing IBM-compatible PCs. During the decade of the 1980s, the number of PCs grew more than 100 fold to more than 100 million (Gantz, 2004).

The continued growth of the PC industry is driven by the well-known Moore's Law, which stipulates that the number of transistors per silicon chip doubles roughly every 18 months; hence, the corresponding performance of the central processing unit—the brain of microcomputers. Gordon Moore, co-founder of Intel Corp., made that stipulation in 1965. Amazingly, Moore's Law has described the state of affairs for the last four decades. The power of exponential growth resulted in dramatic cost and performance improvement of computer hardware. Once scarce and expensive, computer systems are now abundant and inexpensive because of the availability of desktop computer, laptop computers, and even handheld computing devices. Low-cost computing changed organizational computing architecture from centralized computing to distributed computing systems in the 1980s.

In the history of IT, the 1990s is perhaps best known as the decade of Internet booming. The Internet started as the U.S. Department of Defense's ARPAnet, with the aim of creating a distributed computer network that can withstand a nuclear attack. In the 1970s and 1980s, the Internet was used mainly by academics and scientists, and was not accessible largely to the general public because its use, although open, required substantial learning of arcane application protocols. Two major events led to the explosive growth of the Internet. The first was the development of the World Wide Web (WWW or the Web) by Tim Berners-Lee, a researcher at the CERN Institute in Switzerland in 1990, and the second is the arrival of (largely free) graphic Web browsers. The Web made it possible to link information resources all over the world on the Internet. Users could retrieve information without knowing the whereabouts of the information by simply following the hyperlinks (or links). However, initial access to the WWW was text-based; hence, its richness in content and usability were limited. The WWW took off after 1993 when the first graphic Web browser, Mosaic, was released by the National Center for Supercomputing Applications (NCSA) at the University of Illinois at Urbana Champaign. The ensuing Internet growth was unprecedented in the history of technology development. Internet users grew from a few thousand to more than 300 million during the 1990s. As of June 2005, there were more than 938 million Internet users worldwide (www.internetworldstats.com/stats.htm).

The Internet provides a low-cost way of connecting virtually everyone in modern society to an open and shared common network. The wide accessibility of the Internet has created numerous opportunities for businesses and brought fundamental changes to the way businesses operate. The value of a network increases with the square of the number of users connected to the network. This is known as Metcalfe's law, attributed to Robert Metcalfe, one of the inventors of the widely used Ethernet standard and founder of 3Com Corporation (Applegate, Austin, & McFarlan, 2003). The Internet has changed the landscape of competition by lowering the barriers for small- and medium-size companies to reach markets that were traditionally accessible only to large corporations.

Since the late 1990s, mobile computing based on wireless network technologies has gained much momentum. Intelligent appliances, such as cellular phones, personal digital assistants and other handheld computing devices, are becoming a significant part of the IS infrastructure. IDC predicts that the number of mobile devices connected to the Internet will surpass that of Internet-connected computers by the end of 2006. The total number of networked devices may approach 6 billion by 2012 (Gantz, 2004). Ubiquitous computing that allows "anytime, anyplace" access to information resources will bring dramatic changes to the business environment.

The Internet has already created fundamental changes in the business world. The WWW brought the first revolution in our networked society. Many believe that the next major development of the Web may be network intelligence through Web services. The non-profit Internet governing organization W3C defines Web services as the programmatic interfaces for application to application communication on the Web. Web services create a promising infrastructure to support loosely coupled, distributed and heterogeneous applications on the Internet (Nagarajan, Lam, & Su, 2004). Applications based on Web services can be described, published, located and invoked over the Internet to create new products and services based on open Internet protocols such as HTTP, XML and Simple Object Access Protocol (SOAP). The significance of Web services is that system-to-system communications can be automated; hence, building business alliances and virtual organizations becomes much easier than with current Internet technology.

IT AS AN ENABLER FOR STRATEGIC MANAGEMENT

Although strategic management and IS developed in parallel over the last 50 years, the two fields have also had substantial impact on each other. The interaction and co-evolution of the two fields have experienced significant increase in recent years. In this section, we will examine such interaction and co-evolution through the motivations and development of computer-based IS used in businesses.

The short history of computer IT development can be divided into three eras: the mainframe era from the 1950s to the 1970s, the microcomputer era from the 1980s to the early 1990s, and the Internet era from the 1990s to the present. The mainframe era is characterized by centralized computing, where all computing needs were serviced by powerful computers at the computer center. The proliferation of microcomputers led to decentralized computing. Computing resources become readily accessible to more users. This is a period that witnessed improved user performance and decision-making quality. When computer networks became pervasive in the Internet era, decentralized computing evolved to distributed computing, where computing resources are located in multiple sites, as in decentralized systems, but all of the computing resources are connected through computer networks. People in the Internet era are far more empowered than in previous eras, because they have access to not only technology tools as before, but also to shared knowledge from others. Table 1 summarizes the IS and their motivations during those three IT evolution eras. Although IS are separately listed in the three eras, we must point out that the lists are not mutually exclusive. In particular, in the Internet era, businesses are still heavily dependent on systems conceptualized and developed in earlier eras, such as TPS, MIS and DSS.

Clearly, the role of business IS has evolved and expanded over the last 5 decades. Early systems in the 1950s and 1960s were used primarily for dealing with business transactions with associated data collection, processing and storage. Management information systems (MIS) were developed in the 1960s to provide information for managerial support. Typical MIS are report based, with little or no decision-making support capabilities. Decision support systems (DSS) first appeared in the 1970s. They offer various analytical tools, models and flexible user interface for decision support at solving difficult problems, such as planning, forecasting and scheduling. Executive support systems (ESS) are specialized DSS designed to support top-level management in strategic decision making (O'Brien, 2005).

The 1990s saw an increased emphasis on Strategic Information Systems as a result of the changing competitive environment. Competitive advantage became a hot strategic management topic. IT and IS were developed to support business strategic initiatives. The commercialization of the Internet in the mid 1990s created an explosive growth of the Internet and Internet-based business applications. Using the Internet standards, corporations are converting their old incompatible internal networks to Intranets. Also based on Internet standards, Extranets are built to link companies with their customers, suppliers and other business partners (Chen, 2005).

What kind of information systems would be considered strategic information systems? Although strategic support systems are almost exclusively used for top executives dealing with strategic problems, a strategic information system can be any type of IS that plays a key role in supporting business strategies. McFarlan's strategic

Table 1. IT evolution and strategic management relevance (Adopted from Applegate, Austin, and McFarlan, 2003)

	Mainframe Era 1950s to 1970s	**Microcomputer Era 1980s to early 1990s**	**Internet Era 1990s to present**
Dominant technology	Mainframes, stand-alone applications, centralized databases	Microcomputers, workstations, stand-alone and client-server applications	Networked microcomputers, client-server applications, Internet technology, Web browser, hypertext, and hypermedia
Information systems	Transaction processing systems (TPS), management information systems (MIS), Limited decision support system (DSS)	Comprehensive decision support system (DSS), executive support systems (ESS), enterprise resource planning (ERP), business intelligence (BI), human resource management (HRM), expert systems (ES)	Supply chain management (SCM), customer relationship management (CRM), knowledge management (KM), strategic information systems (SIS), multi-agent systems (MAS), mobile information systems
IS motivation	Efficiency	Effectiveness	Business value
Strategic management relevance	Provide information for monitoring and control of operations	Provide information and decision support for problem solving	Support strategic initiatives to transform organizations and markets

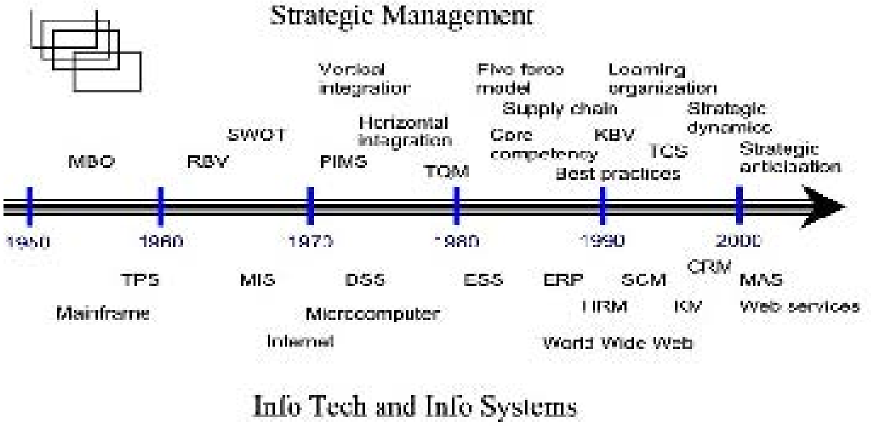
grid defines four categories of IT impact: Support, Factory, Turnaround and Strategic (Applegate, Austin & McFarlan, 2003). When the IT has significant impact on business core strategy, core operations or both, the corresponding IS are considered strategic information systems. Thus, various information systems may be dealt with in strategic management.

Many researchers have written on the strategic importance of information and knowledge in the networked economy. Nasbitt (1982) observed that the world was transforming from an industrial to an information society, and IT would dominate the economic growth of developed nations. Quinn (1992) argued how knowledge- and service-based systems are revolutionizing the economy. Shapiro and Varian (1999) discussed information-based products and services, and how to use information to maximize economic gain.

IT and IS have made it possible to access vast amounts of information easily and quickly. Systems such as enterprise resource planning (ERP) give managers the ability to monitor the operation of the entire organization in real time. Executive information portals have allowed senior managers to take a much more comprehensive view of strategic management than ever before. Tools such as the balanced scorecard (Kaplan & Norton, 1992) give a holistic view of the business performance by integrating factors in multiple business functions.

In the last few years, business process management (BPM) software has been designed with the intent of closing gaps in existing ERP deployments. As companies are increasingly faced with problems associated with incompatible functional systems from different vendors, enterprise application integration (EAI) has become an important research. BPM systems have been deployed to lower the cost and complexity of application and data integration. Another recent development is Web services enabled by standards-based protocols (such as XML, SOAP, UDDI and WSDL). The wide acceptance of Internet protocols also led to the emergence of service-oriented architectures (SOA). SOA focus on building robust and flexible systems that provide services as they are requested in a dynamic business process environment. Instead of being programmed in advance, services are generated, brokered and delivered

Figure 1. Chronology of strategic management and IT development



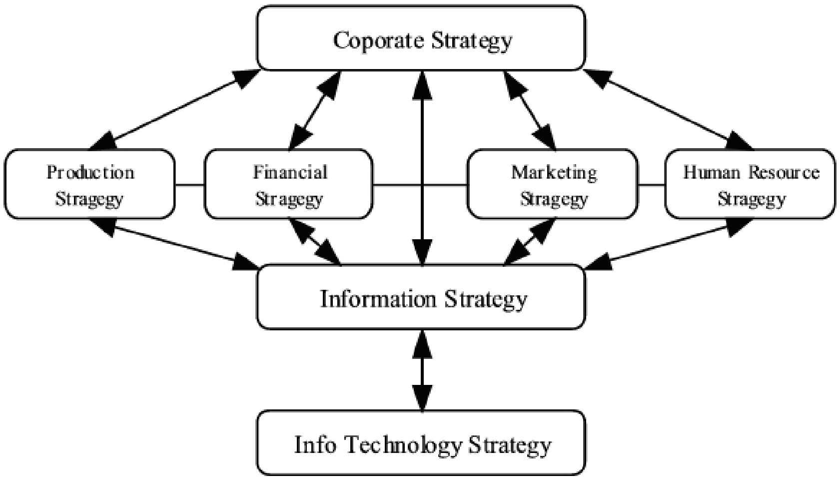
on the fly. Figure 1 presents a timeline that lists major developments in strategic management and IT/IS. Although the two fields have progressed in their separate paths, there are many instances where their paths crossed. As shown in Table 1 and the discussion following it, the motivation of IS has shifted from efficiency to effectiveness, and in the Internet era, to value creation. On one hand, IT is playing a more active and important role in strategic management. On the other hand, strategic management concerns have influenced the development of IS. In many cases, the theories and principles of strategic management led the way of IS development. IT and IS, in turn, have made it more feasible for those theories and principles to be practiced in businesses.

IT ALIGNMENT WITH BUSINESS STRATEGIES

IT in business has evolved and become increasingly integrated with business organizations. Strategic management now encompasses corporate strategy, functional business strategy, information strategy, and IT strategy, as shown in Figure 2. For most businesses, their strategies form a multi-level hierarchy. At the very top is corporate strategy, which sets the direction for corporate-level decision making. Below corporate strategy, there are functional strategies, business unit strategies and operational strategies. Building a comprehensive strategic IT plan that aligns with the business strategy is essential to ensuring the success of the organization.

Numerous researchers have indicated that IT alignment with business strategy is vital to achieve expected results. Sabherwal and Chan (2001) studied the benefit of alignment between business and IS strategies, and concluded that the alignment can improve business performance. They also developed a framework that can be used to analyze the level of alignment between business and IS strategy. Symons (2005) claimed that IT alignment has been one of the top three issues confronting IT and business executives for more than 20 years. Symons reported that a recent poll of CIOs and business executives revealed that the alignment of IT and business goals is their no. 1 or 2 priority. Measuring the degree of IT alignment has been difficult for many businesses. Borrowing the idea from the Capacity Maturity Model (CMM) of the Software Engineering Institute, Symons proposed a strategy alignment maturity model with five distinct levels:

Figure 2. Alignment of information technology with strategies



- At the base level, called Nonexistent, there is IT alignment with business strategy. IT plays only a supportive role of operations.
- At the Ad hoc level, the need for IT alignment is recognized, but there is a lack of systematic approach. IT supports business goals on a case-by-case basis. There is no attempt to measure the success of IT alignment.
- At the Repeatable level, IT alignment is considered at the enterprise level. However, it is only implemented in some business units. Limited measures of IT alignment exist.
- At the Defined process level, IT alignment is systematically implemented throughout the enterprise, with appropriate policies and procedures to monitor and measure the benefits of the IT alignment.
- At the Optimized level, IT strategy is seamlessly aligned with business strategy at all managerial levels and in all business units. IT alignment processes have been extended to external best practices with other organizations. Measures of IT alignment and feedback mechanisms exist to ensure that IT alignment stays at this level.

Obviously, IT alignment is one of the key issues in strategic management. However, IT alignment is more than simply formulating IT strategy to fit the business strategy. Business strategy is future oriented and subject to external forces and environmental uncertainty. IT alignment should build adaptability into IT strategy. Furthermore, for some technology companies, IT may be the driver of corporate strategy (Clarke, 2001).

Strategic management is concerned with the long-term survival and prosperity of organizations. As the environment changes, organizations must also adapt to maintain their viability. Organizations evolve, and so do strategies. Thus, strategic management is also a learning process. There are four basic learning behaviors in strategy formulation; namely, natural selection, imitation, reinforcement and best reply (Young, 1998). In each of the four learning processes, IT and IS are becoming indispensable.

Natural selection stipulates that organizations that use high-payoff strategies have competitive advantages over those using low-payoff strategies. As a result, high-payoff strategies have a better chance to be continued by surviving organizations. Determining the payoff of strategies, thus, is very important in this kind of strategic learning behavior.

Imitation describes how organizations mimic the practices of successful peers in their industry. This is the cause of herding behavior in which the outcome is not clear, but organizations jump on the bandwagon, simply following what many of their peers are doing. A classic example is the dot.com boom during the late 1990s.

Reinforcement is concerned with how organizations monitor their own behaviors and favor the strategies that resulted in high payoffs in the past. In contrast to *natural selection*, *reinforcement* learning is based on one's own experience rather than others' experience.

Best reply is the behavior wherein organizations formulate their strategies based on what they expect their competitors will do. Many of the popular competitive strategies, such as low-cost leadership and differentiation, fall into this category.

RESEARCH ISSUES IN IT-ENABLED STRATEGIC MANAGEMENT

There is no doubt that the application of IT and strategic information systems has aided businesses in gaining competitive advantages. However, the extent to which IT/IS helps businesses to succeed varies, as many other factors also contribute to the long-term performance. Kettinger and colleagues (1994) studied a large number of cases of strategic information systems and found that 40% of the companies had above-average performance in the short to intermediate term, while only 20% of the companies sustained long-term (10 years or more) competitive advantages. Thus, for many of those companies, their strategic investment in IT and IS did not achieve their long-term goals.

In 2003, *Harvard Business Review* published a controversial article titled "IT Doesn't Matter." The author of the article, Nicolas Carr, contends that since IT cost has dropped precipitously in recent years, and now IT is widely accessible to businesses large and small, IT no longer provides a competitive advantage to businesses. Thus, companies should stop investing heavily in advanced IT products and services. Rather, they should spend the resources on reducing operational risks associate with IT (Carr, 2003). Although many scholars and industrial leaders, such as Warren McFalan, Richard Nolan, Paul Strassmann, John Brown, John Hagel and Vladimir Zwass (see Stewart, 2003), have debated Carr's view, and have shown evidence of the strategic importance of IT, it is generally agreed that IT alone is not enough to sustain strategic advantages. Although IT plays an important role, it is only one facet of the comprehensive framework of strategic management. As Clemons and Row (1991) argued, IT's value is not so much in its intrinsic properties, but in how it can be effectively deployed to support business strategies. Although numerous previous researchers have studied IT's importance and its strategic value (e.g., Clarke, 2001; Porter & Miller, 1985), there is a lack of strategic research on integrating IT into strategic management.

In recent years, IT-enabled business changes have become more frequent and more crucial. Prahalad and Krishnan (2002) have surveyed business executives in large companies and found that almost invariably, the executives indicated that the quality of their IT infrastructure fell short of their need and desire for strategic change. In such a case, (existing) IT became an impediment to innovations and other strategic initiatives. Many companies have started large IT projects, such as ERP, CRM and SCM projects, in their effort to revamp their business processes. However, as Prahalad and Krishnan (2002) pointed out, packaged enterprise systems are designed for stability in processes, not ability to evolve. One of the key issues in IT-enabled strategic management is creating an IT infrastructure that offers speed for change and flexibility needed for strategic management.

Understanding how businesses create and sustain competitive value from their investments in IT has been a challenge for strategic management researchers as well as IS researchers. A more comprehensive way of conceptualizing the interplay of IT and strategic management is needed. As more companies are transforming into e-businesses, obviously, information and communication technologies are becoming an integrated part of the organization. However, what is the role of IT in strategic management when computing and network become pervasive and IT becomes invisible? How will emerging IT, such as grid computing, Web services and SOA, change strategic dynamics of organizations? Those questions need to be addressed by both IS and strategic management researchers.

Clearly, the intersection of IT and strategy is ripe for research. Opportunities abound with regard to strategy making and strategy implementation enabled by IT. Research questions falling within the scope of interest could cover a wide range of issues, from various product/market approaches to strategic decision processes to diversification management to corporate governance, to name just a few. For instance, the pursuit of combination, or hybrid, business-level strategies may be more possible now with IT advances. Whereas Porter (1980, 1985) advised organizations generally to pursue one coherent strategy (e.g., the choice between low-cost and differentiation), the advent of flexible manufacturing and highly sophisticated customer database systems may provide more latitude at the business level. A worthy research question is to what extent, and in what contexts, combination forms of competitive advantage can indeed be pursued, and in what ways these strategies are enabled by IT. Likewise, strategic decision processes, such as environmental scanning, analysis and planning, have been aided immensely by the development of executive IS, Internet capabilities and real-time access to business intelligence. These developments enable richer and more abundant information to reach executives, but a key challenge is how to provide relevant information in the proper form and at the right time so the organization can capitalize on opportunities. To what degree might IT advances enable the optimum breadth and depth of information to enter the strategic decision process, given contingencies such as decision makers' characteristics and organizational strategy? These are examples of research questions that would merely begin to scratch the surface.

CONCLUSION

We have explored concepts and issues involving the use of IT as an enabler for strategic management. We discussed the parallel development of strategic management and IT, and their co-evolutions over the last 5 decades. In general, the theoretical research in strategic management has led the way in the co-evolution. IT and IT-enabled IS are developed to support strategic management needs. The fields are at a unique point in their development, enabling cross-disciplinary research of both practical and theoretical interest dealing with a vast array of organization process and performance issues. We hope the succeeding chapters are helpful in providing a start toward fruitful research agendas and in offering practical guidance to those who are responsible for implementation in organizations.

Chapter 1.4

Enterprise Systems Strategic Alignment and Business Value

Euripidis Loukis
University of the Aegean, Greece

Ioakim Sapounas
University of the Aegean, Greece

Konstantinos Aivalis
ICAP, Greece

ABSTRACT

This chapter is dealing with the alignment of enterprise systems with business strategy and its impact on the business value that enterprise systems generate. Initially the research on the strategic potential of ICT, which constitutes the basic theoretical foundation of the need for strategic alignment of enterprise systems, is analyzed. Then the previous research that has been conducted concerning enterprise systems strategic alignment is critically reviewed. It is grouped into three basic streams. The first of them is dealing with the conceptualization and basic understanding of enterprise systems strategic alignment. The second research stream aims at the development of models and frameworks for directing and assessing enterprise systems strategic alignment. The third research stream examines the impact of enterprise systems strategic alignment on business performance. Finally, an empirical investigation that has been conducted by the authors concerning the impact of enterprise systems strategic alignment on business performance as a guidance for future research on this topic is described. We expect that this chapter will sufficiently inform on strategic alignment, both researchers and practitioners in the area of enterprise systems, so that they can incorporate this highly important concept in their research and practice respectively.

INTRODUCTION

The strategic alignment of information systems (IS) has been ranked as the most important issue that IS managers face in the two most recent formal surveys conducted by the Society for Information Management (SIM) of USA (www.simnet.org) concerning the key IS management issues (Luftman & McLean, 2004; Luftman, 2005). Also, the strategic alignment of IS has been ranked in very high positions in most of the surveys of the key IS management issues that have been conducted in various countries (e.g. Palvia et al, 2002). Several definitions of IS strategic alignment have been proposed by the relevant literature. According to Broadbent & Weil (1993) as IS strategic alignment is defined the extent to which business strategies are enabled, supported and stimulated by information strategies. Luftman (2000) provides a more detailed definition stating that 'Business-IT alignment refers to applying Information Technology in an appropriate and timely way, in harmony with business strategies, goals and needs. This definition of alignment addresses: 1. how IT is aligned with the business and 2. how the business should or could be aligned with IT' (p.3). Duffy (2002) in an IDC Report states that IT technical people have criticized corporate general management for a lack of interest in the IS function; at the same time general management people have criticized the IT technical people for not understanding the business and for not being profit-oriented, being interested mainly in solving technical problems and not business problems. However, at the same time he remarks that 'However valid both of these criticisms may have been, there is evidence that the gap between the two groups is now narrowing" (p.2), and defines 'IT/Business Alignment' as 'the process and goal of achieving competitive advantage through developing and sustaining a symbiotic relationship between IT and Business' (p.4).

The strategic alignment of enterprise systems consists in the establishment of a bilateral relationship between the enterprise systems planning process and the business/strategy planning processes, which allows:

- The mission, goals, competitive strategy, future directions and action plan of the enterprise, and also the analysis of its external environment (e.g. competition, opportunities, threats) and the analysis of its internal environment (e.g. resources, capabilities, strengths, weaknesses), which are basic elements of its business/strategy plan, to be taken into account for the formulation of its enterprise systems plan,
- And also the capabilities, strengths and weaknesses of existing enterprise systems, the planned enterprise systems, the forms and the extent of information and communication technologies (ICT) usage in the industry and the capabilities offered by existing and emerging ICTs that may interest and influence the enterprise, which are basic elements of the enterprise systems plan, to be taken into account for the formulation of the business/strategy plan.

The basic objective of this bilateral relationship is to exploit ICT in the enterprise in the best possible manner for both supporting and enriching its business strategy, and to take advantage to the highest possible extent of the significant strategic potential of ICT.

This chapter is dealing with the alignment of enterprise systems with business strategy and its impact on the business value that enterprise systems generate. It aims to inform on this highly important issue both researchers and practitioners in the area of enterprise systems, so that they take it into account and incorporate it in their research and practice respectively. In this direction in the following second section of this chapter is reviewed briefly the research that has been conducted on the strategic potential of ICT, which constitutes the basic theoretical foundation of the need for strategic alignment of enterprise systems. Then in the third section the previous research that has been conducted concerning enterprise systems strategic alignment is critically reviewed. In the fourth section is described an empirical investigation that has been conducted by the authors concerning the impact of enterprise systems strategic alignment on business performance, based on the construction of complete econometric models, which are founded on the well-established and validated Cobb-Douglas production function, and using objective measures of business performance and enterprise systems investment, and on. Finally the conclusions and the future trends concerning enterprise systems strategic alignment are discussed.

THE STRATEGIC POTENTIAL OF ICT

There has been for more than two decades a high level of interest of both researchers and practitioners in the alignment between enterprise systems and business strategy, which is founded on the recognition that ICT have a significant strategic potential, i.e. if properly exploited they can have a significant strategic impact on the enterprise and provide valuable competitive advantages. The initial research on this strategic potential of ICT has been based on the work of M. Porter (1980) on competitive strategy, which identifies three generic business strategies: differentiation, cost leadership and focus; also it concludes that organizations use these generic strategies in order to control five basic industry forces, which determine their competitive position and profitability: rivalry among existing competitors, bargaining power of suppliers, bargaining power of buyers, threat of substitute products/services and threat of new entrants. Parsons (1983) applied the above work of M. Porter to the ICT and reached the conclusion that IS can have a significant strategic impact if the are used to change the products, services, markets or production economics of an industry, to affect the buyers and suppliers of the enterprise, to prevent customers from buying products and services from competitors, to preclude new competitors, to alter the degree of rivalry, or to support one of the abovementioned M. Porter's generic strategies. McFarlan (1984) applied the above work of M. Porter to the ICT and concluded that they can have a strategic impact, if they are used in order to build barriers against new entrants, build switching costs, change the basis of the competition, generate new products and services and change the balance of power in supplier relationships. Building on these conclusions Benjamin et al (1984) enriched the perspective of the strategic potential of ICT by concluding that it is not only IS affecting customers or supporting new products and services that can have a strategic impact, but also IS affecting internal operations and supporting traditional products and services can be of high strategic importance as well and provide competitive advantages. Ives and Learnmonth (1984) applied the concept of value chain to the interaction of a customer with an enterprise and concluded that an IS that fits into customer lifecycle and differentiates products or services from those of the competitors can be of high strategic importance. Wiseman (1985) concludes that IS supporting the internal operations or the traditional products and services of an enterprise can have strategic impact if they support its 'strategic thrusts', such as M. Porter's generic strategies, innovation, growth or alliances, in a manner that influences relationships with customers, suppliers or competitors. Important is the contribution of Porter & Millar (1985) on this topic, who identify three basic ways that ICT can affect competition: by altering industry structures, supporting differentiation and cost leadership strategies, and also by spawning entirely new businesses; they also argue that ICT have strategic potential if they can add value to a product or service in at least one of the primary activities (inbound logistics, operations, outbound logistics, marketing and sales, after-sales support and services) or one of the support activities (human resources management, technology development, infrastructure management, procurement) of the value chain. At the same time been many case studies have been published on this topic describing and analyzing 'real-life' IS that have provided valuable competitive advantage (e.g. Earl, 1989; Hopper, 1990; Robson, 1997; Pemberton et al, 2001; Picolli & Applegate, 2003), which validate and prove the practical applicability of the above research conclusions.

Subsequent research on this topic emphasizes the need for combining ICT with other resources of the enterprise in order to have a strategic impact. In this direction Carr (2003) argues that a narrow and exclusively technological focus cannot result in competitive advantages ('IT Doesn't Matter'). Powell and Dent-Micallef (1997) from an empirical study in the retail industry found that ICT alone cannot produce sustainable performance advantages, but such advantages can be gained only by using ICT in order to leverage intangible, complementary human and business resources. Miller (2003) found that sometimes these complimentary resources can be of low value, or even considered as liabilities, until they are they are incorporated in a new ICT-based 'engine of value creation'; therefore ICT can be instrumental in leveraging existing enterprise resources of low value, or even liabilities, into valuable resources that offer (in combination with other resources and ICT) competitive advantage. Another important dimension of the strategic potential of ICT as enablers of 'strategic agility' is proposed by Sambamurthy et al (2003), who argue that the capabilities of ICT can create new strategic 'digital options' for the enterprise and enable it to launch new competitive initiatives and respond quickly and effectively to changes in its environment.

Also, research has been conducted concerning the sustainability of the competitive advantages provided by ICT. Mata et al (1995), based on a resource-based view of the firm, conclude that 'managerial ICT skills' (defined as the ability of ICT management to understand the business needs of other functional units, customers and suppliers, and in cooperation with them to develop IS that cover these needs) is the only ICT attribute of an enterprise that can provide a sustainable competitive advantage. Bharadwaj (2000) adopting also a resource-based perspective and using a matched-sample comparison group methodology found that superior firm-specific ICT resources (ICT infrastructure, human ICT resources and ICT-enabled intangibles) result in superior financial performance. Picolli & Ives (2005) from an extensive literature review identified four basic barriers to the erosion of the competitive advantages provided by 'IT-dependent strategic initiatives': IT resources barrier, complementary resources barrier, IT project barrier and preemption barrier; they conclude that the existence of one or more of these barriers can make the competitive advantages offered by 'IT-dependent strategic initiatives' sustainable for long time.

In conclusion, from the above research considerable theoretical support and empirical evidence has been produced that ICT can provide (usually in combination with other resources of the enterprise) significant competitive advantages, which under specific conditions can be sustainable; it has also been concluded that the realization of this strategic potential is not an easy task and necessitates the establishment of a connection between ICT and the overall strategy of the enterprise.

REVIEW OF RESEARCH ON ENTERPRISE SYSTEMS STRATEGIC ALIGNMENT

The above conclusions gave rise to considerable research in the last twenty years concerning various dimensions of enterprise systems strategic alignment. This research can be grouped into three basic streams: i) conceptualization and basic understanding of enterprise systems strategic alignment, ii) development of models and frameworks for assessing and directing enterprise systems strategic alignment, and iii) investigation of the impact of enterprise systems strategic alignment on the business performance. These three research streams are briefly reviewed next.

Conceptualization and Basic Understanding of Enterprise Systems Strategic Alignment

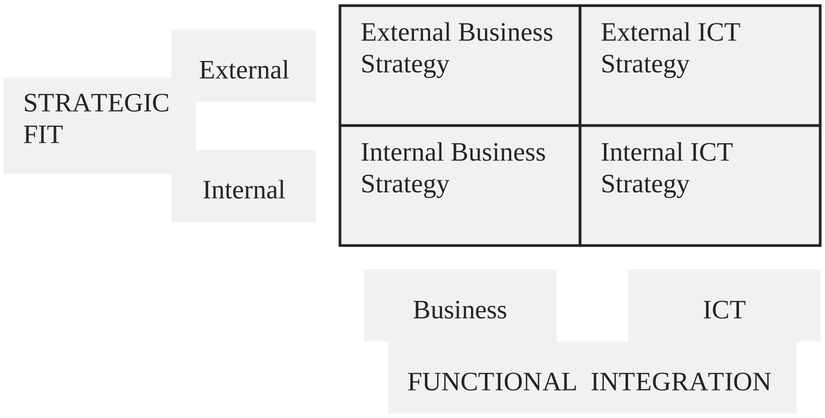
The main objective of this research stream is to conceptualize and understand the strategic alignment of enterprise systems, focusing on the identification of its basic processes, barriers, critical success factors and benefits (King, 1978; Lederer & Mendelow, 1988; Earl, 1989; Jarvenpaa & Ives, 1990; Zviran, 1990; Chan, 1992; Earl, 1993; Luftman, 1996; Reich & Benbasat, 1996; Armstrong & Sambamurthy, 1999; Luftman, Papp & Brier 1999; Luftman & Brier, 1999; Kearns & Lederer, 2000; Reich & Benbasat, 2000; Allen & Wilson, 2003; Campbell et al, 2005; Rantham et al, 2005). Due to space limitations we are going to outline briefly only the most representative publications of this research stream. Lederer and Mendelow (1988) argue that one of the most important barriers of enterprise systems strategic alignment is the difficulty of convincing top management of the strategic potential of ICT, because the top management usually lacks sufficient awareness on ICT strategic potential, regards the use of computers as a strictly operational support tool, perceives a credibility gap, does not view information as a resource, demands financial justification and also is action-oriented; for overcoming these difficulties the authors propose a number of techniques: educate top management, market IS department accomplishments to the top management, have users to do this ‘selling’, promote the business image of the IS department, respond to ‘outside forces’ influencing top managers, capitalize on changes in management and perform highly sophisticated IS planning that necessitate top management involvement. Jarvenpaa & Ives (1991) conclude that the ‘involvement’ of executives in IS activities (i.e. the ‘psychological state’) is more strongly associated with the progressive use of ICT in the enterprise than the ‘participation’ of executives in IS activities (i.e. their ‘actual behaviors’); also executive involvement is influenced by a CEO‘s participation, prevailing organizational conditions, and the executive‘s functional background. Earl (1993) identified five basic approaches that are adopted by businesses for achieving enterprise systems strategic alignment: the business-led approach, the method-led approach, the administrative approach, the technological approach and the organizational approach; each of these approaches has different characteristics and therefore different likelihood of success, the organizational approach appearing to be more effective. Luftman, Papp and Brier (1999) identified a number of enablers of alignment between business and ICT strategies: senior-executive support for IT, IT involvement in strategy development, IT understanding the business, partnership between IT and non-IT units, well-prioritized IT projects and IT demonstrating leadership). Reich & Benbasat (2000) investigated the influence of four factors on the ‘social dimension’ of enterprise systems strategic alignment (defined as the extent to which business and IT executives mutually understand and are committed to both the business and the IT mission, objectives, and plans): shared domain knowledge between business and IT executives, IT implementation success, communication between business and IT executives, and connections between business and IT planning processes; they found that all these four factors influence ‘short-term alignment’, while only the shared domain knowledge influences ‘long-term alignment’. Campbell et al (2005), based on a review of the previous research on enterprise systems strategic alignment, identify two basic approaches in it: the ‘social’ (focusing primarily on the people involved in achieving alignment) and the ‘intellectual’ (investigating mainly the relevant plans and planning methodologies); also, they remark that most of the research on enterprise systems strategic alignment adopts the intellectual approach, and recommend a combination of these two approaches as the optimal approach. Also adopting such a combined approach and based on the analysis of the content from a number of interviews with senior ICT managers they concluded that all of them believed that strategic alignment generally depends upon communication, collaboration, development of trust and shared domain knowledge, as suggested in the relevant literature; however, it was practically problematic to achieve these prerequisites, due to the prevalent culture in their organizations that promoted competition between departments.

This research stream has provided a basic conceptualization and understanding of the strategic alignment of enterprise systems, concerning mainly its basic processes, barriers, critical success factors and benefits. However, more in-depth research is required on these topics, in various types and sizes of enterprises, in various industries and national and cultural contexts, and for various types of ICT, in order to get a deeper and more complete understanding of them.

Development of Models/Frameworks for Directing/assessing Enterprise Systems Strategic Alignment

This research stream aims to support the practical application in 'real-life' of the ICT strategic alignment concept by developing models/frameworks for assisting the technical and the business management in directing and assessing enterprise systems strategic alignment. The most widely used of the models/frameworks that have been developed for directing strategic alignment is the 'Strategic Alignment Model' (SAM) developed by Henderson and Venkatraman (1999). As we can see in Figure 1 it is based on two basic dimensions of required linkage: i) the 'strategic fit' (=linkage between 'external components' (concerning the external environment of the enterprise) and 'internal components' (concerning the internal environment of the enterprise)) and ii) the 'functional integration' (=linkage between the 'business domain' and the 'IS domain'). In the strategic fit dimension the model views strategy as consisting of two components, the 'external' and the 'internal' one, which should be well integrated. In particular, it views ICT strategy as consisting of one component concerning the 'external domain' (=decisions on how the enterprise is positioned in the ICT marketplace, e.g. which of the existing ICT in the marketplace it is going to use, which are their required performance and cost attributes, what kind of relations it has with their vendors, such as outsourcing, strategic alliances, etc.) and one component concerning the 'internal domain' (=decisions on how the internal ICT infrastructure of the enterprise will be configured and managed: ICT architecture, processes and skills), which should be well integrated. Similarly it views business strategy as consisting of two components which should be also well integrated:

Figure 1. The 'Strategic Alignment Model' (SAM)



one component concerning the 'external domain' (= decisions about business scope, distinctive competencies and business relations with other organizations) and one component concerning the 'internal domain' (= decisions about its administrative infrastructure/architecture, business processes and human resources skills). In the functional integration dimension the model views two domains, the business domain and the IS/ICT domain, and proposes integration between them at two levels: 'strategic integration' (=integration between their external domain components) and 'operational integration' (=integration between their internal domain components).

Based on the above dimensions the SAM proposes that the complete enterprise systems strategic alignment consists in the integration between these four domains of strategic choice: business external strategy, ICT external strategy, business internal strategy and ICT internal strategy. Also using this model the authors propose and describe four alignment perspectives: business strategy execution (external business strategy → internal business strategy → internal ICT strategy), technology-based transformation (external business strategy → external ICT strategy → internal ICT strategy), exploitation of ICT competitive potential (external ICT strategy → external business strategy → internal business strategy) and service level improvement (external ICT strategy → internal ICT strategy → internal business strategy).

Smaczny (2001) argues that a major disadvantage of the SAM is that its basic alignment approach is the sequential development of strategies; he states that this approach was the appropriate one for the period in which SAM was developed (characterized by a more stable business environment), but latter, due to major market changes and also due to the increased reliance of organizations on ICT, it has become slow and insufficient (at least for some industries and business contexts). For this reason he proposes a 'fusion' approach instead, which allows business and ICT strategies to be developed and implemented simultaneously. On the contrary Avison et al (2004) used successfully and validated this SAM in a financial services firm, and finally concluded that it has a good conceptual and practical value; also they developed a framework for its practical application, which enables the technology and business management to determine the current level of alignment and to monitor and change it in the future as required. Furthermore, it is worth mentioning another approach that developed by Van Der Zee & De Jong (1999) for planning and setting goals for ICT and evaluating its results based on the business context, which is founded on the concepts of the Balanced Business Scorecard.

Also, a number of models/frameworks have been developed for assisting technical and business management in assessing the level of enterprise systems strategic alignment in their organization. The most widely used of them is the 'Strategic Alignment Maturity Model' (SAMM) developed by Luftman (2000); it is based on six criteria of ICT strategic alignment maturity (Communications Maturity, Competency/Value Measurement Maturity, Governance Maturity, Partnership Maturity, Scope & Architecture Maturity, Skills Maturity), each of them consisting of a number of attributes (sub-criteria), which are evaluated in a five-levels scale (Initial/Ad-hoc Process, Committed Process, Established Focused Process, Improved/Managed Process, Optimised Process). The SAMM enables the evaluation of ICT alignment practices in an organization and also the design of improvements of them. Another IT alignment maturity model has been developed by the IT Governance Institute (ITGI) (www.itgi.org) as part of the CobiT (Control objectives for IT and related Technologies) framework (ITGI, 2005). In particular, CobiT includes a process named 'Define a Strategic Information Technology Plan', which aims to satisfy 'the business requirement to strike an optimum balance of Information Technology opportunities and IT business requirements'; this process includes a strategic alignment maturity model consisting of six levels (0:Non-existent, 1:Initial/AdHoc, 2:Repeatable and Intuitive, 3:Defined Process, 4:Managed and Measurable, 5:Optimized) and also guidance for using it in order to assess the maturity level of an organization. Bleistein et al (2006a, 2006b) argue that ICT strategic alignment is necessary not only at the executive level, but also at the level of the individual IT projects as well; in this direction they propose a requirements engineering framework that addresses the business strategy and the alignment of IT projects' requirements with business strategy.

In conclusion, the research of this stream has produced some first 'high-level' models/frameworks for directing and assessing enterprise systems strategic alignment, which offer some basic guidance, but in general they require further elaboration, evolution and adaptation to the new ICT that are continuously emerging and the new models of their exploitation by modern organizations. Therefore further research is required for the development of 'lower-level' and more practically applicable models/frameworks, which offer a more specific and complete guidance for directing and assessing enterprise systems strategic alignment, and also are adapted to the technological advances and the new globalized and highly competitive business environment; moreover, further research is required for validating such models/frameworks in 'real-life' conditions and situations.

Impact of Enterprise Systems Strategic Alignment on the Business Performance

This third research stream aims to investigate the impact of enterprise systems strategic alignment on business performance or on the contribution of enterprise systems to business performance. In this stream, despite its significance, has been conducted less research work that in the other two. In the following we review the main empirical studies that have been conducted in this direction. King & Teo examined empirically the impact of four types of integration between the business plan (BP) and the information systems plan (ISP) (administrative, sequential, reciprocal and full integration) on the perceived contribution of enterprise systems to various measures of organizational performance and on the perceived extent of various types of ISP problems (organization problems, implementation problems, database problems, hardware problems and cost problems) (Teo and King, 1996; King and Teo, 2000); using data from 157 large USA firms from the Corporate 1000 Book and performing independent sample t-tests and calculating correlations they found that the extent of BP-ISP integration and also its proactive orientation has a statistically significant positive relation with the perceived enterprise systems contribution to organizational performance, and also a statistically significant negative relation with the perceived extent of ISP problems. Chan et al (1997) investigated empirically the impact of enterprise systems strategic alignment on perceived enterprise systems effectiveness and perceived business performance; using data from 164 North-American financial services and manufacturing firms (from USA and Canada) with more than 100 employees from the Dun and Bradstreet directories they constructed a structural equations model (SEM), from which it was concluded that enterprise systems strategic alignment has statistically significant positive contributions to both perceived enterprise systems effectiveness and perceived business performance. Using the same data Sabherwal and Chan (2001) addressed the same research question, but in regard to the business strategy the enterprise follows; they considered three different business strategies: 'defenders', 'prospectors' and 'analyzers' and found that the strategic alignment of enterprise systems affects perceived business performance, only in enterprises following a 'prospector' or 'analyzer' business strategy, but not in the ones following a 'defender' business strategy. Cragg et al (2002) examined the link between enterprise systems strategic alignment and four measures of perceived firm performance (long term profitability, sales growth, financial resources availability and public image & customer loyalty) in the context of small firms; using data from 250 small UK manufacturing firms and performing analysis of variance (ANOVA) they found that the subgroup of firms having higher levels of alignment had also higher levels of all these four measures of perceived firm performance than the ones with lower levels of alignment. Bergeron et al (2003), based on data collected through a mail survey from 110 Canadian small and medium firms, and using cluster analysis found that low-performance firms exhibited a conflictual coalignment pattern of business strategy, business structure, IT strategy and IT structure.

It should be mentioned that all the above empirical studies have used subjective (perceived) measures of business performance and/or enterprise systems contribution to business performance. The only empirical investigation of the impact of enterprise systems alignment on business performance that uses objective measures of business performance has been the one conducted by Byrd et al (2005); based on data from 275 fabricated metal products manufacturing companies from South-eastern USA they constructed econometric models with sales revenue per employee and profit per employee as dependent variables, while as independent variables they used the IT expenditure per employee, a measure of enterprise systems strategic alignment and an interaction term equal to the product of the above two variables. In these econometric models the coefficient of this interaction term was found to be positive and statistically significant, so it is concluded that there is a synergistic coupling (positive interaction) between IT strategic alignment and IT investment with respect to both these measures of firm performance. However, the econometric models constructed in this study did not include some fundamental independent variables, such as non-IT capital and labour, which constitute basic determinants of firm output according to production economics (Nicholson, 2004).

In conclusion, from the research of this stream has been produced some first evidence of a positive contribution of enterprise systems strategic alignment to business performance. However, further research is required in order to understand better the contribution of different types of strategic alignment of enterprise systems to various dimensions of business performance, in various types and sizes of enterprises and in various sectoral, national and cultural contexts, based on objective business performance measures and also on sound theoretical foundations from the area of production economics. Also it is necessary to investigate the dependence of the contribution of enterprise systems strategic alignment to business performance on various external and internal environment factors (e.g. business strategy, competition, etc.) and to identify its main moderators.

AN EMPIRICAL INVESTIGATION

In this section are presented briefly the main results of an empirical study conducted by the authors, which contributes to the third of the above research streams, investigating the effect of enterprise systems strategic alignment on the contribution of enterprise systems investment to business performance. It aims to overcome the two main deficiencies of the previous research on this issue, which have been mentioned in the previous section: use of subjective (perceived) measures of business performance and/or enterprise systems contribution to business performance, and construction of models that do not include all fundamental independent variables.

In this direction our study is based on two objective measures of business performance as basic dependent variables, the value added (=yearly sales revenue minus yearly expenses for buying materials and services) and the labour productivity (=value added per employee), and also on an objective measure of enterprise systems investment. We constructed theoretically sound econometric models for both these business performance measures, which are based on the theory developed in the area of production economics, and in particular on the Cobb-Douglas production function (Nicholson, 2004), and include all fundamental variables. The Cobb-Douglas production function has been successfully used in the past for estimating the contribution to firm output of various firm inputs, including ICT investment (e.g. Brynjolfsson & Hitt, 1996; Stolarick, 1999; OECD, 2003; OECD, 2004). As recommended by this literature we used an extended form of the Cobb-Douglas production function, in which the capital is divided into ICT capital and non-ICT capital:

$$VA = e^{\beta_0} L^{\beta_1} K^{\beta_2} ICK^{\beta_3} \qquad (1)$$

where VA is the yearly firm value added, and L, K and ICK are the yearly labour expenses, the non-ICT capital and the ICT capital respectively, while the $\beta_1 - \beta_3$ are the corresponding output elasticities with respect to these inputs. By log-transforming equation (1) we obtain the following linear model:

$$\ln VA = \beta_0 + \beta_1 \ln(L) + \beta_2 \ln(K) + \beta_3 \ln(ICK) \qquad (2)$$

In order to investigate the effect of enterprise systems strategic alignment on the contribution of the ICT capital to firm value added we added to this model one ‘interaction term’ (Greene, 2003; Gujarati, 2003), which is equal to the product of a ‘strategic alignment factor’ F (=degree of bilateral relationship between the ICT Plan and the Overall Business/Strategy Plan) and the ln(ICK):

$$\ln VA = \beta_0 + \beta_1 \ln(L) + \beta_2 \ln(K) + \beta_3 \ln(ICK) + \beta_4 \ln(ICK) \cdot F \qquad (3)$$

Similar models have been also been constructed for the second business performance measure (dependent variable), the value added per employee, but with all the above independent variables (L, K, ICK) normalised (divided by the number of firm employees N).

For constructing the above econometric models we used data that have been collected through a survey among Greek companies, which has been conducted in cooperation with ICAP, one of the largest business information and consulting companies of Greece. This survey was based on a structured questionnaire, which included questions about the basic financial data of the company (yearly sales revenue, expenses for materials and services, labour expenses, value of capital, value of ICT capital, etc.) and also about enterprise systems strategic alignment. We received completed questionnaires from 281 companies (99 small, 98 medium and 84 large ones) from the 27 most important sectors of Greek economy. Their average yearly sales revenue was 183.7 million Euro and their average number of employees was 493.

Initially for the value added (VA) we estimated the two models of the above equations (2) (basic model) and (3) (model with interaction term) and the results are shown in Tables 1 and 2 respectively.

In the estimated basic model of Table 1 we remark that the coefficients of labour, non-ICT capital and ICT capital are all positive and statistically significant, so we conclude that all these three inputs make a positive contribution to firm value added. These results confirm the conclusion of our previous study (Loukis & Sapounas, 2005), which had been based on a different data set, that ICT investments of Greek companies make a positive and statistically significant contribution to their output, so there is no evidence for ‘ICT Productivity Paradox’ in the Greek context. Also, we can see that the standardised coefficient of the ICT capital is higher than the one of the non-ICT capital, so we can conclude that the investment on enterprise systems contributes to value added

Table 1. Regression model for the impact of labour, non-ICT capital and ICT capital on firm value added

Dependent variable : ln (VA)			
Independent variable	Coefficient	Standardized Coefficient	Significance
constant	2.313		0.000
ln (L)	0.608	0.581	0.000
ln (K)	0.122	0.140	0.002
ln (ICK)	0.235	0.233	0.000
R-squared : 0.723			

Table 2. Regression model for the impact of labour, non-ICT capital, ICT capital and interaction between ICT capital and strategic alignment factor on firm value added

Dependent variable : ln (VA)			
Independent variable	Coefficient	Standardized Coefficient	Significance
constant	2.739		0.000
ln (L)	0.607	0.580	0.000
ln (K)	0.122	0.128	0.004
ln (ICK)	0.196	0.195	0.000
ln(ICT)* STR_ALIGN	0.113	0.112	0.003
R-squared : 0.733			

more than the investment on ‘traditional capital’. In the model of Table 2 we can see that the coefficients of labour, non-ICT capital and ICT capital remain all positive and statistically significant, and that the coefficient of the interaction term is positive and statistically significant as well and also of considerable magnitude; therefore it is concluded the strategic alignment of enterprise systems increases considerably their contribution to value added.

Next we estimated similar models for the labour productivity (=VA/N), but with all the independent variables divided by the number of firm employees N, and the results are shown in Tables 3 (basic model) and 4 (model with interaction term) respectively.

In the model of Table 3 we can see that the coefficients of normalised labour, non-ICT capital and ICT capital are all positive and statistically significant, so we conclude that all these three inputs make a positive contribution to labour productivity as well. The comparison of their standardised coefficient leads to a conclusion similar to the one drawn from the model of Table 1: the investment per employee on enterprise systems contributes to labour productivity more than the investment per employee on ‘traditional capital’. Finally from the model of Table 4 we can see that the coefficients of normalised labour, non-ICT capital and ICT capital remain all positive and statistically significant and also that the coefficient of the interaction term is positive, statistically significant and also of considerable magnitude; therefore it is concluded that the strategic alignment of enterprise systems increases considerably their contribution to labour productivity.

Table 3. Regression model for the impact of normalised labour, non-ICT capital and ICT capital on labour productivity

Dependent variable : ln (LP=VA/N)			
Independent variable	Coefficient	Standardized Coefficient	Significance
constant	3.194		0.000
ln (L/N)	0.551	0.495	0.000
ln (K/N)	0.097	0.126	0.018
ln (ICK/N)	0.201	0.208	0.000
R-squared : 0.376			

Table 4. Regression model for the impact of normalised labour, non-ICT capital, ICT capital and interaction between normalised ICT capital and strategic alignment factor on labour productivity

Dependent variable : ln (LP=VA/N)			
Independent variable	Coefficient	Standardized Coefficient	Significance
constant	3.339		0.000
ln (L/N)	0.551	0.494	0.000
ln (K/N)	0.088	0.113	0.030
ln (CK/N)	0.170	0.176	0.001
ln (CK/N)*STR_ALIGN	0.101	0.151	0.004
R-squared : 0.398			

In conclusion, this empirical investigation contributes to the third of the research streams mentioned in the third section of this chapter and provides sound evidence that the strategic alignment of enterprise systems increases considerably their contribution to both these objective measures of business performance (value added and labour productivity). This evidence is theoretically sound and reliable, since it has been produced based on the construction of econometric models including all fundamental variables founded on the production economics theory (Cobb-Douglas production function), and also using objective measures of business performance and enterprise systems investment. Further research is in progress by the authors for investigating the impact of various types of enterprise systems strategic alignment at different hierarchical levels on the contribution of enterprise systems to business performance, and also on its dependence from various external and internal environment factors.

CONCLUSION AND FUTURE TRENDS

This chapter dealt with the alignment of enterprise systems with business strategy and its impact on the business value that enterprise systems generate. The research that has been conducted on the strategic potential of ICT (reviewed in the second section of this chapter), has generated considerable theoretical support and empirical evidence that ICT can provide (usually in combination with other enterprise resources) competitive advantages, which under specific conditions can be sustainable. This strategic potential of ICT has given rise to considerable research in the last twenty years concerning the strategic alignment of enterprise systems. This research (reviewed in the third section of this chapter) has produced a basic body of knowledge concerning various dimensions of the strategic alignment of enterprise systems, which can be quite useful for both researchers and practitioners in the area of enterprise systems. In particular, it has produced a basic conceptualization and understanding of enterprise systems strategic alignment, and some first 'high-level' models/frameworks for directing and assessing enterprise systems strategic alignment; also it has been produced some first evidence of a positive contribution of enterprise systems strategic alignment to business performance.

However, further research is required in this area and also further practical exploitation by practitioners of the knowledge produced in this research. In particular, further research should be conducted first concerning the strategic potential of ICT and ways of exploiting them strategically in enterprises and combining them with other enterprise resources for achieving sustainable ICT-based competitive advantages. Also, further research is required for understanding better and in more depth the basic processes, barriers, critical success factors and benefits of enterprise systems strategic alignment, and for developing practically applicable models/frameworks, which can offer clear and complete guidance for directing and assessing the strategic alignment of enterprise systems. Finally, extensive research should be conducted concerning the 'value' generated by the strategic alignment of enterprise systems, in order to understand better the contribution of different types of strategic alignment of enterprise systems at different hierarchical levels to various dimensions of business performance; this research, in order to give reliable and practically useful results, and also to allow meaningful comparisons between different types of strategic alignment applied in different in various sectoral, national and cultural contexts, etc., should be based on objective business performance measures and also on sound theoretical foundations from the domain of production economics, such as the Cobb-Douglas production function. In the fourth section of this chapter is described an empirical investigation conducted by the authors that follows these principles, as a guidance for future research on this topic. Also it is necessary to investigate the dependence of the value generated by strategic alignment of the enterprise systems from various external and internal environment factors (e.g. business strategy, competition, etc.) and to identify its main moderators.

At the same time it is highly important that this knowledge on the basic concepts, methods and value of enterprise systems strategic alignment be practically exploited to a larger extent and be incorporated much more in the practice and processes of enterprises.

KEY TERMS

Business/Strategy Plan: A document describing the mission, goals, competitive strategy, future directions and action plan of the enterprise, which are based on the analysis of its external environment (e.g. competition, opportunities, threats) and its internal environment (e.g. resources, capabilities, strengths, weaknesses).

Cobb-Douglas Production Function: A particular widely used form of production function, which posits that firm output in a particular time period is an exponential function of the capital and the labour employed in this period.

Enterprise Systems Plan: A document with the capabilities, strengths and weaknesses of existing enterprise systems, the forms and the extent of information and communication technologies (ICT) usage in the industry, the capabilities offered by existing and emerging ICTs that may interest and influence the enterprise and also the planned enterprise systems.

ICT Strategic Potential: Capability of ICT to provide valuable competitive advantages and make a significant strategic impact on the enterprise, if properly exploited.

Information Systems Strategic Alignment: The extent to which business strategies are enabled, supported and stimulated by information strategies

Production Function: A function that connects the output produced by an enterprise during a particular time period (dependent variable) with the quantities of the inputs it has used in the same period (independent variables).

Strategic Alignment Maturity Model: A model that aims at assisting technical and business management in assessing the level of enterprise systems strategic alignment in their organization, based on a number of proposed criteria/sub-criteria.

Strategic Alignment Model: A model that aims at directing and assisting strategic alignment in an organization by proposing and describing required steps.

Chapter 1.5

Behavioral Factors and Information Technology Infrastructure Considerations in Strategic Alliance Development

Purnendu Mandal
Lamar University, USA

ABSTRACT

Since behavioral and cultural factors play a major role in strategic alliances between partners, IT managers must understand the intricacies involved in the development of resultant IT infrastructure in satisfying both business requirements and cultural fit of the aligned partnering units. This paper first highlights the IT-related issues and cultural issues which are important in the process of developing a strategic alliance between partners. Then, a case study involving a major telecommunications organization and several retail electricity organizations is presented to illustrate the IT requirements and human-related considerations. The analysis focuses on the requirements of pre-strategic alliance phase of the negotiation process.

INTRODUCTION

Information technologies (IT) such as the Internet, WWW, EDI, and so forth, have already changed, and are still changing, the way organizations do business today (Housel & Skopec, 2001; Mandal & Gunasekaran, 2003). Significant movement that has occurred relatively recently is the push toward worldwide and national integration of information systems (Dutta, Lanvin, & Paua, 2003; Kumar & van Hillegersberg, 2000; Laughlin, 1999; Palaniswamy & Tyler, 2000; Shore 1996) for organizations to achieve competitive advantages. Since it has become critical for businesses to be able to get to relevant data and information quickly and easily, large information systems such as enterprise resource planning (ERP) systems, supply chain management (SCM), enterprise resource/relationship management (ERM), enterprise application integration (EAI), Web services, and customer relationship management (CRM), have recently grown in importance.

Large information systems are helping organizations to deal with increasing competition. Many organizations can no longer compete effectively by themselves; so, they must consider having partners to cope with the competition. The number of strategic alliances formed between organizations has increased dramatically and are projected to continue to increase in the future. Strategic alliances are a mutual agreement between two or more independent firms to serve a common strategic (business) objective (Bronder & Pritzel, 1992). Alliances have had a growth rate of 25% and are projected to have a value of $40 trillion by the year 2004 (Parise & Sasson, 2002). The "make versus buy" decision is becoming the "make versus buy versus partner decision". Through empirical analysis, Yasuda (2005) shows that the primary motivation of strategic alliances is the access to resources, followed by the shortening of time required for development or marketing.

A successful alliance should not imply an imposition of one organization's culture over another. Rather, it should create a new culture that brings together the best elements of each. Unfortunately, "creation of a new culture" is rarely practiced as alliances are often viewed solely from a financial perspective, leaving the human resource issues as something to be dealt with later and without a great deal of effort. The creation of a new culture involves operations, sales, human resources management, technology, and structure among other issues. It is undoubtedly expensive and time consuming to create a new culture, but, in the end, employees become contented and productive.

For an organization to exploit the benefits of alliances, human factors and information technology (IT) factors must be among the basic components for any analyses and plans. Yet, the literature is poor in this regard. Evidences of failure in the implementation of IT systems due to the lack of considerations of human factors have come to light in recent years, but a comprehensive consideration of human factors in strategic alliance, which is prompted by the possibility of major IT systems alignment, is still rare in IT literature. The main objective of this paper is to highlight the human-related issues in IT-centered strategic alliances. We focus specifically to human-related considerations before the actual negotiations for an alliance and its implementation.

To facilitate the discussion, we have used the case of a telecommunication (TEL) company. TEL identified a new market opportunity as a result of changed market conditions. The company is in the traditional business of telecommunications and information services, but identified a new market opportunity in the retail electricity distribution business that became apparent as a result of market deregulation in the electricity industry. The deregulation of the electricity industry presented TEL with a diversification opportunity. Should TEL enter into an electricity retailing business, or concentrate on its existing communications business, which is increasingly becoming more competitive? TEL's own strength in IT areas, its strong market position, and the opportunities in forming alliances with other business partners in the electricity industry are the main considerations for this strategic move.

The paper is organized in several sections: starting with a brief review of IT and strategic alliance. Cultural aspects in alliances and IT issues in alliances are discussed in the next two sections. The research methodology is presented next. This is followed by a short description of the case study. The cultural issues raised in this case study are discussed before the discussion section.

ISSUES IN STRATEGIC ALLIANCE

Strategic alliance focuses on combining resources of various organizations through acquisition, joint venture, or contracts. The main purpose of an alliance is to create one or more advantages such as product integration, product distribution, or product extension (Pearlson, 2001). Strategic alliances also help in utilization of resources even in small organizations (Gunasekaran & Ngai, 2003). In alliances, information resources of different organizations require coordination over extended periods of time.

Bronder and Pritzl (1992) suggest a strategic alliance exists when the value chain between at least two organizations (with compatible goals) are combined for the purpose of sustaining and/or achieving significant competitive advantage. Four critical phases of strategic alliance are: strategic decision for an alliance, alliance configuration, partner selection, and alliance management. These four phases provide basis for a continuous development and review of the strategic alliance, which increases the likelihood of the venture's success.

Typically, the first phase of a strategic alliance is the strategic decision. Phase I answers the question: Is this strategic alliance justified? Phase II (Configuration of a Strategic Alliance) focuses on setting-up the alliance's structure. Phase III (Partner Selection) is one of the most important success factors of the strategic alliance. Considerations such as fundamental fit (do the company's activities and expertise complement each other in a way that increases value potential?), strategic fit (do strategic goal structures match?), and cultural fit (is there a readiness to accept the geographically and internally grown culture of the partners?) are some of the concerns in this phase. The final phase, Phase IV, is concerned with managing a strategic alliance; how do partners continually manage, evaluate, and negotiate within the alliance to increase the odds of continued success?

According to Currie (2000), there are three major forces that are influencing the formation of alliances between organizations: globalization, deregulation, and consolidation. But, before organizations commit to strategic alliance, they should have a management plan on how to deal with human behavior aspects of the new organizational unit. Once a strategic alliance is a "done deal", the organizations must manage the alliance. Parise and Sasson (2002) discuss the knowledge management practices organizations should follow when dealing with a strategic alliance. They break the creation of a strategic alliance down in to three major phases:

- *Find* — making alliance strategy decisions and screening and selecting potential partners.
- *Design* — structuring and negotiating an agreement with the partners.
- *Manage* — organizations should develop an effective working environment with the partner to facilitate the completion of the actual work. This phase includes collecting data relating to performance and feedback from both partners on how they think the alliance might is progressing. Managing relationships and maintaining trust are particularly critical during the Manage Phase.

Knowledge management techniques are especially important for a successful alliance (Parise & Sasson, 2002). They discuss the need to develop a systematic approach for capturing, codifying, and sharing information and knowledge, a focus on building social capital to enable collaboration among people and communities, an emphasis on learning and training, and a priority on leveraging knowledge and expertise in work practices. They also state their study indicates easy access to information and knowledge is a recurring theme in successful alliances.

Parise and Sasson (2002) provide a list of the building blocks of alliance management. Four of their building blocks relating specifically to human behavior factors are:

- *Social capital.* Building trust and effective communication with the partner are necessary ingredients for an effective relationship.
- *Communities.* Communities of practice allow for the sharing of personal and experiences and tacit knowledge based on a common interest or practice. Communities can be realized using electronic meeting rooms and forums or more formal alliance committees.
- *Training.* Companies that rely heavily on strategic alliances should have formal training for managers and team members.
- *Formal processes and programs.* Alliance know-how should be institutionalized. An example of this is Eli Lilly, a leading pharmaceutical firm, created a dedicated organization, called the Office of Alliance Management, responsible for alliance management.

Company's that use alliance management techniques that stress knowledge management are more successful than those who do not. Leveraging knowledge management across a company's strategic alliance is a critical success factor for partnering companies. Strategic alliance is a management issue. Both cultural and information technology aspects play a significant role in strategic alliance, which is the topic of discussion in the next two sections.

CULTURAL ASPECTS IN ALLIANCES

As discussed in the preceding sections, alliance among firms naturally would result in many organizational changes. Leavitt (1965) concluded there are four types of interacting variables to consider when dealing with organizational change, especially in large industrial organizations: task variables, structural variables, technological variables, and human variables. He proposed structural, technological, and people approaches to organizational changes, which derive from interactions among the four types of variables mentioned earlier.

The earlier-mentioned four variables are highly interdependent so that a change in any one variable usually results in compensatory changes in other variables. The introduction of new technological tools — computers, for example — may cause changes in structure (communication system), changes in people (their skills and attitudes), and changes in performance and tasks. Therefore, it is imperative to consider all areas that might be affected when a company plans to introduce change to an organization.

Pre-existing, people-related problems at a target company often cause many alliances to fail to reach their full financial and strategic potential. Numerous case studies report failure of alliances due to lack of consideration for the potential impact of behavioral and structural aspects (Brower, 2001; Numerof & Abrams, 2000). To build an effective alliance, institutions must pay particularly close attention to cultural, personality, and structural incompatibilities. Leaders from alliance institutions need to recognize the personality differences in their managers as well as the demands required by the life cycle stage of their organizations (Segil, 2000). It has also been demonstrated that successful alliance partners share many strong similarities regarding performance and relationships (e.g., people skills) (Whipple & Frankel, 2000). Understanding potential incompatibilities gives institutions contemplating alliances a solid foundation on which to explore the feasibility of joint projects. It also increases the likelihood that the alliance will operate successfully (Whipple & Frankel, 2000).

Successful alliances are impeded when the culture of one or both associations highly differ in value. "High control value" is inconsistent with the toleration for ambiguity and the "willingness to compromise" often required for strategic alliances.

Maron and VanBremen (1999) suggests the use of William Bridges' Organizational Character Index (OCI), which can be a useful tool for analyzing the cultural differences between two associations to determine how well they might work together. It promotes better understanding between two associations; fosters an appreciation for what both partners could bring to an alliance; and identifies underdeveloped qualities in both associations that could inhibit the success of an alliance.

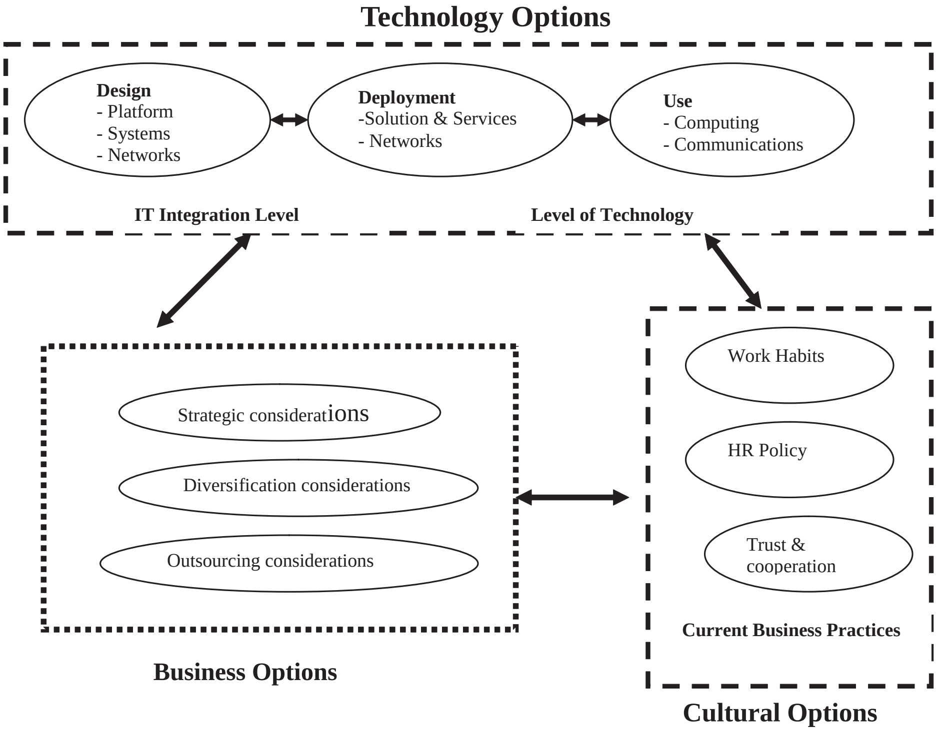
IT ISSUES IN ALLIANCES

Long-term IT considerations, such as IT architecture, is a major consideration. A strategic consideration, such as new alliances, would require visioning of a different IT architecture. Applegate, McFarlan, and McKenney (1999) view IT architecture as an overall picture of the range of technical options as well as business options.

> *Just as the blueprint of a building's architecture indicates not only the structure's design but how everything — from plumbing and heating systems, to the flow of traffic within the building — fits and works together, the blueprint of a firm's IT architecture defines the technical computing, information management, and communications platform.* (p. 209)

Figure 1 brings out the dynamic nature of the IT architecture development process. The technology part, shown by dotted oval, is concerned with design, deployment, and how it is used. This part is the core of IT architecture and a huge proportion of IT professionals' time is devoted to these activities. Consideration of business options, which feed to various technology options, are higher level activities in the IT architecture development process. Business options, such as strategic alliances, mergers and acquisitions, outsourcing, diversification, and so forth, are

Figure 1. Forces affecting overall IT architecture



influenced by major internal as well as external factors, such as current business practices, business opportunities, and organizational strategy. There is a direct link between technology and organizational strategy. The technology (with its operational and technical settings) exerts a strong influence on the organization's future strategic direction. Thus, one can observe (as shown in Figure 1 through connecting lines), a close link between technical and other business factors, and, like ever-changing business, the IT architecture is a dynamically evolving phenomena.

An alliance can exist between any types of organization. For example, a telecommunication organization could form an alliance for international joint ventures, or an alliance can be established between a banking organization and an IT supplier. The notion of developing a strategic alliance suggests an organization's performance can be significantly improved through joint, mutually dependent action. For a strategic alliance to be successful, business partners must follow a structured approach to developing their alliances and should include as part of this process, strategic planning, communication, efficient and effective decision-making, performance evaluation, relationship structure, and education and training.

Strategists have often suggested that organizations should consider entering into similar or somewhat-related markets sectors to broaden their product/service portfolios (Henderson & Clark, 1990; Markides & Williamson, 1997). Both the dimensions of market (customer and product) in a related market can easily be identified and strategies formulated for deployment. The main advantage of adopting such a strategy is that an organization can easily use its competencies and strategic assets in generating a strategic competitive advantage (Markides & Williamson, 1997). Determining the design and the requirements of a new information system (IS) is a relatively simple task. In contrast, diversification into a significantly different market for an IT/IS organization is a very challenging task, which needs considerable evaluation of IT infrastructure and human relations.

RESEARCH METHODOLOGY

The focus of this research has been to understand the complexities that may arise in an alliance, particularly when an ICT organization *moves away from its traditional business activity arena*. From practitioners' point of view, this research aims to provide guidance in four avenues while an organization is negotiating various terms and conditions of strategic alliance with partners:

1. to define the new environment for the organization and its partners;
2. to highlight the complexity and complementarities in the alliance;
3. to provide details of technical strengths and limitations for the new situation; and
4. to provide an assessment of human-related strengths and limitations for the new situation.

There has been limited published research that has examined the pre-strategic alliance structures, particularly in the telecommunications industry. Thus, a case study approach was used to gain an in-depth understanding about the way in which the organizations went about examining the strategic alliance structure. A case study is basically a "methodology based on interviews, which are used to investigate technical aspects of a contemporary phenomenon with its real life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used" (Yin, 1994). Thus, a case study approach may lead to a more informed basis for theory development. It can provide analytical rather than pure statistical generalizations. Thus, "theory" can be defined as a set concepts and generalizations.

A theory can provide a perspective and a way of seeing an interpretation, which ultimately leads to understanding some phenomenon (Benbasat, Goldstein, & Mead, 1987). In this case, the technical and human factors that need to be considered when forming a strategic alliance.

Interviews were conducted with CEOs of electricity operating agencies and market regulating organizations. IT managers in some of these organizations were also contacted to get an appreciation of how transactions and information flows take place within the electricity industry. The duration of each interview was approximately 40 minutes, where every interview was conducted on a one-to-one basis, so as to stimulate conversation and breakdown any barriers that may have existed between the interviewer and interviewee.

Information for this research was also collected from various sources such as government publications, industry reports, trade publications and informal/formal discussions with industry experts. WWW and the Internet were also a good source of information.

THE CASE STUDY

The telecommunication organization (TEL) provides services to its customers through its own telecommunications network and would like to improve its customer base by forming a strategic alliance with the retail electricity distribution organizations. TEL is a Fortune 500 company with annual revenue over $14.5 billion. TEL provides a full range of services in telecommunication markets to more than 10 million fixed line and 6 million mobile subscribers. Many experts believe that a handful of global power companies will soon provide the majority of the world's energy needs (Brower, 2001), and TEL aspires to be one among them. As large telecommunication organizations exhibit structural inertia, generating a competitive advantage in a new market poses an enormous challenge (Henderson & Clark, 1990). An organization must make a distinction between a new product and the means to achieve that new product. The recent merger between America Online and Warner Publishing clearly demonstrates that it is not too difficult for an IT organization to offer new products in an existing market. Considering this point, strategic alliances and partnership could be a way out for an IT organization to enter into a completely new product market. From a systems development perspective, alliances may result in the development of new interfaces to the existing ISs or alternatively a new integrated IS.

As per the deregulation rules, a retail distributor must make financial settlement with other suppliers of the electricity industry supply chain. This needs to cover the cost of electricity from the wholesale electricity market, tariffs for distribution of the same by the transmission and distribution service providers, and meter data collection from meter providers (MPs) and meter data agents (MDAs). The processes and systems therein must be able to interface with retail energy distributors accounting and billing, service activation, and service assurance processes and systems.

To conduct business as a market participant TEL must purchase wholesale electricity and services for the physical delivery and metering to the customer. There are two clear options available to TEL to purchase electricity:

- By *direct participation* and trading in the national electricity market (NEM). This means that TEL would perform all electricity trader functions, including the act to bid and settle wholesale purchases in the national electricity market from its own resources and carry all market and prudential risks and responsibilities.
- By *engaging an existing specialist energy trader.* This means that TEL would form a close and long-term relationship with one (or more) existing trader(s) who would operate all market trader functions and processes on

> TEL's behalf. This would be an outsourced supply arrangement. The sharing of risk and responsibilities is a matter for specific agreement with the trader.

The management of TEL must first realize the complexity and limitations of the IT infrastructure before they venture into the new business. TEL follows a standard procedure called PDOM (product development operational model) for any IT product development and this procedure was also applied in developing its IT architecture design. PDOM is very similar to standard SDLC (systems development life cycle).

Figure 2. Relationships between TEL and third parties

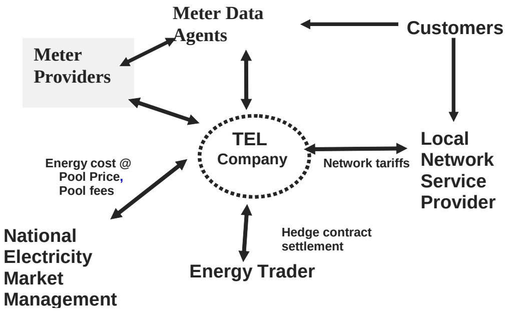


Figure 2 shows the relationship between TEL and third parties that it must reconcile.

Reconciliation with these third parties is critical to ensure that the following items are accurate for customers: charges, dates (i.e., customer's start and end dates), rates, services received, usage, and loss factors. Reconciliation is also necessary to ensure that payments are settled for the correct dollar amount and are on time. The third parties with whom TEL will be required to settle with are NEMMCO (National Electricity Market Management Company), LNSPs (local network service provider), MDAs, MPs, energy traders, and other retailers.

For the proposed alliance to become effective, TEL will be required to develop a number of third party relations with electricity retailers. These relationships are shown in Table 1.

To forge a meaningful alliance TEL would be required to make a number of major business decisions, which would influence the overall IT architecture. These decisions would form the core of the IT system and partnership relations and are presented in Table 2.

Table 1. Electricity retailers and third party relationships

Retailers	**Relationships**
Electricity sourcing	TEL will need to contract energy traders to purchase electricity in the national electricity market. TEL will be required to settle periodically with these organizations for services rendered.
NEMMCO	Tel will be required to settle periodically with National Electricity Market Management Company (NEMMCO) for wholesale electricity purchases. NEMMCO will provide billing reconciliation data.
MDA	TEL will contract with NEMMCO accredited MDAs for the collection and provision of customer electricity usage data for billing purposes. TEL will be required to settle periodically with MDAs for services rendered
MP	TEL, as an RP, will have a relationship with MPs in the provision and maintenance of meter installations, and TEL will be required to settle periodically for services rendered
LNSP	TEL will enter into service agreements with each local network service provider (LNSP) for the use of their distribution network and for the connection and supply of electricity. TEL will be required to settle periodically with LNSPs in terms of distribution fees for network use.
NEMMCO and State Regulators	TEL will pay fees to NEMMCO and state regulators for operating licences and other regulatory charges
Generators	TEL may contract with generators (outside of the spot market) for long-term energy requirements.
TEL Partner sales commissions	TEL could potentially enter into sales partnerships and pay appropriate commissions.

Table 2. Major business decisions TEL must make

Decision
TEL will require a customer-signed application form before the retail transfer process can commence.
TEL will not enter into and conduct a customer transfer under the BETS process.
The company will negotiate contracts with a LNSP, which will ensure that LNSPs will connect customers to their network at a customer-nominated date and time or within a reasonable time. Noteworthy each LNSP will perform service location work for the electricity connection.
TEL will appoint only registered to read meters at agreed customer start date and times.
An MP will install and remove electricity meters only with company's written instructions.
Each LNSP is responsible for fault rectification and maintenance of their electricity distribution network in their local area. TEL will hand off to the appropriate LNSP for fault calls made to TEL. TEL will pay the relevant service fee, but if the customer is culpable for the fault, the onus will be on the LNSP to recover costs.
MDAs are to provide all customer electricity usage to the retailer for billing purposes, typically daily overnight for smart meters. MDAs will employ manual meter readers to read SIMs at a minimum interval of monthly regardless of the billing cycle.
TEL will settle with MDAs, LNSPs, MPs, energy traders and the pool for electricity energy cost of goods sold.
TEL must provide energy forecasts to energy traders so they can determine the amount of energy to hedge.

If these alliances are to eventuate, the existing processes and systems will be used to generate reports to partner sales and commissions. TEL would be required to provide a lot of technical support to potential strategic partners, since partners in the electricity retail business in general do not have well-developed information systems. In fact, most electricity retailers had manual settlement systems. This would be a serious limitation to full-scale system integration.

CULTURAL FIT BETWEEN TEL AND ITS PARTNERS

Table 3 shows that there are significant differences between TEL and the other partners. A strategic alliance in this situation would require a careful evaluation of the strengths and weaknesses of each firm, and detailed planning of what the reorganized alliance would look like. The IT architectural planning would not only present the overview of future challenges, but would also provide the chief information officers (CIOs) a summary of the nature of human-related activities they would be faced with once the alliance became a reality.

Before companies agree to participate in the strategic alliance, they should first determine if their organizations can work together harmoniously. To determine whether they can work well together, each company should attempt to determine what type of organization it is, that is, does an organization have a certain personality

Table 3. Structural and behavioral differences

Factors	TEL	Partners
Company organizational structure/size	Very complex and large in sales volume (Annual revenue $14.5 billion, Assets $24.9 billion)	Small to medium size, relatively simple structure (revenue in the order of million $)
Employee work habit	Flexible work hours	Relatively rigid work hours
Customer relations	Good relations with existing customers — excellent customer services	Indifferent to customer complaints
Employee training	Good opportunity for skill upgrading (formal training department)	Reasonable opportunity to technical skill development
IT system compatibility	Highly developed IT system	Manual or primitive IT systems
Employee satisfaction	Highly motivated, well paid work force.	Competent, but low paid work force.
Employee turn over	High turn over	Relatively low employee turnover.

or culture? As shown in Table 3, both TEL and its partners exhibit a different cultural setting, this suggests the need for further investigation to make the proposed alliance effective.

The cultural differences between TEL and potential industry partners are so high, as evident from Table 3, that one might suggest the proposed alliance is a recipe for disaster. Unless there is a higher authority to ensure compliance, this alliance is likely to head for a failure. The perception of relational risks plays a dominant role in strategic alliance. As uncertainty regarding partner's future behavior and the presence/absence of a higher authority to ensure compliance dominate strategic alliance considerations, it seems to be that the relational risks are very high in this case. Delerue (2004) suggests that informal contextual factors have more influence on relational risks than the formal contextual factors.

There are three important reasons related to human behavior factors that might lead to partnership failure in this situation. The reasons are (as per Dixon & Marks, 1999): *inattention to the human resources issues; failure to plan for other human resources issues such as benefits, loyalty, identity, etc.; and poor communication*. In addition, it would be necessary to build a new culture and learning environment.

DISCUSSION AND FUTURE SCOPE

In today's competitive business environment, new methods of evolution from independence to interdependence are continuing to unfold; strategic alliance is one of those methods that can be used to achieve competitive advantage. In the process of developing a strategic alliance, IT infrastructure and human factors play important roles. In addition to considering the projected information systems the organization will require, information officers should focus on the human factors of its organization to increase the odds that an alliance will be successful. IT planning highlights major weaknesses and incompatibilities with information systems of various parties within an organization. Those incompatibilities, however, can intensify further due to operational and work practices in partner organizations. The development of an IT system and the serious consideration of human issues would lead to practical improvements in the way most organizations approach strategic alliance development planning.

As further enhancement in analysis of human-related issues, the author advocates the deployment of organizational character index (OCI) tool (Bridges, 1992), mentioned earlier in the paper. To determine whether partners should work together on possible strategic alliances, the American Society of Clinical Pathologists (ASCP) and the College of American Pathologists (CAP) suggest the use of the OCI tool (Maron & VanBremen, 1999). Bridges (1992) explains how OCI can be used to categorize organizations, similar to the way the Myers-Briggs Type Indicator describes the characteristics of the individual. OCI, a public domain tool, consists of a written questionnaire that takes 10 to 15 minutes to complete. Bridges stresses that there are not right or wrong types of organizations; it merely brings out organizational personalities. OCI categorizes organizations for the following types (Maron & VanBremen, 1999):

- its orientation or source of energy (extroverted or introverted);
- how it gathers information or what it pays attention to (sensing or intuitive);
- its way of processing information, how it judges situations, and how it makes decisions (thinking or feeling); and
- how it deals with the external world (judging or perceiving).

The OCI tool was most useful in its ability to stimulate constructive discussions about the two company's cultural differences. Using the OCI tool, ASCP and CAP accomplished the following objectives:

- it promoted better understanding between the two associations;
- fostered an appreciation for what both partners could bring to an alliance; and
- identified "underdeveloped" qualities in both associations that could inhibit the success of an alliance.

The OCI provides valuable insights into difficulties organizations with certain characteristics might face in a joint venture such as a strategic alliance. It also highlights the underdeveloped qualities of an organization. These qualities might then be improved. Improving on the qualities can increase the likelihood that a joint venture will be successful.

Maron and VanBremen (1999) stress that the "OCI is not a definitive diagnostic tool. It is best used as a way to stimulate discussion, largely because it helps potential partners better understand and articulate their own, and each other's values and expectations." To use the OCI tool, the following set of simple steps could be followed:

- Administer the OCI questionnaire.
- Tabulate the responses.
- Use the results as the basis for discussion by volunteer leadership and staff.

The OCI could assist the organizations in determining whether their organizational cultures might work well together, but there are other human factors to consider. Burrows (2000) stresses the importance of understanding the "people situation at the target company," if a successful long-term relationship is to result. Burrows (2000) argues that most companies misunderstand or ignore "pre-existing people problems", and once the joint ventures are created, man problems reveal themselves, which undermine value-creation opportunities, jeopardize relationships with customers, and reduce productivity.

Chapter 1.6

Developing and Analyzing Core Competencies for Alignment with Strategy

Keith Sawyer
Alpha Omega International, UK

John Gammack
Griffith University, Australia

ABSTRACT

Although it is widely accepted that alignment of knowledge with corporate strategy is necessary, to date there have been few clear statements on what a knowledge strategy looks like and how it may be practically implemented. We argue that current methods and techniques to accomplish this alignment are severely limited, showing no clear description on how the alignment can be achieved. Core competencies, embodying an organisation's practical know-how, are also rarely linked explicitly to actionable knowledge strategy. Viewing knowledge embedded in core competencies as a strategic asset, the paper uses a case study to show how a company's core competencies were articulated and verified for either inclusion or exclusion in the strategy. The study is representative of similar studies carried out across a range of organisations using a novel and practically proven method. This method, StratAchieve, was used here in a client situation to show how the core competencies were identified and tested for incorporation or not in the strategy. The paper concludes by considering the value of the approach for managing knowledge.

INTRODUCTION

Many companies have developed or adopted various knowledge management (KM) initiatives to try to surface and differentiate what they do know from what they need to know and also to identify the location of their knowledge gaps. Processes and tools that support efforts to capture knowledge are well known and widely used, such as expertise directories, intranets, communities of practice, knowledge audits, discussion forums, knowledge maps, building and documenting knowledge based and expert systems, storytelling, benchmarking, and the like. These efforts serve the strategy functions of organisations, aligning capability and know-how with strategic objectives.

Although the importance of strategic alignment is recognised, what is less understood is the practical means to determine what knowledge is strategically important and how this knowledge can be incorporated into the corporate strategy. Zack (1999) for example suggests that companies may have unique ways of doing this, (itself a competitive advantage) using techniques such as SWOT analysis. Zack's work, while providing a framework and some high-level questions, is light on actionable detail, and is silent on how the output of such efforts can be strategically assessed with sufficient reach to be implemented. The available literature on knowledge strategy alignment is generally very limited: although many documents refer to these issues, few go beyond noting the desirability of alignment, and even fewer provide any detailed methodological guidance. Few empirical studies appear to exist, and whilst academic comparison across unique cases is not always appropriate, the study reported in this paper describes a generic method that has also been used in several other organisations. The approach described here addresses *what* organisations know, and how it aligns with their wider strategy.

All organisations need to "know what they know" (and know what they don't know) to make strategic decisions on (for example) sourcing, customer satisfaction, recruitment and training, investment, and in identifying areas for process re-engineering, market development, or innovation. The familiar saying, "If only we knew what we know" is, however, flawed because it presumes that what exists as knowledge in organisations is always useful and needs to be formalised and actioned. More appropriate is to say "If only we knew what we need to know". This means that organisations must also know what they no longer need to know because it no longer has a sufficient impact on the corporate objectives. Similarly, organisations must know what knowledge is most important and determine whether they already have this knowledge or need to acquire it. Apart from the rather limited SWOT analysis, or proprietary methods (e.g., AMERIN, n.d.) that may or may not include tools that help identify knowledge gaps, there are few clear statements on how, in practice, strategy may be structured in actionable alignment with organisational knowledge.

Organisations must structure their strategy so that strategic decisions and actions can be made on a variety of fronts, such as retaining and growing profitable customers, selling the right products to the right market, and recruiting and developing staff. To achieve this, organisations must manage their knowledge effectively to ensure it is directly translatable into strategic actions. Without knowing how to effectively manage their own stock of intellectual capital, such decisions cannot be actioned nor can the company be properly valued[1].

When turnover or loss of key staff is potentially a consequential threat, failure to manage the implicit knowledge assets underpinning this value may be seen as negligent. Intellectual capital is the main source of value creation (Edvinsson & Malone, 1997) and thus strategically linked directly to the organisation's future. In larger organisations especially, formalisation of this activity is required, not only for internal purposes, but also externally, such as shareholder value creation and outperformance of competitors. Identifying, securing and managing the various forms of intellectual capital (human and structural) within an organisation has thus become a central theme for knowledge management research as well as for knowledge valuing and reporting.

KM initiatives typically centre on the personnel who embody and can apply their knowledge in project or other business activity settings, and often entail recording or abstracting from the traces of their contextualised activities. Such KM initiatives implicitly recognise the centrality of the competencies of individuals and groups in transacting the strategic aims of the organisation at operational levels, and in potentially identifying the specific knowledge and abilities that give comparative advantages. Rarely, however, are such initiatives directly linked to corporate strategy and are (often inappropriately) typically designed and implemented through the organisation's IT support function (Berkman, 2001). A focus on the competencies related to strategic objectives and alignment with operational competencies is vital and is addressed in the following case study.

If organisations are centrally reliant on their knowledge for their survival, value and prosperity, their knowledge management strategies must be fully congruent with wider corporate strategy. Hackney, Burn, and Dhillon (2000) note, however, that comments on implementing such congruence have been few, and there remains a "prevalent disconnect between (business) and IT strategies". Their analysis of contemporary business strategy implies a reappraisal of the conventional and rational assumptions implicit in strategic IS planning (SISP) and where installing an IT "solution" is insufficient without coherent linkage to business strategy.

Hackney, Burn, and Dhillon (2000) cite research suggesting a necessary relationship between innovation and organisational *competence* and see assessing organisational competencies as a critically relevant challenge for SISP. The terms *competences* and *competencies* are both used in the literature to refer to such organisational abilities: we prefer to use *competencies* in this paper. The knowledge embedded in organisational competencies can be a key strategic asset, and conversely, strategy emerging from inherent capabilities and competencies provides flexibility and responsiveness. Identifying such competencies is prerequisite to their assessment, valuation, and incorporation into strategy. These competencies, which are typically knowledge based, can form the essence of a knowledge strategy embedded within a wider corporate strategy that is not simply cast in terms of KM technologies over some planning period.

A company's core competencies (Prahalad & Hamel, 1990) are the areas in which it has competitive strength and thus form a platform for its strategic thrusts. Not knowing or appreciating these means its strategies may fail and compromise proper valuation of a company's knowledge assets underlying the support, adaptation, and maintenance of its activities. Core competencies are the "cognitive characteristics of an organisation, its know-how…" (Hatten & Rosenthal, 2001, p. 50), that is, an organisation's collective (functional) expertise. Built on the skills and experience of individuals and teams, they are housed in characteristic business functions: examples Hatten and Rosenthal (2001) cite include McDonald's HR competency in recruiting, hiring, training, and retaining part time labour and Intel's technology competency in state of the art design of microprocessor chip families. Although such functions are not necessarily unique to an organisation, the know-how and processes involved in them may well be, thus conferring advantage.

Core competencies are necessarily part of a knowledge strategy which itself is part of the overall strategy. A focus on competencies (which implies active and generative abilities) rather than the knowledge traces itself is preferable, since in times of change, accumulated knowledge may be a hindrance to new thinking: what Leonard-Barton (1995) has called "core rigidities". To give a sustainable strategic advantage, competencies should be valuable, rare, hard to imitate or substitute, and ideally will confer a dominating ability in their area. Bollinger and Smith (2001) view the knowledge resource as a strategic asset, with the "collective organisational knowledge, (rather than that) of mobile individuals", that is the essential asset. This suggests a focal shift towards organisationally understood activity and process, not merely data and record storage requiring leverage by particular individuals for effectiveness.

In the knowledge based view, nicely contrasted with the conventional rational view of strategy by Carlisle (1999) the strategic focus is on value *creation* arising from uniquely effective internal capabilities and competencies, rather than value *appropriation*, which emphasises "optimisation" activity in imperfect markets. Although over time advantages may be eroded, organisations with developed "capabilities for managing knowledge creation and exploiting (its value) are better able to adapt by developing new sustainable core competencies for the future" (Carlisle, 1999, p. 24). Dawson (2000, p. 323) also notes "It is far more useful to think (about developing) dynamic knowledge capabilities than about knowledge as a static asset …to be managed".

The theoretical literature on core competencies does not however generally relate their development to concepts of knowledge management operation, nor to strategy implementation. Nor, although recognising that some competencies are more important than others, does it distinguish strategic from operational core competencies. Although the literature does not imply that strategic competencies arise from operational ones, we find it useful in practice to differentiate these since the only way strategy can be realised is at the operational level, by competent people performing activities that achieve strategic goals. For this to occur, an explicit linkage between strategic goals and operational activity, between strategic core competencies and their implementation (and reciprocally between operational competencies and strategic objectives) must be articulated. This theoretical claim is demonstrated in the present case study.

Since contemporary thinking on strategy emphasises ability to respond to environmental changes quickly at all levels rather than planning in a controlled environment, an embedded knowledge strategy will act as the medium through which these levels can be brought into alignment and allow for emergent strategy to be developed across the organisation.

Klein (1998) asks the question "But how does a firm decide what set of operating-level initiatives would best meet its strategic goals?" and goes on to identify the "challenge of linking strategy with execution at the knowledge level" (p. 3) by a focus on various activities around intellectual capital. As an open research question however, specific implementation guidance is not offered, and associated literature (e.g., Graham & Pizzo, 1996) often notes only generic steps (identify strategic business drivers, determine business critical knowledge characteristics and locations, construct knowledge value chains, and find competency gaps).

Apart from private ownership tools, which may lack academic evaluation or an underlying original research base, there are few existing public domain management tools that offer help in modelling the different aspects a comprehensive knowledge-centric strategy development entails. These candidates include the "enterprise model" (Hatten & Rosenthal, 1999), later renamed the "action alignment (AA) model" and extended in Hatten and Rosenthal (2001); and more recently strategy maps (Kaplan & Norton, 2004). These generally provide broad areas for consideration, but give little or no guidance on strategy development or implementation beyond a flimsy structural outline. For knowledge strategy evaluation in financial terms, the KM valuation methodology of Clare and Detore (2000) applies, but this starts from a developed business strategy or KM project proposal.

The AA (Action Alignment) model is essentially a grid showing classical business functions (e.g., HRM, IT, and so on) crossed with business processes (e.g., order fulfilment) allowing visualisation of core junctures or problem (misaligned) areas, with supplementary tools to assess the fit or otherwise between customers and organisational capabilities and competencies. This appears to be essentially reactionary to the need for cross-functional alignment occasioned by new economy realities, but problematises the issue within an assumed industrial-era organisational structure of functionally defined silos, and without highlighting the knowledge activities required. The AA model has various other serious limitations in a knowledge-based view, in which traditional "Balkanised" organisational structures are considered obsolescent, and not conducive to the strategic planning and development of intangible assets and associated capabilities (Chatzkel, 2000).

The Balanced Scorecard (Kaplan & Norton, 1996) is a widely used performance measurement tool and has evolved since its origination in the early 1990s to more explicitly focus on strategy. Originally it aimed to address aspects of a company's performance not covered in simpler measures oriented primarily to financial performance. A customer perspective, an internal business perspective, an innovation and learning perspective, and a financial perspective provide a set of measures indicating aspects of performance relevant to various stakeholders. The strategy maps and supporting theory outlined in Kaplan and Norton (2004) are however very sketchy and conventional in relation to the knowledge based view — competency is effectively equated with job description (p. 225 et seq), and the references to the concepts of knowledge and KM are very shallowly treated. Furthermore, although the strategy maps show some linkages, the map's theoretical formulation is silent about the detailed linkages between these giving no guidance as to how the knowledge embodied in them can be identified, related to strategic competencies and leveraged with respect to achieving financially quantifiable targets such as market share, net profit or shareholder value, or other non-financial performance measures. Tools such as Kaplan and Norton's strategy map thus do not explicitly address knowledge-centric strategy development and indeed a series of google searches in mid 2004 yielded few hits relevant to this aspect.

Yet an organisation's ability (or otherwise) to knowledgeably enact and leverage corporate processes and technologies is the essence of strategic competency. In a view of strategy that is not purely top down, but is essentially enacted dynamically by the knowledgeable activity of people in the "middle", it is crucial to reify these competencies in relation to strategy formulation. Current tools do not go far enough in guiding this, nor do they provide explicit methods for systematic engagement at this level.

THE CASE STUDY

Overview

We offer an approach addressing this by using a case study embodying action research techniques, beginning with a brief description of the organisation, its strategic position and the context of the fieldwork. A case study approach has been chosen since contemporary phenomena are being investigated in their real life context, with multiple variables of interest and converging sources of data; where the boundaries between the phenomena and the context are unclear and where the researcher has little control over behavioural events (Yin, 2002). The case study approach allows depth of understanding across many variables to occur. In this research an interpretivist position is adopted in which the organisation's own meanings and their negotiation are prioritised.

The case study reported here is of a UK accountancy company, and entailed the elicitation and reification of its hitherto poorly understood core competencies. The knowledge strategy was developed within a comprehensive corporate strategy overhaul and was built around the knowledge audit of its core competencies embodied in people and processes, supported by relevant technology.

The paper proceeds as follows. Having identified the need to provide detailed guidance on reifying an organisation's core competencies and to relate those effectively to knowledge strategy, we outline processes that address this weakness and show how they can be implemented within more generic strategic planning processes.

We illustrate these in the case study context to show how the organisation systematically identified its core competencies, as well as determining the core competencies that are no longer of strategic importance. In the process, learning that the company not only did not have the strategic competencies it thought it had, but that it had knowledge assets which it had not realised, provided the capability to explicitly incorporate the competencies into the strategy.

The result was an articulation of what the company "knew" as well as what it did not know but needed to know, both strategically and operationally. This enabled the company to consciously leverage its strengths but also identify areas in which it was deficient and therefore strategically vulnerable. The case study concludes by showing how the company had achieved a strong competitive position from which to strategically value its knowledge and other intangible assets in an informed manner for forward planning and reporting to shareholders and others. The detailing of this valuation is part of our ongoing research.

The Organisation

The UK accountancy company featured in this case study is involved in a broad range of financial services to a wide variety of customers, both large and small. For purposes of this paper, the company shall be called Target Accountancy. The company has 56 employees and has been existence since 1987. Staff turnover is low as a result of high loyalty and good conditions of employment.

Target Accountancy had never produced a formal strategy plan but realised it could not achieve the success it wanted without one. The saying "if you don't plan your company's future, it won't have one" was very pertinent in their case. The company possessed a rich abundance of talent but this was tacitly held in the minds of individuals; it wanted to be the formal owner of its capital knowledge. One of the aims of Target Accountancy was to verify whether the competencies it thought it possessed were being successfully engineered to generate the required competitive differentiators. There was thus a strong need to strategically specify and test the impact of its core competencies, to determine which were the most productive and identify gaps where new competencies were required.

The StratAchieve Method

One of us (Sawyer) was the external facilitator. The StratAchieve method[2] was chosen because of its proven capability in over 400 organisations to create and achieve strategies. Other tools currently on the market are geared either for helping to produce a strategy plan or to conduct project management, but not both. StratAchieve produces and combines the two, enabling iteration between the plan and implementation to take place.

The method is supported by software produced by Alpha Omega, which is used throughout the change programme. During a workshop session, a map is projected onto a screen and interactively developed through discussions, suggestions and learning from workshop delegates. An important aspect of the approach is its ability to integrate the various types of organisational strategies, such as customers, financial, HR, marketing, product, IS, and (crucially) knowledge, into a single, coherent corporate strategy.

The method enables organisations to determine, construct, legitimise, and achieve their strategy and conduct monitoring and controlling during implementation and provides the structure for all organisational strategic actions to be integrated. Thus, marketing, HR, finance, IT, and knowledge strategies are all holistically integrated into one coherent and comprehensive strategy. This will become apparent in the examples that follow.

The Strategy Tree provides the theoretical framework of the method (Sawyer, 1990) consisting of four or five layers of verb-fronted activities, logically related through *Why* and *How* connections. These Why and How relations provide a path that simultaneously justifies a given action at a higher level, whilst specifying an operational activity that achieves higher level aims. In discussions any given statement can be explored in either direction. For example rationale for the expressed operational competency "*Keep in regular contact with all clients*" was explored. The next higher-level activity was determined by asking, "why should we *Keep in regular contact with all clients*"? which elicited the response, because we want to "*Maintain excellent personal relationships with our clients*". A further Why interrogation on this activity produced the parent, "*Retain our current clients*" and a further Why activity resulted in the parent "*Increase our revenues*". A final Why activity generated the high-level statement "*Increase our gross margin*" linked directly to strategic mission. In this example, a set of Why interrogations produced the higher-level activities which linked to the pre-set vision (increase our gross margin). Conversely, How statements can be elicited by starting with a high-level aim, and identifying child activities that follow from it, as reversing the previous example shows. Turning a competence into verb-fronted form emphasises a capability focus for knowledge, and leads eventually to activity based costing and specific required operational actions. The software tracking the map thus developed shows what must be done, when, how, why and by whom through specific supporting functions, and aids dynamic strategy construction.

Workshop Preparation

The process was initiated through a one-day workshop, attended by all senior members of Target Accountancy together with a range of staff from a variety of departments.

The Knowledge Positioning Matrix (KPM)

The KPM was developed to accommodate the core competency dimensions, as shown in Figure 1. The four quadrants provide a means for noting the knowledge that is strategically needed, and is already known; the knowledge that is required, but is not known; knowledge that is known, but not strategically required; and gaps in knowledge that do not bear on strategy anyway. Target Accountancy wanted to know whether its current set of core competencies were sufficiently robust to maximise their competitive performance. The company thus wanted to know what it *needed* to know (i.e., if only we knew what we needed to know) as opposed to the familiar saying "if only we knew what we know", to identify gaps in required knowledge, and to identify areas of knowledge that were no longer required. In other words, the company wanted to know which core competencies should be modified, deleted and created.

The StratAchieve Structure

The method naturally provides the structure and operations for the Knowledge Positioning Matrix.

Figure 1. The Knowledge Positioning Matrix showing examples from the workshop

	Do Know	**Don't Know**
Need to Know	**Contact all our profitable customers monthly**	**Provide online accountancy services** **Provide hospitality packages**
Don't Need	**Provide doctoring services to ailing**	✕

Figure 2 shows a four-level map. The *vision* is the prime focus of the organisation's strategy. Each successive level below the vision provides increased detail about the vision — what it is, what it means and how it can be achieved. The mechanism that does this is through top-down *How* and bottom-up *Why* explorations and checking.

The top-most activity of the tree represents the vision in the case of a company-wide strategy or the key objective of a department, division, or sub-strategy such as a marketing or a finance strategy. The levels below the top-most activity increase in specificity so that the day-to-day actions can be specified and actioned. There is thus full alignment between the vision and the day-to-day operations.

The second level of the StratAchieve Map is occupied by the Critical Success Factors (CSFs). CSFs are the vital factors that must be successfully actioned if the vision is to be fully achieved. The third level has the core competencies which in turn must successfully produce the CSFs. Traditionally, the number of organisational core competencies is suggested as five or six (Robson, 1994) at the maximum.

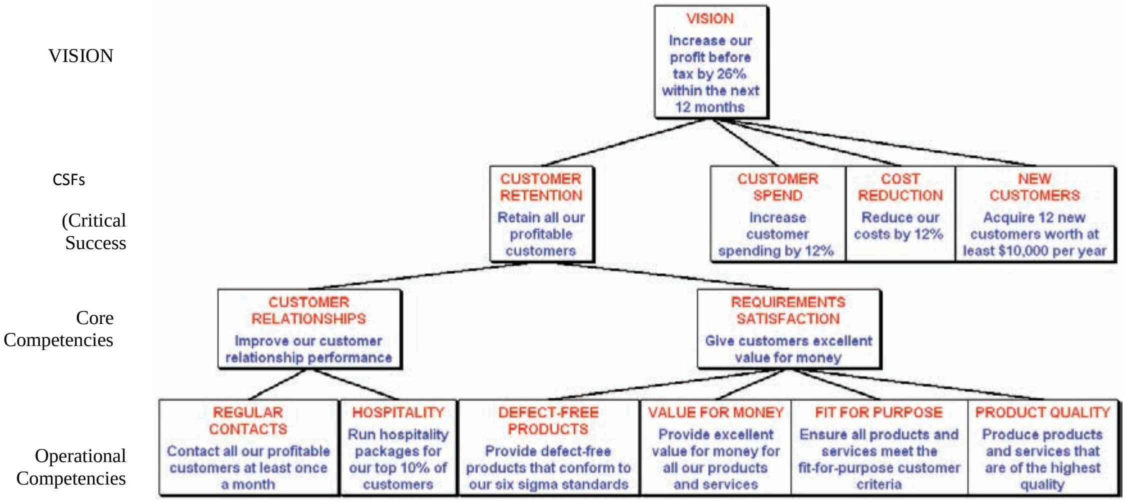
The top-down *How* and bottom-up *Why* structuring also provides the all-important alignment from the vision to the operational competencies on the lowest level of the StratAchieve Map. Only through this logical connectivity can alignment be achieved. This also provides a clear understanding to the fourth-level operational competencies. This also provides a clear understanding of what operational competencies must be actioned to achieve the core competencies, the CSFs and the vision. The process then provides for detailed operational specification of the requirement.

Knowing What We Need to Know

As mentioned, organisations need to "know what they need to know" (and know what they don't know) to make strategic decisions on various fronts. The first task in actioning the Knowledge Positioning Matrix is thus to establish "what needs to be known". From this capture, what is known and not known can then be determined.

To establish "what needs to be known", a set of core competencies was logically produced from the CSFs (top-down Hows) and verified through the operational competencies (bottom-up Whys).

Figure 2. A four-level StratAchieve Map showing all four company CSFs and two of the core competencies



A fourth level of operational competencies were initially produced through logical How unpackings from the core competencies. Figure 2 shows two of the core competencies identified at the workshop, namely Customer Relationships and Requirements Satisfaction.

Although it would have been competitively desirable for Target Accountancy to action every operational competency, in practice this was not feasible through resource and time constraints.

In the course of establishing "what we need to know", it was found that two of the competencies were not distinct but instead were linked in a parent-child relationship. Figure 3 shows that two core competencies, namely Value for Money and Product Quality, share two child operational competencies. The more children that share the same two parents indicate the amount of overlapping of the parent activities. As a consequence of producing the StratAchieve Map, it was found that Product Quality should be a sub-set of Value for Money. Figure 4 shows how this competency structure was re-configured to account for the family resemblance.

Figure 5 shows two core competencies, Customer Satisfaction and Product Quality. Each has a set of identical sub-activities. This duplication of sub-activities indicates that the two seemingly different core competencies are actually the same because they share exactly the same competency children. The degree of similarity between competencies is thus verifiable through the amount of shared sub-activities. Where there are no shared sub-activities, the core competencies are distinctly separate. The workshop delegates wanted to Product Quality to be featured on the StratAchieve Map and therefore showed it as a sub-activity. Alternatively, they could have eliminated the activity, and shown its two sub-activities under Customer Satisfaction.

Need to Know and Do Know

Once the set of core competencies were identified (need to know), the next stage was to identify which core competencies were known (available expertise) and those that were unknown (unavailable expertise). Figure 2 shows how the CSF, *Customer Retention* was unpacked, first into

Figure 3. Product Quality shares child competencies fully with Value for Money which means Product Quality is a sub-competency

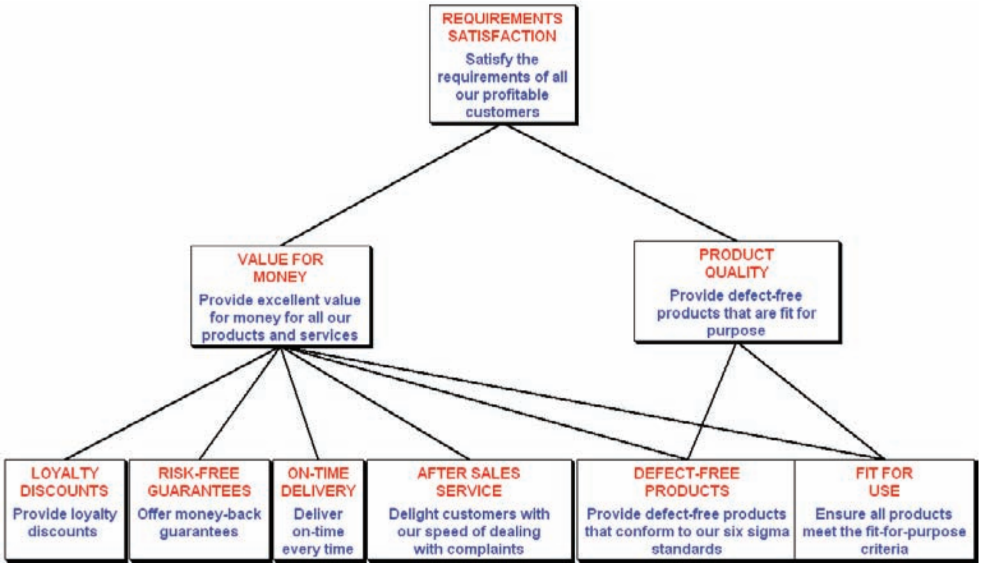


Figure 4. The revised structure showing Product Quality is a sub-set of Value for Money

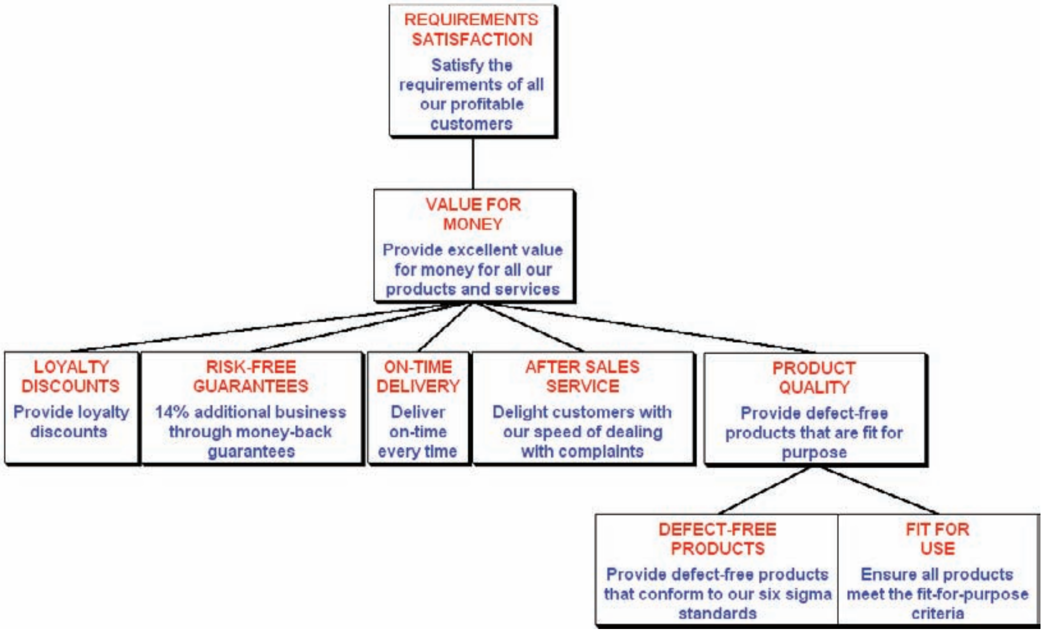

Figure 5. Product Quality and Customer Satisfaction are semantic duplications

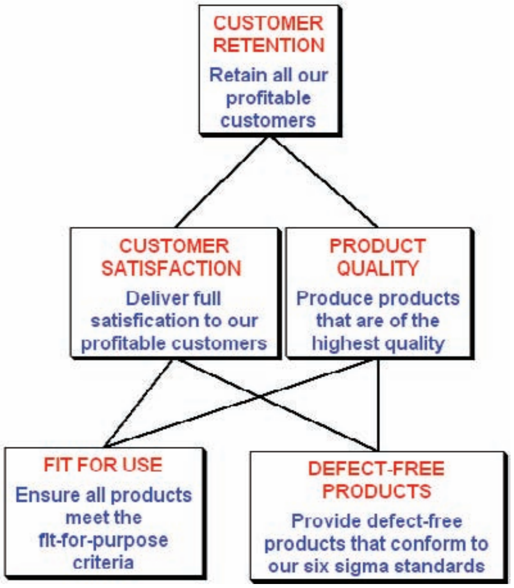

the respective core competencies, and then into operational competencies.

At the workshop, delegates were asked to produce a knowledge map showing their key actions. A comparison was then made between the logically derived core competencies using StratAchieve and those competencies actually held by the individuals. Several competencies were matched while others were unmatched. Examples are shown in Figure 1.

Need to Know and Don't Know

The StratAchieve Why and How creations and connections produced the activity "use the Internet to increase sales". It was agreed that this activity was important enough to be regarded as a potential core competency, where new skills would be needed. The exercise thus identified a knowledge gap, identifying what should be possessed as expertise and what was lacking.

The logical operational competency "operate hospitality packages" was created from the core competency "improve our customer relationship performance". The workshop delegates agreed that this activity (operate hospitality packages) was an important competency that needed to be included in the strategy as part of the core competency "improve our customer relationship performance".

A further action the company took after the workshop was to determine which competencies they lacked and needed to purchase through recruitment and consultancy. The core competencies were also prioritised, based on agreed criteria such as contribution impact on the CSFs, resource demands (cost implications) and risk quantification. Through this process, it was possible to weight the core competencies and produce a ranked order of importance. Although supported within the method, this is not detailed further here.

Don't Need to Know and Know

The Knowledge Positioning Matrix shows "provide doctoring services to ailing companies" as a known competency, but one that does not have any impact on the current company-wide CSFs. Thus is because there is no logical Why connection into the newly formed CSFs. For example, there is no *Why* connect to Customer Retention since once the customer's company has been restored it will cease to be a customer. With no logical connection for this in the developed map, it was thus excluded.

Don't Need to Know and Don't Know

It follows that not knowing what we do not need to know is a null set and therefore is left blank in the Knowledge Positioning Matrix.

CONCLUSION

This paper described the importance of core competencies and demonstrated the utility of the StratAchieve method for testing the validity of knowledge-laden core competencies for strategic goals. It has shown how to test core competencies for logical compatibility with the strategy plan as well as to identify core competencies that are essential for strategic success. The software support links these logically, and through separate functionality relates them to timescales, costing, human resources, and progress indicators for subsequent monitoring. In doing this, we needed to unpack the meaning of the word "know". For example, in the phrase *do we know what we need to know*, two uses of the term can be discerned, namely know-what and know-how respectively. Both relate to awareness, not necessarily the skills available.

The case study has demonstrated the formulation of a corporate strategy from a consideration of the core operational activities and associated knowledge competencies forming the organisation's intellectual capital resource. Meanings of the operational and other activities that produce the emergence of achieved strategic objectives have been systematically elicited, negotiated, and agreed within a multi-stakeholder framework, which explicitly links the strategic requirement to the necessary activities and identifies the knowledge requirements for each strategic objective.

Although simplified and indicative examples only have been shown here, linked and cohesive *Strategy Trees* for major business functions have been produced in a form that translates directly into actionable specifications, with a motivated logic chain of abstraction upwards towards, or implementation downwards from, strategic activities and competencies. Core strategic competencies, such as "contact all our profitable customers monthly" have been illustrated to show the alignment of activities, and how a competency at one level can provide an advantage at another. Equally less advantageous competencies, without strategic import, are highlighted by the method. An emphasis on the terminology and meanings understood within the company, and its reporting norms, helps strategy ownership and implementation. A sort of "mediated objectivity" applies, which explicitly links the strategic requirement to the necessary activities and identifies the knowledge requirements for each one.

By expressing the required activities in the structure the focus is shifted towards dynamic strategy achievement through knowledge capability, rather than merely managing the organisational resources and by-products of business activity. Evaluation of the strategy is provided for within the method, though beyond the scope of this paper to describe. Monitoring, activity based costing, resource allocation, and progress and performance indicators are all linked explicitly to the strategy model developed. During the case study, each core competency was analysed to determine its value and hence impact contribution on the company's goals and vision. This core competency valuation and ranking method has been the subject of ongoing research.

The case study reported in this paper is one of several conducted over a 15-year period with organisations large and small, public and private and whilst the case is unique, the methods involved are considered generic and stable. Individual studies such as this one lie within a "declared intellectual framework of systemic ideas, ultimately allowing general lessons to be extracted and discussed" as recommended by Checkland (1991, p. 401).

Although a case study does not aim at generalisation rich, contextual understanding and utility value are indicated. Apart from the direct pragmatic value to the organisation, the "story told" in reporting the notion of mediated objectivity may help convey insights that transfer to the understanding of similar situations. Results from action research studies can provide rich and useful descriptions, enhancing learning and understanding which may itself be abstractly transferable to other organisations, or provide an underpinning to future inductive theory development. This potentially allows further contextualisation of the work in the more nomothetic terms implicit in multiple case study research designs.

This case study has shown the development of strategy: further action research with the company will evaluate its impact and value. In general through work with this, and with other organisations we aim to develop a competency valuation method so that the value of operational competencies in relation to strategy may be assessed.

Chapter 1.7
Strategic Alliances of Information Technology Among Channel Members

H. Y. Sonya Hsu
Southern Illinois University, USA

Stephen C. Shih
Southern Illinois University, USA

ABSTRACT

This chapter explores novel ways of improving flexibility, responsiveness, and competitiveness via strategic information technology (IT) alliances among channel members in a supply chain network. To gain competitiveness, firms have to constantly update their operational strategies and information technologies through collaborative efforts of a "network" of supply chain members rather than the efforts of an individual firm. In sum, the foci of this chapter are: (1) an overview of supply chain management (SCM) issues and problems, (2) supply chain coordination and integration, (3) the latest IT applications for improved supply chain performance and coordination, and (4) strategic IT alliances. This chapter concludes with a discussion of business implications and recommendations of future research.

INTRODUCTION

Supply chain management (SCM), characterized by interorganizational coordination (Hill & Scudder, 2002), deals with how each company in a supply chain coordinates and cooperates with its business partners. Along the supply chain, most business activities are integrated for effectively supplying products and services to customers via a continuous, seamless flow. Drawing on the concepts of value chain and value system (Porter, 1985), SCM inherits the viewpoint of "process." In a value system, simply a series of integrated processes is insufficient to support a supply chain and offer fully synchronized operations of all supply chain partners (Williamson, Harrison, & Jordan, 2004).

Recently, it has been realized that information technology (IT) plays an important role in supporting systematic integration and synchronization by providing automatic information flows throughout the entire supply chain. More and more SCM researchers have emphasized the need to embrace the enabling information technologies and explore the essential capabilities of effective information management for supply chain integration (Dai & Kauffman, 2002a). Kopczak and Johnson (2003) stated that the synchronization in a value system required a sophisticated information system (IS) to foster real-time information processing and sharing, coordination, and decision making by the entire supply chain. In line with Kopczak and Johnson's research, other researchers (Dai & Kauffman, 2002b; Gunasekaran & Ngai, 2004) have utilized a systematic study to classify the landscape of emerging online business-to-business (B2B) marketplaces.

In addition, Internet technology is then conceived as an enabling tool for effective integration of the information-intensive SCM processes via ubiquitous availability of timely information (Boyson, Corsi, & Verbraeck, 2003). Information transfer via Internet facilitates more interactive partnerships in multi-directions as opposed to the traditionally linear movement of information within a supply chain (Boyson et al., 2003). This information sharing from multiple directions has boosted the power of process integration and synchronization as well as effective collaboration among the supply chain members.

The remainder of this chapter is organized as follows. First, an overview of issues and problems existing in SCM (such as free-riding phenomenon, negative externalities, and bullwhip effects) is presented. Next, it describes the importance of supply chain coordination and integration, followed by a discussion of the latest IT applications that improve supply chain performance and coordination. The following sections focus on (1) the importance of supply chain portal (SCP) in term of e-collaboration between firms, and (2) the "spillover" effect of IT investments.

With these two foci, the authors attempt to classify the differences between supply chain management systems (SCMS) and SCP in terms of major functions, applications, performance matrices, and the like. Two forms of strategic IT alliances for effective SC coordination are then discussed in detail, including technology similarity or geographic proximity. A typology of competitive advantage positions in terms of alliances and spillovers is also presented. In In addition, the researchers intend to emphasize a new selection of IT, namely, SCP, and a different perspective of SCM, namely, a "spillover" effect of IT investments and a strategic alliance of IT. Last but not least, this chapter attempts to find an innovative way to improve a company's flexibility and responsiveness in terms of competitiveness. Finally, the last section concludes this chapter by discussing a number of business implications and recommendations for future research.

SUPPLY CHAIN COORDINATION PROBLEMS AND ISSUES

Free-Riding Phenomenon

A noticeable "free-riding" phenomenon has become more prevalent in a multichannel supply chain (Wu, Ray, Geng, & Whinston, 2004). With the occurrences of free riding, a channel member may acquire relevant sales data from one upstream member but actually purchase the products or receive the services from other vendors, possibly at a lower price. In other words, one channel member carries out the final sale transactions, while another channel member debuts the activities that are required to sell the products/services. In practice, a number of advanced information technologies, particularly the Internet, have increased supply chain channel members' caliber to access a wide range of handy information at a much modest cost. Without doubt, companies that sell their products through multiple-channel sales and distribution are often concerned about the free-riding phenomena for fear that the downstream retailers would have less incentive to promote their products.

Another problem with the free-riding phenomenon is likely to arise when additional efforts made by one channel member bring about increasing revenue that is shared by other channel members in a supply chain. As a consequence, a member may be inclined to work less and enjoy a free ride of improved financial rewards realized by other member(s) in the supply chain. One way to alleviate this problem is to implement an incentive program to motivate the channel members to bring forth adequate contributions in order to receive the comparable compensation. On top of that, a monitoring system should be constructed to measure the effort of each member and to ensure the financial gains of each individual member match their contributions.

Negative Externalities

An effect of externality occurs in a supply chain when a business decision or action results in costs or benefits to members other than the member actually making the decision or carrying out the action. In other words, the decision maker does not bear all of the costs or reap all of the gains from the action. On the other hand, the spillover costs, or negative externalities, may be imposed on a certain channel member without compensation from other parties. For example, a delivery delay caused by the vendor will spill superfluous production costs or excessive inventories over to the manufacturer or other downstream member(s) in a supply chain. Mostly, inferior decisions or deficient data can cause subsequent spillovers on invoices and shipment notices, which will, in turn, lead to incorrect shipments, delays, and costly reductions.

The Bullwhip Effect

In a supply chain, demands can be distorted by members attempting to achieve local optimization. This phenomenon of information distortion on demands is referred as the "bullwhip" or "whiplash" effect (Lee & Padmanabhan, 1997). This phenomenon may occur in many echelons where the variability of demand increases at each stage of the supply chain (Kopczak & Johnson, 2003). In reality, the bullwhip effect may exist in various industries at different levels of a supply chain network. This effect can also cause unnecessary costs and excessive inventories in production, distribution, logistics, and intermediaries.

SUPPLY CHAIN COORDINATION AND INTEGRATION

Horizontal vs. Vertical Coordination

In earlier SCM studies, the adoption of IT was mainly on the use of advanced planning systems to reduce uncertainty of the demand side and to optimize flows (Kumar, 2001). Integrated supply chains strive to achieve not only "horizontal coordination" but also "vertical coordination" (Kumar, 2001, p. 61). Horizontal coordination refers to communication and process synchronization within an industry, while vertical coordination is across industry or firms. Vertical coordination can be further explored from the aspect of transaction costs in a supply chain (Williamson, 1995). With vertical coordination, the possible costs (e.g., the investment costs, spillover costs, or "free-rider" costs) should be properly applied to all the business transactions for each participating channel member in a supply chain during the movement of a product and/or a service, business transactions. Enhanced by the "transaction costs" point of view, Jap, Bercovitz, and Nickerson (2005) argued that the level of expected cooperative exchange norms (i.e., joint transaction-specific investments) could be beneficial to interorganizational performance.

In addition, Williamson (1993) further indicated that the partnership entails the willingness to realize some risks, which imply the uncertainties between partners. To resolve the uncertainties among members, the "trust" relationship may evolve over time under a certain governance structure (Kogut, 1988) and information-sharing mechanism for safeguarding against potential risks or certainties. Upstream members are often characterized as "power asymmetries" (Subramani & Venkatraman, 2003, p. 46) compared to downstream members. The investment costs among supply chain members may be shared under contractual agreements or long-term alliances. The former is a "close, fast-developing, short-lived exchange" relationship (Lambe, Spekman, & Hunt, 2000, p. 213), whereas the latter are equity based or strategic resources alliances (Colwell & Vibert, 2005). As far as effective information sharing goes, both horizontal cooperation and vertical cooperation would require a well-structured information communication technology (ICT) platform to carry out such an operation (Kumar, 2001).

Positive Externality: IT Investment Spillover Effect

In contrast to negative externality, there is a positive externality (or beneficial externality) existing in a supply chain, especially the spillover effect in IT investments. The effect of spillovers from a channel member's IT investments is well documented in the literature (Harhoff, 1996; Lambertini, Lotti, & Santarelli, 2004; Mahajan & Vakharia, 2004; Owen-Smith & Powell, 2004; Rosenkopf & Almeida, 2003). Typically, the spillover costs in IT investment exist in a supply chain when there is a more powerful upstream member who covers some or the majority of costs. As a result, spillovers were mainly studied from a perspective of upstream supply chain.

Utilizing mathematical modeling, Mahajan and Vakharia (2004) developed two strategies that underpinned the IT investment decisions from the supplier perspective: (1) myopic strategy, making the IT investment solely on maximizing its own gain, and (2) global strategy, resulting in gains accruing to the entire value chain. According to their research results, the "global strategy" is a comparably better decision than the "myopic strategy." Furthermore, the "global strategy," with or without a distributor's own investments in IT accruing to the entire supply chain, was tested with better results as well. Based on their results, it is apparent that some free riders may exist among the IT investments from the upstream members, such as distributors and other downstream members. However, overall spillovers or positive externalities can still offer a competitive advantage to a firm or a supply chain in a marketplace at times.

Another aspect of spillover is related to R&D investments. According to Harhoff (1996), the R&D investment can be specific to a firm's product and production methods. As a result of the supplier's R&D contribution, the outputs in the downstream can be greatly expanded and enhanced (Harhoff, 1996). Additionally, on the supplier's side, the demand is shifted to a higher level, and its R&D expenditure is furnished with a higher profit gross. In a sense, a higher profit gross indicates a higher return on investment that is one of important performance metrics for evaluating the outputs of IT investment (Gunasekaran & Ngai, 2004). About a 1% upsurge in IT investments in manufacturing industries will trim down the labor intensity of their suppliers by about 0.01%. In time, investments in IT appear to have spilled over through the supply chain. Other research data show that increasing IT investments in manufacturing industries by 1% will boost the supplier investments by 0.6%, and customer investments by 0.3% (Gorman, 2005).

In sum, the spillovers from the upstream supply chain can add value to the entire supply chain. To reap the global benefits of positive externalities, a control over spillovers (Lambertini et al., 2004) or intentional spillovers (Harhoff, 1996) may be necessary. However, according to the results of empirical studies by Lambertini et al., the extent to which the firms can endogenously control the spillovers is low. Instead, the tight cooperation between the firms can embrace a higher level of spillovers because of increasing information sharing across the firms.

Information Sharing and Integration in a Coordinative Environment

To a great extent, effective information sharing is indispensable due to the efficiency required from each channel member in a supply chain. Defined by Ganeshan, Jack, Magazine, and Stephens (1999, p. 851), information sharing "specifies schemes for coordination" that apply to the efficient operation in a supply chain. Srinivasan and Yeh (1991) supported that some state-of-the-art information-sharing technologies, such as electronic data interchange (EDI), could significantly improve the suppliers' shipment performance in a just-in-time environment. Furthermore, the research showed that performance of the production and logistics can be dramatically enhanced by accurate and timely information through the facilitation of EDI.

Going beyond information sharing, Kulp, Cohen, Hau, and Ofek (2004) emphasized "information integration," which is similar to Lee and Padmanabhan's (1997) concept of "decentralization" in a supply chain. To better support SCM, Kulp et al. combined the methods of vendor-managed inventory (VMI), new products/services, and reverse logistic systems, along with effective information integration and sharing on customer needs, inventory levels, and so forth. In their research, the task of information integration was empirically tested with significances to improve the supply chain performance at different levels. To further assess other supply chain performance measures, information sharing was associated with higher manufacture performance, while collaboration of new products/services was positively related to intermediate performance. The uncertainty resulting from fluctuating customer demands will, in turn, require seamless information integration for better decision making in a more timely fashion.

IT for Improving Relationship-Specific Investments

Williamson (1995), a transaction cost economist, has pointed out that relationship-specific investments have notably contributed to value creation in a supply chain. The relationship-specific investments can be specifically interpreted as customized business processes catering to the requirements of a particular buyer (Subramani, 2004). According to Subramani and Venkatraman's (2003) field study, the companies that possess intangible, relationship-specific assets are usually capable of imposing an enhanced value creation over those competitors operating without such assets. In light of supplier investments, Subramani (2004) identified two types of intangible asset specificity—business-process specificity and domain-knowledge specificity. Business-process specificity refers to the development of relationship-specific routines or standard operating procedures for efficient task execution. On the other hand, domain-knowledge specificity arises from an understanding of cause-effect relationships that facilitate effective actions and provide resolutions of ambiguities in task planning and execution. By emphasizing IT-mediated buyer-supplier interactions, a firm creates and retains value of domain-knowledge based on the combination of transactions-cost and resource-based views (Subramani, 2004).

The investments of IT within a firm create a resource-based view, whereas the transactions-cost view occurs when the investment "spills over" its supply chain members. Spilling over the

IT investments from suppliers to their distributors (Mahajan & Vakharia, 2004) is one field of research, whereas the IT investments from a R&D perspective is another important area of research (Harhoff, 1996; Lambertini, Lotti, & Santarelli, 2004; Rosenkopf & Almeida, 2003). Having conducted a case study involving the ship repair industry, Chryssolouris, Makris, Xanthakis, and Mourtzis (2004) demonstrated how modern IT could promote effective communications among different partners and enable seamless information flows within value-added chains. The IT investments can lead to enormous benefits from an efficient product life cycle, a shorter lead-time, better product quality, or simply cost reductions.

IT IN SUPPLY CHAIN MANAGEMENT

According to Kumar (2001), three factors have contributed to the needs of effective supply chain management. On the demand side, more sophisticated customers are increasingly demanding a customized value from the supply chain. On the other hand, suppliers are increasingly embracing IT to obtain a forward-looking perspective of the entire supply chain and, in turn, to optimize the processes for meeting the demands. Finally, on both the demand and supply sides, the emergence of global markets has stretched a supply chain to a longer distance. These longer chains—along with the accumulated demands of variability, uncertainties, costs, distances, and time lags—make SCM vulnerable yet in great need of advanced information technologies.

From an enterprise-centric perspective, SCM is considered an extension of enterprise resource planning (ERP) (Kumar, 2001) and has evolved into numerous interwoven information-intensive networks focusing on improving the coordinating and collaborative relationships among supply chain members. Along the line, the trend of a modern supply chain is to fulfill uncertain demands with an array of variety and desired product quality in a timely fashion at the least possible cost (Kumar 2001). If the products and/or services can be delivered by a supply chain with sufficient value at a lower cost than other competitive supply chains, then it has a competitive advantage. Kumar (2001) stated that an innovative use of IT could dramatically increase the competitive advantage via changing the cost and value equation in a supply chain. In the following sections, a number of cutting-edge SC coordination practices and information technologies are described.

EDI, ECR, CPFR, and VMI

Electronic data interchange (EDI) was once used just for transferring information (Hill & Scudder, 2002). Lately, many SCM practitioners have increasingly embraced a number of emerging SCM practices, such as efficient consumer response (ECR), collaborative planning, forecasting and replenishment (CPFR), and cross docking, to facilitate improved coordination among channel members. Launching in the United States, the ECR movement was initiated in 1993 as a result of modern consumers who are more sophisticated and increasingly demand higher quality, more product variety, and better services for less money and less lead-time. ECR responds to tailor products through continuous improvements, focusing on both the demand and supply sides.

CPFR, first adopted by companies like Wal-Mart, Pillsbury, and Procter and Gamble, is an emerging SCM initiative that pursues greater profits through improved operational efficiencies and better collaboration and information sharing between trading partners. By embracing the CPFR technology, Wal-Mart's retailing is able to establish a solid information-rich relationship with most of its customers and suppliers (Gottfredson, Puryear, & Phillips, 2005), which has dramatically strengthen its coordinative capability with its business partners and greatly enhanced its fundamental economies of scale in distribution

(Moore, 1993). Different levels of coordination have led to a lower inventory level and lower operating costs, successfully sustaining Wal-Mart's dominance and superior bargaining power.

In supply chain operations, inaccuracy in the information flow may significantly hold up inventory levels and undercut production rates. Addressing this issue, the participating supply chain members need to acquire necessary information about sales forecasting and replenishment to improve the deficient product throughputs. To satisfy this need, CPFR can be used as a novel way of sharing and disseminating information in a supply chain network. With CPFR, participating supply chain partners are required to collaborate and share information throughout the entire design and production life cycle, from planning to execution (Esper & Williams, 2003).

Addressing the bullwhip effect mentioned previously, Lee and Padmanabhan (1997) analyzed the sources of the bullwhip effect and called for cooperation and coordination among members to lessen its negative effects. For example, by using CPFR with the philosophy of vendor-managed inventory (VMI), channel members can share forecast and demand information and further streamline replenishment, which leads to significant reduction of the bullwhip effect (Kopczak & Johnson, 2003). To achieve better coordination and diminish the phenomenon of demand distortion, more and more companies have started sharing point-of-sales (POS) information throughout the supply chain (Steckel, Gupta, & Banerji, 2004).

Cross Docking

Between 1972 and 1992, Wal-Mart went from $44 million in sales to $44 billion, partially because this retailing giant has been capable of optimizing its distribution and logistics (Hammer, 2004) by adopting the so-called "cross docking" technique. Cross docking refers to a logistic process whereby the goods transported to a distribution center from the suppliers are immediately transferred to the stores (Hammer, 2004). In other words, cross docking is a process of taking a finished good from the manufacturing plant and delivering it directly to the customer with little or no handling in between. Simply put, the cross-docking process means receiving goods at one door and shipping them out through the other door almost immediately, without ever putting them in storage. As a result, the step of filling a warehouse with inventory before shipping it out can be virtually eliminated. In practice, implementation of the cross docking process requires seamless coordination of products transportations among different suppliers, distribution centers, and retail stores in a timely fashion.

Internet Technology for SC Coordination

The Internet and its associated technologies (e.g., intranet and extranet) provide enormous opportunities for companies to make significant improvements in managing and optimizing their supply chains through efficient and effective information flows (Boyson et al., 2003). Shared information enabled by the Internet helps break down functional barriers. Further, Internet technology can help supply chain members to develop a common understanding of the marketplace (Boyson, Corsi, Dresner, & Harrington, 1999). With effective use of the Internet, the entire network of a supply chain allies as a whole instead of just a single member or chain to compete in the marketplace. As an example, Dell responds to supply-demand imbalance by changing its price options or price bundling to steer demand by making the most of Internet. Dell's marketing scheme—Sell What You Have—would not exist without Internet technology (Kopczak & Johnson, 2003) because price elasticity can be managed easier online. For example, the price changes at the Dell site can be seen by all participating members. As a result, there is no need for Dell to inform any of its channel members via paper invoices that slow down the business processes.

Stretching the use of the Internet, Johnson and Whang (2002) divided Internet-enabled e-business and e-supply chain technologies into three categories: e-commerce, e-procurement, and e-collaboration. According to their definitions, e-commerce helps a network of supply chain partners identify and respond quickly to changing customer demands captured over the Internet. E-procurement allows companies to use the Internet for procuring direct or indirect materials as well as handling value-added services like transportation, warehousing, customs clearing, payment, quality validation, and documentation. E-collaboration facilitates coordination of various decisions and activities beyond transactional operations among partners, suppliers, and customers over the Internet.

Internet-Enabled Supply Chain Portal for Heterogeneous IT Environment

Transmitting information electronically reduces errors and increases reuses of information. However, each supply chain member may not adopt the same standards and/or systems to communicate with each other during the business processes. Addressing this issue, a Web-based supply chain portal (SCP) is one of Internet technologies that can be used to solve the problems associated with different standards and systems in SCM. Examining recent business practices, the SCP has actually taken SCM in an electronic form to a new level. Managed and designed by an organization, a SCP can support any business processes in supply chain management (Boyson et al., 1999). The portal is also capable of supporting collaboration among business partners on related business processes. In practice, the collaborative partners are not limited to suppliers and sellers/retailers but can also include customers downstream in a supply chain. On the demand side, a typical SCP solution facilitates an e-commerce, front-end interface for promoting products or services and processing transactions. On the supply side, a portal streamlines and coordinates internal business transactions and interorganizational operations in a real-time mode (McCormack & Johnson, 2001).

A portal can manage many peer-to-peer relations as well as simplify numerous business processes (McCormack & Johnson, 2001). Unifying supply chain partners in a single portal will make the transactions easier for the buyers and, in the meantime, more efficient for the suppliers despite different standards and communication technologies throughout the whole supply chain. With the use of SCP, any authorized partner in a supply chain can bypass excessive security procedures, such as log-on access, and immediately retrieve the relevant information (McCormack & Johnson, 2001). With SCP, the user's access privilege in a portal depends upon his or her level of security clearance. Meanwhile, information on a portal can be updated in real-time from multiple sources.

In terms of the functionality and practicality of SCP, McCormack and Johnson (2001) summarized that the SCP can be adapted to:

- provide a unified format and middleware platform;
- use real-time messaging to assure supply chain operations within optimal inventory level parameters;
- personalize portal views based on user requirements and security/access classifications;
- distribute field-based data gathered from scanners, PDA devices, and other information appliances to multiple users; and
- construct a seamless grid of information on key operational performance areas.

Supply Chain Management Systems

Evidence provided by Subramani (2004) showed that IT-enabled electronic integration technologies, such as supply chain management systems

(SCMS), could create and retain greater value for each channel member in a supply chain. According to Subramani, there are two major functions of SCMS: automating and informating. These functions are further distinguished in two different perspectives, namely, exploitation and exploration. Exploitation is the extension or elaboration of old certainties, whereas exploration is the method of pursuing new possibilities (Subramani, 2004). More precisely, exploitation refers to using the system to perform structured, repetitive tasks, while exploration is meant to use SCMS for unstructured tasks that may seek or create new business processes and/or opportunity (Subramani, 2004). In general, exploitation can be a supplement to exploratory uses of SCMS.

Derived from several research studies, Table 1 summarizes the differences between SCMS and SCP in several categories including major functions, functionalities (Johnson & Whang, 2002), communication, channels, applications (Boyson et al., 1999), performance metrics (Otto & Kotzab, 2003), and their drawbacks. Performance metrics in an organization perspective are represented by transaction costs, time to network, flexibility, and density of relationships (Otto & Kotzab, 2003). The density of relationships is then evaluated by the density of a relation based on the distance of "social, technological, cultural, geographical, and time" (Otto & Kotzab, 2003, p. 315).

IT ALLIANCES FOR EFFECTIVE SC COORDINATION

Transitioning from controlled spillovers to strategic alliances of IT investments reveals a new, promising aspect of knowledge sharing for seamless coordination among supply chain members. Essentially, IT alliances between channel members are formed to search for "new capabilities" and interdependencies within lim-

Table 1. Comparison of SCMS and SCP

	SCMS	SCP

Drawbacks	Disconnection Broken channel links Lack of interoperation	Vulnerable to malicious attacks Trust & commitment issue among trading partners

ited social networks (Rosenkopf & Almeida, 2003, p. 753). These limited social networks are the clusters close to each other in some way. Alliances of IT-related R&D facilitate the growth and/or profit of a supply chain because alliances offer great accessibility to essential business and SCM-related knowledge. In a study of the semiconductor industry, Rosenkopf and Almeida (2003) illustrated overall knowledge flows across supply chain networks, while the firms allied and worked together as networks of networks. Further strategic IT alliances can be formed by either technology similarity or geographic proximity among participating members.

Technology Similarity

When firms form alliances, they are more likely to cooperate with other companies that have similar technologies. In other words, the firms that maintain similar positions in constructing their technological landscapes will build their allied relationships upon the knowledge stock of the firms' core competencies. For example, common patent citations are used to form alliances in a semiconductor industry (Stuart & Podolny, 1996). Using a secondary data analysis, Kalaignanam, Shandar, and Varadarajan (2005) provided some insights about information technology industry. They found that the alliance scope contributed to financial gain in large firms, while the alliance type (scale or link alliance) contributed to financial gain in small firms. Evidently, the sizes of firms matter to the IT alliances strategically.

Geographical Similarity

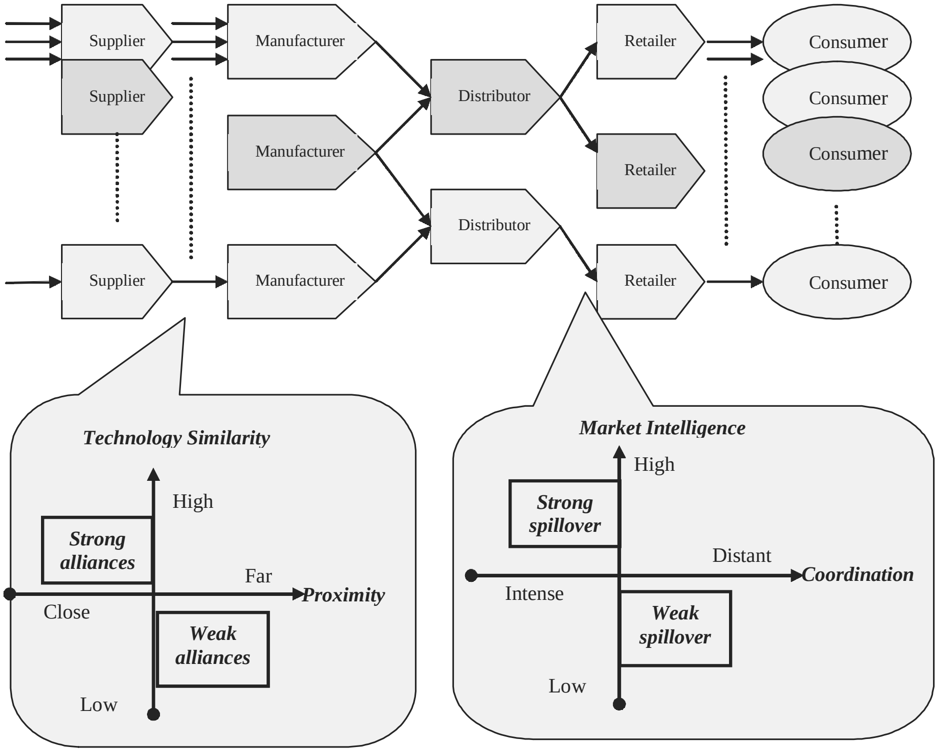
Silicon Valley is a good example of strategic alliances in a geographical cluster. Having conducted a social network analysis, Owen-Smith and Powell (2004) documented alliances as knowledge flows among the firms within the Boston region. According to the analysis results, the local links can be formal, that is, a strategic alliance, or informal, such as a social network that recognizes each other via professional courtesies in a region. Rosenkopf and Almeida (2003) suggested that geographic proximity should reduce costs and increase the frequency of personal contacts in a regional network. The more frequent contacts occur among firms, the better alliances they can organize. Therefore, the knowledge can easily flow among the allied members while geographic local searches can be reciprocally stimulated. The local searches, then, reinforce the organizational and/or regional establishment in terms of technology alliances.

Owen-Smith and Powell (2004) suggested that the spillovers resulting from proprietary alliances were a combination of the institutional commitments and members' practices in the network. Specifically, they made an attempt to capture any possible links by utilizing social network analyses. Between information spillovers and the strengths of regional networks, Owen-Smith and Powell found that contractual linkages along with physical proximity represented relatively strong alliances (Figure 1).

The strengths of alliances are embedded in a mechanism of a rich ecology and a regional labor market. Similarly, while studying technology-based alliances, Stuart (2000) also found that strong alliance increased innovation rates in the semiconductor industry. However, he discovered that those affiliations depended strongly on partner characteristics in terms of IT alliances. Also, Colwell and Vibert's (2005) study illustrated that firms were likely to be satisfied to collaborate with those with whom they had engaged in a satisfying partnership previously. Therefore, commitment and trust are embedded in a longer term of partnership.

One typology, developed by Tapscott, Ticoll, and Lowy (2000), and further interpreted by van der Vorst, van Dongen, Nouguier, and Hilhorst (2002), defines four different types of e-business initiatives based on economic control and value integration. This typology represents the value-added IT alliances into four categories:

Figure 1. Strong vs. weak alliances among upstream vs. downstream channels (Rosenkopf & Almeida, 2003; Lancioni et al., 2003b; van der Vorst et al., 2002; van der Vorst, Beulens, & van Beek, 2000)



- E-marketplaces that facilitate the exchange bring together sellers and buyers.
- Information chains that provide the transparency of information through the value chain and focus on the demand-driven information for monitoring customers' demands and behaviors.
- Virtual enterprises (or alliances) that play a role as a broker who leads a network of community to collect knowledge for every participating member.
- Value chains or "extended enterprises" (van der Vorst et al., 2002) that are represented as a form of "supply chain integration" (p. 133).

According to van der Vorst et al. (2002), "virtual enterprises" and "value chains" are different in terms of economic control. Every member in virtual enterprises has been empowered to access, create, and update the knowledge in the network, whereas "value chains" are controlled by a hierarchy that dominates the supply chain. Jap and Anderson (2003) have illustrated goal congruence as a powerful governance tool in alliances. In reality, the breadth and intensity of the relationship between alliances will either grow or discontinue over time (Dyer, 1997). For example, opportunists in a supply chain may eventually be dropped out of the cooperation for lacking commitment or contribution. The alliances may grow if the IT investments have added benefits to each channel member throughout the supply chain in addition to the harmonious relationships among the allies. Two potential benefits—short-term operational efficiency and longer-term new knowledge creation (Clark, 1989; Malhotra & Gosain, 2005)—may be generated in allied relationships.

To configure supply chain capacity, Malhotra and Gosain (2005) presented "structure" and "cognitive" impacts for alliances in electronic business (p. 31). The structural impact is the adoption of standardized interfaces for linking potential partners in a timely fashion, while the cognitive impact stands for the uses of new knowledge to reduce managers' cognitive loads (Malhotra & Gosain, 2005). The quick coordination between partners increases the capacity to create market intelligence that, in turn, enhances decision-making processes. Figure 1 presents such a model demonstrating that coordination and market intelligence may result from the IT alliances in the upstream.

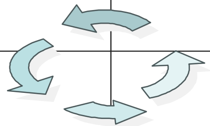
Despite the importance of technology similarity and proximity, economical control, or value integration, Toyota has switched to a system of "dynamic learning capability" to encourage suppliers' involvement, promote knowledge sharing, and prevent free riders in its supply chain (Kim & Im, 2002). Doz (1996) explored alliances as a learning process that could occur in several dimensions, such as environment, tasks, processes, skills, and partner goals. The "dynamic learning capability" has led a whole supply chain to its competitive advantage. The value-added functions are distributed across the participating members who are interactively coordinated. The interactive coordination is indeed facilitated by a knowledge-sharing network known as "virtual enterprises," as mentioned above. According to Kim and Im (2002), the knowledge-sharing network facilitates a supply chain in three ways: (1) saving in procurement and transaction costs; (2) alleviating the bullwhip effect and lowering inventory; and (3) allying the R&D support and co-engineering.

In light of Otto and Kotzab's (2003) performance metrics (i.e., time to network, flexibility, and density of relationship), this chapter intends to incorporate the performance metrics to the downstream spillovers that are created from the upstream investments. Figure 1 shows such an effort. Future research is required to investigate how the spillover effect (resulting from either strong alliances or weak alliances) can add value and benefits to the supply chain as a whole. The researchers classify the possible spillovers outcomes with two determinants—market intelligence and coordination. The downstream spillover effect depicted in Figure 1 can be interpreted by a "technology similarity" that may make possible more knowledge sharing while "proximate" alliances lead to a better coordination in a supply chain. The knowledge sharing and coordination can also be explained by Malhotra and Gosain's (2005) "structure" and "cognitive" impacts.

The transaction costs may decrease or the values may increase while the spillover effect (mainly resulting from the IT investments in the upstream) moves to the downstream. Derived from value chain (Porter, 1985), transaction cost (Williamson, 1993, 1995), resource-based view (Barney, 2002) principles, and resource-advantage theory, Table 2 summaries a typology of competi-

Table 2. The typology of competitive advantage positions in terms of alliances and spillovers in a supply chain

	Downstream Weak Spillovers	*Downstream Strong Spillovers*
Upstream Weak Alliances	1. Money Pit	3. Competitive Advantage without Sustainability
Upstream Strong Alliances	2. Possible ROI in a Longer Term	4. Competitive Advantage with Sustainability



tive advantage positions in terms of alliances and spillovers.

The four arrows in the table represent the emergent competitive advantage positions that synchronize with the market changes. These four positions of the typology are described in detail next.

Position 4: Competitive Advantage with Sustainability

Strong alliances in the upstream supply chain are likely to engage more sturdy spillovers that will lead to a more sustainable competitive advantage. Prior to reaching this phase of affiliation, the alliances between upstream members may have previously formed their partnership with satisfaction (Colwell & Vibert, 2005). The partners have learned from each other on how to work with each other (Jordan, 2004; Kim & Im, 2002). Therefore, they can team up with great ease, comfort, and trust. The more satisfied the partnership is, the more likely the firms are to ally repeatedly. While robust alliances can support stronger spillovers and sustain a better position in competitive advantage as a whole, the long-term relationships may collapse because of economic situation, market changes, consolidations, or conflicts of new alliances. The strength of upstream alliance diminishes and this sustainability could retreat to the third position.

Position 3: Competitive Advantage Without Sustainability

This position is characterized by the mixture of strong downstream spillovers and weak upstream alliances. The strong spillovers may support the supply chain with a competitive advantage; however, they may not be able to provide sufficient sustainability in competitive advantage. The argument here is that the competitive advantage may have been generated from the strong spillovers derived simply from weak resources, namely, less innovative technology, lack of coordination, or short of investment effort. From the perspective of resource-advantage (R-A) theory, this position is similar to Hunt's (2000) "Cell 6" of competitive position matrix. In Hunt's research, the competitive position matrix contributing to the thrust of R-A theory represents nine possible competitive positions based on the combinations of a firm's resource-produce value and relative costs for producing such value. The "Cell 6" represents an "effectiveness" advantage because "their parity costs produce superior value" (Hunt, 2000, p. 139). Simply put, Position 3 can be effective but not sufficient to sustain a competitive advantage over time. It is possible that it would recede to Position 1 or move to Position 4, depending on the fact that alliances become stronger or spillovers become weaker. To assume pessimistically, Position 3 is more likely moving towards to Position 1.

Position 2: Possible Return on Investment (ROI)

In this position, the ROI will take a longer time to evolve to stronger spillovers that will show beneficial impact to the supply chain. Jap et al. (2005) presented the "overshooting the target" situation to illustrate the long-haul investment in partnerships. Some R&D alliances may range from three to 10 years. Therefore, commitment and trust need to be established in addition to a governance structure. With strong upstream alliances, the downstream spillovers should be increasingly strengthened to move forward to Position 4. Nevertheless, there always are some possibilities that R&D may not be able to completely follow through. If that is the case, Position 2 can then turn into Position 1. However, with strong alliances or previous satisfying cooperation experiences, the spillovers in the downstream will eventually come around and cause the state of competitive advantage to move towards Position 3.

Position 1: Money Pit

This position represents a combination of weak alliances and weak spillovers that is likely to dangle the firms over the precipice of a potential money pit. Jordan (2004) has stressed that alliance success depends on the combination of a high level of cooperation and knowledge/information sharing. If the allies fail to learn or share from one another, then the supply chain's ability to compete may be compromised (Jordan, 2004; Kim & Im, 2002). Therefore, the investments may not realize a return. However, as the allied partners' learning experience becomes more satisfying, futile partnerships will eventually evolve to partnerships that are more favorable. Therefore, it is possible that Position 1 can swing towards Position 2. In this case, stronger downstream spillovers may come about due to increasing coordination and knowledge sharing.

CONCLUSION

As there are multiple channels, there are multiple combinations in grouping a supply chain (refer to the gray shaded areas in Figure 1). In other words, the reconfigurations continuously evolve as long as there is a change of trading partners in a supply chain or one of the trading partners changes the way of dealing with businesses. For example, if Wal-Mart switches to CPFR, then all of its distribution partners must change their business processes accordingly.

For most firms, their IT investments still remain in the upstream of the supply chain for better performance, more efficient throughput, shorter lead time, and improved customer satisfaction. Nevertheless, as IT improves the upper channels, it will be highly likely to enhance the performance for the entire chain because of the "spillover" effect. Hence, the spillover effect has been recognized as a viable enabler to turn the supply chain into a sustainable competitive advantage as a whole.

Furthermore, there is an increasing emphasis on the R&D investments in a supply chain in terms of strategic alliances in IT investment. In most cases, similarities in technology and geographic proximity are the two ultimate factors for forming such IT alliances. In reality, IT investments can be very costly. If a firm can strategically plan out the investments and properly spread out the costs among the trading partners, it can acquire a better marginal benefit and return on investment.

Since the late 1990s, Internet technology has introduced different aspects of innovative processes, such as mass customization, real-time inventory management, and, most importantly, the diminishing of intermediaries (Porter, 2001). Not only does the Internet move businesses from "brick and motor" to "click and play," it also facilitates the companies to fundamentally reengineer their businesses. Internet technology makes business processes among suppliers, customers, intermediaries (if they exist), and business partners more efficient and effective because of its real-time, ubiquitous capabilities. Nowadays, Internet technology has changed the landscape of SCM in almost every aspect, including business process integration, coordination, collaboration, and information/knowledge sharing.

Several issues on strategic alliances of IT among supply chain channel members have been illustrated in this chapter. However, there are a number of limitations needing to be addressed in future research. First, in extension of the typology of van der Vorst et al. (2002), Gunasekaran and Ngai (2004) introduced a framework for the development of IT for effective SCM. The framework includes such integral components as strategic planning of IT, virtual enterprise, e-commerce, IT infrastructure, knowledge management, and IT management and implementation. Making it more complete, it is suggested that the framework should include the study of organizational issues related to IT establishment as one of the future research activities.

As far as strategic alliances of IT investments are concerned, another important area of future research is to investigate how the spillovers can be properly incorporated into a firm's strategic planning needs (Mahajan & Vakharia, 2004). From a longer term perspective, a firm's R&D investment introduces a firm's specific capabilities. In line with a firm's investment in R&D, there are two important issues that ought to be in the spotlight for future research: (1) how the knowledge-sharing network can enhance its "dynamic learning capability" (Kim & Im, 2002), and (2) how the knowledge-sharing network fits into the landscape of the whole supply chain in a rapidly changing business environment.

In Mahajan and Vakharia's (2004) article, it was mentioned that the accruing benefits from each channel member may help increase efficiency and productivity of the entire supply chain. To assist investors in figuring out more financial measures beyond just ROI, some performance metrics should be in place. In light of this need, Otto and Kotzab (2003) offered a complete list of performance metrics of SCM, along with associated problems and suggested solutions. Furthermore, to prevent the free-riding phenomenon in a supply chain, the "fee-for-use" of IT was tested by the mathematical models developed by Mahajan and Vakharia (2004, p.681). Extending from Mahajan and Vakharia's research, examination of how much or how often to subsidize or charge the participating members in a supply chain is recommended.

Chapter 1.8

Strategic Positioning and Resource-Based Thinking:

Cutting Through the Haze of Punditry to Understand Factors Behind Sustainable, Successful Internet Businesses

John Gallaugher
Boston College, USA

ABSTRACT

This article synthesizes and leverages two strategic frameworks when analyzing the true nature of strategy and the Internet: (1) the concept of strategic positioning, and (2) the resource-based view of the firm. When considered together, these approaches create a powerful tool for understanding the factors determining the winners and losers among Internet businesses. Several examples of the applied framework are demonstrated. These frameworks also help challenge broken thought around many of the postbubble assertions regarding strategy and the Internet. This analysis is based on a series of case studies, with information drawn both from secondary sources as well as over 60 field visits with senior managers at technology firms in Seattle, Silicon Valley, and Tokyo conducted from 2005-2006.

UNDERSTANDING COMPETITIVE ADVANTAGE

Strategic Positioning

To understand strategic positioning it is important to first recognize what it is not. Many firms claim to have crafted a sustainable strategy, only to realize that their competitive position is vulnerable and will be eroded over time. Vulnerable business models are often the result of relying on operational effectiveness. Operational effectiveness involves "performing *similar* activities *better* than rivals perform them" (Porter, 1996). Being operationally effective is critical for sustained business. Firms must strive for improved quality and design, lower costs, and increased efficiency. However, operational effectiveness alone is almost never sufficient enough to determine winners over the long term. This is particularly true of Internet-based businesses where technologies are highly replicable (Shapiro & Varian, 1998).

Technology-based competition leveraging operational effectiveness often pushes firms to improve quality and lower cost. However, given that the steps taken are readily replicable, firms engaged in this sort of hyper competition often see profits decrease rather than increase (D'Aveni, 1994; Wiggins & Ruefli, 2005). There are many examples illustrating the challenges relating to the intensity of competition among Internet firms. For example, Gallaugher and Downing (2000) demonstrated that among leading Web portal firms, leadership in feature innovation played no role in achieving market dominance. Rivals engaged in a rapid response feature war in which the average first competitive response matching a pioneering technical innovation was only 1.5 months. Forrester and Gomez rankings of the user experience among online brokerage firms reveal a similar pattern over time, with firms that have ranked last in one quarter's reports subsequently moving up in less than a year to obtain top honors. Also consider the fate of many firms that are recipients of the Webby Awards. The Webbys, awarded by an international committee of 500, are considered by many to be the oscars of user interface design. Yet despite being recognized for excellence, dozens of prior winners of the Webby Awards have gone bankrupt, had their stocks delisted, or dramatically scaled back operations (Wired, 2003). Design and feature innovation are vital and too many firms have failed in execution due to poorly conceived user experiences; however, design excellence alone is not enough to build a sustainable online winner.

So how do firms succeed? Proponents of strategic positioning suggest sustainable advantage is achieved through differences. Strategic positioning refers to "performing *different* activities from rivals' or performing similar activities in *different ways*" (Porter, 1996). To return to the case of discount brokerages, while the various online discount brokerages have jockeyed for position in usability rankings, one firm, Schwab, has achieved consistent and sustainable competitive advantage, ranking #1 in market share leadership since first going online in the mid 1990s. Schwab's differences are not attributable to easily matched advantages such as lower fees or superior interface, but rather to difficult-to-acquire assets including the nation's largest branch network and the strong Schwab brand. A full 70% of new Schwab members open accounts through the branch network, while the vast majority of these new customers are immediately migrated to electronic trading channels for subsequent interactions (Myers, Pickersgill, & Van Metre, 2004).

Proponents of strategic positioning argue that organizational *differences* can help a firm avoid the self-inflicted wound of hyper competition by insulating a firm against competitive convergence enabled by the rapid diffusion of best practices (Porter, 2001). Firms are advised to choose strategies that confront competitors with tradeoffs that these rivals are unable or unwilling to efficiently undertake. Such trade-offs would result in competitors straddling markets, often resulting in rivals attempting to deploy business models with divergent capital structures, alternate margin and volume demands, and nonsynergistic assets (Porter, 1995). The classic nontech example of straddling is the response of major carriers to Southwest Airline's position. By eschewing hub and spoke systems, tiered service classes, meals, travel agents, and flying one fleet of aircraft, Southwest has built a value chain that is so efficient that competing carriers would need to cut roughly 20% of their cost structure to attain comparable margins. Many firms, including Continental with

Continental Lite and British Airways with Go, have attempted to emulate Southwest's model, but failed due to straddling. Most recently, Delta announced the folding of Song after losing a reported $13 million in a single year on the effort (Serwer, 2004; Mullaney, 2005).

Tech and the Resource-Based View of the Firm

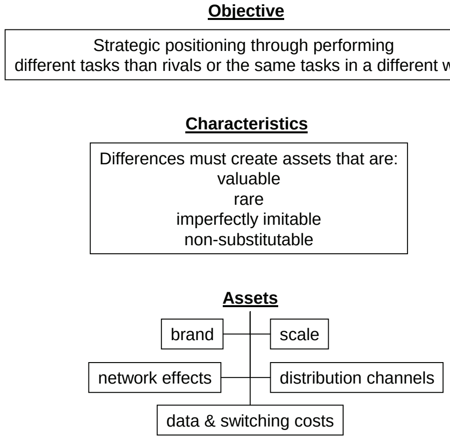
The strategic positioning perspective, however, is limited in that it does not clearly articulate the types of differences that a firm should pursue. The resource-based view (RBV) of competitive advantage (Barney, 1986, 1991; Wernerfelt, 1984) is particularly useful in helping to shape thinking regarding strategic positioning. In the resource-based view, firms are seen as having the potential to earn sustainable returns ahead of industry rivals if and only if they have superior resources that are protected by some form of isolating mechanism preventing their diffusion throughout the industry (Barney, 1991).

In an earlier analysis, Mata, Fuerst, and Barney (1995) examined four variables: capital requirements, proprietary technology, technical IT skills, and managerial skills, and identified that of these, only managerial IT skills could provide sustainable advantage. However this analysis ignores assets that are created or enabled by information technology (Smith, Vasudevan & Tanniru, 1996). While technology can be copied, oftentimes the resources *created* or *enabled* by technology cannot be. This goes beyond the process view espoused by Smith and Fingar (2003) and recognizes that technology is not only a component of most modern strategic processes, but further, strategic technology implementation can create assets that satisfy the four characteristic criteria of the resource-based framework. In this sense, it isn't the technology that is the advantage. It is what a firm does with the technology. The capability to conceptualize and deploy technology that can create or reinforce strategic assets is critical (Bassellier & Benbasat, 2004; Clemons & Row, 1991).

Considering this in the context of Internet firms, a set of key strategic resources emerges. Unlike the picture painted by Porter (2001) in which low barriers to entry erode competition and margins, eliminating profitability and sustained advantage, the opposite seems to be taking place. Strategic resources seems stronger online than in the physical world. There are winners—large consistent winners—among online firms. Perhaps what is most interesting is that in so many cases, it is startup firms, not established firms, which have acquired these resources. This dynamic seems to have taken place largely because these entrants have struck with models that create exploitable strategic resources. As *Businessweek* has stated, when compared to off-line threats and new entrants it seems that "the online winners today are the winners, period" (Hof, 2002).

Resources leveraged by the online winners rely on a subset of key resources not unlike those exploited by off-line giants, but given the special circumstances of the Internet channel, these resources are exploited in different ways and are not necessarily transferable from one channel to another. Assets include scale, network effects,

Figure 1. Combined strategic positioning & RBV model: From objective to characteristics to assets



data and switching costs, brand, and distribution channels. This is not an exhaustive asset list, however some subset combination of these assets is typically present in firms that have proven to be sustainably dominant in the Internet space. Figure 1 shows the development of the proposed model from objective through characteristics and asset identification. The following examples and theory critique demonstrate the application of the model in various contexts.

Netflix: Defeating Two Goliaths

To illustrate the above model's ability to identify the factors associated with the strategic success of Internet business models, consider the example of Netflix. The Los Gatos, California firm pioneered a DVD subscription service where users pay a flat fee to have DVDs delivered to their home via postal mail. Customers hold DVDs as long as they want with no penalty. Plan fees determine how many DVDs a customer can have at a given time, with the most popular plan offering 3 DVDs at a time for $17.99. Customers choose movies online through a Web browser. If a movie is not available, the customer's next available selection is shipped.

In 2004, many analysts were predicting the death of Netflix (Friesen, 2005). Both Blockbuster and WalMart had entered the market for online DVD subscription services. With over 9,000 outlets and rental cards held by 43 million U.S. households, Blockbuster was by far the nation's leading video rental chain. Wal-Mart at the time was #1 on the Fortune 500 list. Both of these late entrants had large existing customer bases, well-known brands, massive scale, and were attempting to synergize online and off-line channels. Blockbuster, for example, offered coupons to its online subscribers, good for two free in-store rentals a month. Wal-Mart heavily promoted the service with in-store displays. Both services undercut Netflix prices with their initial subscription plans. Increased competition forced Netflix to advertise more at a time when online ad rates were increasing. The outlook for the pioneer was not good.

Fast forward to the end of 2005 and it seems that David has trounced both Goliaths. Netflix profits were up seven fold. During the same period, Blockbuster had posted a loss of $1.2 billion and Wal-Mart withdrew entirely from the subscription DVD market (McGregor, 2005). Subscribers at Netflix topped 5 million, while the firm's year-end customer churn of 4% was at an all time low. Rather than being crippled by competition, Netflix ended the year in its best shape ever.

How could this happen? Netflix possessed key resources for competitive advantage, scale, data, brand, and proprietary technology, which others were not able to match. And even though rivals possessed these resources off-line, none of these advantages significantly translated into the market for online DVD subscription.

In terms of infrastructure scale, by year-end 2005 Netflix had 37 distribution centers capable of reaching over 90% of the country with one day mail turnaround. The model becomes profitable when this warehouse scale is combined with customer scale. With five times the customer base of its next rival, Netflix sends out an estimated 1 million DVDs each day. This huge customer base allows the firm to offer a deeper movie selection than any new entrant. Indeed, Netflix is a poster child for the *long tail* phenomenon where firms offering a large selection find profitable markets for less popular items (Anderson, 2006). Warehouses can afford to stock 42 million DVDs encompassing 55,000 titles categorized in 250 genres. By one estimate, 35,000 unique titles are processed in a given day, vs. a maximum title catalog of 3,000 at most video stores (*The Economist*, 2005).

Managing this selection requires sophisticated tools for collaborative filtering. Netflix's proprietary, home grown ratings system, Cinematch, contains over 1 million lines of code and is considered best-in-class. Users are encouraged to rate content they have seen, and these data are used to make additional recommendations. The average subscriber has rated more than 200 movies. Netflix claims that a million new ratings are added to the system each day, and that the system contains well over half a billion ratings in total. The power of the database to move back catalog content has allowed the firm to partner with studios. The studios provide DVDs to Netflix at a reduced cost, while the firm shares a percentage of its subscription take with the studios based on titles shipped. Studios gain costless marketing of content that has already been produced. One analysis suggests Netflix makes 90-95% of its recommendations from the back catalog rather than new releases (Goldstein & Goldstein, 2006). The revenue sharing alliance with studios also raises an example of channel conflict. In 2001, the only film studio not participating in revenue sharing with Netflix was Paramount. At the time, Paramount parent Viacom also owned Blockbuster. Executives at Viacom, fearing support for a subsidiary's rival, refused to engage in revenue sharing. As retaliation, Netflix refused to recommend Paramount films in Cinematch. In 2001 a Paramount film, the Mel Gibson comedy *What Women Want*, was the #4 most popular rental in the United States, but on Netflix it did not even crack the top 100 (O'Brien, 2002).

The efficiency of the Netflix system and its processes improve over time with applied organizational learning. Earlier in the firm's history, Netflix had 115,000 customers and 100 support reps. But by year end 2005, the firm needed just 43 reps to service a customer base that had grown by a factor of 50. Netflix currently holds over 100 patents broadly covering multiple aspects of the firm's operations, and it has sued to protect the firm from copycat competitors. The continued excellence of the Netflix customer experience has reinforced the firm's brand strength. In 2005, market research firm Foresee ranked Netflix #1 in customer satisfaction among all Internet retailers (McGregor, 2005).

Netflix should be celebrated as a conventional wisdom defying example of how Internet startups with novel models can create resources so powerful, they can defeat category-leading firms that dominate adjacent channels. However, the business is not without grave vulnerabilities. The model works as long as there is no better alternative to long tail content distribution than the firm's dominant DVD-through-mail system. It is highly likely that new competition from video-on-demand services, as well as online rental and purchase opportunities such as Apple iTunes and Amazon Unbox, will present customers with a value proposition that exceeds the Netflix switching cost. While Netflix has announced plans for a video-on-demand business, the firm's CEO has stated that the new service will be underwhelming due to a lack of content from studios. The threat that studio partners may bypass Netflix in the next round of technical shock is significant and concerning.

ING Direct: Same Resources but Different Strength?

While the resources in the model can be powerful advantages, it is important to analyze the strength of any apparent resources within an industry's context. As an example of this, consider the online banking market in the United States. The market share leader in this space is ING Direct, a division of Dutch financial giant ING. The division is highly profitable, due largely to its scalable and highly efficient operating model. The firm deliberately seeks self-service customers for products that have very little marginal cost per transaction. ING Direct only offers paperless checking accounts (all bill pay handled online – ING will mail a check to those that can't accept e-payments), and did not offer any checking until summer 2006. Customers who use labor-intensive phone service too frequently risk being *fired* from the firm (Esfahani, 2004). Each month, ING sheds roughly 3-4% of its unprofitable customers this way. All this leads to a radically high degree of efficiency. The firm holds roughly $42 million in assets per employee, compared to an industry average of just $5 million (Engen, 2005).

On the surface it would seem that ING Direct has at least three of the strategic resources that NetFlix benefits from. As the market share leader, ING should enjoy both a brand and a scale advantage. And the cost to open an account and migrate any automatic payment systems is a switching cost working to keep existing customers with ING. However the existence of an asset alone is not enough to determine if a business can leverage it for sustainable advantage. One must also consider the asset's strength relative to the industry in which it operates. ING Direct's orange bouncing ball logo is well recognized among the firm's target demographic. However the quality of ING's customer base is questionable. Customers are attracted to ING Direct because of low rates, and these price sensitive customers are potentially the industry's most disloyal. Scale plays a key role in asset efficiency, and a true scale advantage suggests that the largest firm should yield the best rates. However, a summer 2006 examination of the highest savings account rates at BankRate.com demonstrates that ING Direct often does not even rank in the top 20. Some banks with higher rates, like MetLife Bank, have strong brands in related financial services markets, but many of the firms that rank higher than ING are relatively unknown firms such as Emigrant Bank of New York, or the Transportation Alliance Bank of Ogden, Utah. While these firms do not advertise direct banking as extensively as ING Direct, the lack of advertising helps these firms keep costs low. In banking, smaller market, privately held firms can run quite lean. Because of this, large size (scale) doesn't necessarily equal the best efficiency, and it certainly does not guarantee the best rates. Because customers seek low rates, this segment is more likely to comparison shop based on rate (a price proxy) than customers in many other industries, suggesting limited brand strength despite high brand recognition. Finally, although switching costs exist, ING is an electronic bank, so migrating accounts is not difficult.

Do these weaknesses mean ING is doomed? No. But it does suggest that ING Direct does not possess resources with the strength to control the market to the extent that Netflix does. The lack of strong strategic resources implies competition based more on operational effectiveness than strategic positioning. While Netflix's strong assets helped the firm achieve a seven-fold increase in profitability in its most competitive year, when ING faced a particularly competitive second quarter in 2006, profits slowed to 3%, vs. a 30 % jump in the fourth quarter of 2006.

Timing, Yahoo, and Google

The role and influence of timing is particularly contentious among strategists who study Internet firms. The case of Yahoo provides interesting examples on the role of timing. From a technical perspective, the Yahoo experience is an easy one to imitate. There are no substantive elements of the user interface that have intellectual property protection. Because of this, during its early rivalry many found the firm's service difficult to distinguish from rivals Excite, Lycos, and Infoseek/Go. Innovation was proven to be insignificant in determining the firm's dominance. The one factor empirically demonstrated to be related to Yahoo's market share was brand (Gallaugher & Downing, 2000). In an admittedly crowded market (firm founders have stated that the first two letters of the firm's name stand for "Yet Another"), Yahoo was first to successfully execute a national branding campaign. Through advertising and most notably PR, Yahoo grabbed media attention ahead of its rivals. An early distribution alliance with Netscape also helped the firm increase its exposure. As such, even in a crowded market, Yahoo was first to create and leverage strategic assets used to trounce its competition. Today Yahoo jockeys with Microsoft, a firm with software platforms and a browser as a distribution asset, for the largest reach in Internet traffic, and Yahoo ranks among the most profitable of U.S. media companies.

While timing played a role in Yahoo's ascendance, it also plays a critical role in its position with respect to its current and greatest challenge: Google. Yahoo was a public company for two years before Google was even founded. Beginning in 2000, Yahoo began paying Google for search, listing results through the subdomain google.yahoo.com. The tactic immediately doubled Google's visitors and helped reinforce Google as a search leader. By the time Yahoo elected not to renew its contract with Google, Google had already exceeded Yahoo in search traffic (Hansell, 2002). Yahoo's failure to see Google as a threat is particularly interesting because the firm continued to innovate with new features when compared to established portal rivals, yet had neglected to improve search. Google's value proposition to users was simple: more accurate search (via the PageRank algorithm), a stripped down user interface containing less than 20 words, and no graphics beyond the firm's logo. Both of these approaches could be duplicated, yet rivals ignored them. During Yahoo's period of search innovation dormancy, Google was able to leverage its technical lead to create brand, grow market share, and thus generate scale. Google's size-based scale advantages today result from both its user and advertiser base, the largest in search advertising, and the size of the infrastructure needed to support its operations (the firm is estimated to use between 500,000 and 1 million servers to power its service). While both Yahoo and Google were started by Stanford doctoral students, the chances of a rival creating a comparable firm today are greatly diminished due to the capital requirements needed to support a competitor. Again, we see Google was not the first entrant, but it was the first to craft defensible assets in its space. And the firm's use of unmatched technology over time directly led to the creation of these assets.

Broken Thought and Breakthrough Models

After examining the model of positioning leveraged through strategic resources we can reflect on some of the most popular writing on the strategic use of the Internet and see that much of the advice offered was wrong or broadly overstated. This broken thought is profoundly dangerous to managers seeking to understand the true nature of competitive advantage and how firms can construct strategies for success. Several examples of this failure are analyzed.

Myth: Moving Early is Unimportant

Michael Porter refers to the "myth of the first mover" in his widely cited piece, "Strategy and the Internet" (2001). Another *Harvard Business Review* article, Nick Carr's "IT Doesn't Matter" offers the advice "follow, don't lead" in a bold call-out (2003). However, much of the evidence suggests this is at best an overly broad platitude and potentially terrible advice for the strategist. It took Barnes and Nobel 17 months to respond to Amazon.com's online effort, but by early 2006, Amazon has three times the profit and seven times the market cap of its late moving rival's online *and off-line* businesses. Wal-Mart, Federated, and many other established retailers have entered markets alongside Amazon, but none has approached the online size of the asset-creating first mover. Schwab launched Web trading in May of 1996, Fidelity in January of 1997. Prior to this, Schwab and Fidelity were closely ranked peers as the top two discount brokers, but by 2000 Schwab had captured 27.5% of the online trading market. Fidelity ranked fifth in trading volume with a share of just 9.3%. In online auctions, Yahoo and Amazon, each an established Internet brand with millions of users, could not break eBay's 80% domestic market share. Yahoo even offered its service commission free the first year, but to no avail. In payment systems, PayPal launched ahead of eBay's home grown service, Billpoint. PayPal's biggest market was in supporting transactions over eBay, but eBay recognized the startup had strategic assets that were simply too strong and eventually acquired PayPal for $1.3 billion. All of these early movers were able to leverage their time lead to create strategic resources, and in every market, the late mover has had to spend more to gain significantly less market share with lower margins.

Myth: Switching Costs Have Limited Impact Online

More broken thinking exists around switching costs. Porter suggests "switching costs are likely to be lower, not higher, on the Internet", and predicts that services like PayPal will allow consumers to migrate from one vendor to anther, avoiding the cost of re-entering order information. In fact, switching costs and attendant data assets have proven to be vitally important. The case of Netflix demonstrated that even when well known rivals enter a market with a cheaper product, consumers were unlikely to switch. Netflix's share and customer base grew well ahead of rivals while customer churn fell. Wells Fargo has stated that firms that use online bill pay, a switching cost source due to time spent entering payee information and learning the interface, are 70% less likely to leave than customers who do not bank online. Part of the reason Yahoo was not able to migrate its user base from eBay to Yahoo Auctions was due to established eBay users' reluctance to give up their seller and buyer ratings and start anew—again, a switching cost. Even a firm like Google, where switching costs apparently are non-existent, has seen its usage rise. While it may be easy in theory for users to move from one service to the other, in practice, despite heavy innovation from rivals, users have not been presented with enough reason to make a switch. These businesses are not special exceptions; they are winners because the dynamics of their markets and models lead to powerful winner-take-most advantages.

Myth: The Benefits of Network Effects are Overstated

Porter has referred to Network Effects as a self-limiting mechanism, suggesting that it is difficult for a single firm to capture their benefits, and that network benefits reach a point of diminishing returns. Porter also argues that "creating a network effect requires a large investment that may offset future benefits". In fact, many firms that have leveraged network effects have done so with a minimum of investment. Firms that establish an early market share lead in markets where network effects are present often find that their consumers become advocates for the service, fueling increased demand with limited advertising. Second generation Internet businesses that have leveraged network effects to achieve half-billion plus valuations with no advertising include MySpace, Facebook, and Skype. While network effects are only significant in industries where exchange is critical (Gallaugher & Wang, 2002), in industries where these factors are at work, a winner-take-all dynamic ensues. EBay's delay in entering the Japanese market led it to withdraw in defeat, ceding a market in excess of $2 billion to Yahoo because of a delay of only 5 months. Network effects, combined with switching costs, are a chief strategic asset at work in establishing the dominance of PayPal, Apple's iPod/iTunes products, Sony's Playstation 2, and major stock exchanges, among other services. Each of these businesses has a value exceeding $1 billion.

Myth: Internet Brands are Weak

Porter suggests a lack of direct contact makes Internet brands more difficult to build than traditional businesses. He cites the high cost of advertising, product discounts, and incentives as part of the difficulty. But as stated previously, early movers have established extremely powerful online brands. In fact, one may argue that truly global brands have never been built faster and at a lower cost than those created by successful Internet firms. Not only is Google's brand strength held despite low switching costs and heavy competition, the firm spends 22 times less than MSN and 7 times less than rival on maintaining its brand advantage (Elgin, 2005). Google executives claim to have spent nothing on advertising through 2003 and continue to spend very little (Hansell, 2002). Amazon, eBay, Skype, Netflix, MySpace have all established themselves as virtually synonymous with their services, creating brands so strong that even rivals with established brands in other channels or markets must overspend to establish a place in the consumer psyche. And in fact consumer behavior demonstrates that there is very little room in the space of consumer mindshare for a second, third, and certainly not forth tier player. Brands lower consumer search costs to find products, they proxy quality, and inspire trust. A failure to establish a strong asset is a recipe for online disaster, and a firm that can secure this asset has a daunting strength for rivals to attempt to match.

Myth: The Online Advertising Business is a Weak Revenue Generator

Early stage Internet investing was excessive, due in part to wild enthusiasm mixed with a lack of understanding regarding the power and necessity of acquiring strategic assets outlined above. However, the anomaly of the dot-com collapse caused many (including Porter) to overstate the case regarding the limitations of ad-centric business models. Porter stated, "Advertisers can be expected to continue to exercise their bargaining power to push down rates significantly, aided and abetted by new brokers of Internet advertising". In fact, once the dust settled from the dot-com collapse, online advertising among mainstream advertisers took off, rates rose, and inventory became scarce (Bonamici & Vogelstein, 2005). Consumer media time continues to accelerate online at the expense of other forms of media. Ford, GM, and Proctor and Gamble are among the firms shifting millions online due largely to the measurable success of their early efforts. And by summer 2006, online advertising had turned Google into the world's largest media company by market cap, earning the firm three quarters of a billion dollars in quarterly profits. At that run rate, the firm's 2006 profits will be greater than Disney's 2005 earnings and nearly as much as Viacom's. Online advertising faces several challenges, including the scourge of click fraud, but the impact and success of the medium has been entirely the opposite of the widespread postbubble punditry.

Myth: Commoditized Technologies Assist Laggards

Nick Carr states that Moore's Law "guarantees that the longer you wait to make your IT purchase, the more you'll get for your money" (Carr, 2003). This is risky and simplistic advice. IT is more than just processor speed. While hardware may be commoditized, suggestions of the value of software commoditization ignore the danger of promoting generic processes or copyable technology in areas where tech can create or strengthen competitive assets. For example, Amazon initially purchased customer profiling and experience customization software from NetPerceptions, yet later decided rolling its own collaborative filtering system would give it an advantage. Apparently users surveyed in the University of Michigan's American Customer Satisfaction Index agree. In 2002, the firm was rated the top service business in any service industry, online or off, ever examined by the study. Netflix dropped Oracle's inventory management system when it realized superiority in delivery was critical to maintaining margin advantages over rivals. And Dell scraped an ERP implementation when it, too, felt that generic processes would be employed over strategic ones (Davenport, 1999). Commodity thinking about technology without regard to the process and resource creating strategic impact of this technology is flawed and potentially damaging.

Myth: The Internet's Low Entry Barriers Mean Firms are More Vulnerable than Off-line Counterparts

In 9 months, iWon.com was able to launch a service that on first blush appeared indistinguishable from Yahoo. But in hindsight it seems the firm had little impact on its larger rival's actions or competitive position. From Yahoo's perspective it was as if iWon never existed. Porter warns that the Internet significantly lowers entry barriers, but as the points above make clear, late entrants have regularly tried and failed at copy the models of existing, strategically positioned firms. Market entry does not equal firm sustainability, and the ability to put up a Web site does not mean a firm will have the resources needed to sustain itself in the market. While low entry barriers can create problems in industries where leaders are unable to craft strategic assets that avoid price-based competition, most firms considered Internet leaders today are not threatened by the low entry barriers because they possess difficult to acquire strategic assets.

CONCLUSION

Firms will make mistakes and markets will evolve. Amazon's highly profitable media retail businesses may be under threat as the firm spends to expand in other categories and confronts established and resource rich firms in digital media. Technology may dismantle the advantages of the Netflix delivery network. MySpace and Facebook may be subject to faddish and changing tastes. Google's assets may be undercut if Microsoft successfully embeds search into Vista. And financial pressures as firms transfer from high growth to mature businesses may cause competitors to engage in costly battles to invade one another's space. By early 2006, Microsoft had $40 billion in cash, Google had $10 billion, Yahoo $4 billion, eBay $2 billion, and Amazon added more new hires in 2005 than any of these firms (Smith & Mangalindan, 2006). The outcomes of any future confrontations are unknown, but the sustainability of any eventual winners will be due to their ability to craft, exploit, and defend strategic resources.

Through cases and examples, this article has demonstrated that Porter's strategic positioning theory can be particularly valuable when combined with resource-based theory. While Porter's frameworks are of great value, practitioners and theorists alike should regard the Internet-related platitudes, suggestions, and examples offered by many writers, including those by Porter and Carr, with skepticism. Strategy requires deep, reflective thinking about the differences across each industry. Technology matters greatly. It plays a key factor in creating valuable resources such as network effects, switching costs, and data assets. It also enables businesses that can leverage an operational lead to establish resources that can include brand and scale. The role of timing remains critical. Moving blindly into an industry with an unsuccessful model is a recipe for failure. It is acknowledged that technology must be sufficiently mature such that customers are prepared to accept a novel product or service (Suarez & Lanzolla, 2005). But comparing failed firms to late moving successes misses a key point: the failed businesses failed many times not because of their early timing but because of their imperfect model or flawed execution. While firms can choose to wait to learn from a rival's failure, if the incumbent is successful, then time leadership may be used to craft powerful resources that are difficult for hesitant rivals to overcome. Betting on rival failure is not a strategy – it is gambling. Strategic thinking about assets, and crafting tactical excellence to create these strategic resources, is a far more appropriate recommendation. It is hoped that the presented framework proves a useful tool in understanding as well as plotting successful businesses.

Chapter 1.9

Decision Support Systems

John Wang
Montclair State University, USA

David J. Radosevich
Montclair State University, USA

INTRODUCTION

Over the four decades of its history, decision support systems (DSSs) have moved from a radical movement that changed the way information systems were perceived in business, to a mainstream commercial information technology movement that all organizations engage. This interactive, flexible, and adaptable computer-based information system derives from two main areas of research: the theoretical studies of organizational decision making done at the Carnegie Institute in the 1950's and early 1960's as well as the technical work on interactive computer systems which was mainly performed by the Massachusetts Institute of Technology (Keen & Morton, 1978).

DSSs began due to the importance of formalizing a record of ideas, people, systems, and technologies implicated in this sector of applied information technology. But the history of this system is not precise due to the many individuals involved in different stages of DSSs and various industries while claiming to be pioneers of the system (Arnott & Pervan, 2005; Power, 2003). DSSs have become very sophisticated and stylish since these pioneers began their research. Many new systems have expanded the frontiers established by these pioneers yet the core and basis of the system remains the same. Today, DSSs are used in the finance, accounting, marketing, medical, as well as several other fields.

BACKGROUND

The basic ingredients of a DSS can be stated as follows: the data management system, the model management system, the knowledge engine, the user interface, and the users (Donciulescu, Filip, & Filip, 2002). The database is a collection of current or historical data from a number of application groups. Databases can range in size from storing it in a PC that contains corporate data that has been downloaded, to a massive data warehouse that is continuously updated by major organizational transaction processing systems (TPSs). When referring to the model management system, it's primarily a stand-alone system that uses some type of model to perform "what if" and other kinds of analysis. This model must be easy to use, and therefore the design of such model is based on a strong theory or model combined with a good user interface.

A major component of a DSS is the knowledge engine. To develop an expert system requires input from one or more experts, this is where the knowledge engineers go to work, who can translate the knowledge as described by the expert into a set of rules. A knowledge engineer acts like a system analyst but has special expertise in eliciting information and expertise from other professionals (Lauden & Lauden, 2005).

The user interface is the part of the information system through which the end user interacts with the system—type of hardware and the series of on-screen commands and responses required for a user to work with the system. An information system will be considered a failure if its design is not compatible with the structure, culture, and goals of the organization. Research must be conducted to design a close organizational fit, to create comfort and reliability between the system and user. In a DSS, the user is as much a part of the system as the hardware and software. The user can also take many roles such as decision maker, intermediary, maintainer, operator, and feeder. A DSS may be the best one in its industry but it still requires a user to make the final decision.

Power (2003) introduced a conceptual level of DSSs, which contains five different categories. These categories include model-driven DSS, communication-driven DSS, data-driven DSS, document-driven DSS, and knowledge-driven DSS. Defining DSS is not always an easy task due to the many definitions available. Much of this problem is attributed to the different ways a DSS can be classified. At the user level, a DSS can be classified as passive, active, or cooperative.

Essentially, DSS is a computer-based system that provides help in the decision-making process. However, this is a broad way of defining the subject. A better way of describing DSS is to say it is a flexible and interactive computer-based system that is developed for solving non-structured management problems. Basically, the system uses information inputted from the decision maker (data and parameters) to produce an output from the model that ultimately assists the decision maker in analyzing a situation. In the following sections, we first discuss design and analysis methods/techniques/issues related to DSSs. Then, the three possible ways to enhance DSSs will be explored.

DESIGN AND ANALYSIS METHODS/TECHNIQUES/ISSUES RELATED TO DSSS

Design Methods

Today, DSSs hold a primary position in an organization's decision making by providing timely and relevant information to decision makers. It has become a key to the success or survival of many organizations. However, there is a high tally of failure in information systems development projects, even though they are a focal point of industrial concern (Goepp, Kiefer, & Geiskopf, 2006). Designing methods have become an important component that assures a successful information system design. This issue is in relevance to the design of a DSS.

There have been many different strategies employed for the design of a DSS. Current research on DSS design has witnessed the rapid expanding of object-oriented (OO), knowledge management (KM), structured modeling (SM), and design science (DS) approaches.

Object-Oriented Approach

The characteristic of OO approach is to use object-oriented software engineering with unified modeling language (UML) in the design and implementation of a DSS. OO approach involves basically three major steps (Tian, Ma, Liang, Kwok, & Liu, 2005). The user's requirements are first captured by using a set of use case diagrams. These diagrams indicate all the functionalities of the system from the user's point of view. Then classes and their relationships are identified and described in class diagrams. Finally, sequence diagrams or collaboration diagrams are developed, which describe the interaction between objects (instances of classes). Tian et al. (2005) designed a DSS with the OO approach for an organization, which was implemented successfully.

Knowledge Management Approach

In some environment (non-preprogrammed applications), end users, especially the less experienced end users, need to have certain knowledge guiding them how to use the system. The KM design approach supports end users by embedding declarative and/or procedural knowledge in software agents. This approach provides better assistance to inexperienced users of spatial DSS, which requires a design approach that will prioritize knowledge support of the end users' decision-making activities (West & Hess, 2002).

Structured Modeling Approach

SM approach "uses a hierarchically organized, partitioned, and attributed acyclic graph to represent models" (Srinivasan & Sundaram, 2000, p. 598). It consists of three levels: elemental structure, generic structure, and modular structure. The elemental structure intends to capture the details of a specific model instance. The generic structure targets at capturing the natural familial groupings of elements. The modular structure seeks to organize generic structure hierarchically according to commonality or semantic relatedness. The leveled structures allow the complexity of a model to be managed and ranked according to its hierarchies. The graph feature allows modelers and decision makers to understand the model better. A key advantage of SM is the ease with which structured models can be visualized (Srinivansan & Sundaram, 2000).

Design Science Approach

The functionality of a DSS evolves over a series of development cycles where both the end users and the systems analyst are active contributors to the shape, nature, and logic of the system (Arnott, 2004). Yet system developers have little guidance about how to proceed with evolutionary DSS development. DSS developers are facing the fact that insufficient knowledge exists for design purpose, and designers must rely on intuition, experience, and trial-and-error methods. Design science approach, on the other hand, can facilitate developers to create and evaluate information technology artifacts that are intended to solve identified organizational problems (Hevner, March, Park, & Ram, 2004). Vaishnavi and Kuechler (as in Arnott, 2006) proposed a design science methodology with the major process steps of awareness of problem, suggestion, development, evaluation, and conclusion. Arnott (2006) proposed a five steps approach, which was adapted from Vaishnavi and Kuechler, for designing evolutionary DSS: problem recognition, suggestion, artifact development, evaluation, and reflection. A research project by Arnott indicates that design science approach can tackle problems of both theoretical and practical importance.

Design Techniques

As we are advancing in information technologies, business decision makers can now have access to a vast amount of information. On one hand, they may gain necessary and important information for making informed decisions, but, on the other hand, they may also become overloaded by the information irrelevant to what they need. Thus, there is a pressing need for decision-aiding tools that would effectively process, filter, and deliver the right information to the decision makers. Proper combination of DSSs and agent technologies could prove to be a very powerful tool for rendering decision support (Vahidov & Fazlollahi, 2003/2004).

A software agent performs interactive tasks between the user and the system. The user instructs the system what he/she intends to accomplish. The software agent carries out the task. By analogy, a software agent mimics the role of an intelligent, dedicated, and competent personal assistant in completing the user's tasks (Bui & Lee, 1999). In the DSS environment, software agents have been more formally described as autonomous software implementations of a task or goal that work independently, on behalf of the user or another agent (Hess, Rees, & Rakes, 2000). As the traditional, direct manipulation interface of our computing environment is much limited (Maes, 1994), software agents would seem to be a suitable and most needed solution for providing procedural assistance to end users (West & Hess, 2002). "These 'robots of cyberspace' can be effectively utilized in automating many information processing tasks" (Vahidov & Fazlollahi, 2003/2004).

In some DSS environment, such as spatial DSS (Sikder & Gangopadhyay, 2002; West & Hess, 2002), Internet-based DSS (Bui & Lee, 1999), and Web DSS (Vahidov & Fazlollahi, 2003/2004), a multi-agent system should be designed and implemented in the DSS to facilitate the decision makers since decision making involves a complex set of tasks that requires integration of supporting agents (Bui & Lee, 1999), and these agents should have behaviors to work in teams (Norman & Long, 1994). Vahidov and Fazlollahi (2003/2004) developed architecture of multi-agent DSS for e-commerce (MADEC), in which the intelligence team (agents), design team (agents), and choice team (agents) were composed. The multi-agent system was implemented in a prototype of MADEC, which received higher user satisfaction.

THREE POSSIBLE WAYS TO ENHANCE DSSS

Creating Knowledge Warehouses (KW)

Nemati, Steiger, Iyer, and Herschel (2002) proposed that a new generation of knowledge-enabled systems provides the infrastructure required to capture, enhance, store, organize, leverage, analyze, and disseminate not only data and information but also knowledge. Expanding data warehouses to encompass the knowledge needed in the decision-making process is the creation of knowledge warehouses (KW). An important component of KW is a very complex process known as knowledge management. Knowledge management allows for knowledge to be converted from tacit to explicit through such processes as filtering, storing, retrieving, and so forth, thus allowing it to be utilized by decision makers.

The goal of KW is to give the decision maker an intelligent analysis standpoint that enhances all aspects of the knowledge management process. The main drawbacks of KW are the amount of time and money that need to be invested as well as some of the same problems that are found in successfully implementing DSSs. Among these factors are the users' involvement and participation, values and ethics, organization and political issues within the company, and other external issues. The development and implementation of KW still has much work to be done, however, DSSs seem to be headed toward knowledge enhancement in the future, and KW looks to have a promising outlook in the upcoming years as a result.

Focusing on Decision Support

While knowledge management systems seem like a logical way to advance the shortcomings of DSSs, another view also exists. By removing the word "system" from DSSs and focusing on decision support, decision making might cause some interesting, new directions for research and practice. Decision support (DS) is the use of any plausible computerized or non-computerized means for improving sense making and/or decision making in a particular repetitive or non-repetitive business situation in a particular organization (Alter, 2004).

DS embodies a broader perspective that seems logical in environments where the user does not necessarily need the technical aspects of DSSs. This is based on the belief that most work systems of any significance include some form of computerized support for sense making and decision making (Alter, 2004). The difference between DSSs and DS is not too drastic but DS is a sensible option for many companies due to the increase in technology since the creation of DSSs; DSSs may not fit the needs of a business as it had in the past.

Integrating DSSs and KMSs

In line with Bolloju, Khalifa, and Turban (2002), integrating decision support and knowledge management may correct some of the deficiencies of DSSs. The decision-making process itself results in improved understanding of the problem and the process, and generates new knowledge. In other words, the decision-making and knowledge creation processes are interdependent. By integrating the two processes, the potential benefits that can be reaped make the concept seem more worthwhile.

Integrating DSSs and KMSs seems to be the best choice out of the three possible ways to enhance DSS. The reasoning behind this selection is that integrating the two seems to provide a way for including both options without sacrificing one for the other. More importantly, while KW appears to have a very bright future, KW currently requires a great amount of time and money. The combination of both areas allows for a better overall utilization in the present. In time, KW may not be as time consuming and costly as it is now. However, to achieve a better balance of usefulness and efficiency, the integration of DSSs and KMSs appears to be the smartest choice.

FUTURE TRENDS

The future of DSSs, Angus (2003) argued and supported by SAS, Inc. (2004), is in the field of *business analytics* (BAs). BAs differ from that of the recently and previously more common business intelligence (BI). With the fast pace of business and life today it would only make sense for a shift to BA because it does focus on the many possibilities and the future outcomes for production and service.

BAs focus on the future of operations. Opposed to that of BI where it focuses on the past and what can be done to change the past if things were done wrong or repeat if things were done right. However, BAs let managers center on what future trends are developing, which allows them not to accumulate a surplus of inventory of outdated products. It also enables managers to change their prices before the market does, or introduce their new product before anyone else gets the chance to. This is known as first-to-market (Gnatovich, 2006). BAs give the companies that use it a tremendous advantage over their competitors in the marketplace.

CONCLUSION

Since their creation in the early 1960's, DSSs have evolved over the past four decades and continues to do so today. Although DSSs have grown substantially since its inception, improvements still need to be made. New technology has emerged and will continue to do so and, consequently, DSSs need to keep pace with it. Also, knowledge needs to play a bigger role in the form of decision making.

Shim, Warkentin, Courtney, Power, Sharda, & Carlson (2002) emphasized that DSSs researchers and developers should: (1) identify areas where tools are needed to transform uncertain and incomplete data, along with qualitative insights, into useful knowledge; (2) be more prescriptive about effective decision making by using intelligent systems and methods; (3) exploit advancing software tools to improve the productivity of working and decision-making time; and (4) assist and guide DSS practitioners in improving their core knowledge of effective decision support.

The prior statement sums up the courses of action that need to be taken. The successful integration of DSSs and KMSs could revolutionize DSSs and propel it to even greater heights in the future. In closing, DSSs have a storied history which spans the course of four decades; however, the greatest mark may be made in the not so distant future as DSSs continue to evolve.

KEY TERMS

Business Analytics (BA): A technological system that collects and evaluates all relevant data then scrutinizes it and puts it into different simulations to find out which one is the most appropriate.

Business Intelligence (BI): A system of technologies for collecting, reviewing, and hoarding data to assist in the decision-making process.

Decision Support Systems (DSSs): An interactive, flexible, and adaptable computer-based information system, especially developed for supporting the solution of a non-structured management problem for improved decision making. It utilizes data, provides an easy-to-use interface, and allows for the decision maker's own insights

Interface (or User Interface): A component designed to allow the user to access internal componenst of a system, also known as the dialogue component of a DSS.

Knowledge Management: The distribution, access, and retrieval of unstructured information about human experiences between interdependent individuals or among members of a workgroup.

Sensitivity Analysis: Running a decision model several times with different inputs so a modeler can analyze the alternative results.

Software Agent: A program that performs a specific task on behalf of a user, independently or with little guidance (Bui & Lee, 1999).

Structured Modeling: A generic design strategy for representing complex objects that are encountered in modeling applications (Srinivasan & Sundaram, 2000).

Transaction Processing System (TPS): Computerized systems that perform and record the daily routine transactions necessary to conduct the business; they serve the organization's operational level.

Use Case: A collection of possible sequences of interactions between the system under discussion and its users relating to a particular goal (Tian et al., 2005).

Chapter 1.10

Decision Support Systems and Decision-Making Processes

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

INTRODUCTION

Decision support systems (DSS) deal with semi-structured problems. Such problems arise when managers in organisations are faced with decisions where some but not all aspects of a task or procedure are known. To solve these problems and use the results for decision-making requires judgement of the manager using the system. Typically such systems include models, data manipulation tools, and the ability to handle uncertainty and risk. These systems involve information and decision technology (Forgionne, 2003). Many organisations are turning to DSS to improve decision-making (Turban, McLean, & Wetherbe, 2004). This is a result of the conventional information systems (IS) not being sufficient to support an organisation's critical response activities—especially those requiring fast and/or complex decision-making. In general, DSS are a broad category of IS (Power, 2003).

A DSS is defined as "an interactive, flexible, and adaptable computer-based information system, specially developed for supporting the solution of a non-structured management problem for improved decision-making. It utilises data, it provides easy user interface, and it allows for the decision maker's own insights" (Turban, 1995). There is a growing trend to provide managers with IS that can assist them in their most important task—making decisions. All levels of management can benefit from the use of DSS capabilities. The highest level of support is usually for middle and upper management (Sprague & Watson, 1996). The question of how a DSS supports decision-making processes will be described in this article. This article is organised as follows: The background to decision-making is introduced. The main focus (of this article) describes the development of the DSS field. Some future trends for the DSS field are then suggested. Thereafter a conclusion is given.

BACKGROUND TO DECISION-MAKING

H. A. Simon is considered a pioneer in the development of human decision-making models (Ahituv & Neumann, 1990). His individual work (Simon, 1960) and his joint research with A. Newell (Newell & Simon, 1972) established the foundation for human decision-making models. His basic model depicts human decision-making as a three-stage process. These stages are:

- **Intelligence:** The identification of a problem (or opportunity) that requires a decision and the collection of information relevant to the decision
- **Design:** Creating, developing, and analysing alternative courses of action
- **Choice:** Selecting a course of action from those available.

The decision-making process is generally considered to consist of a set of phases or steps which are carried out in the course of making a decision (Sprague & Watson, 1996). Decision-making can be categorised as:

- Independent
- Sequential interdependent
- Pooled interdependent (Keen & Scott Morton, 1978).

Independent decision-making involves one decision-maker using a DSS to reach a decision without the need or assistance from other managers. This form of DSS use is found occasionally. Sprague & Watson (1996) contend that it is the exception because of the common need for collaboration with other managers. Sequential interdependent decisions involve decision-making at a decision point and are followed by a subsequent decision at another point. In this case the decision at one point serves as input to the decision at another point. A practical example is corporate planning and budgeting where a department formulates a plan which then serves as input to the development of the budget. Sprague & Watson (1996) indicate that DSS are frequently used in support of sequential dependent decision-making but not as frequently as pooled interdependent decision-making.

Pooled interdependent decision-making is a joint, collaborative decision-making process whereby all managers work together on the task. A group of product marketing managers getting together to develop a marketing plan is an example of this type of decision. Specialised hardware, software, and processes have been developed to support pooled interdependent decision-making but for the purposes of this study, these are not explored.

PROBLEMS AND DECISION-MAKING PROCESSES

Ackoff (1981) cites three kinds of things that can be done about problems—they can be *resolved, solved*, or *dissolved*:

- **Resolving:** This is to select a course of action that yields an outcome that is good enough that satisfices (satisfies and suffices).
- **Solving:** This is to select a course of action that is believed to yield the best possible outcome that optimises. It aspires to complete objectivity and this approach is used mostly by technologically oriented managers whose organisational objective tends to be thrival than mere survival.
- **Dissolving:** This to change the nature and/or the environment of the entity in which it is embedded so as to remove the problem.

Sauter (1997) indicates that a DSS will not solve all the problems of any given organisation. The author adds, “however, it does *solve* some problems” (italics added by author).

In a structured problem, the procedures for obtaining the best (or worst) solution are known. Whether the problem involves finding an optimal inventory level or deciding on the appropriate marketing campaign, the objectives are clearly defined. Common business objectives are profit maximisation or cost minimisation. Whilst a manager can use the support of clerical, data processing, or management science models, management support systems such as DSS and expert system (ES) can be useful at times. One DSS vendor suggests that facts now supplement intuition as analysts, managers, and executives use Oracle DSS® to make more informed and efficient decisions (Oracle Corporation, 1997).

In an unstructured problem, human intuition is often the basis for decision-making. Typical unstructured problems include the planning of a new service to be offered or choosing a set of research and development projects for the next year. The semi-structured problems fall between the structured and the unstructured which involves a combination of both standard solution procedures and individual judgment. Keen & Scott Morton (1978) give the following examples of semi-structured problems: (USA) trading bonds, setting marketing budgets for consumer products and performing capital acquisition analysis. Here a DSS can improve the quality of the information on which the decision is based (and consequently the quality of the decision) by providing not only a single solution but a range of alternatives. These capabilities allow managers to better understand the nature of the problems so that they can make better decisions.

Before defining the specific management support technology of DSS, it will be useful to present a classical framework for decision support. This framework will assist in discussing the relationship among the technologies and the evolution of computerised systems. The framework, see Figure 1, was proposed by Gorry & Scott Morton (1971) who combined the work of Simon (1960) and Anthony (1965).

The details of this framework are: The left-hand side of the table is based on Simon's notion that

Figure 1. Decision support framework (Source: adapted from Turban, McLean, & Wetherbe, 1999)

	Type of Control			
Type of Decision	**Operational Control**	**Managerial Control**	**Strategic Planning**	**Support Needed**
Structured	① Accounts receivable, order entry	② Budget analysis, short-term forecasting, personnel reports, make-or-buy analysis	③ Financial management (investment), warehouse location, distribution systems	Management information system, operations research models, transaction processing
Semi-structured	④ Production scheduling, inventory control	⑤ Credit evaluation, budget preparation, plant layout, project scheduling, reward systems design	⑥ Building of new plant, mergers and acquisitions, new product planning, quality assurance planning	DSS
Unstructured	⑦ Selecting a cover for a magazine, buying software, approving loans	⑧ Negotiating, recruiting an executive, buying hardware	⑨ R&D planning, new technology development, social responsibility planning	DSS, ES, neural networks
Support needed	Management information system, management science	Management science, DSS, ES, EIS	EIS, ES, neural networks	

decision-making processes fall along a continuum that ranges from highly structured (sometimes referred to as programmed) to highly unstructured (non programmed) decisions. Structured processes refer to routine and repetitive problems for which standard solutions already exist. Unstructured processes are "fuzzy" for which no cut-and-dried solutions exist. Decisions where some (but not all) of the phases are structured are referred to as semi-structured, by Gorry and Scott Morton (1971).

The second half of this framework (upper half of Figure 1) is based on Anthony's (1965) taxonomy which defines three broad categories that encompass all managerial activities:

- **Strategic planning:** The long-range goals and the policies for resource allocation.
- **Management control:** The acquisition and efficient utilisation of resources in the accomplishment of organisational goals.
- **Operational control:** The efficient and effective execution of specific tasks.

Anthony and Simon's taxonomies are combined in a nine-cell decision support framework in Figure 1. The right-hand column and the bottom row indicate the technologies needed to support the various decisions. For example, Gorry and Scott Morton (1971) suggest that for semi-structured and unstructured decisions, conventional management science approaches are insufficient. They proposed the use of a supportive information system, which they labelled a decision support system (DSS). ES, which were only introduced several years later, are most suitable for tasks requiring expertise.

The more structured and operational control-oriented tasks (cells 1, 2, and 4) are performed by low-level managers. The tasks in cells 6, 8, and 9 are the responsibility of top executives. This means that DSS, executive information systems (EIS), neural computing, and ES are more often applicable for top executives and professionals tackling specialised, complex problems.

The true test of a DSS is its ability to support the design phase of decision-making as the real core of any DSS is the model base which has been built to analyse a problem or decision. In the design phase, the decision-maker develops a specific and precise model that can be used to systematically examine the discovered problem or opportunity (Forgionne, 2003). The primary value to a decision-maker of a DSS is the ability of the decision-maker and the DSS to explore the models interactively as a means of identifying and evaluating alternative courses of action. This is of tremendous value to the decision-maker and represents the DSS's capability to support the design phase (Sprague & Watson, 1996). For the DSS choice phase, the most prevalent support is through "what if" analysis and goal seeking.

In terms of support from DSS, the choice phase of decision-making is the most variable. Traditionally, as DSS were not designed to make a decision but rather to show the impact of a defined scenario, choice has been supported only occasionally by a DSS. A practical example is where a DSS uses models which identify a best choice (e.g., linear programming) but generally they are not the rule.

DEVELOPMENT OF THE DSS FIELD

According to Sprague and Watson (1996), DSS evolved as a "field" of study and practice during the 1980s. This section discusses the principles of a theory for SS. During the early development of DSS, several principles evolved. Eventually, these principles became a widely accepted "structural theory" or framework—see Sprague and Carlson (1982). The four most important of these principles are now summarised.

The DDM Paradigm

The technology for DSS must consist of three sets of capabilities in the areas of dialog, data, and modeling and what Sprague and Carlson call the DDM paradigm. The researchers make the point that a good DSS should have balance among the three capabilities. It should be easy to use to allow non-technical decision-makers to interact fully with the system. It should have access to a wide variety of data and it should provide analysis and modeling in a variety of ways. Sprague and Watson (1996) contend that many early systems adopted the name DSS when they were strong in only one area and weak in the other. Figure 2 shows the relationship between these components in more detail and it should be noted that the models in the model base are linked with the data in the database. Models can draw coefficients, parameters, and variables from the database and enter results of the model's computation in the database. These results can then be used by other models later in the decision-making process.

Figure 2 also shows the three components of the dialog function wherein the database management system (DBMS) and the model base management system (MBMS) contain the necessary functions to manage the database and model base respectively. The dialog generation and management system (DGMS) manages the interface between the user and the rest of the system.

Even though the DDM paradigm eventually evolved into the dominant architecture for DSS, for the purposes of this article, none of the technical aspects is explored any further.

Levels of Technology

Three levels of technology are useful in developing DSS and this concept illustrates the usefulness of configuring DSS tools into a DSS generator which can be used to develop a variety of specific DSS quickly and easily to aid decision-makers; see Figure 3. The system which actually accomplishes the work is known as the specific DSS, shown as the circles at the top of the diagram. It is the software/hardware that allows a specific decision-maker to deal with a set of related problems. The second level of technology is known as the DSS generator. This is a package of related hardware and software which provides a set of capabilities to quickly and easily build a specific DSS. The third level of technology is DSS tools which facilitate the development of either a DSS generator or a specific DSS.

DSS tools can be used to develop a specific DSS application strictly as indicated on the left-hand side of the diagram. This is the same

Figure 2. Components of DSS (Source: adapted from Sprague & Watson, 1996)

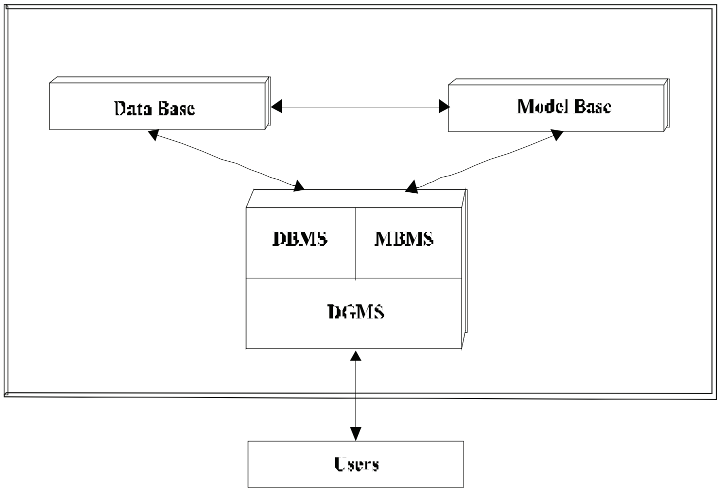

Figure 3. Three levels of DSS technology (Source: adapted from Sprague & Watson, 1996)

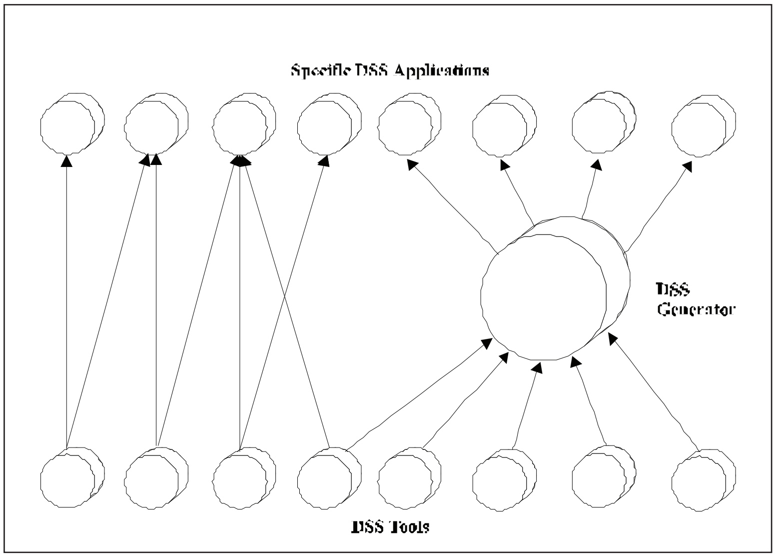

approach used to develop most traditional applications with tools such as general purpose languages, subroutine packages, and data access software. The difficulty of the approach for developing DSS is the constant change and flexibility which characterises them. The development and use of DSS generators create a "platform" or staging area from which specific DSS can be constantly developed and modified with the co-operation of the user and with minimal time and effort.

Iterative Design

The nature of DSS requires a different design and development technique from traditional batch and online systems. Instead of the traditional development process, DSS require a form of iterative development which allows them to evolve and change as the problem or decision situation changes. They need to be built with short, rapid feedback from users thereby ensuring that development is proceeding correctly. In essence, they must be developed to permit change quickly and easily.

Organisational Environment

The effective development of DSS requires an organisational strategy to build an environment within which such systems can originate and evolve. The environment includes a group of people with interacting roles, a set of software and hardware technology, a set of data sources, and a set of analysis models.

DSS: PAST AND PRESENT

Van Schaik (1988) refers to the early 1970s as the era of the DSS concept because in this period the concept of DSS was introduced. DSS was a new philosophy of how computers could be used to support managerial decision-making. This philosophy embodied unique and exciting ideas for the design and implementation of such systems. There has been confusion and controversy over the interpretation of the notion decision support system and the origin of this notion is clear:

- Decision emphasises the primary focus on decision-making in a problem situation rather than the subordinate activities of simple information retrieval, processing, or reporting.

- Support clarifies the computer's role in aiding rather than replacing the decision-maker.
- System highlights the integrated nature of the overall approach, suggesting the wider context of machine, user and decision environment.

Sprague and Watson (1996) note that initially there were different conceptualisations about DSS. Some organisations and scholars began to develop and research DSS which became characterised as interactive computer based systems which help decision-makers utilise data and models to solve unstructured problems. According to Sprague and Watson (1974), the unique contribution of DSS resulted from these key words. They contend that the definition proved restrictive enough that few actual systems completely satisfied it. They believe that some authors have recently extended the definition of DSS to include any system that makes some contribution to decision-making; in this way the term can be applied to all but transaction processing. However, a serious definitional problem arises in that the words have certain "intuitive validity;" any system that supports a decision (in any way) is a "Decision Support System." As Sprague and Watson (1996) indicate, the term had such an instant intuitive appeal that it quickly became a "buzz word." Clearly, neither the restrictive nor the broad definition help much as they do not provide guidance for understanding the value, the technical requirements, or the approach for developing a DSS.

A further complicating factor is that people from different backgrounds and contexts view a DSS quite differently: a computer scientist and a manager seldom see things in the same way. Turban (1995) supports this stance as DSS is a content-free expression whereby it means different things to different people. He states that there is no universally accepted definition of DSS and that it is even sometimes used to describe any computerised system. It appears that the basis for defining DSS has been developed from the perceptions of what a DSS does (e.g., support decision-making in unstructured problems) and from ideas about how the DSS's objectives can be accomplished (e.g., the components required and the necessary development processes).

FUTURE TRENDS

New technology continues to affect the dialog, data, and models components. Differences in data, knowledge, and model structures may necessitate the development of new technologies for model retrieval tasks (Forgionne, 2003). Relational database technology and object-oriented databases and data warehousing are influencing how data is stored, updated, and retrieved. Drawing from artificial intelligence advances, there is the potential for representing and using models in new and different ways.

Decision support technology has also broadened to include monitoring, tracking, and communication tools to support the overall process of ill-structured problem solving. DSS implemented on a corporate intranet provides a means to deploy decision support applications in organisations with geographically distributed sites. Clearly these technologies and other emerging Web-based technologies will continue to expand the component parts of a DSS domain. An area of rapid growth is Web-based DSS. Even though Web-based technologies are the leading edge for building DSS, traditional programming languages or fourth generation languages are still used to build DSS (Power, 2003).

CONCLUSION

Moving from the early DSS concept era to almost 35 years later, DSS still comprise a class of IS intended to support the decision-making activities of managers in organisations. The concept has been buffeted by the hyperbole of marketing people and technologies have improved or changed (Power, 2003). While some major conceptual problems may be found with the current terms associated with computerised decision support (and which has been catalysed by marketing hype), the basic underlying concept of supporting decision-makers in their decision-making processes still remains important.

KEY TERMS

Decision-Making: A three-stage process involving intelligence, design, and choice.

Decision Support System: An interactive, flexible, and adaptable computer-based information system, specially developed for supporting the solution of a non-structured management problem for improved decision-making.

Expert System: An IS which provides the stored knowledge of experts to non experts.

Management Science: An approach that takes the view the managers can follow a fairly systematic process for solving problems.

Pooled Interdependent Decision-Making: A joint, collaborative decision-making process whereby all managers work together on a task.

Semi-Structured Problem: Only some of the intelligence, design, and choice phases are structured and requiring a combination of standard solution procedures and individual judgement.

Structured Problem: The intelligence, design, and choice phases are all structured and the procedures for obtaining the best solution are known.

Unstructured Problem: None of the intelligence, design, and choice phases is structured and human intuition is frequently the basis for decision-making.

INTRODUCTION

Decision support systems (DSSs) have been researched extensively over the years with the purpose of aiding the decision maker (DM) in an increasingly complex and rapidly changing environment (Sprague & Watson, 1996; Turban & Aronson, 1998). Newer intelligent systems, enabled by the advent of the Internet combined with artificial-intelligence (AI) techniques, have extended the reach of DSSs to assist with decisions in real time with multiple informaftion flows and dynamic data across geographical boundaries. All of these systems can be grouped under the broad classification of decision-making support systems (DMSS) and aim to improve human decision making. A DMSS in combination with the human DM can produce better decisions by, for example (Holsapple & Whinston, 1996), supplementing the DM's abilities; aiding one or more of Simon's (1997) phases of intelligence, design, and choice in decision making; facilitating problem solving; assisting with unstructured or semistructured problems (Keen & Scott Morton, 1978); providing expert guidance; and managing knowledge. Yet, the specific contribution of a DMSS toward improving decisions remains difficult to quantify.

Many researchers identify a single metric, or a series of single metrics, for evaluation of the DMSS in supporting decision making, if it is evaluated at all (Phillips-Wren, Mora, Forgionne, Garrido, & Gupta, 2006). The authors suggest outcome criteria such as decreased cost, or process criteria such as increased efficiency, to justify the DMSS. Yet no single integrated metric is proposed to determine the value of the DMSS to the decision maker.

The objective of this article is to review literature-based evaluation criteria and to provide a multicriteria evaluation model that determines the precise decision-making contributions of a DMSS. The model is implemented with the analytical hierarchy process (AHP), a formalized multicriteria method.

Building on other core studies (Forgionne, 1999; Forgionne & Kohli, 2000; Keen, 1981; Leidner & Elam, 1993; Money, Tromp, & Wegner, 1988; Phillips-Wren & Forgionne, 2002; Phillips-Wren, Hahn, & Forgionne, 2004; Phillips-Wren, Mora, Forgionne, Garrido, et al., 2006; Phillips-Wren, Mora, Forgionne, & Gupta, 2006; Pieptea & Anderson, 1987), this article focuses on the performance and evaluation of a planned or real DMSS in supporting decision making. Unlike previous DSS studies (Sanders & Courtney, 1985; Leidner, 1996; Wixom & Watson, 2001; Mora, Cervantes, Gelman, Forgionne, Mejia, & Weitzenfeld, 2002) or general information-system studies (DeLone & McLean, 1992, 2003), this study develops a DMSS evaluation model from a design research paradigm, that is, to be built and evaluated (Hevner & March, 2003).

BACKGROUND

Although developers of DMSSs generally report a single criterion for a DMSS, the use of multiple criteria to evaluate a DMSS has been reported in the literature. Chandler (1982) noted that information systems create a relationship between users and the system itself, so that its evaluation should consider both user and system constraints. He developed a multiple-goal programming approach to consider trade-offs between goals and performance. Adelman (1992) proposed a comprehensive evaluation for assessing specifically DSSs and expert systems using subjective, technical, and empirical methods to form a multifaceted approach. User and sponsor perspectives were included in the subjective methods. The analytical methods and correctness of the analysis were assessed in the technical evaluation. Finally, a comparison of performance with and without the system was evaluated in the empirical-methods section. The three approaches were combined to form an overall evaluation of the system. Turban and Aronson (1998) indicate that information systems, including DMSSs, should be evaluated with two major classes of performance measurement: effectiveness and efficiency. According to general systems principles (Checkland, 1999), effectiveness deals with how well the results or outputs contribute to the goals and achievements of the wider system, and efficiency measures how well the system processes inputs and resources to achieve outputs. A third measure, efficacy, deals with how well the system produces the expected outputs. This third measure complements the three general performance or value-based measures for any general system. For example, Maynard, Burstein, and Arnott (2001) proposed evaluating DMSSs by directly including the perspectives of different constituencies or stakeholders in a multicriteria evaluation.

DECISION VALUE OF DMSS

Multicriteria Model

Of the many studies of applied DMSSs published in the last 30 years, assessment usually consisted of characteristics associated with either the process or outcome of decision making using a DMSS (Forgionne, 1999; Phillips-Wren, Mora, Forgionne, Garrido, et al., 2006; Phillips-Wren, Mora, Forgionne, & Gupta, 2006). Process variables assess the improvement in the way that decisions are made and are often measured in qualitative terms. Process variables that have been used to judge a DMSS are increased efficiency, user satisfaction, time savings, more systematic processes, better understanding of the problem, and ability to generalize. Outcome variables assess the improvement in the decision quality when the DM uses the DMSS for a specific decision and are often measured in quantifiable terms. Outcome variables in the literature are, for example, increased profit, decreased cost, accuracy of predicting annual returns, and success in predicting failures.

These two categories of outcome and process are classical descriptions of decision making. Simon (1997) characterized decision making as consisting of the phases of intelligence, design, and choice. The intelligence phase concerns the identification of the problem and data collection, design includes the formulation of the model and search for alternatives, and choice includes the selection of the best alternative. Once the decision is made, the outcome of the decision can be evaluated. Since DMSSs affect both process and outcome, particularly in real-time systems, DMSSs should be evaluated on both criteria.

Previous research (Forgionne, 1999; Phillips-Wren & Forgionne, 2002; Phillips-Wren et al., 2004) has shown that a multicriteria model for the evaluation of DMSSs can be developed based on criteria in the literature. Although other authors have addressed multiple dimensions for information systems success in general (DeLone & McLean, 1992, 2003) and multiple factors for DSS evaluation in particular (Maynard et al., 2001; Sanders & Courtney, 1985), our proposed evaluation model focuses on how well the DMSS supports the specific decision for which it is intended. Our position is that the decision value of a DMSS should be evaluated based on its support for both the process and outcome of decision making. The decision value of the system can be determined quantitatively using a multiple-criteria model such as the AHP with the additional advantage that the precise contributions of the system to the subcomponents in the model can be determined. A stochastic enhancement of the AHP allows the determination of the statistical significance of the contributions (Phillips-Wren et al., 2004).

The AHP (Saaty, 1977) is a multicriteria model that provides a methodology for comparing alternatives by structuring criteria into a hierarchy, providing for pair-wise comparisons of criteria at the lowest level of the hierarchy to be entered by the user, and synthesizing the results into a single numerical value. For example, the decision value of alternative DMSSs can be compared based on criteria and subcriteria. The AHP has been extensively used in decision making for applied problems (Saaty & Vargas, 1994). Once the hierarchy is established, the alternatives are evaluated by pairs with respect to the criteria on the next level. The criteria can be weighted, if desired, according to the priority of each criterion. An eigenvalue solution is utilized to reconcile the initial judgments, and a ranking of the alternatives on the specific criteria is produced using the judgments and the weighting of the criteria.

To evaluate a DMSS using the AHP, a hierarchy of criteria is needed. Although traditional DMSSs have been researched extensively, few, if any, studies have addressed a unifying architecture for the evaluation of DMSSs. A novel and first effort for such an architecture has been recently reported (Phillips-Wren, Mora, Forgionne, Garrido, et al., 2006; Phillips-Wren, Mora, Forgionne, & Gupta, 2006). The following description is a summarized analysis of the proposed evaluation architecture.

Unified Architecture for Evaluation and Design of DMSS

The authors recently reported a conceptualized framework to guide the design and evaluation of intelligent DMSSs for an integrated evaluation approach (Mora, Forgionne, Cervantes, Garrido, Gupta, & Gelman, 2005). It includes both management (i.e., process and outcome) and technical (i.e., services, architectural, and computer mechanisms) views. According to Mora et al. (2005), the primary research premise of intelligent DMSS research can be established as the following.

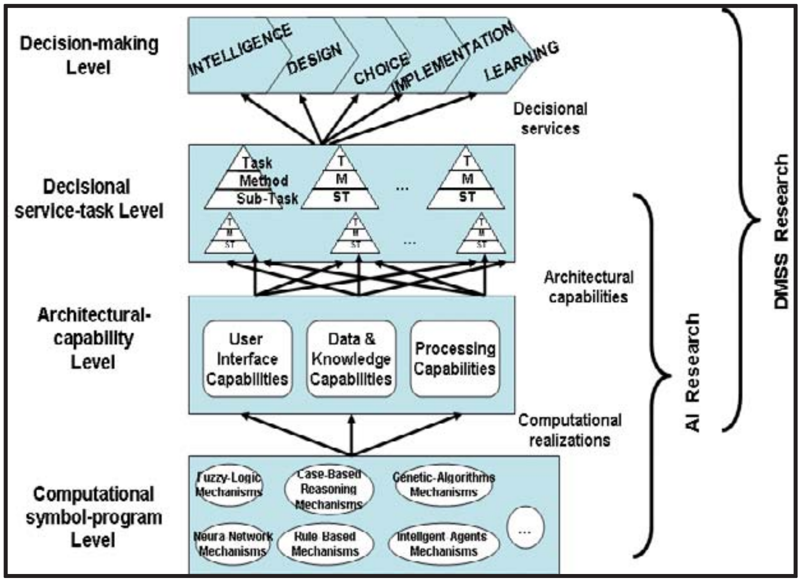
Decision-making phases and steps can be improved by the support of decisional services and tasks, which are provided by architectural capabilities that can or could in the future be computationally implemented by symbol- or program-based mechanisms.

These perspectives (Forgionne, 1999; Phillips-Wren & Forgionne, 2002; Phillips-Wren et al., 2004; Phillips-Wren, Mora, Forgionne, Garrido, et al., 2006; Phillips-Wren, Mora, Forgionne, & Gupta, 2006) propose that any improvement related to the phases and steps of the decision-making process will or should be related to impacts on outcomes to consider a DMSS as satisfactory. Consideration of both premises suggests that any DMSS evaluation must consider metrics associated with outcomes, phases, and steps of the decision-making process as well as with technical issues such as its decisional services, its architectural capabilities, and its internal computational mechanisms. Figure 1 (Mora et al., 2005) depicts the conceptual design and evaluation foundation framework with the four levels as follows:

- **Decision-making level:** To account for intelligence, design, choice, implementation, and learning in the decision-making phases and activities to be executed by a decision maker using a DMSS
- **Decisional service-task level:** To account for the decisional support services of the DMSS, for example, the Newell knowledge levels of task, method, and subtask
- **Architectural capability level:** To account for the user interface capabilities, data and knowledge capabilities, and processing capabilities provided by the components of the architecture of the DMSS
- **Computational symbol-program level:** To account for specific AI computational mechanisms that implement the architectural components of the DMSS such as fuzzy logic, neural networks, case-based reasoning, genetic algorithms, and intelligent agents

In particular, the design and optimization of new mechanisms at the lowest level (i.e., Computational Symbol-Program Level) is an ongoing research area in AI and computer science to provide the design of new or improved algorithms. From the information-systems viewpoint, the

Figure 1. Conceptual framework for design and evaluation of DMSS (Mora et al., 2005)



lowest level contains mechanisms where input-output issues and computational efficiencies are the primary features of interest. In contrast, the next two levels (i.e., the Architectural Capability and Decisional Service-Task Levels) should be addressed jointly with the user in the design and evaluation tasks so that the DMSS designer or evaluator has a comprehensive and integrated view of the decision-making paradigm. The Architectural Capabilities Level has been discussed in previous work (Mora, Forgionne, Gupta, Cervantes, & Gelman, 2003) so it will not be repeated here.

In a study of the Decisional Service-Task Level, Mora et al. (2005) developed a synthesis of the relevant studies of intelligent DMSSs in the DSS and AI literature from 1980 to 2005. Table 1, borrowed from the authors, exhibits the analysis of the Decisional Service-Task Level. Decisional services are classified as services for analysis, synthesis, and hybrid tasks. Although the conceptual description is a high-level view, it also provides for core services that could be developed or implemented by component-based software engineering approaches in the near future as unit building blocks.

In turn, Table 2 reports a general analysis of the main decisional services (i.e., analysis, synthesis, or hybrid services) demanded by each step of the decision-making process.

Example of Utilization of the Unified Architecture for Evaluation of DMSS

Given the architecture for a DMSS presented in Figure 1, the decision value of alternative DMSSs can be determined by evaluating their impact on the process and outcome of decision making. As suggested, the multicriteria model can be implemented with the AHP, and the structure is shown in Figure 2.

An advantage of the structure is that the precise contributions of each DMSS to each element of the architecture as well as to the process and outcome of decision making can be determined.

As an example, suppose that five alternative AI mechanisms are to be evaluated for incorporation into a DMSS: fuzzy logic (FL), neural network

Table 1. Classification of decisional services for DMSSs

Taxonomy of Decisional Services and Tasks		
TASK TYPE	**GENERIC SERVICES (inputs): outputs**	**GENERIC TASKS**
ANALYSIS	CLASSIFY(data): system state	CLASSIFICATION
	MONITOR(system): system variations	CLASSIFICATION
	INTERPRET(data): state assessment	IDENTIFICATION
	PREDICT(system): future system state	IDENTIFICATION
SYNTHESIS	CONFIGURE(parts, constraints, goals): system structure	DESIGN
	SCHEDULE(activities, constraints, goals): states sequence	DESIGN
	FORMULATE(elements, goals, constraints): system structure	COMPLEX DESIGN
	PLAN(activities, resources, constraints, goals): (states sequence, system structure)	COMPLEX DESIGN
HYBRID	EXPLAIN(data, system): system cause-effect links	COMPLEX
	RECOMMEND(system state): system recommendations	COMPLEX
	MODIFY(system, system changes): new system	COMPLEX
	CONTROL(system state, goals):input system actions	COMPLEX
	LEARN(system, knowledge on system): new knowledge	COMPLEX

Table 2. Requirements of decision-making phases and steps compared to analysis, synthesis, and hybrid services

(NN), case-based reasoning (CBR), genetic algorithm (GA), and intelligent agent (IA). The alternatives are compared in pairs with regard to their contribution to the next level consisting of the user interface (UI), data and knowledge (DK), and processing (P) capabilities. An eigenvalue solution in the AHP reconciles the pair-wise comparisons to yield the input scores shown in Column 1 of Table 3. Each branch in Figure 2 can be weighted to indicate its importance to the next level. Each of our branches is weighted; for example, the outcome is weighted 0.6 compared to the process of 0.4 to indicate that the outcome is more important in our sample problem.

Column 1 shows the amount that each AI alternative contributes to three capabilities on the Architectural Capability Level in the opinion of the user. (Note that the sum of each subcolumn for the values under UI, DK, and P is equal to 1.0.) For instance, in Table 3 we see that the CBR contributes 0.4090 (Column 1) to the UI while GA at 0.3577 is most important to the DK capability (Column 1). The AHP then calculates that NN contributes most significantly to the process (Column 2) and outcome (Column 3). The overall decision value indicates that NN is preferred with the highest score, although NN and CBR are close. A stochastic enhancement of the AHP would permit one to determine if the differences are significant (Phillips-Wren et al., 2004). The analysis provides guidance to the decision maker in the selection of the AI method to be used. In

Figure 2. Multicriteria model implementation to evaluate DMSSs

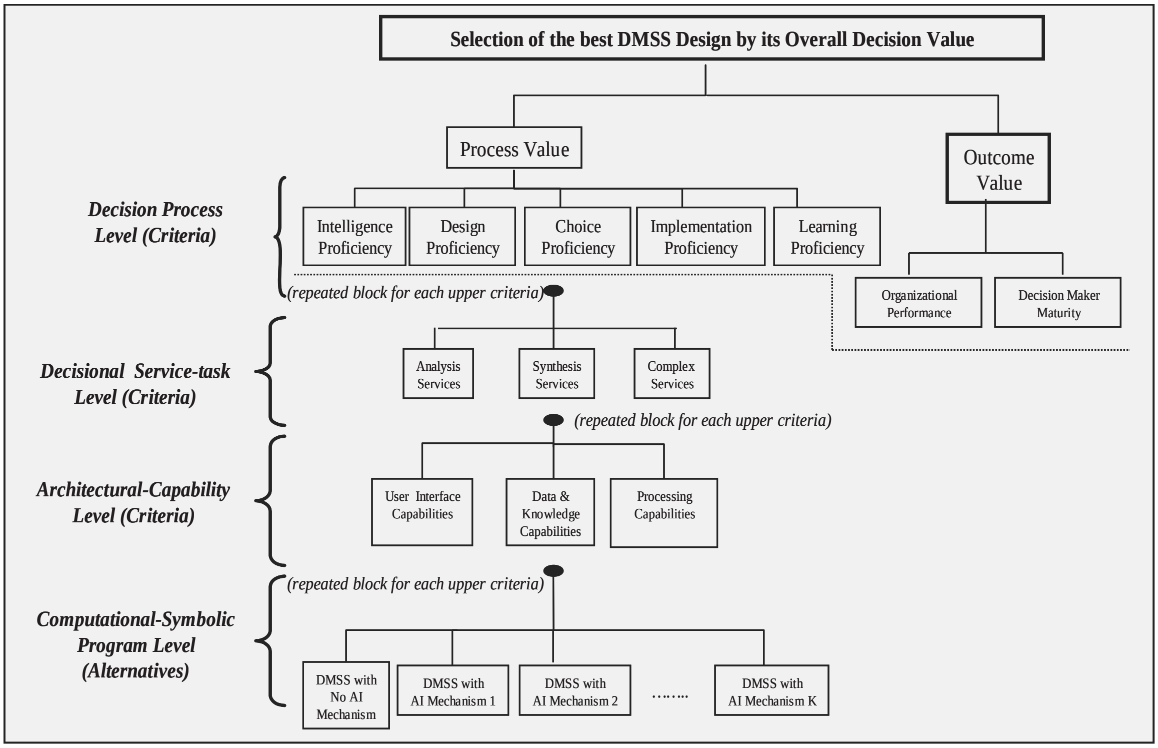

Table 3. Illustration of decision value with user input alternatives

Alter-native	Column 1: Input Scores to UI, DK, and P Criteria	Column 2: Process Value (0.40)	Column 3: Outcome Value (0.60)	Column 4: Overall Decision Value
FL	0.1373, 0.0059, 0.1571	0.0853	0.0854	0.0854
NN	0.1346, 0.2867, 0.3176	0.2496	0.2510	0.2505
CBR	0.4090, 0.1709, 0.1971	0.2488	0.2471	0.2478
GA	0.1844, 0.3577, 0.0760	0.2311	0.2303	0.2306
IA	0.1347, 0.1789, 0.2522	0.1852	0.1862	0.1858

a similar manner, we can trace the contribution of each alternative to each of the subcriteria in Figure 2.

FUTURE TRENDS

Previous AHP-based DMSS evaluations have offered hierarchies that define the nature of support to the outcome and process in decision making. In practice, outcome and process measures can vary across organizations and entities. The organizational and problem context, then, can serve as an additional layer in the AHP hierarchy between the system and the outcome and process levels. This expanded hierarchy would show how outcome and process results are determined by the organizational context and provide guidance for

DMSS design, development, and implementation within the specific context.

There is another hierarchical expansion that can be instructive. In the original formulation, DMSS choices do not disclose the specific architectural elements within the compared systems. It is possible to add a level that would identify the specific decision-making tools delivered by the DMSS. This added hierarchy would link the tools to process and outcome, enabling the researcher or practitioner to identify the specific contributions of the tools to decision value.

Although the additional hierarchical levels can potentially provide useful information, it is not clear if the enhanced clarity would add to decision value. Research, then, is needed to determine if the added information is worth the added cost and complexity of the expanded hierarchy. Put another way, will the extra layers lead to a better (or even different) decision value than the original formulation?

Other unresolved issues involve the weighting and priority schemes used in the AHP methodology. Weights and priorities for the criteria and subcriteria are assigned by the decision maker or researcher and then are used to compute weighted averages from the evaluator's initial pair-wise comparisons. It would be useful to determine how sensitive the calculated decision value would be to alterations in the weights and priorities. Previous DMSS evaluations have not fully addressed this sensitivity analysis issue.

A final potentially fruitful area of further research deals with the data creation process for the AHP analysis. Since the AHP pair-wise comparisons are inherently subjective in nature, there has been a tendency to apply the concept through actual user studies. Such studies have typically involved small samples with dubiously representative participants. Simulation offers a potentially superior data creation approach. Each pair-wise comparison implicitly converts subjective user system alternative ratings to a 0-to-1 scale. Over a population of users, these 0-to-1 values can be expected to follow some probability distribution. It is possible, then, to use randomly generated values from theoretical probability distributions to generate the pair-wise comparisons in the AHP analysis. Analyses with various probability distributions can be used to determine the sensitivity of decision value to alterations in population characteristics

CONCLUSION

The proposed AHP-determined model of decision value provides a mechanism to integrate all previous measures of DMSS value. This formulation is comprehensive, intuitive, and complete. Moreover, the AHP analysis provides a single decision value that is linked to the outcomes and processes that generated the value. As such, the framework can serve as a guide to effective system design, development, and implementation.

KEY TERMS

Analytic Hierarchy Process (AHP): AHP is a multicriteria model that provides a methodology for comparing alternatives by structuring criteria into a hierarchy, providing for pair-wise comparisons of criteria at the lowest level of the hierarchy to be entered by the user, and synthesizing the results into a single numerical value.

Decision-Making Support System (DMSS): A DMSS is an information system whose purpose is to provide partial or full support for decision-making phases: intelligence, design, choice, implementation, and learning.

Decision Support System (DSS): A DSS is an information system that utilizes database or model-base resources to provide assistance to decision makers through analysis and output.

Decision Value: It is the metric provided by a multicriteria model of the DMSS that quantitatively combines both process and outcome criteria to form a single measure.

Evaluation Criteria: These are qualitative or quantitative metrics on which the DMSS is evaluated.

Multicriteria Method: This is the methodology that integrates two or more criteria to form a single value.

Chapter 1.12

Interactive, Flexible, and Adaptable Decision Support Systems

John Wang
Montclair State University, USA

James Yao
Montclair State University, USA

Jeffrey Hsu
Fairleigh Dickinson University, USA

INTRODUCTION

Over the four decades of its history, decision support systems (DSSs) have moved from a radical movement that changed the way information systems were perceived in business, to a mainstream commercial information technology movement that all organizations engage. This interactive, flexible, and adaptable computer-based information system derives from two main areas of research: the theoretical studies of organizational decision making done at the Carnegie Institute in the 1950s and early 1960s as well as the technical work on interactive computer systems which was mainly performed by the Massachusetts Institute of Technology (Keen & Morton, 1978).

DSSs began due to the importance of formalizing a record of ideas, people, systems, and technologies implicated in this sector of applied information technology. But the history of this system is not precise due to the many individuals involved in different stages of DSSs and various industries while claiming to be pioneers of the system (Arnott & Pervan, 2005; Power, 2003). DSSs have become very sophisticated and stylish since these pioneers began their research. Many new systems have expanded the frontiers established by these pioneers yet the core and basis of the system remains the same. Today, DSSs are used in the finance, accounting, marketing, medical, as well as many other fields.

BACKGROUND

The basic ingredients of a DSS can be stated as follows: the data management system, the model management system, the knowledge engine, the user interface, and the users (Donciulescu, Filip, & Filip, 2002). The database is a collection of current or historical data from a number of application groups. A database can range in size from storing it in a PC that contains corporate data that have been downloaded, to a massive data warehouse that is continuously updated by major organizational transaction processing systems (TPSs). When referring to the model management system, it is primarily a stand-alone system that uses some type of model to perform "what if" and other kinds of analysis. This model must be easy to use, and therefore the design of such model is based on a strong theory or model combined with a good user interface.

A major component of a DSS is the knowledge engine. To develop an expert system requires input from one or more experts; this is where the knowledge engineers go to work to see who can translate the knowledge as described by the expert into a set of rules. A knowledge engineer acts like a system analyst but has special expertise in eliciting information and expertise from other professionals (Lauden & Lauden, 2005).

The user interface is the part of the information system through which the end user interacts with the system; it is a type of hardware and the series of on-screen commands and responses required for a user to work with the system. An information system will be considered a failure if its design is not compatible with the structure, culture, and goals of the organization. Research must be conducted to design a close organizational fit, to create comfort and reliability between the system and user. In a DSS, the user is as much a part of the system as the hardware and software. The user can also take many roles such as decision maker, intermediary, maintainer, operator, and feeder. A DSS may be the best one in its industry but it still requires a user to make the final decision.

Power (2003) introduced a conceptual level of DSSs, which contains five different categories. These categories include model-driven DSS, communication-driven DSS, data-driven DSS, document-driven DSS, and knowledge-driven DSS. Defining a DSS is not always an easy task due to the many definitions available. Much of this problem is attributed to the different ways a DSS can be classified. At the user level, a DSS can be classified as passive, active, or cooperative.

Essentially, a DSS is a computer-based system that provides help in the decision-making process. However, this is a broad way of defining the subject. A better way of describing a DSS is to say it is a flexible and interactive computer-based system that is developed for solving nonstructured management problems. Basically, the system uses information inputted from the decision maker (data and parameters) to produce an output from the model that ultimately assists the decision maker in analyzing a situation. In the following sections, we first discuss design and analysis methods/techniques/issues related to DSSs. Then, the three possible ways to enhance DSSs will be explored.

DESIGN AND ANALYSIS METHODS/ TECHNIQUES/ISSUES RELATED TO DSSS

Design Methods

Today, DSSs hold a primary position in an organization's decision making by providing timely and relevant information to decision makers. It has become a key to the success or survival of many organizations. However, there is a high tally of failure in information systems development projects, even though they are a focal point of industrial concern (Goepp, Kiefer, & Geiskopf, 2006). Designing methods have become an important component that assures a successful information system design. This issue is in relevance to the design of a DSS.

There have been many different strategies employed for the design of a DSS. Current research on DDS design has witnessed the rapid expanding of object-oriented (OO), knowledge management (KM), structured modeling (SM), and design science (DS) approaches.

Object-Oriented Approach

The characteristic of an OO approach is to use object-oriented software engineering with unified modeling language (UML) in the design and implementation of a DSS. OO approach involves basically three major steps (Tian, Ma, Liang, Kwok, & Liu, 2005). The user's requirements are first captured by using a set of use case diagrams. These diagrams indicate all the functionalities of the system from the user's point of view. Then classes and their relationships are identified and described in class diagrams. Finally, sequence diagrams or collaboration diagrams are developed, which describe the interaction between objects (instances of classes). Tian et al. (2005) designed a DSS with the OO approach for an organization, which was implemented successfully.

Knowledge Management Approach

In some environment (nonpreprogrammed applications), end users, especially the less experienced end users, need to have certain knowledge guiding them on how to use the system. The KM design approach supports end users by embedding declarative and/or procedural knowledge in software agents. This approach provides better assistance to inexperienced users of spatial DSS, which requires a design approach that will prioritize knowledge support of the end users' decision-making activities (West Jr. & Hess, 2002).

Structured Modeling Approach

The SM approach "uses a hierarchically organized, partitioned, and attributed acyclic graph to represent models" (Srinivasan & Sundaram, 2000, p. 598). It consists of three levels: elemental structure, generic structure, and modular structure. The elemental structure intends to capture the details of a specific model instance. The generic structure targets at capturing the natural familial groupings of elements. The modular structure seeks to organize generic structure hierarchically according to commonality or semantic relatedness. The leveled structures allow the complexity of a model to be managed and ranked according to its hierarchies. The graph feature allows modelers and decision makers to understand the model better. A key advantage of the SM is the ease with which structured models can be visualized (Srinivansan & Sundaram, 2000).

Design Science Approach

The functionality of a DSS evolves over a series of development cycles where both the end users and the systems analyst are active contributors to the shape, nature, and logic of the system (Arnott, 2004). Yet system developers have little guidance about how to proceed with evolutionary DSS development. DSS developers are facing the fact that insufficient knowledge exists for design purpose, and designers must rely on intuition, experience, and trial-and-error methods. Design science approach, on the other hand, can facilitate developers to create and evaluate information technology artifacts that are intended to solve identified organizational problems (Hevner, March, Park, & Ram, 2004). Vaishnavi and Kuechler (as in Arnott, 2006) propose a design science methodology with the major process steps of awareness of problem, suggestion, development, evaluation, and conclusion. Arnott (2006) proposes a five steps approach, which was adapted from Vaishnavi and Kuechler, for designing evolutionary DSS: problem recognition, suggestion, artifact development, evaluation, and reflection. A research project by Arnott indicates that the design science approach can tackle problems of both theoretical and practical importance.

Design Techniques

As we are advancing in information technologies, business decision makers can now have access to a vast amount of information. On one hand they may gain necessary and important information for making informed decisions, but on the other hand they may also become overloaded by the information irrelevant to what they need. Thus, there is a pressing need for decision aiding tools that would effectively process, filter, and deliver the right information to the decision makers. Proper combination of DSSs and agent technologies could prove to be a very powerful tool for rendering decision support (Vahidov & Fazlollahi, 2003/2004).

A software agent performs interactive tasks between the user and the system. The user instructs the system what the user intends to accomplish. The software agent carries out the task. By analogy, a software agent mimics the role of an intelligent, dedicated, and competent personal assistant in completing the user’s tasks (Bui & Lee, 1999). In the DSS environment, software agents have been more formally described as autonomous software implementations of a task or goal that work independently, on behalf of the user or another agent (Hess, Rees, & Rakes, 2000). As the traditional, direct manipulation interface of our computing environment is much limited (Maes, 1994), software agents would seem to be a suitable and most needed solution for providing procedural assistance to end users (West & Hess, 2002). “These ‘robots of cyberspace’ can be effectively utilized in automating many information processing tasks” (Vahidov & Fazlollahi, 2003/2004, pp. 87-88).

In some DSS environments, such as spatial DSS (Sikder & Gangopadhyay, 2002; West & Hess, 2002), Internet-based DSS (Bui & Lee, 1999), and Web DSS (Vahidov & Fazlollahi, 2003/2004), a multiagent system should be designed and implemented in the DSS to facilitate the decision makers since decision making involves a complex set of tasks that requires integration of supporting agents (Bui & Lee, 1999), and these agents should have behaviors to work in teams (Norman & Long, 1994). Vahidov and Fazlollahi (2003/2004) developed architecture of multiagent DSS for e-commerce (MADEC), in which intelligence team (agents), design team (agents), and choice team (agents) were composed. The multiagent system was implemented in a prototype of MADEC, which received higher user satisfaction.

THREE POSSIBLE WAYS TO ENHANCE DSS

Creating Knowledge Warehouses (KW)

Nemati, Steiger, Iyer, and Herschel (2002) propose a new generation of knowledge-enabled systems that provides the infrastructure required to capture, enhance, store, organize, leverage, analyze, and disseminate not only data and information but also knowledge (Nemati et al., 2002). Expanding data warehouses to encompass the knowledge needed in the decision-making process is the creation of knowledge warehouses (KW). An important component of KW is a very complex process known as knowledge management. Knowledge management allows for knowledge to be converted from tacit to explicit through such processes as filtering, storing, retrieving, and so forth, thus allowing it to be utilized by decision makers.

The goal of KW is to give the decision maker an intelligent analysis standpoint that enhances all aspects of the knowledge management process. The main drawbacks of KW are the amount of time and money that need to be invested as well as some of the same problems that are found in successfully implementing DSSs. Among these factors are the users' involvement and participation, values and ethics, organization and political issues within the company, and other external issues. The development and implementation of KW still has much work to be done, however, DSSs seem to be headed toward knowledge enhancement in the future and KW looks to have a promising outlook in the upcoming years as a result.

Focusing on Decision Support

While knowledge management systems seem like a logical way to advance the shortcomings of DSSs, another view also exists. By removing the word "system" from DSSs and focusing on decision support, decision making might cause some interesting, new directions for research and practice. Decision support (DS) is the use of any plausible computerized or noncomputerized means for improving sense making and/or decision making in a particular repetitive or nonrepetitive business situation in a particular organization (Alter, 2004).

DS embodies a broader perspective that seems logical in environments where the user does not necessarily need the technical aspects of DSSs. This is based on the belief that most work systems of any significance include some form of computerized support for sense making and decision making (Alter, 2004). The difference between DSSs and DS is not too drastic but DS is a sensible option for many companies due to the increase in technology since the creation of DSSs; DSSs may not fit the needs of a business as they have in the past.

Integrating DSSs & KMSs

In line with Bolloju, Khalifa, and Turban (2002), integrating decision support and knowledge management may correct some of the deficiencies of DSSs. The decision-making process itself results in improved understanding of the problem and the process, and generates new knowledge. In other words, the decision-making and knowledge creation processes are interdependent. By integrating the two processes, the potential benefits that can be reaped make the concept seem more worthwhile.

Integrating DSSs and KMSs seems to be the best choice out of the three possible ways to enhance DSS. The reasoning behind this selection is that integrating the two seems to provide a way for including both options without sacrificing one for the other. More importantly, while KW appears to have a very bright future, KW currently requires a great amount of time and money. The combination of both areas allows for a better overall utilization in the present. In time, KW may not be as time consuming and costly as it is now. However, to achieve a better balance of usefulness and efficiency, the integration of DSSs and KMSs appears to be the smartest choice.

FUTURE TRENDS

The future of DSSs, Angus (2003) argues and supported by SAS (2004), is in the field of *business analytics* (BAs). BAs differ from that of the recently and previously more common business intelligence (BI). With the fast pace of business and life today it would only make sense for a shift to BA because it does focus on the many possibilities and the future outcomes for production and service.

BAs focus on the future of operations. Opposed to that of BI, where it focuses on the past and what can be done to change the past if things were done wrong or repeat if things were done right. However, BAs let managers center on what future trends are developing, which allows them not to accumulate a surplus of inventory of outdated products. It also enables managers to change their prices before the market does, or introduce their new product before anyone else gets the chance to. This is known as first-to-market (Gnatovich, 2006). BAs give the companies that use it a tremendous advantage over their competitors in the market place.

CONCLUSION

Since their creation in the early 1960s, DSSs have evolved over the past four decades and continues to do so today. Although DSSs have grown substantially since their inception, improvements still need to be made. New technology has emerged and will continue to do so and, consequently, DSSs need to keep pace with it. Also, knowledge needs to play a bigger role in the form of decision making.

Shim, Warkentin, Courtney, Power, Sharda, and Carlson (2002) emphasize that DSSs researchers and developers should (i) identify areas where tools are needed to transform uncertain and incomplete data, along with qualitative insights, into useful knowledge, (ii) be more prescriptive about effective decision making by using intelligent systems and methods, (iii) exploit advancing software tools to improve the productivity of working and decision making time, and (iv) assist and guide DSSs practitioners in improving their core knowledge of effective decision support.

The prior statement sums up the courses of action that need to be taken very well. The successful integration of DSSs and KMSs could revolutionize DSSs and propel them to even greater heights in the future. In closing, DSSs have a storied history that spans the course of four decades; however, the greatest mark may be made in the not-so-distant future as DSSs continue to evolve.

KEY TERMS

Business Analytics (BA): A technological system that collects and evaluates all relevant data then scrutinizes them and puts them into different simulations to find out which are the most appropriate.

Business Intelligence (BI): A system of technologies for collecting, reviewing, and hoarding data to assist in the decision making process.

Decision Support Systems (DSSs): An interactive, flexible, and adaptable computer-based information system, especially developed for supporting the solution of a nonstructured management problem for improved decision making. It utilizes data, provides an easy-to-use interface, and allows for the decision maker's own insights

Interface (or User Interface): A component designed to allow the user to access internal components of a system, also known as the dialogue component of a DSS.

Knowledge Management: The distribution, access, and retrieval of unstructured information about human experiences between interdependent individuals or among members of a workgroup.

Sensitivity Analysis: Running a decision model several times with different inputs so a modeler can analyze the alternative results.

Software Agent: A program that performs a specific task on behalf of a user, independently or with little guidance (Bui & Lee, 1999, p. 226).

Structured Modeling: A generic design strategy for representing complex objects that are encountered in modeling applications (Srinivasan & Sundaram, 2000, p. 598).

Transaction Processing System (TPS): Computerized systems that perform and record the daily routine transactions necessary to conduct the business; they serve the organization's operational level.

Use Case: A collection of possible sequences of interactions between the system under discussion and its users relating to a particular goal (Tian et al., 2005, p. 406).

Chapter 1.13

The Evaluation of Decision-Making Support Systems' Functionality

Giusseppi Forgionne
University of Maryland, Baltimore County, USA

Stephen Russell
University of Maryland, Baltimore County, USA

INTRODUCTION

Contemporary decision-making support systems (DMSSs) are large systems that vary in nature, combining functionality from two or more classically defined support systems, often blurring the lines of their definitions. For example, in practical implementations, it is rare to find a decision support system (DSS) without executive information system (EIS) capabilities or an expert system (ES) without a recommender system capability. *Decision-making support system* has become an umbrella term spanning a broad range of systems and functional support capabilities (Alter, 2004). Various information systems have been proposed to support the decision-making process. Among others, there are DSSs, ESs, and management support systems (MSSs). Studies have been conducted to evaluate the decision effectiveness of each proposed system (Brown, 2005; Jean-Charles & Frédéric, 2003; Kanungo, Sharma, & Jain, 2001; Rajiv & Sarv, 2004). Case studies, field studies, and laboratory experiments have been the evaluation vehicles of choice (Fjermestad & Hiltz, 2001; James, Ramakrishnan, & Kustim, 2002; Kaplan, 2000).

While for the most part each study has examined the decision effectiveness of an individual system, it has done so by examining the system as a whole using outcome- or user-related measures to quantify success and effectiveness (Etezadi-Amoli & Farhoomand, 1996; Holsapple & Sena, 2005; Jain, Ramamurthy, & Sundaram, 2006). When a study has included two or more systems, individual system effects typically have not been isolated. For example, Nemati, Steiger, Lyer, and Herschel (2002) presented an integrated system with both DSS and AI (artificial intelligence) functionality, but they did not explicitly test for the independent effects of the DSS and AI capabilities on the decision-making outcome and process. This article extends the previous work by examining the separate impacts of different DMSSs on decision effectiveness.

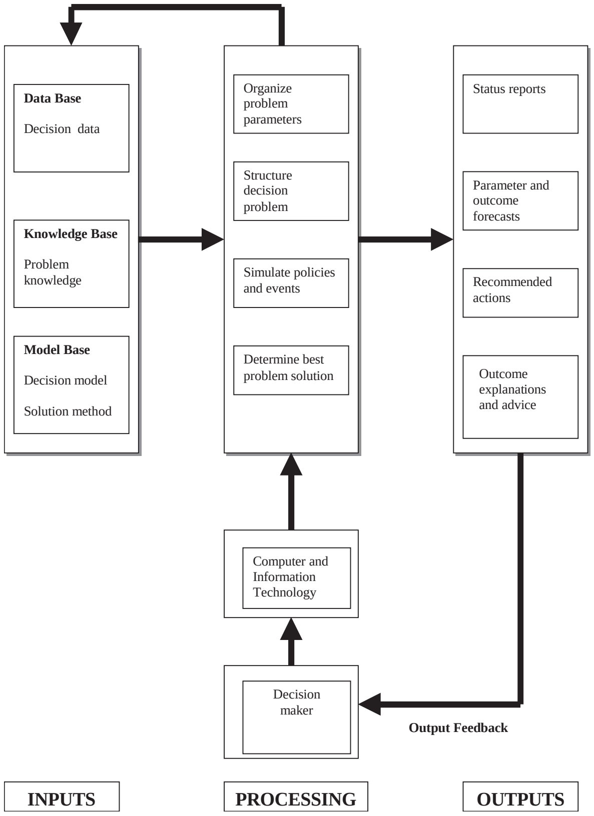
BACKGROUND

DMSSs are information systems that directly support the decision-making process for complex, high-level problems in an interactive manner (Alter, 2004; Mora, Forgionne, & Gupta, 2002). The specific DMSS can be a traditional DSS, EIS, ES, knowledge-based system (KBS), or a system that combines the functionalities of DSS, EIS, KBS/ES.

An architecture that incorporates the functionality of the various proposed systems is shown in Figure 1 (adapted from Forgionne, 2003).

In the typical DSS, the decision maker utilizes computer and information technology to (a) structure the problem by attaching the parameters to a model and (b) use the model to simulate (experiment with) alternatives and events and/or find the best solution to the problem (Borenstein, 1998; Raghunathan, 1999). Results are reported as parameter conditions (status reports), experimental outcome and parameter forecasts, and/or recommended actions. Feedback from user processing guides the decision maker to a problem solution, and created information is stored as an additional input for further processing. A DSS, then, would not include the knowledge base on the input side

Figure 1. General DMSS



or offer explanations on the output side of Figure 1's conceptual architecture.

In a typical EIS, the decision maker utilizes computer and information technology to (a) access dispersed data, (b) organize the data into user-specified broad categories, (c) view the data from interesting perspectives, and (d) highlight important patterns by scanning current trends (Leidner & Elam, 1994; Seely & Targett, 1999). Results are reported as categorical summaries and drill-down details (status reports) and/or suggested problem parameters (parameter forecasts). Feedback from the user processing guides the decision maker to a general problem understanding, and the created parameters are stored as additional inputs for further processing. An EIS, then, would have a limited model base and not include the knowledge base on the input side. Additionally, the system would not offer recommended actions or explanations on the output side of Figure 1's conceptual architecture.

A typical KBS/ES captures and stores as inputs problem-pertinent knowledge, either from experts, cases, or other sources, and the models (inference engine or reasoning mechanisms) needed to draw problem-solution advice from the knowledge (O'Leary, 1998; Preece, 1990; Ullman, 1988; Waterman, 1985). Results are reported as knowledge summaries (status reports), forecasted outcomes, and/or problem advice and explanations for the advice. Feedback from the user processing guides the decision maker to the advice, and the created events and advice pathways are stored as additional inputs for further processing. A KBS/ES, then, would have a limited model base and not include the database on the input side, and similar to an EIS, the system would not offer recommendations on the output side of Figure 1's conceptual architecture.

An MSS integrates the functions of a DSS, EIS, and KBS/ES into a single system (Turban, Aronson, & Liang, 2004). Similar to its component systems, an MSS will have a model base and a database. The database contains data relevant to the decision problem, including the values for the uncontrollable events, decision alternatives, and decision criteria. The knowledge base holds problem knowledge, such as guidance for selecting decision alternatives and uncontrollable inputs, problem relationships, or advice in interpreting possible outcomes. The model base is a repository for the formal models of the decision problem and the methodology for developing results (simulations and solutions) using these formal models. Processing will generate status reports on events and alternatives, simulated outcomes, decision recommendations, and explanations for the recommendations and further processing advice. Feedback provides additional data, knowledge, and models created from the processing.

As such, the MSS will enable the user to perform the operations and computations involved in all four processing tasks and generate all outputs shown in Figure 1.

EVALUATION OF DMSS COMPONENT SYSTEMS THROUGH SIMULATION

Issues, Controversies, and Problems

In theory, the support offered by DSS, EIS, and KBS/ES should improve the process of, and outcomes from, decision making (Forgionne, 1999; Kumar, 1999). Case studies (Lilien, Rangaswamy, Bruggen, & Starke, 2004; Sarter & Schroeder, 2001), field studies (Adelman, Gualtieri, & Riedel, 1994; Kanungo et al., 2001; Sojda, 2004), and experiments (Adleman, 1991; Maynard, Burstein, & Arnott, 2001; Parikh, Fazlollahi, & Verma, 2001; Pratyush & Abhijit, 2004) have all offered evidence that generally supports this theory. Conceptually, the synergistic effects from the integrated functionality of an MSS should further improve decision making when compared to individual DMSSs. There is also some experimental evidence to support this theory (Forgionne

& Kohli, 2000). Yet, there are important gaps in this body of empirical testing. First, it is difficult to acquire and motivate case- and field-study participants, and the acquired participants may not be representative of the population. Second, few, if any, comparative studies measure the separate decision contributions of the individual DMSSs or functional components in the MSS.

These gaps are important for several reasons. Proper isolation of individual or functional contribution can contribute to a proper matching of system types with decision problems. Linking the effects of the isolated contribution to decision-making phases also will facilitate situational system design, development, and implementation. Such linkages can reduce the time and costs involved in the DMSS analysis and design process and provide direct measures of comparative system benefits. This approach combined with population studies will enable researchers and practitioners to generalize results and findings.

Solutions and Recommendations

Simulation can be used to gather pertinent data and conduct the comparative DMSS analyses. Since an extremely large number of trials can be performed in a very short period of time, simulation can generate the population information needed for generalization. While the approach is best suited to problems involving tangible variables, simulation also can incorporate intangible factors through the use of categorical and dummy variables (Coats, 1990; Wildberger, 1990). Once stated categorically, the intangible factors can be linked to the tangible factors through the simulation model equations.

The simulation study utilizes a complex semistructured problem, frequently used in management training and evaluation and typically requiring decision-making support (McLeod, 1986). This problem involves a market in which top management uses price, marketing, research and development, and plant investment to compete for a product's four-quarter total market potential. Demand for the organization's products will be influenced by (a) management actions, (b) competitors' behavior, and (c) the economic environment. The decision objective is to plan a four-quarter strategy that would generate as much total profit as possible.

Strategy making requires (a) setting the product price, marketing budget, research and development expenditures, and plant investment and (b) forecasting the competitors' price, competitors' marketing budget, a seasonal sales index, and an index of general economic conditions. Twelve additional variables, including plant capacity, raw-materials inventory, and administrative expenses, will be calculated from the strategy. Initial values for these twelve variables form the scenario for decision making. These 20 (controllable, uncontrollable, and calculated) variables jointly influence the profitability of the organization.

The problem is sequential in nature. Current decisions are affected by decisions and forecasts in previous and subsequent quarters. In this dynamic environment, poor strategies will have unrecoverable negative consequences over the planning horizon.

A precise and explicit model of the decision problem was programmed in the SAS System for Information Delivery. This software provided a robust programming environment where the decision support system simulation can be created and evaluated (Spector, 2001). Unlike other software approaches, SAS provides a series of linked modules that deliver, in an integrated and comprehensive manner, the wide range of mathematical and statistical tasks needed to perform the simulations.

In a typical DSS, the user would provide the controllable and uncontrollable variable values for the decision model. To incorporate the diversity of inputs from a population of users, each variable was assumed to follow a standard normal distribution with a mean of 0 and a standard deviation of 1. Using the scenario values, the permissible management game ranges, and SAS's random normal function, formulas were developed to ensure that input values would fall within the permissible ranges according to normal probability distributions. Figure 2 presents the corresponding SAS program.

The simulation study includes EIS capabilities within the management game. An EIS focuses on the intelligence (gaining a general problem understanding) phase of decision making. Insights about the decision environment, such as forecasted economic conditions and competitors' potential actions, are an essential form of intelligence. Within the management game, such intelligence can be expressed as guidance for selecting the values of the uncontrollable variables (economic index, seasonal index, competitor's price, and competitor's marketing). Guidance was provided for the selections through the documentation provided with the management game, and the guided values would generate good, although not likely optimal, profits for the organization.

In practice, users may not accept the intelligence guidance. To account for this possibility, guidance acceptance was assumed to follow a standard normal distribution with a mean of 0 and a standard deviation of 1. Simulated values greater than 0 from this distribution represented user acceptance of the guidance, while values of 0 or less constituted rejection of the advice. When users rejected guidance, uncontrollable-variable values were simulated with Figure 2's uncontrollable-inputs section. Figure 3 presents the relevant SAS program.

The simulation study also included KBS/ES capabilities. The focus in a KBS/ES is on the choice (selection of preferred alternatives) phase of decision making. Within the management game, this focus can be expressed as guidance for selecting the values of the controllable variables (price, marketing, research and development, and plant investment). The management-game documentation again provided the guidance for the selections. As with the EIS, guidance acceptance was assumed to follow a standard normal distribution with a mean of 0 and a standard deviation of 1, and simulated values greater than 0 represented user acceptance. When users rejected guidance, controllable-variable values were simulated with Figure 2's controllable-inputs section. Figure 4 presents the relevant SAS program.

By combining the capabilities of DSS, EIS, and KBS/ES, the management game represents an MSS. Consequently, there would be guidance

for both the controllable- and uncontrollable-variable values. As with the EIS and KBS/ES, (a) guidance acceptance was assumed to follow a standard normal distribution with a mean of 0 and a standard deviation of 1, (b) simulated values greater than 0 represented user acceptance, and (c) when users rejected guidance, variable values were simulated with Figure 2's program.

Figure 5 presents the relevant SAS program. The various simulations were run for 100 users across 100 years, with each year involving four quarters. This methodology generated 40,000 observations for the comparative analysis, including values for the controllable, uncontrollable, and calculated variables, including the organization's net profit after tax. These data were used in an ANOVA (analysis of variance) to test whether there were any significant differences in net profits from DSS, EIS, KBS/ES, and MSS use.

Figure 6 summarizes the ANOVA statistics, and this exhibit also presents means for net profit (the outcome variable in the study).

As Figure 6 demonstrates, there was a significant net-profit difference between the simulated DSS, EIS, KBS/ES, and MSS users. Furthermore, Scheffe's test indicates that EIS, KBS/ES, and MSS users all did better than DSS users. MSS and KBS/ES users also did better than EIS users, but there were no significant differences between the net profits of KBS/ES and MSS users. Although the analyses are not reported here, the same relative results occurred when only accepting-user data were utilized.

         CM = cmp[quarter];
         CP = cpp[quarter];
                output;
      end;

/* Determine the values for nonaccepting subjects   */
         if accept LE 0 then do;
/* controllable inputs        */
         P = 65 + (20 * RANNOR (0));
         M = 250000 + (70000 * RANNOR (0));
         RD = 0 + max(0,(1000000 * RANNOR (0)));
         PI = 10000000 + (333333 * RANNOR (0));
/* uncontrollable inputs     */
         CM = 350000 + (100000 * RANNOR (0));
         CP = 68 + (20 * RANNOR (0));
         E = 1.1 + (.3 * RANNOR (0));
         SI = .75 + (.25 * RANNOR (0));
         output;
      end;
   end;
 end;
 end;
run;
```

Since the differences can be traced to the guidance offered by each system, these results suggest that controllable-variable guidance is more important in this decision problem than uncontrollable-input advice. The negative profits across the system types suggest that the advice provided by the management-game documentation was flawed.

FUTURE TRENDS

As this simulation study illustrates, the type of advice can lead to different decision outcomes. This study examined the effects of static advice typically offered through EIS and KBS/ES. Other DMSSs may offer dynamic guidance, changing the advice depending on the evolving circumstances

in the decision situation. Such dynamic advice can be derived from the decision model's mathematical relationships and rendered in real time through the system. The simulation approach can also be used to alter the mathematical relationships as the decision environment evolves.

Results from any simulation are only as good as the assumptions used in the analyses. This study assumed that the management game was a reasonable representation of many organizations' strategic decision-making problems. Different organizations, however, may utilize different management philosophies, accounting principles, and decision objectives. If so, the decision model should be changed to reflect the organization's practices, philosophies, objectives, and decision environments. In particular, the profit equation may be replaced with an alternative measure or measures of performance, some tangible and others intangible. Variables and relationships may be defined and measured differently. Additional environmental factors may be added to the equations. While such alterations would change the specific form of the simulation model, the general model and experimental methodology would still be applicable.

This study also assumed that acceptance rates and input values would follow normal distributions. A variety of other distributions is possible, including the binomial and Gamma distributions.

```

Further studies, then, should examine the sensitivity of the results to changes in distributions.

Finally, this study examined only four types of DMSSs. There are others, including creativity-enhancing, decision technology, and machine learning systems. In addition, the functionality of the studied systems was operationalized in particular ways. Other operational possibilities exist, such as providing AI-based guidance to model formulations. The other DMSSs with different forms of guidance and assistance warrant further study.

CONCLUSION

The results of this study confirm that EIS, KBS, and MSS all improve decision making when compared to a basic DSS. In addition, these results suggest that guidance for controllable variables is relatively more important than guidance for uncontrollable variables in achieving decision objectives. Since the results are expressed in dollars of net profit, the findings provide an objective measure of determining the relative decision value of the various DMSS functions. Moreover, as large-scale simulation that approaches a census is studied, the evaluation results should be more generalizable in comparison to sample studies that use participants in laboratory, field, or case settings.

The study does not support the concept that higher synergistic value can be achieved through higher levels of functional integration. Instead, it may be sufficient in many circumstances to stop the integration at intelligent decision-making support, adding KBS/ES or other artificially intelligent capabilities to a basic DSS.

KEY TERMS

Decision Making Process: This is the process of developing a general problem understanding, formulating the problem explicitly, evaluating alternatives systematically, and implementing the choice.

Decision Support System (DSS): A DSS is an information system that interactively supports the user's ability to evaluate decision alternatives and develop a recommended decision.

Executive Information System (EIS): An EIS is an information system that accesses, reports, and helps users interpret problem-pertinent information.

Knowledge-Based or Expert System (KBS or ES): This is an information system that captures and delivers problem-pertinent knowledge and advice for users.

Management Game: It is a model used by a participant to experiment with decision strategy plans in a simulated organization.

Management Support System (MSS): An MSS is an information system that integrates the functional capabilities of a decision support system, executive information system, and knowledge-based or expert system.

Simulation: A simulation is an approach to data creation and analysis that utilizes a model to represent reality.

Computer-Supported Collaborative Work and Learning:

A Meta-Analytic Examination of Key Moderators in Experimental GSS Research

ABSTRACT

Evident and growing research interest has been witnessed on the relationship between the use of computer-based systems and effective communication in group-related activities such as collaborative learning and training. The various terms accorded to this research stream include virtual teams, e-collaboration, computer-supported collaborative work, distributed work, electronic meetings, etc. A notable and well-accepted aspect in the information system field is group support systems (GSS), the focus of this article. The numerous GSS studies have reported findings which may not be altogether consistent. An overall picture is much in want which attends to the synthesizing of the findings accumulated over decades. This article presents a meta-analysis study aimed at gaining a general understanding of GSS effects. We investigate six important moderators of group outcomes, namely group size, task type, anonymity, time and proximity,

level of technology, and the existence of facilitation. The results point to important conclusions about the phenomenon of interest; in particular, their implications vis-à-vis computer-supported collaborative learning technologies and use are discussed and highlighted along each dimension of the studied variables.

INTRODUCTION

Group or team-based work and collaborations are becoming an integral part of education and learning environments. With the advance of information communication technologies, there has been a growing potential for utilizing computerized systems to support idea generation, project assignment, instant communication among the IT-age students and educators. The phenomenon has arrested the interest of both educational field and information systems (IS) researchers. In education realm, an emerging area in the instructional technology field called *computer-supported collaborative learning* (CSCL) has focused on the ways to support group learning in different forms of technologies; the technologies include electronic discussion environments, distance learning systems, and intelligent agents (e.g., Koschmann, 1996; Ready, Hostager, Lester, & Bergmann, 2004; Strijbos, Martens, & Jochems, 2003).

In IS literature, *Group Support System*s (GSS) research has accumulated a substantial body of knowledge on the effects of computer-based systems in supporting group work in related to a variety of tasks such as idea generation and decision making. Based on the success of using GSS technology to support groups in nonacademic settings, researchers have begun to explore ways to apply GSS technology in classroom to support and enhance group-based learning (Tyran & Shepherd, 2001). GSS are used in a classroom setting or distance learning groups to support and structure group communication and learning activities (e.g., Alavi, Marakas, & Yoo, 2002; Sawyer, Ferry, & Kydd 2001; Leidner & Jarvenpaa, 1995).

While the past studies centered along using GSS to enhance group work outcomes are numerous, the findings are not altogether consistent. Many researchers have devoted towards efforts in figuring out what GSS can help the group to achieve by reviewing and summarizing the previous studies. Several early meta-analyses exist (e.g., Benbasat & Lim, 1993; McLeod, 1992; Shaw, 1998). Other reviews involve tabular methods which are unavoidably less rigorous (Fjermestad & Hiltz, 1999). Tyran and Shepherd (2001) presented a GSS research framework for analyzing the impact of collaborative technology on group learning, by referring to an earlier framework concerning electronic meeting systems on group processes and outcomes (Pinsonneault & Kraemer, 1990). Nevertheless, as the framework is built based on face-to-face or "same time, same place" research studies (Leidner & Jarvenpaa, 1995), it is somewhat limited in its applicability to group work or learning in other forms such as distributed work or Web-based distance learning. Dennis and Wixom (2002) examined five moderators (task, GSS tools, type of group, group size, and facilitation) and their potential effects on GSS use. It has been noted that for GSS researchers trying to extend the common body of knowledge—and for GSS technology practitioners, such as teaching facilitators, seeking to apply research appropriately—it is necessary for them to "look deeper than the overall effects of GSS use" (p. 236, Dennis & Wixom, 2002). A pertinent question is *under what conditions* collaborative technology use would improve group performance because there are *moderators* that influence the specific effects of GSS (Beauclair, 1989; Dennis & Wixom, 2002;).

Following this idea, instead of focusing on examining the effect of GSS technology alone, the current study attempts to look into *how key moderators individually and jointly influence important group work outcomes* using a meta-analytic technique to help us arrive at conclusions backed by quantitative analysis, as well as provide insights that can be brought into both CSCL and GSS areas. Specifically, our primary interest concerns the use of GSS technology and research in the learning environment. Correspondingly, the article focuses on six important moderators which are pertinent to both organizational and educational contexts; they are group size, task type, anonymity, time and proximity, level of technology, and the existence of facilitation. Hypotheses of the effects they may bring to the group along with the use of GSS, as well as the research model, are articulated. Next, we present a meta-analysis on 33 quantitative experimental studies to gain a synthesized view of the GSS effectiveness. The subsequent sections dwell on the results and discussions relating to each of the outcome variables. We conclude the article by pointing out the relevance to, and implications for, computer-supported collaborative learning research; as well, future research avenues are identified.

THE RESEARCH FRAMEWORK

Learning and GSS Technology

Collaborative learning, as compared to individual learning, is helpful and important for understanding and exploring the process of learning. Embedded within the definition of cooperative learning is an enormous diversity of cooperative approaches. These may be informal as short meetings to simply discuss and share information, or formal approaches where structure is imposed with specific ways of forming teams. Students may be working together on projects or other creative activities involving specific contents.

Growing interests in supporting the needs of collaborative learning, along with concurrent improvements in GSS, have led to the emergence of a research area in the instructional technology field in CSCL; research in CSCL centers on the interaction of computer-supported learning systems and GSS by integrating collaborative learning and Information Technology (IT) (O'Malley, 1995). The rising importance of teamwork and group decision-making has triggered vast research efforts since the 1960's when the GSS concept was first raised by Doug Engelbart (Wagner, Wynne, & Mennecke, 1993). GSS are defined as computer-based systems that support group decision making which is the result of the integration of communication, information processing and computer-based group structuring and support (DeSanctis & Gallupe, 1987; Huber, 1984; Poole & DeSanctis, 1990). The CSCL research domain encompasses benefits derived from GSS applications to support group-oriented methods of instruction, including networked discussion environments and distance learning systems.

Desktop conferencing, videoconferencing, co-authoring features and applications, electronic mail and bulletin boards, meeting support systems, voice applications, workflow systems, and group calendars are key examples of groupware (Grudin, 1991). In addition to a set of common features, different applications provide users with different tools and functions. Many IS researchers have used GSS in the classroom and experiments to enhance the learning experience (Kwok, Ma, & Vogel, 2002), whereas other works in IS and related fields have developed asynchronous learning networks (ALNs) (Coppola, Hiltz, & Rotter, 2002). These systems enable affective learning objectives related to interactive communication and teamwork to be achieved, on top of meeting the traditional cognitive learning objectives.

GSS were originally designed to support discussion and decision making in the commercial/business sector, but in the last few years there has been a surge of interest in their usage to support collaborative learning (Khalifa & Kwok, 1999; Vogel, Davison, & Schroff, 2001). DeSanctis and Gallupe's (1987) two-by-two framework for GSS has been applied to understanding IT usage in learning environments. Although this framework enables us to classify learning settings based on

Table 1. GSS features and their facilitation of group communication

GSS support feature	Feature description	Potential benefit
Anonymity	It supports group members to input information to the group anonymously by means of an electronic communication channel.	It may help to reduce evaluation apprehension by allowing group members to submit their ideas without having to speak up in front of the rest of the group.
Parallel Communication	It supports all group members to communicate at the same time, implemented in a GSS by means of an electronic communication channel.	It may help to reduce domination in a group by one or more members, since parallel communication allows more than one person to express ideas at a time. In larger groups, the feature may also reduce problems associated with limited airtime for group members, since all group members can submit information concurrently without having to wait for other to finish speaking. This feature is able to support more complex communication in groups as compared to that in groups without the aid of GSS (Bandy & Young, 2002).
Process Structure	It supports the process techniques or rules that guide the content, pattern or timing of communication. Besides, it provides structure to a group process by establishing an approach the group may follow in order to perform a group activity. This feature is implemented in a GSS by means of one or more group-oriented software tools that support group activity.	It may help to reduce coordination problems for a group by keeping the group focused on the task or agenda. For example, to focus on electronic discussion, an idea generation activity may be structured by using an electronic discussion system with predefined categories (Bandy & Young, 2002). The process structured by this feature contributes to effective learning (Kwok & Khalifa, 1998).

the dimensions of space and time, it does little to improve our understating of the technologies required to support the learning objectives in different settings. Sharda, Romano, Lucca, Weiser, Scheets, and Chung (2004) propose extending DeSanctis and Gallupe's framework by adding a third dimension, learning objectives achieved (cognitive and affective in classroom form vs. cognitive, affective and psychomotor in lab). Craig and Shepherd (2001) have drawn from the GSS and education literatures to develop a research framework that may be used to analyze the impacts of collaborative technology on learning. This framework is an extension from Pinsonneault and Kraemer's (1990) framework for electronic meeting systems research. Table 1 illustrates how the GSS features can support groups in collaborative learning (Craig & Shepherd, 2001).

Effects of Important Moderators

Fjermestad (1998) attempts to integrate various GSS research models into a comprehensive model. He included four major categories of variables: *contextual* or *independent* variables, *intervening* variables, *group adaptation processes*, and *outcomes* or *dependent variables*. However, the variables included in this framework are overwhelming with some may not be important in practice and difficult for manipulating. Therefore, for the interest of this article, we selected the potential moderators from this framework cautiously.

The basic criteria for choosing the moderators necessitate them to be practically important and to have a clearly defined measurement. We need a theoretical basis for each moderator to suggest that it might have the effects on the group activities. Therefore, we choose to consider six moderators from the four categories defined by Fjermestad (1998): group size, task type, anonymity, time and proximity, level of technology, and the existence of facilitation.

Group performance and satisfaction serve as the two categories of outcome variables, as consistent with previous studies (e.g., Sambamurthy & Poole, 1992; Tan, Raman, & Wei, 1994). We defined these two outcomes according to Benbasat and Lim (1993) and Dennis and Kinney (1998) in the following way: (1) performance includes decision quality, number of ideas and time to reach decision; (2) satisfaction includes process satisfaction and decision satisfaction.

The rationales for studying group performance in collaborative learning are explained in the following. Group collaborative technologies have been found to help to increase teacher-student interaction, and to make learning more student-centered (Hiltz, 1995). Collaborative technologies may potentially eliminate geographical barriers while providing increased convenience, flexibility, currency of materials, knowledge retention, individualized learning, and feedback (Kiser, 1999). In practice, more and more professionals have to collaborate and it is an important goal for any educational institution to improve students' performance in collaborative situations. With the group evaluation approach, one may verify whether the performance of a specific group has increased or assess if group members have developed some generic ability to collaborate which they could possibly reuse in other groups (Dillengourg, 1999). An important potential benefit of CSCL environment is the support of diverse learning styles (Wang, Hinn, & Kanfer, 2001). Hiltz and Turoff (1993) found a strong tendency toward more equal participation, and that more opinions tended to be asked for and offered.

Group Size

Research on the effects of group size in nonGSS-supported group work has a long history. The general consensus is that as group size increases, effectiveness increases because there are more individuals who will contribute to knowledge and skills (Hare, 1981; Thomas & Fink, 1963). However, upon the reach of a certain optimal value, the difference in participation becomes more pronounced so that a few members will dominate the group meeting (Shaw, Hinn, & Kanfer, 1981; Diehl & Stroebe, 1987) and thus the effectiveness and member satisfaction will decrease (Hare, 1981). The optimum size for groups without GSS support is suggested to be no more than six in the perception of managers (James, 1951; Rice, 1973). Empirical research has drawn similar conclusions suggesting the optimum size to be five (Hackman, 1970; Hare, 1981; Shaw, 1981).

In the case of GSS-supported group meetings, the optimum size of the group is unknown. Two studies have found no differences on the effects due to group size (Watson, DeSanctis, & Pool, 1988; Zigurs et al., 1988). Both of the studies used groups of three and four. In addition, GSS have the potential to reduce the barriers to communication that will increase with group size, thus we expect the performance of groups—and larger groups in particular—will be improved (DeSanctis & Gallupe, 1987). Therefore, we believe that the optimum size for GSS groups will be larger than the nonGSS groups.

Previous nonGSS research suggests that performance does not increase as group size becomes larger (Dennis, Valacich, & Nunamaker, 1990). GSS research has found that larger groups benefit more from GSS use than smaller groups (Dennis, 1991; Dennis et al., 1990; Dennis & Valacich, 1991; Gallupe, Dennis, Cooper, Valacich, Nunamaker Jr., & Bastianutti, 1992; Nunamaker et al., 1988; Valacich, Dennis, & Connolly, 1994). Theories suggest that GSS can reduce the following process losses which are common to nonGSS groups: air time, production blocking, evaluation apprehension, free riding, and cognitive inertia (Dennis et al., 1990).

H1a: Large groups will generate more ideas than small groups.
H1b: Large groups will have higher decision quality than small groups.
H1c: Large groups will have a shorter time to reach decision than small groups.

Previous research has found decreased user satisfaction in larger groups in the context of non-GSS-supported group meetings due to the decreased performance, increased evaluation apprehension and the lack of equality of participation (Shaw, 1981; Diehl & Stroebe, 1987). In the GSS-supported meeting environment, we expect increased performance, decreased evaluation apprehension and increased equality of participation. Therefore, the user satisfaction will be higher for larger groups in GSS supported environment.

H1d: Large groups will have higher process satisfaction than small groups.
H1e: Large groups will have higher decision satisfaction than small groups.

Task Type

The reason for studying task type as a moderator is that groups in an organization engage in a wide variety of tasks, thus necessitating investigations of the differential effects of various task types (Hackman, 1968). According to McGrath (1984), tasks can be divided into four quadrants (generating, choosing, negotiating and executing). The first two types are relevant to the GSS context, and commonly studied in GSS experimental studies. Likewise, the current work focuses on idea generation tasks and decision-making tasks, as they are considered most common forms of collaborative learning tasks (Ready et al., 2004).

Idea generation tasks involve participants to work together to generate ideas or plans. The results are best obtained through the active contribution of each participant. The number of ideas and quality of the ideas are most important in such tasks. However, for decision-making tasks, members have to reach consensus to make a decision. The decision has to be superior to other alternatives. Therefore, the quality of the decision is the most important for this type of tasks. As the measures for the results of these two task types are different, we will be unable to compare the performance outcome for the different task types.

Since idea generation tasks are additive tasks which do not need to reach a consensus as in the case for decision-making tasks, the level of conflict will be lower for idea generation tasks. Shaw (1998) compared the GSS groups performing the two tasks and found that the group performing idea generation tasks had higher satisfaction. Therefore, we have the following hypotheses:

H2: Process satisfaction will be higher for idea generation tasks than for decision-making tasks.

Anonymity

One important feature that GSS can provide to group meetings is anonymity compared to nonGSS meetings. Participants can sit in front of each terminal to input text with their identities being unrevealed. The anonymity provided through GSS sessions have been hailed as the primary way through which GSS help groups overcome process losses (the difference between the group's potential and actual performance (Kerr & Bruun, 1981)). Anonymity can facilitate group processes by moderating those who dominate group discussions (decision by minority rule), have a high position in the group (decision by authority method), and rely on nonverbal cues to get their point across. Wilson and Jessup (1995) propose that anonymous GSS groups should allow more ideas to be generated during a meeting, because group members with low-status can contribute ideas more freely and openly. One of the benefits of anonymity is that it may reduce the pressure to conform to the groups thought the process and minimize evaluation apprehension. These process gains are often tempered by an increase in free riding because it is more difficult to determine when someone is free riding (Albanese & VanFleet, 1985). Other benefits such as more objective evaluation and the creation of a low-threat environment are attributed to anonymity and can ultimately result in improved decision quality (Nunamaker, Applegate, & Konsynski, 1993). Anonymity removes the identity of individuals which eliminates minority influence. The anonymous discussion tends to be more open, honest, and free-wheeling (Nunamaker et al., 1993).

H3a: Anonymous groups will generate more ideas than identified groups.
H3b: Anonymous groups will have higher decision quality than identified groups.
H3c: Anonymous groups will take a shorter time to reach decision than identified groups.

Rao and Monk (1999) stated that if participants made a decision anonymously, the need for external justification would not exist and the participants' level of commitment to the group decision would be lower than the commitment of identified participants because the identified participants would require external justification. If the participants are anonymous, they only need to maintain an internal sense of competence. This difference in desire to appear externally competent results in a higher level of commitment when participants are identified. Thus the level of anonymity provided in a problem-solving environment (either GSS or face-to-face) will negatively impact user satisfaction with the group outcome. Anonymity also increases objective evaluation. In this case, contributions are judged based on their merits rather then on the source of the contribution. Criticism is perceived as being directed at the idea, not the contributor (Nunamaker et al., 1993). Therefore, it is hypothesized that increased anonymity should improve user attitudes because of the depersonalization of the comments and ultimately the critiques of the comments.

H3d: Anonymous groups are less satisfied with decision than identified groups.
H3e: Anonymous groups are more satisfied with process than identified groups.

Time and Proximity

Meeting environment can be divided into four categories with the different combination of the two dimensions, time and proximity (DeSanctis & Gallupe, 1987). They are: synchronous and colocated, synchronous and remote, asynchronous and co-located, and asynchronous and remote. We classify the synchronous and colocated meeting environment as face-to-face environment while the other three as Virtual Team environment. CSCL can be grouped in similar fashion, for example "same time, same place" learning (Leidner & Jarvenpaa, 1995), virtual classroom (Hiltz & Turoff, 1993), distance learning (Verdejo, 1993), and telelearning (Alavi, Wheeler, & Valacich, 1995).

Previous experimental studies mainly focus on the synchronous and colocated meetings which are called face-to-face meetings. However, today's global economy requires many organizations to coordinate work across a variety of intra- and inter-organizational boundaries (Armstrong & Cole, 1995; Carmel, 2006; Lipnack & Stamps, 1997). Virtual Teams allow organizations to improve efficiency and productivity, procure expert knowledge from internal and external sources, and transfer "best practice" information nearly instantaneously (Huber, 1990). Therefore, studying the GSS effect in Virtual Team environment attracted our attention.

GSS that supports Virtual Team have their own characteristic which is the store-and-forward capability across time and space. This characteristic allows members to attend to information at any time at which they can turn their attention to group problems; furthermore, it liberates message senders from having to wait for other members to finish (Watt, Walther, & Nowak, 2002), preventing "production blocking" (the tendency to hold back or forget information while waiting for a live speaking turn; see Connolly, Jessup, & Valacich, 1990). "Production blocking" is a very common problem in face-to-face group meetings as parallel input is often lacking in face-to-face meetings. Therefore, we have the following hypothesis:

H4a: Virtual Teams will generate more ideas than face-to-face teams.
H4b: Virtual Teams will have higher decision quality than face-to-face teams.
H4c: Virtual Teams will take a shorter time to reach decision than face-to-face teams.

Existing research suggests that team members' satisfaction may depend on the type of communication technology being used. Researchers suggest that the richness of the communication technology media may reduce many of the problems associated with Virtual Team interaction (Daft & Lengel, 1986; Dennis & Kinney, 1998). Face-to-face communication provides a richer medium for group communication since participants can use gestures, expressions and voice to communicate with each other. Therefore, we expect that the satisfaction level for Virtual Team will be lower.

H4d: Virtual Teams will have higher process satisfaction than face-to-face teams.
H4e: Virtual Teams will have higher decision satisfaction than face-to-face teams.

Level of Technology

DeSanctis and Gallupe (1987) identified three levels of GSS design to characterize the degree of technological sophistication of the system. Previous studies focused on the effects of level-1 GSS and level-2 GSS since level-3 GSS were not mature enough and the tools were rarely available in the market. Therefore, we choose to compare the effects of level-1 GSS and level-2 GSS.

Level-1 GSS attempt to remove common communication barriers through technical features such as anonymous input of ideas and preferences, large screen for simultaneous display of ideas and preferences, electronic message exchanging among members and compilation and display of members' assessments. Level-2 GSS provide decision modeling and group techniques aiming at reducing the uncertainty and "noise" in the group process. The former one supports primarily communication activities (such as entering ideas and simple rating, ranking and voting) while the latter provides support for communication and consensus activities (providing the structured decision techniques). An important enhancement in level-2 GSS is the support for both idea generation and synthesis.

The existing theories indicate the differences in the two systems result in the different of meeting outcomes in the following ways. Level-1 GSS provide support primarily for communication and do not impose strict structure on the meeting which does not hinder the participants' creativity compared to level-2 GSS (Sambamurthy & DeSanctis, 1990). As a result, we propose that level-1 GSS will provides better support for idea generation. However, level-1 GSS often lack the support for reaching group consensus. Level-2 GSS help groups reach agreement on fewer number of members' expectations, generate more valid and important assumptions, and achieve a superior quality of decision in a shorter time (Sambamurthy & DeSanctis, 1990). Level-2 GSS provide structure for groups to manage both communication and consensus activities. Groups using them may perceive that they have compared all ideas and know the differences and similarities between these ideas. As a result they may perceive their decision as a better one than others' (Sambamurthy & DeSanctis, 1990). They are also satisfied in the consensus reaching process since the support for consensus reaching helps them manage conflicts more easily (Sambamurthy & DeSanctis, 1990).

H5a: Groups using level-1 GSS will generate more ideas than those using level-2 GSS.
H5b: Groups using level-2 GSS will have higher decision quality than those using level-1 GSS.
H5c: Groups using level-2 GSS will take a shorter time to reach decision than those using level-1 GSS.
H5d: Groups using level-2 GSS will have higher process satisfaction than those using level-1 GSS.
H5e: Groups using level-2 GSS will have higher decision satisfaction than those using level-1 GSS.

The Existence of Facilitation

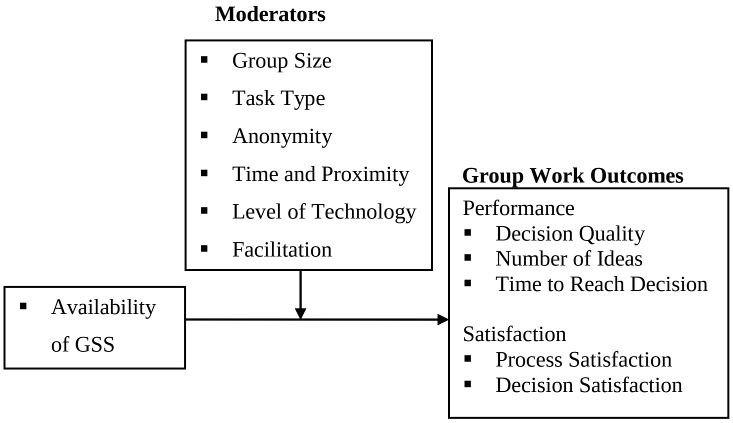
Facilitation is the external assistance on the group meeting while remaining neutral as to the content of discussion. A facilitator brings expertise regarding effective procedures and techniques to the meeting. The facilitator elicits, selects, and modifies structures drawn from expertise, from the available GSS tools, or from the members (Anson, Bostrom, & Wynne, 1995). It is generally believed that facilitation can improve meeting outcomes (Nunamaker et al., 1987). Adaptive Structuration Theory (AST) (DeSanctis & Poole, 1991; Gopal, Bostrom, & Chin, 1992; Poole & DeSanctis, 1987, 1989) highlights an additional, special role of group interaction—a means to appropriate technology-based and nontechnology structures to guide further group interaction. Structures are meant to organize and direct group behavior process. Appropriation is the "fashion in which a group uses, adapts, and produces a structure" (Poole & DeSanctis, 1989). When well-designed and relevant structures are successfully appropriated, the group interaction will be improved, which will in turn contribute to higher performance. Poole and DeSanctis (1989) suggest three dimensions which affect the appropriation of structures: faithfulness, attitudes and level of consensus. A facilitator can help the group successfully appropriate structures by providing guidance to encourage faithfulness, as well as encourage positive attitudes and consensus over the structures' use (Anson et al., 1995). Poole (1991) argues that freely interacting groups often do not effectively apply procedures unless assisted. Therefore, although the leaders and members can provide structures and support, the process may not be as effective as that with the presence of facilitators.

H6a: Groups with facilitators will generate more ideas than those without.
H6b: Decision quality will be higher for groups with facilitators than those without.
H6c: Groups with facilitators will reach decision in a shorter time than those without.

Relationships among group members may require mediation by an external source because of conflicts or power differences (Ackermann, 1996; Pinsonneault & Kramer, 1989). A facilitator can apply his or her expertise and experience of conflict management to mediate the group process effectively. Therefore, we expect the improved process satisfaction of group members. Facilitators are often experienced and well trained. Group members with facilitation support tend to think they have followed the guidance and instruction of a well-trained and experienced while neutral outsider. Therefore, they may imagine they have reached the decision under the guidance of an expert.

H6d: Groups with facilitators are more satisfied with process than those without.
H6e: Groups with facilitators are more satisfied with decisions than those without.

Figure 1. The research framework



The Research Framework

Figure 1 presents our research framework which encompasses hypotheses earlier raised.

THE META-ANALYSIS

Over almost three decades of GSS research, researchers conducted plenty of both quantitative and qualitative studies. Quantitative studies are mainly those experimental studies where the students are the main subjects and the researcher has control on the experimental settings. Researchers collect quantitative data from experts' judgment on the meeting outcomes and through post-session questionnaires.

Meta-analysis is a set of statistical procedures designed to accumulate experimental results across independent studies in the literature that address a related set of research questions. It is to deal with secondary data which are quantitative in nature. Unlike traditional research methods, meta-analysis uses the summary statistics from individual studies as the data points. A key assumption of this analysis is that each study provides a differing estimate of the underlying relationship within the population. By accumulating results across studies, one can gain a more accurate representation of the population relationship than is provided by the individual study estimators. The typical steps for meta-analysis studies include selection of studies and outcome measures, followed by analytic procedure and hypotheses testing. We adopt the meta-analysis approach as developed and detailed by Hunter and Schmidt1 (Hunter & Schmidt, 1990). Essentially, the meta-analysis procedure produces the mean effect size and a standard deviation across all studies. Positive effect sizes indicate that the mean effect of GSS use across all included studies was to increase the outcome measure (e.g., the use of GSS will increase decision quality). The following sections outline our research procedures.

Selecting Studies and Outcome Measures

The first step is to select the appropriate studies that investigate the performance of both a control group and a treatment group. We selected those studies that compare the GSS-supported groups with non-GSS-supported groups on the five outcome variables which are decision quality, number of ideas, time to reach decision, process satisfaction and decision satisfaction with statistical results. We searched various major databases such as ProQuest. Various journals are searched for relevant studies. We have also included the proceedings of Hawaii International Conference on System Sciences. The result includes studies from early 1980's to present. Since some studies have comparison for the selected moderators such as Gallupe et al. (1992) compared the effect of GSS on groups with different sizes—the study alone resulted in five data points. Therefore, we obtained 33 studies (Appendix A) with 62 data points (Appendix B).

In the included studies, the outcome variables are measured as follows: Decision quality was defined by most researchers as the correctness (intellective tasks with correct answers) or "goodness" (decision-making tasks without correct answers); Number of ideas was defined as number of ideas generated for idea generation tasks or number of alternatives generated for decision-making tasks); Time to reach decision was measured the time taken by the group to reach consensus on a particular decision; Process satisfaction and decision satisfaction are measured through the post-experimental surveys or interviews. Some variables have different measurement, thus we have adjusted them to unsure reliability during the analysis.

Analytic Procedure

In short, this procedure computes an average effect size (d) for a given dependent variable across an entire set of studies corrected for sampling error and unreliability. One shall convert the individual study statistic to d for accumulation later. Hunter and Schmidt (1990) presented the conversion equation:

$$d = \frac{X_e - X_c}{S_p}$$

X_e: Experimental group mean
X_c: Control group mean
S_p: Pooled standard deviation
and

$$S_p = \frac{(N_e - 1)S_e^2 + (N_c - 1)S_c^2}{N_e + N_c - 2}$$

The net effect of this transformation is that the differences are now standardized to a common metric across all studies, and this in turn means that effect sizes may be statistically combined and evaluated.

After converting data to a common statistic, reliability information was collected. Since not all the studies for calculating d provide reliability information, we have included all the studies that provide the reliability information of the studied moderators and outcome variables. Then we calculated the mean reliability for each moderator and outcome variable for correcting the unreliability later.

The next step is to eliminate the bias caused by sampling error. Sampling Error refers to the random variation in study results due to sample size. Smaller sample sizes tend to vary more widely from the true relationship within the population than do studies that have large samples. Accordingly weighting the effect size of a study by its sample size will provide a more accurate approximation to the relationship within the population, unaffected by the size of the sample. The sample weighted mean d is:

$$\overline{d} = \frac{\sum [N_i d_i]}{\sum N_i}$$

N_i: Number of subjects in the study
d_i: Effect size for the individual study

The sample weighted variance of d is defined by the following formula:

$$S_d - \frac{\sum [N_i (d_i - \overline{d})^2]}{\sum N_i}$$

While the sample weighted mean correlation is not affected by sampling error, its variance is greatly increased. A two-stage procedure is used to correct the variance of the sample weighted mean correlation. The first stage calculates the sampling error variance:

$$S_d^2 - \frac{K(1-\bar{d}^2)^2}{\sum N_i}$$

K: Number of studies in the analysis

To estimate the biased population variance, the sampling error variance is subtracted from $S_e{}^2$.

$$S_{BP}{}^{2\,=}\,S_d{}^{2}—S_e{}^{2}$$

So far this meta-analysis technique has corrected for one source of error, sampling error. There is another form of error: Measurement Error. Measurement Error or Test reliability is assessed by using the two reliabilities which apply to the study: $\underline{r}_{xx}$ and $\underline{r}_{yy}$. Hunter and Schmidt (1990) presented a method of correcting the sample weighted mean effect size using a distribution of reliability estimates. Any study that assesses the pertinent reliability estimates can be used to construct the reliability distribution. To conduct the reliability corrections, we constructed a distribution of reliability using all available sources. This distribution has the mean of:

$$\bar{r}_{xx} = \frac{\sum\sqrt{r_{xx}}}{K}$$

$\underline{r}_{xx:}$ Reliability for the individual study
K: Number of reliability studies

The variance for this distribution is defined as:

$$S_{xx} = \frac{\sum\sqrt{r_{xx}} - \bar{r}_{xx})^2}{K}$$

The mean reliability and variance for the dependent variable use the same formulas.

Given these statistics, the relationship within the population can be estimated. Correct the sample weighted mean of d for measurement error using the following formula:

$$\bar{d}_P = \frac{\bar{d}}{r_{xx}r_{yy}}$$

$$S_P{}^2 = \frac{S_{BP}{}^2 - \bar{d}_P(r_{xx}S_{yy}2 + r_{yy}S_{xx}{}^2)}{r_{xx}r_{yy}}$$

By now, we have the estimates of the mean and standard deviation for the population, $\bar{d}_P$ and S_P. The mean effect sizes indicate that the mean effect of GSS use across all included studies was to increase the outcome variable.

Hypotheses Testing

To test our hypotheses, we used a three-step approach developed by Hunter and Schmidt (1990). First, the studies are divided into two sets according the different criteria on the moderators. Second, a meta-analysis is performed separately on the studies within each set to produce relevant statistics for each set. Third, t-tests are used to compare the mean effect sizes between the two sets to see if there are significant differences among them.

For H1 (group size), we have split the data set into two partitions: small (five or fewer members) and large (more than five members). We choose the split point of five because it is argued that the optimum group size for nonGSS-supported groups is five (Shaw, 1981). For H2 (task type), we have split the data set into one set which deals with idea generation tasks, and another set which deals with decision making tasks. For H3 (anonymity), we have split the data set into one set that requires members to remain anonymous and another set with members identified. For H4 (time and proximity), we have split the data set into one set in which members communicate face-to-face in real time and one set with members communicating either remotely or asynchronously or both. For H5 (level of technology), we have split the data set into one set with level-1 GSS support and another set with level-2 GSS support. For H6 (the existence of facilitation), we have split the data set into one set with the support from facilitators and another set without facilitators.

RESULTS

The result of the meta-analysis is summarized from Table 2 to Table 6. They are arranged according to different outcome variables. The set of moderators that may have impact on the specific outcome variable is included in the respective Table. The first column "Number of Data Points" indicates the number of studies partitioned to this set. Rxx refers to reliability of the moderator and Ryy refers to reliability of the outcome variable. The column labeled "Uncorrected d" represents the mean effect size *d* after correcting sampling error but before correcting unreliability. The "Corrected d" column represents the mean effect size after correcting both sampling error and unreliability. "Significantly Different?" indicates whether the difference between "Corrected d" for two partitions of each independent variable is significant over dependent measures. "Hypothesis supported?" column indicates whether each hypothesized relationship is supported (Yes) or not (No), or there was not enough data to report (N.A.).

Decision Quality

Table 2 shows the moderator effects on decision quality. The first major column is the number of data points in the meta-analysis for the respective moderators, for example, 29 data points with the description of level of technology with 17 of which are using level-1 GSS. The second column is the reliability of the moderator. Since all the moderators we included in the study have definite and single measurement, the reliabilities should be 1 by definition. The third column is the reliability of the outcome variable which is decision quality. As we have mentioned above, this number is the mean value across all studies not only included

Table 2. Moderator effects on decision quality

	Number of Data Points	Rxx	Ryy	Uncor-rected d	Corrected d	Significantly Different?	Hypothesis supported?

**p<0.05, **p<0.01*

in the meta-analysis but all the studies that have included the measurement of decision quality as there are different measurement for this outcome variable, such as “goodness” and “correctness” of the decision outcome. The fourth column is the uncorrected effect size and the fifth column is the corrected effect. Since reliability is always below 1, the corrected effect size is larger than the uncorrected one. Positive numbers indicate that moderators have improved the outcome variables (with the time to reach decision as exception since a positive number indicates that the moderator has increased the time to reach a decision which means the GSS-supported meeting is less efficient). The next column reports the *p*-value for a two-tailed *t*-test of the hypotheses which compares the mean effect sizes on different values of the moderator, e.g., comparing the effect size between level-1 GSS and level-2 GSS. The final column shows whether the hypothesis is supported.

Table 2 suggests that anonymous group meetings and level-1 GSS have negative effects on decision quality (-0.079 and -0.031 respectively) comparing between the GSS groups and control groups. But neither of them is significant. In the other situations, the decision quality is improved when GSS are used. However, not all the effect sizes are statistically significant. The decision quality is improved when meeting is supported by GSS in either of the four situations or any combination of them: identity revealed (0.354); Virtual Team setting (0.652); level-2 GSS support (0.531); with the existence of facilitation (0.758).

Overall, comparing GSS groups and control groups, large groups have significantly higher mean effect size on decision quality than small groups. Using level-2 GSS also results in significantly higher decision quality than using level-1 GSS. Facilitated group meetings have higher mean effect size than non-facilitated group meetings and significant. Therefore, H1a, H5a are supported.

Number of Ideas

Table 3 shows the moderator effects on number of ideas. In all the situations when GSS are used (with the exception where Virtual Team setting is used since there are no enough studies to test the effect size), the number of ideas are not significant different compared to control groups. The moderator effect of time and proximity cannot be tested due to the lack of data in the Virtual Team setting. Hence H1b, H3b, H5b, H6b are not supported, and H4b cannot be tested.

Time to Reach Decision

Table 4 shows the moderator effects on the time to reach decision. In all the situations when GSS are used, the mean time needed to reach a specific decision is increased compared to control groups with the increase in time occurred (effect sizes) in the following conditions: small groups supported by GSS (2.357), meetings with identified participants (2.376), Virtual Teams formed to make decisions (2.638), level-1 GSS used (2.221), and group meeting without facilitation (2.376). Therefore, H1c, H3c, H4c, H5c, H6c are not supported.

Process Satisfaction

Table 5 summarizes the moderator effects on satisfaction of meeting process. The resulting effect sizes are mixed. In some situations, the effect size is negative that is, participants are less satisfied with the meeting process in the GSS-supported group meetings than in the non-GSS-supported group meetings. In these situations, when the group size is small or the group is targeting a decision-making task, there is a significant decrease on the process satisfaction (-0.545). In the other situations, the effect size is positive. In these situations, only when the group size is large, there is a significant increase on the process satisfaction (0.32).

**p<0.05, **p<0.01*

Large groups are significantly more satisfied with meeting process; Groups dealing with idea-generation tasks have significantly higher process satisfaction than those dealing with decision-making tasks; The moderator effect of time and proximity cannot be tested due to the lack of data in the Virtual Team setting. Therefore, H1d, H2 are supported while H3d, H4d, H5d, H6d are not.

Decision Satisfaction

Table 6 summarizes the moderator effects on decision satisfaction. The resulting effect sizes are mixed. In most situations, the use of GSS decreases the participants' satisfaction on decision outcome (only when level-2 GSS are present, the decision satisfaction is increased but not significantly). However, none of the effect sizes is significant except when level-1 GSS are in place.

The moderator effect of group size cannot be tested due to the lack of data in case that group size is 6 or above; The difference between anonymous group meetings and identified ones is small and not significant; The difference between Virtual Teams and face-to-face teams is also small and not significant; Level-2 GSS can achieve better decision satisfaction than level-1 GSS, but the difference is not significant; The presence of facilitators helps the group to increase the decision satisfaction but neither significantly different. Therefore, H1e cannot be tested; H3e, H4e, H5e and H6e are not supported.

DISCUSSIONS

The main objective of this study was to better understand the moderators that affect group performance when using collaborative technologies. The

$*p<0.05$

interaction between the moderators and factors is also investigated in the article. We investigated six potential moderators on five different outcome variables. We tested 26 hypotheses while only 4 of them (H1a, H1d, H2, H5a) are supported by the results from meta-analysis. H4b and H1e cannot be tested due to the lack of quantitative evidence we can find. The remaining 20 hypotheses are not supported. None of these hypotheses can be tested by tabular review on qualitative part of the research because the past research focuses on certain type of GSS application and environment, for example, those studies mainly studied groups under face-to-face setting. However, they generally proved that GSS do help groups achieve better meeting and group outcomes in the above mentioned five dimensions.

Group Size

Group size plays an important role on decision quality and process satisfaction. In the context of computer supported collaborative learning, group size has been identified as an important factor that requires further investigation with respect to group interaction (Strijbos et al., 2003). Interaction patterns and learning benefits differ among dyads (two members), small groups (three to six members) and large groups (seven or more), especially if participation equality or group-generated products are required (Strijbos et al., 2003; Wilkinson & Fung, 2002). Larger groups can achieve higher decision quality and are more satisfied with the process. However, there was no significant difference between decision qualities of larger GSS groups and non-GSS groups. Neither is there between smaller GSS groups and non-GSS groups. But after the comparison of the mean effect sizes, we were able to show that larger groups did obtain more significant improvement on decision quality than smaller groups. Whereas, smaller groups were significantly less satisfied with the process (*d*=-0.545) while larger groups were significantly more satisfied with the process (*d*=0.32). In previous research on nonGSS groups, larger group size is often related to production blocking and free riding. However, with the presence of GSS and the parallel input feature, large group size (six and above) does not contribute as a hindrance to optimum group outcomes any more (Sawyer et al., 2001). In contrary, larger groups promote more individual contribution to the group and more justification on the decisions.

On the other side, with the presence of GSS, larger groups do not help on groups to generate more ideas. One plausible reason is related to the issue of group composition involved in the experiments. In most studies, the groups were mostly formed by student subjects from similar backgrounds and cultures. They tend to think and behave as shaped by their background, culture and experiences. This similarity prevents them from thinking in completely different view of points, which does not make GSS a significantly better tool for larger groups to generate more ideas than smaller groups. This result has important implications in designing collaborative learning activities for distributed learners in CSCL system designers; GSS may enable a more effective communication in large groups involving learners from different cultural backgrounds.

Task Type and Level of Technology

Task type has a significant influence on process satisfaction. The effect size on process satisfaction was significantly higher for groups dealing with idea generation tasks than for groups dealing with decision making tasks. Specifically, GSS groups dealing with idea generation tasks were more satisfied with the process than non-GSS groups (*d*=0.388). Whereas, GSS groups dealing with decision making tasks were significantly less satisfied with the process than non-GSS groups (*d*=-0.453). That is mainly because the idea generation process is easier to be supported by GSS. In idea generation process, the GSS need only provide an electronic communication media to facilitate parallel inputs. However, for decision-making process, additional technologies that help the group in conflict management and facilitate the group to reach consensus are required. The use of GSS adds in additional challenge and complexity. Therefore, groups are less satisfied with the process.

In this regard, the features and structures supported by GSS should vary according to the task. **The level of technology** does affect significantly on decision quality. Level-1 GSS did not improve the decision quality (*d*=-0.031) while level-2 GSS improved the decision quality significantly (*d*=0.531). This can be explained that level-2 GSS provide additional support on decision making and consensus reaching compared to level-1 GSS. Level-2 GSS can help groups clearly organize, rank and present information and ideas by providing supporting tools. Therefore, the group members can have a clear and well-organized picture of the problems and possible solutions. The decision quality thus can be improved based on this deeper understanding.

The objectives of supporting collaborative learning through GSS are not only to duplicate the feature and effectiveness of face-to-face environment, but also to use the technology to create a more effective learning environment (Alavi et al., 2002; Turoff & Hiltz, 1995). Findings regarding task types and level of GSS support have highlighted the notion of the fit between the learning tasks and GSS support when instructors design the collaborative learning activities. As idea generation and decision making are both common activities in collaborative learning (Ready et al., 2004), level-1 GSS are generally more suitable for idea generation (e.g., brainstorming) and level-2 GSS are more preferable if learners are required to make a decision as a group. The level-2 GSS could improve the efficiency and effectiveness of group decision making either by optimizing the decision marking process or maximizing the quality of the outcome (Kwok, Lee, Huynh, & Pi, 2002).

Anonymity

Anonymity has been considered as one of the important features that help ease the cognitive load and encourage participation so as to improve the efficiency and effectiveness of group meeting (Dennis, Tyran, Vogel, & Nunamker, 1997; Kwok et al., 2002). However, we find in this study that anonymity did not make significant differences on the outcome variables. A plausible reason is that anonymity is hard to maintain in long-term and established groups (Guiller & Durndell, in press). Although it is claimed to be anonymous, other members can still guess the one's identity by looking into the styles of writing and ways of organizing ideas. In an ad-hoc group, anonymity can hardly have significant effects since the group members are new to each other, thus whether to keep the identity unrevealed does not make much sense unless the group has worked collaboratively on some projects before.

The anonymity feature tends to reduce interpersonal communication (Markus, 1994); as a result, in the educational contexts, students may be less responsive to the ideas of their peers during discussion, therefore hampering the extent of affective learning. On the other hand, due to the anonymity feature, the absence of social context cues in discussion is able to eliminate the undesirable influences caused by hierarchy, status and power, thus leading to relatively more equal participation among all learners (Guiller & Durndell, in press). Indeed, the effects of anonymity and how to use this feature properly deserve a closer look in future research.

Time and Proximity

The key role of technology application in supporting CSCL is to enable flexibility, timeliness, and increased frequency of group interaction and communication processes (Alavi et al., 2002). In this study, we found that **time and proximity** did not make any significant differences on decision quality, time to reach decision and decision quality in decision making tasks (the difference on number of ideas and process satisfaction could not be tested due to the lack of data). This indicates the potential of GSS in supporting collaborative learning across different locations and time zones. Furthermore, in most of the primary studies, users have access to communicate verbally either through Video-conferencing or telephone networks. Therefore, verbal communication is believed to remain critical for the group to converge on a decision and it should not be overlooked in collaborative learning activities. This suggests that instructors should try to provide means for learning groups to communicate verbally to achieve better decision-related outcomes such as decision quality, time and satisfaction.

Existence of Facilitation

Finally, the **existence of facilitation** does not have significant effects on the outcome variables. Careful and effective facilitation skills—by taking into consideration facilitator's expertise, prior experience, group member expectations and group task—are important to achieve better outcomes in using GSS in collaborative learning (Khalifa, Davison, & Kwok, 2002). However, intensive training to ensure facilitators equipped with careful and effective facilitation skills may not be attainable in the experimental settings; this possibly explains the absence of effects of facilitation on the outcome variables in the meta-analysis. Nevertheless, the role of facilitation is not to be totally dismissed in the context of CSCL. Along this line, Khalifa et al. (2002) call for more studies to address the effects of facilitation on the process and outcome of e-learning. Accordingly, we suggest that in order to make facilitation a means to effectively improve group outcomes, the facilitators must carefully manage the technologies as well as the meeting process. It is conceivably more effectively for the leadership and facilitator roles to be assumed by the same individual. Facilitators who are using

GSS to support collaborative learning need to be aware of as well as attempt to meet the related new requirements (Clawson, Bostrom, & Anson, 1993). For example, facilitators should select the appropriate technology, promote understanding of the technology, and help reinforce an open, positive, and participative environment in learning groups.

CONCLUSION

The central theme of the article is to assemble the findings from a set of studies to draw overall conclusions about a phenomenon of interest (Hunter & Schmidt, 1990). The current study has utilized the mechanism of meta-analysis to attain a deep understanding on prior studies and to provide direction for future research.

Based on the results of the analysis, we have highlighted the patterns on how key factors play their roles in affecting important outcomes of concern to computer-supported group work. The implications to CSCL technology design and implementation would contribute to advancement of understanding of enhancing collaborative work in educational settings.

Although GSS were originally designed to support discussion and decision making in the commercial organizations, there has been a growing interest in their usage to support collaborative learning (Alavi, 1994; Khalifa et al., 2002; Vogel et al., 2001). Studies have shown that group-based collaborative learning methods have been applied successfully for university as well as primary school students (Johnson & Johnson, 1994; Salomon & Globerson, 1989). It is not surprising for groups of learners to experience the same or similar types of problems faced by groups in non-educational settings (Tyran & Shepherd, 2001). In this light, findings born by this meta-analysis can have important implications for the CSCL context. Flexibility is a key in the design of GSS in order that maximum benefits may be reaped when catering to the needs of different task and group conditions. In past research, level-3 GSS were rarely used since the technology was not sufficiently mature. With the advancements of computer and communication technology, a more powerful and improved GSS can be built which may include artificial intelligence to automate the facilitator's job.

The use of the meta-analytic technique naturally implies inheritance of the limitations of the technique itself (Hunter & Schmidt, 1990). A limitation of the current analysis is the exclusive use of experimental studies. While quantitative studies are required for meta-analysis, generalization to the real-world situation may not be desirably strong. Future research should take into account both quantitative and qualitative findings to enrich the understanding towards a holistic view of computer-support group work.

Further efforts are called for to address the following. First, while technology has enabled Virtual Team to perform the same tasks as face-to-face teams, there exist disproportionately few studies that have examined Virtual Teams in the context of collaborative distance learning. More work is needed in this regard. Next, while the current study has selected six moderators from the model of Fjermestad (1998), there are conceivably a good number of other potential moderators. It is necessary for future research to investigate their effects. Another focus concerns the possible interactions between moderators; these should be examined to arrive at a richer theoretical framework.

Chapter 1.15

Supply Chain Information Systems and Decision Support

Liam Doyle
Waterford Institute of Technology, Ireland

INTRODUCTION

Supply chains have become have become increasingly important as organisations have moved from competing on a stand-alone basis to recognizing that their success depends upon their trading partners. This includes their upstream suppliers and downstream customers. A supply chain involves a number of tiers of suppliers and customers that extends from the initial source of raw materials through to the final consumer of the finished product.

Supply chain management involves the coordination of a number of functional areas in multiple organisations. Large amounts of information can be captured describing the activities in these organisations. It is possible to use this information in order to assist in decision making at strategic, tactical, and operational levels of the supply chain. The large volume of information available and the interdependencies between the activities within these multiple organisations means that it is necessary to employ computerized decision support systems to optimize supply chain activities.

BACKGROUND

Christopher (2005, p. 4) defines logistics as

> *the process of strategically managing the procurement, movement and storage of materials, parts and finished inventory (and the related information flows) through the organisation and its marketing channels in such a way that current and future profitability are maximised through the cost-effective fulfillment of orders.*

While logistics focuses on the movement of materials, Christopher (2005) describes supply chain management as being broader and defines supply chain management as "the management of upstream and downstream relationships with suppliers and customers to deliver superior customer value at less cost to the supply chain as a whole" (p. 5).

Porter's value chain model describes an organisation as a set of primary and support activities. The excess of the value added by the primary activities over the costs incurred by all the activities of the organisation provide the organisation's margin (Porter, 1985). The excess of value delivered to the customer over costs incurred throughout the supply chain represents the margin available to be shared among the supply chain participants. There has been a move away from traditional, transaction-oriented logistics practices which served to maximise the profitability of the individual firm. The relationship between supply chain participants has changed from being adversarial in nature to being cooperative. Organisations seek to increase the profitability of the supply chain as a whole and to share the available margin. Relationships between organisations have changed from a zero-sum game to a win-win situation.

Since the early 1990s, the process view of organisations has been mooted as a preferred alternative to the traditional functional structure. A process is a set of related activities which take place in a number of different functional units. A process-oriented organisation seeks to optimise the overall process in order to meet the needs of the end-customer of that process. This contrasts with the functional view which seeks to optimise individual functional units and which leads to suboptimal overall performance and which tends to ignore the needs of the customer.

The supply chain concept extends the process view to include multiple organisations. Processes which extend across organisational boundaries seek to satisfy the needs of the end-customer in an optimal manner. The profitability of each organisation in the supply chain depends on the success of the supply chain as a whole in serving the needs of the customer. Ultimately it is from the end-customer that funds are made available throughout the entire supply chain.

The execution of these interorganisational processes generates large amounts of data which can be shared among supply chain members. This information can be used to aid decision making to support the complex task of managing the supply chain. The major areas which require decision support are production planning, transportation, and inventory control.

SUPPLY CHAIN INFORMATION SYSTEMS AND DECISION SUPPORT

The process view of organisations as espoused by Hammer (1990) and Davenport and Short (1990) identified the interdependent nature of activities within organisations and promoted the alignment of these activities to focus on the customer. The move away from functional silos, which treated each functional unit as independent, required a sharing of information between these functional areas. The move to process-oriented organisations was hampered by the limited power of available information technologies at that time. Many organisations had computer applications which existed as islands of automation within these functional silos. These applications were not designed to share information and in many cases the applications and their data were incompatible. There emerged a business requirement for applications which were more process-oriented and which could serve to integrate multiple functional areas within the organisation. This period also saw the development of more powerful information and communication technologies. Local area networks, client-server computing, database servers, application servers, and Internet technologies were adopted by many organisations and facilitated the deployment of interfunctional information systems. Linked applications helped move away from islands of automation to provide a seamless flow of information.

Supply chains can be seen as a set of linked value chains. For example, the outbound logistics activity of one value chain links with the inbound logistics activity of its downstream partners. Cooperation can also exist in activities such as marketing and research and development. In order to meet the needs of the end-customer, the principles of integration that have been applied to internal company activities should be extended to activities that span the supply chain. The development of integrated activities requires a strategic approach. Organisations that have taken a process view of their internal activities have moved from having strategies which have an intracompany intraoperation scope which seeks to minimise local costs to having strategies with an intracompany interfunctional scope. Extending the strategy to include supply chain partners leads to an intercompany interfunctional scope (Chopra & Meindl, 2004, pp. 44-49).

Organisational structure and processes should be designed in order to support the chosen strategy. Harmon (2003) advocates the development of a process architecture to meet the goals set out in the organisation's strategy. Information technology (IT) planning should be informed by, and support, the process architecture. An intercompany interfunctional strategy requires processes that cross organisational boundaries and interorganisational information systems to support these processes. These processes should be designed to meet the needs of the end-customer and the information systems used should assist in the operation and management of these processes.

A number of generic supply chain processes have been proposed. The Supply Chain Council has proposed the Supply Chain Operations Reference (SCOR) model. This model includes five top level processes which are plan, source, make, deliver, and return. These are decomposed into a number of level 2 and level 3 subprocesses (Harmon, 2003). Lambert and Cooper (2000) propose a number of supply chain processes. These are customer relationship management, customer service management, demand management, order fulfillment, manufacturing flow management, procurement, product development and commercialization, and returns. These processes rely on the flow of information across the supply chain.

STRUCTURE OF THE SUPPLY CHAIN

The structure of the supply chain depends upon the nature of the product and the nature of demand for the product. Fisher (1997) stated that functional products require efficient supply chains whereas innovative products require responsive supply chains. Efficient supply chains are associated with the concept of leanness, which developed from the Toyota Production System and which emphasizes cost reduction. Responsive supply chains are associated with the concept of agility which developed from flexible manufacturing systems. Christopher (2000) associates lean supply systems with products that have low variety/variability and high volume demand conditions. He associates agile supply systems with products that have high variety/variability and low volume demand.

Webster (2002) states that the appropriate supply chain structure exists on a continuum from lean to agile. Lean supply chains, which can be regarded as rigid supply pipelines, use a fixed streamlined approach with dedicated links and long-term trusting relationships. Lean supply chains emphasise the meeting of customer requirements in an efficient manner. Agile supply chains have a more fluid and flexible structure and can be regarded as virtual organisations which form to meet market demand and disperse once the need has been met. Agile supply chains are loosely based and use short-term flexible contracts. Agile supply chains emphasise the meeting of customer requirements in an effective manner (Webster, 2002).

SUPPLIER SELECTION

It is important that an organisation selects suppliers that can match the needs of the chosen supply chain structure. Zeng (2000) describes supplier selection as a strategic decision. A supplier selection process seeks to identify and choose appropriate suppliers. The selection decision should involve participation from a number of functional areas within the organisation including quality assurance, research and design, manufacturing, purchasing, and accounting. The selection criteria should include material specification review, equipment capability, quality assurance, financial capability, cost structure, supplier value analysis effort, and production scheduling (Zeng, 2000). Boer, Labro, and Morlacchi (2001) provide a review of supplier selection methods. Weber and Ellram (1993) describe a decision systems approach to supplier selection. Kahraman, Cebeci, and Ulukan (2003) describe a decision support system that uses fuzzy analytic hierarchy process (AHP) to select suppliers based on supplier, product performance, service performance, and cost criteria.

Organisations may choose to use multiple sourcing where a number of suppliers are chosen for a given product or family of products. This allows flexibility, helps reduce risks, and increases competition between suppliers. Multiple sourcing may be more appropriate for short-term contracts (Zeng, 2000). The use of multiple sourcing can help reduce the bargaining power of suppliers and may be more appropriate for agile networks.

In single sourcing, one supplier is selected to meet the needs of the organisation for a given product or family of products. Single sourcing leads to improved communication and closer cooperation between the organisation and its suppliers. Transaction costs may be reduced and the trading partners can enjoy a stable long-term relationship (Zeng, 2000). Single sourcing arrangements may be more appropriate for lean supply chain structures.

Given the increasing globalization of markets, many organisations are considering global sourcing. Global sourcing enables an organisation to rationalize its supply base on a worldwide basis. Monczka and Trent (1991, in Zeng, 2003, p. 367) define global sourcing as “the integration and coordination of procurement requirements across worldwide business units, looking at common items, processes, technologies and suppliers.” A number of factors take on an increasing importance in the sourcing decision when using global sourcing. These factors include customs procedures, transport and communications infrastructure, and transport lead times for various modes of transport.

There has been a movement away from simple outsourcing arrangements to contract manufacturing. This enables the creation of virtual organisations based on the dynamic creation of links to suppliers. The Li & Fung trading company of Hong Kong is an example of a company which operates an agile supply system based on contract manufacturing and linking suppliers and buyers on a global basis. This agile system allows Li & Fung to match the rapidly changing demands of its customers with the production capabilities of thousands of suppliers (Chan & Chung, 2002).

Appelqvist, Lehtonen, and Kokkonen (2004) describe a framework for supply chain decision making in which different approaches to decision making are appropriate depending on whether a new or existing supply chain, and whether a new or existing product is involved. These situations vary in terms of availability of data, constraints and decision variables, and time horizons. Different approaches to modeling are appropriate in these cases.

The performance of suppliers must be monitored in order to facilitate decisions which impact on the optimal functioning of the supply chain.

Lambert and Cooper (2000) describe a number of types of supply chain process links. Managed process links are links that the company regards as important to integrate and manage. These include links to first-tier suppliers and customers and other important links further along the supply chain. Monitored process links are not as important to the company but are considered as important to be integrated between the other participants. Not-managed process links are not actively managed and are not considered important enough to monitor. Zeng (2003) describes a generalised five-stage process which can be used for supplier selection and management decisions. The stages in this process are investigation and tendering, evaluation, supplier selection and development, implementation, and performance measurement and continuous improvement.

The decisions taken regarding choice of lean or agile supply chain, and single or multiple sourcing leads to a network structure that can be described by a number of variables. Horizontal structure determines the number of links from initial supplier to end-customer. Vertical structure determines the number of participants at each stage of the supply chain. Horizontal position describes how close the organisation is to the end-customer or initial source of supply. Organisations must decide which processes they will implement across the supply chain (Lambert & Cooper, 2000).

For each process implemented, a set of performance measures should be selected. These measures should focus on the steps necessary to satisfy the needs of the end-customer. Data should be captured for these measures and this data should be monitored. This information should be made available, as appropriate, across the supply chain. This data can be used as feedback to facilitate decision making in order to control the processes (Harmon, 2003).

An information flow facility allows transactional and management data to be distributed across the supply chain on a real-time basis (Lambert & Cooper, 2000). This facilitates integration of process activities in various supply chain participants. It also supports real-time decision making to respond to the needs of the end-customer and to respond to changing conditions. The information flow facility can influence the efficiency and effectiveness of the supply chain.

The management of supply chain processes can help overcome supply chain uncertainties. Uncertainties exist in terms of the volume and nature of demand and the availability of supply. Demand uncertainty exists in terms of required volumes, response times, variety, service levels, and price. Supply uncertainty exists because of breakdowns, predictability of yields, quality, supply capacity, supply flexibility, and maturity of production process (Chopra & Meindl, 2004 pp. 31-34). Organisations must make informed decisions in light of supply chain uncertainties.

Demand uncertainty is the greatest source of demand variability. In addition, variability in demand tends to become amplified along the supply chain thus causing difficulties in the planning and execution of operations. This tendency for increasing variability has been labeled the bullwhip effect (Lee, Padmanabhan, & Whang, 1997). In many cases the level of variability further up the supply chain is greater than the actual underlying customer demand. A major cause of the bullwhip effect is that planning decisions are based upon forecasts, which, by their very nature, are inaccurate. As forecasts further up the supply chain are based on forecasts downstream in the supply chain the level of error is compounded. Other causes of uncertainty arise from issues such as forward buying to take advantage of favourable trade terms such as discounts and overordering to overcome rationing of scarce products. The timely availability of actual underlying marketplace demand data can help overcome the difficulty whereby many participants in the supply chain cannot respond appropriately to the marketplace (Handfield & Nichols, 2002; Lee et al., 1997; Mason-Jones & Towill, 1997).

INFORMATION AND INVENTORY

Inventory exists at the interface between organisations in the supply chain. This can take the form of raw materials, components, and subassemblies. Inventory is held by suppliers in order to meet possible future demand from downstream. Inventory is held by buyers in order to offset any delays in supply. The outbound logistics function and inbound logistics function of organisations are therefore involved in handling levels of inventory that exceed the immediate demands. In many cases, the level of excess inventory can be measured as many months of actual demand. Decision making, based on shared information regarding actual market demand and available capacity, can help reduce the amount of inventory held at various stages, and in different forms, along the supply chain. This has been a driver for various initiatives such as Just-in-Time (JIT), vendor managed inventory (VMI), collaborative planning forecasting and replenishment (CPFR), and efficient customer response (ECR) (Handfield & Nichols, 2002; Lee et al., 1997).

The integration of logistics capabilities of supply chain participants requires information visibility. This enables the balancing of demand with available capacity. Capacity exists in a number of forms including production, inventory, and transport. Given the interdependence of these functions, both within and across organisations, decision making requires an integrated view be taken.

It is often at the interface between functional units or organisations that difficulties arise in business processes. It is at these interfaces that particular attention needs to be paid in process design efforts (Harmon, 2003). The existence of excess inventories is an example of such difficulty. The availability of up-to-date demand and supply information can help reduce the level of excess inventory held. Information can therefore act as a substitute for inventory.

Webster (2002) proposes information and inventory as two supply chain management variables. Technology and relationships are the two variables proposed. Technology is described as an enabler of integration. The form taken by these management variables should be appropriate to the supply chain structure which exists on a continuum from agile to lean. The structure depends on the product type and demand profile. The performance of the supply chain depends on these management variables and can be measured in terms of effectiveness and efficiency (Webster, 2002).

INFORMATION SYSTEMS FOR SUPPLY CHAIN MANAGEMENT

Information systems for use in supply chain management have evolved over a number of decades. They progressed from stand-alone islands of automation supporting narrow functions within business units to become highly integrated systems spanning organisational boundaries. Manufacturing planning and control systems have their origin in the double-entry bookkeeping system developed by Luca Pacioli in 1494 (McCarthy, David, & Sommer, 1996), and in the manual stock reordering systems operated by foremen in the industrial plants in the 1800s. Initial computer applications were automated reorder point systems. Functionality was extended to include forward looking demand based planning and production reporting tool thus giving computerized materials requirements planning (MRP) systems. The addition of capacity requirements planning led to the development of manufacturing resource planning (MRP-II) systems. Further expansion to include functional areas such as marketing, finance, and human resources led to the development of enterprise resource planning (ERP) systems (Rondeau & Litteral, 2001).

The development of systems such as electronic data interchange (EDI) for sharing information across organisational boundaries means that information systems now link functional units in a number of organisations. A well known example is that of Wal-Mart and Procter and Gamble. Wal-Mart shares point-of-sale data with Procter and Gamble, who use this data to manage the replenishment of stock in Wal-Mart stores. Wal-Mart benefits by having well stocked stores while Procter and Gamble benefits by being able to respond to actual market demand thereby improving decision making for production and distribution (Mason-Jones & Towill, 1997).

Organisational complexity demands integrating mechanisms (Lawrence & Lorsch, 1967). These large-scale integrated information systems act as integrating mechanisms for complex systems such as supply chains. The evolution of these systems is recognition of the interdependent nature of the activities involved. ERP systems provide horizontal integration across functional units. At an operational level, execution systems assist in the planning and control of daily activities. Manufacturing execution systems (MES) facilitate the planning and control of the production function. Warehouse management systems (WMS) assist in the planning and operation of activities involved in inventory control. Transportation management systems (TMS) assist in planning and operation of activities involved in the physical movement of goods along the supply chain. Vertical integration links these execution systems with enterprise systems.

ANALYTIC SYSTEMS

An information flow facility can help integrate information systems across organisational boundaries and enable integrated supply chain processes. Integration can also be achieved between analytical and transactional systems (Helo & Szekely, 2005). Analytical IT systems can be used to model and optimise the supply chain at a number of levels. Modeling systems can be used for strategic analysis and long-term tactical analysis. Modeling can also be employed for short-term tactical analysis for production planning optimization and logistics optimization. Operational analysis can assist in decision making for optimization of production and distribution scheduling. Operational analysis systems can have integrated links with transactional IT systems (Helo & Szekely, 2005; Shapiro, 2002). A wide variety of analytical techniques can be used for advanced planning and scheduling. These include linear programming, heuristic programming, genetic programming, and constraint based programming. The use of analytical techniques combined with transactional data from across the supply chain can provide for improved accuracy, reliability, and control. The large volumes of data involved suggests that data warehousing, data mining, statistical analysis, and online analytic processing (OLAP) techniques can be employed to facilitate decision support.

FUTURE TRENDS

As information technology becomes embedded in physical systems, the availability of information to assist in supply chain management increases. Examples include the use of geographical positioning systems (GPS) to track movement of vehicles, radio frequency identification (RFID) tags to trace movement of containers and packages, and the use of laptop computers on forklift trucks. Data obtained with these systems can be captured in execution systems such as WMS and TMS systems. This data in turn can be integrated with enterprise level systems. Information can therefore enable coordination of activities across the supply chain and can enable the supply chain to operate on a sense-and-respond basis (Kumar, Karunamoorthy, Roth, & Mirnalinee, 2005; Power, 2005).

To date, many supply chain information systems have operated on the basis of passing data in standardized structured formats such as EDI messages. In the future, it is likely that supply chain systems will use technologies such as the extensible markup language (XML), component based systems, service oriented architectures (SOA), and Web services. Instead of simply the passing of data, there is likely to be a greater lever of integration between applications. Enterprise application integration (EAI) will allow applications to be developed which call on the processing capabilities of other applications some of which may exist in other organisations in the supply chain.

Folinas, Manthou, Sigala, and Vlachopoulou (2004) describe the changing nature of information and decision making processes as supply chains evolve. Decision support applications to support supply chain management have been designed to operate at different levels of the organisational hierarchy. A system to assist with the selection of suppliers and the dynamic configuration of supply networks has been described by Helo, Xiao, and Jianxin (2006). Verwijmeren, van der Vlist, and van Donselaar (1996) described a design for a system to assist in the management of inventory at multiple stages along the supply chain. Swanepoel (2004) describes an integrated decision support system that supports decision making at both operator and managerial level in a manufacturing setting.

CONCLUSION

The availability of more powerful technologies to process, store, and transmit information will facilitate the development of supply chain applications. The large amounts of transaction data and process monitoring data generated by these applications, coupled with the complexity of the supply chain and of the marketplace and the need to react swiftly to the changing needs of customers, necessitates the use of powerful decision support applications. Further research is needed to investigate how decision support technologies can be applied in this area.

KEY TERMS

Information Flow Facility: An information flow facility is the combination of information technologies which facilitates the bidirectional flow of information between participant organisations in a supply chain.

Manufacturing Execution System: A manufacturing execution systems allows for recording, reporting, online enquiry, planning, and scheduling of production floor activities.

Process Architecture: A process architecture is a hierarchical description of the large scale processes, subprocesses, and activities that occur within an organisation.

Supply Chain: A supply chain is a network of organisation involved in producing and delivering a finished product to the end-customer. Supply chains exist for goods and services. From the viewpoint of a focal organisation, a supply chain involves a number of tiers of suppliers and of buyers. A supply chain involves the flow of products, funds, and information.

Supply Chain Management: Supply chain management is the set of activities carried out at strategic, tactical, and operational levels to manage the interorganisational processes involved in providing products that meet the needs of end-customers.

Transportation Management Systems: A transportation management system (TMS) is used for the short term planning of movement of material in a manner which optimises the use of resources. A TMS facilitates the scheduling of both intercompany and intracompany movement of materials, processes the associated transactions and assists in the preparation of associated documentation.

Warehouse Management System: A warehouse management system is used to control the movement and storage of materials with one or more warehouses in a manner which seeks to optimise the use of space, labour, and equipment.

Chapter 1.16

Strategic Decision Making in Global Supply Networks

Ozlem Arisoy
University of Pittsburgh, USA

Bopaya Bidanda
University of Pittsburgh, USA

INTRODUCTION

Globalization has inexorably affected the economies of many nations in both the developed and developing world. As a consequence, national boundaries are becoming less important to the large, multinational corporations who now operate on a global scale.

Corporate global networks range from short term outsourcing contracts to long term investments in developing countries that offer low cost operations and/or the promise of future market expansion. Today the Internet and high-speed data networks enable knowledge tasks to be completed practically anywhere in the world, allowing companies in the developed world to achieve cost savings or simply stay competitive enough to survive by shifting work offshore (Saunders, 2003; Schultz, 2004). As a result, an increasing shift of work to low-cost countries will continue for the foreseeable future.

Global supply networks decisions such as supplier selection and distribution assignments are strategic decisions that involve medium to long term commitment. These decisions in turn affect the organization's future business structure, competitiveness and market value. In the literature there are numerous studies dealing with global supply network decisions in the context of mathematical modeling, risk assessment and conceptual strategic evaluations. The literature can be divided into two categories with respect to the application of tools that are used to analyze and model the corporate decision making processes. One stream of literature extensively utilizes operations research techniques to model the supply networks and assess the profitability of production (or service) operations on the basis of quantitative variables. The other stream of literature concentrates on intangible determinants and evaluates the drivers and consequences of global operations by examining the business conditions, risk factors, opportunities and many other qualitative as well as quantitative variables. In the next sections, a conceptual framework will be developed to examine the structure, determinants, and outcomes of global operations. A broad review of the literature will be presented, and novel modeling approaches will be summarized while discussing the complexity of global supply network decisions and the necessity for integrated methodologies.

GLOBAL SUPPLY NETWORKS AND OUTSOURCING

The ever-increasing pace of information and communication technology allowed corporations to distribute their operations all over the world. Today the global supply network refers to a complex set of business relationships that consist of not only the distinct elements of the supply chain (i.e., supplier, distributor, and retailer) but also the operational divisions within a company, including accounting operations, human resources and customer service among others. The intense competition among many industries imposes pressure on corporations to elevate productivity and reduce costs by transferring activities to more efficient vendors that can add a competitive edge with their specialization. Offshore outsourcing (or simply “outsourcing”) especially is a growing trend leading to further transnational distribution of corporate activities. Research indicates that, when well designed and well managed, outsourcing reduces operating costs, enhances competitive strategy, and enlarges shareholder value (Bryce & Useem, 1998).

There are many reasons for companies to distribute their operations either in the form of outsourcing to different parties or by investments in different regions of the world. The primary objective is to reduce the costs of services and products by utilizing the low labor-rates in developing countries such as China and India. The initiative towards improving the focus of core competences such as R&D and market research also plays an important role. According to Ferrell (2003), and more than 800 executives in the United States and Europe think that cost savings are still a key outsourcing benefit, but the additional business controls generated by outsourcing are driving the trend to external providers.

The determinants of global supply network decisions can be divided into two interrelated classes in terms of the elements of competitiveness: cost competitiveness and organizational competitiveness.

Cost Competitiveness

Cost is usually the initial major determinant in global supply network decisions. The selection of supplier location, logistic structure, distribution network and many other components of decisions are based on the objective of minimizing the total cost. For a global supply network, the total cost accounts for the aggregation of product/service costs along with the costs of relocation, documentation and communication. Although in many cases, supply networks are designed based on calculations of projected variable and fixed costs, the actual practice of operations involves the hidden costs that are frequently overlooked. The cost of selecting a vendor, contracting costs, transfer costs and many other costs associated with organizational change and management are incurred over the lifetime of global operations. Vining and Globerman (1999) describe the cost of outsourcing as a function of three variables: Production costs, bargaining costs and opportunism costs, with the latter two being costs of governance. Bargaining costs include the costs arising from negotiating contract details, costs of negotiation changes to the contract in the post contract stage, the cost of monitoring whether performance is being adhered to by the other party, and the cost of disputes. Opportunism is defined as any behavior by a party to a transaction that endeavors to change the agreed terms of a transaction in its favor.

Therefore, the cost of a global supply chain should be perceived as the sum of foreseeable financial values as well as the possible fees and expenditures that can emerge as a result of segmentation of business processes. To facilitate an increase in cost competitiveness, the strategic decisions on global supply networks should be based on a projection of complete cost values.

Organizational Competitiveness

Competitive advantage is the ability of a firm to outperform rivals on the primary performance goal: profitability (Grant, 2004). By this definition, an organization inevitably elevates its profitability, and therefore gains competitive advantage if the costs of products/services are lowered in comparison to the other existing players in the market. In addition to the cost advantage, in order to maintain competitiveness in the long run, an organization needs to differentiate itself relatively to its rivals. For many organizations, research and development activities are of the utmost importance in maintaining the core competence. Even in mature markets where there is little room for innovation, it is important to create new marketing ideas and achieve quality improvement to preserve market share. Organizations are able to focus on these core functions by transferring custom business processes, such as accounting and information systems, to specialized vendors around the world. On the other hand, other factors of competitiveness such as responsiveness, customer service, and flexibility may be adversely affected by the decentralization of operations and authority. The risk of intellectual property theft due to the multiplicity of vendors and the irregularity of protection laws is another area that underscores the importance of indefinable elements of supply chain decisions.

DECISION MODELS

Researchers and practitioners have investigated the performance, design and analysis of global supply networks and provided numerous decision models based on a diversity of methodologies. While incorporating the entire dynamics of the problem into one method is difficult, the majority of the work presented in the literature delineates promising schemes for superior strategic decisions in global supply networks.

Mathematical Formulation Based Approaches

The mathematical formulation based literature on decision models in global supply networks mostly includes tools from decision sciences, operations research and economics. These models typically include financial parameters and solve global supply network problems to provide solutions to production quantities, production locations, distribution routes, etc. The following gives examples from various disciplines that model the global supply network decisions utilizing different techniques.

Arnzten et al. (1995) represent a global supply chain model (GSCM) that minimizes a weighted combination of total cost and activity days where the total cost includes production costs, inventory costs, taxes, facility fixed charges, production line fixed costs, transportation costs, fixed costs associated with a particular method of manufacturing, and duty avoidance. The MIP model is solved for a digital equipment corporation that is in a decision making process to determine plant charters and allocation of production loads. The model is then utilized to analyze the supply chain for new products as well as the supply bases for existing commodities. The decision model is applicable to multi-stage, multi-product manufacturing environment.

Huchzermeier and Cohen (1996) develop a stochastic dynamic programming formulation for the valuation of global manufacturing options. These options are delineated by distinct time periods that are defined by the available sources of supply, plant capacities, product allocations to market regions, and open supply linkages within the global supply chain. There is a cost associated with switching between options over the time horizon of the strategic decision. The model maximizes the global after-tax profits and incorporates option valuation and exchange rates.

Nagurney et al. (2003) develop a framework for the modeling, analysis, and computation of solutions to global supply networks. The authors build extensive mathematical models that include dynamics of price and behaviors of supply chain partners. The model maximizes the total profit by deciding on the amount of product shipments based on the costs as well as the equilibrium prices of products in different currencies at the demand markets in different countries. It allows for the analysis and solution of the equilibrium product flows and prices by considering the behavior of multiple parties (customers, retailers, etc.) at the supply network. The authors apply discrete-time algorithm to compute solutions to several numerical examples.

Grossman and Helpman (2005) study the determinants of outsourcing and model outsourcing activities as the equilibrium of production and trade between parties. The authors present an economic model of location selection with respect to market conditions, supplies and demands. The authors first study how the labor supplies, country sizes and technological investments affect the pattern of outsourcing and location equilibrium. Then they investigate the role of the contracting environment by incorporating the legal setting of countries. Based on macroeconomic and product cost data, authors draw conclusions on how an organization should proceed in choosing specific locations to transfer activities.

Kouvelis and Munson (2004) develop a mixed integer programming (MIP) model to represent the cost of global facility networks that incorporates government subsidies, tariffs and taxations. The MIP model maximizes the net present value of profit subject to demand and capacity constraints. The model incorporates the time value of money by including the interest rates on loans and discount rate of after tax cash flows at each country. Based on the MIP formulation, the authors provided a structural equation modeling approach.

Goetschalckx et al. (2002) present two global logistics system models. The first one is a non-convex optimization problem that focuses on the transfer prices in a global supply chain with an objective of maximizing the after tax profit of an international corporation. The second one focuses on the production and distribution allocation of a single country system when customers have seasonal demands.

Steenhuis and De Burijn (2004) follow a different approach and compare manufacturing location alternatives in a global supply network by using productivity measures as a basis for analyzing the international location/industry combination options. Gross domestic product (GDP) values and dependencies of industries are used to calculate the productivity levels in each country (or region) and a decision process that can be utilized by both corporations and governments is suggested.

Qualitative Reasoning Based Approaches

Decisions in global supply networks incorporate multidimensional variables that cannot always be expressed in terms of monetary values. In the literature, there are also studies that concentrate primarily on the qualitative determinants of global operations such as risks, knowledge bases and market opportunities. Researchers in both academia and industry have generated various studies that emphasize the value of intangible attributes in global supply network decision making.

MacCormack et al. (1994) examine the impact of qualitative factors on the performance and efficiency of global supply networks. They call attention to the importance of incorporating parameters such as exchange rates, tax systems, government regulations and technological capabilities. The authors present an overview of the macroeconomic and business level trends while summarizing the technological advances in production systems and related trends in management philosophies. After highlighting the insufficiency of cost based decision models, the authors propose a new framework for assisting in site location decisions and a model of the future global manufacturing firm.

The global management consulting firm A.T. Kearney (2004) has developed a scheme for offshore decisions based on the offshore location attractiveness indices of countries. Their report also highlights the issues that corporations must balance in their strategic offshore decisions. Countries are evaluated based on corporate surveys, current offshore IT and business process outsourcing activities, people skill levels and availabilities, business environment, infrastructure, culture adaptability, security of intellectual property, and financial structure.

The Global Outsourcing Report 2005 (Minevich & Richter, 2005) assesses countries in terms of two indices: the global outsourcing index (GOI) and the future outsourcing rank (FOR). According to this report, India and China are the two distinct low-cost labor countries that emerge as leaders for organizations considering outsourcing. China is mostly known for low cost manufacturing labor, whereas India has the advantage of an English speaking population and thus attracts a large amount of business process outsourcing (BPO) contracts. Alternatively, Taiwan and Korea are known as the centers of the semi-conductor industry. Besides these big players, countries such as Indonesia, Philippines and Malaysia also can also effectively compete for the outsourcing business.

Multi-attribute modeling approaches are also exploited in order to integrate intangible decision variables into supply network decisions. Udo (2000) employs the analytic hierarchy process (AHP) technique to analyze information system outsourcing decisions. The vendor of choice is selected based on the five criteria: strategic importance, stakeholder's interest, vendor's issues, cost of operations and industry environment. The vendor alternatives are assessed by pairwise comparisons and the decision is made based on the overall synthesized ranking values associated with each vendor. In another application, Badri (1999) combines AHP with goal programming for a global facility location allocation problem. The author first defines seven quantitative goals, including minimizing the total cost and maximizing the environmental quality. Then, AHP is used to determine weight factors for each goal, and goal programming is used to solve the aggregate model.

A majority of work done on evaluating the non-cost related determinants of global supply network decisions relies on empirical studies. Many consulting firms have separate departments that specialize in decisions related to transfer of operations overseas and relocation of corporate divisions. Their reviews mostly include extensive evaluations of risks, benefits, hidden costs, and stakeholder incentives.

Integrated Models and Future Trends

The major objective in global supply network decisions is to maximize profit (or minimize cost). For instance, initial cost differentials of approximately 40% are often cited as a major factor in relocating business processes offshore (Hickey, 2005). However, these decisions engage dimensions other than financial variables. Moreover the decision making process involves many stakeholders who often have conflicting interests, and it is difficult to satisfy all of these interests.

Global supply network decisions are, in large part, based on organizational strategies. A small shift from the optimal decision can have disastrous effects on organizational competitiveness. Therefore, these decision processes should ideally occur within a structured and constrained discipline rather than with a model from a single perspective considering a single element of measurement such as cost. Multidimensionality necessitates the integration of different stakeholder views while taking into account all of the qualitative and quantitative variables.

Mathematical modeling is a reliable technique to solve complex decision problems that involve variables of numerical values such as cost, size and quantity. It is a common technique used to solve global supply network problems. On the other hand, the intangible elements cannot be exactly expressed as functions of numerical variables. In literature, the intangible values are either quantified by using techniques such as multi-attribute utility functions or are heuristically interpreted by empirical studies. Although these approaches are valuable in their wide scope for incorporating many factors, they are not sufficient to generate effective multidimensional decisions. The list below presents some of the research initiatives for integrating intangible and tangible variables for a variety of problems. Many of these research initiatives are not directly geared towards global supply networks but can be utilized as a direction towards composite models.

Cook et al. (1997) present the application of the Cook and Kress (CK) model for evaluating alternatives in multiple criteria decision modeling. This approach has the strength of applicability even when some alternatives do not share the same criteria. The authors propose lemmas for the relation of proportions, and the paper concludes with a performance evaluation.

Yang (2001) proposes two methods for transforming qualitative and quantitative attributes (rule based and utility based). The author presents an evidential reasoning (ER) based approach that integrates qualitative and quantitative data. This approach is also applicable for problems with partial information. Certain monetary equivalent (CME) is used to estimate utilities of quantitative variables, whereas a Probability Assignment approach is used to estimate utilities of qualitative variables.

Yeh et al. (2001) formulate dredger dispatching (a complex decision making process) as a fuzzy multi-criteria analysis model. The authors present an empirical study based on a fuzzy multi-attribute algorithm. They are able to integrate quantitative and qualitative factors and make conclusions accordingly. A similar study is performed by Prodanovic and Simonovic (2003). The authors combine a multi-criteria technique (fuzzy compromise programming) with group decision making by means of multiple criteria and multiple participants. Both quantitative and qualitative criteria are modeled via fuzzy sets.

The strategic problem of designing the optimal global supply networks is also a research area at the University of Pittsburgh, where the authors develop novel integrated methods to assist corporate decision makers in global supply networks. The integration of continuous and discrete decision spaces under qualitative and quantitative criteria is established by utilizing mathematical modeling (i.e., mixed integer programming) and qualitative data analyses (i.e., analytic network process), and integrating them under the multi-objective optimization (MOP) techniques. The multi-criteria feature is structured by MOP where the continuous decision spaces can be treated with a mathematical programming approach. Quantification methods enable the input of multiple experts and provide a theoretical basis for the preference reasoning.

As in the case for most of the decision problems in real life, global supply network decisions consist of several objectives, such as maximization of opportunities and minimization of costs. For an integrated global supply network decision model, intangible and tangible variables are formulated within different objectives and constraints. The optimization of mathematical objectives with quantitative variables can be achieved by means of operations research (OR) tools. Moreover, if the intangible variables are quantified by a qualitative data analysis, the objective functions associated with these intangible variables can also be combined with the quantitative objectives in a multi-objective optimization problem.

In multi-objective optimization problems an optimum solution that optimizes all of the conflicting objectives does not exist. Formulation of a multi-objective optimization problem (Sawaragi, 1985) is given as:

Minimize $f(x) = (f_1(x), f_2(x), ..., f_p(x)$ over $x \in X$
where f_i is an objective function

Instead of a single optimum value, there is a set of best solutions in multi-objective problems. When one or more objective functions are conflicting, the concept of "optimality" does not apply directly in the multi-objective setting. A useful replacement is the notion of *Pareto optimality.*

Definition 1. *A point* $x^* \in X$ *is said to be Pareto optimal solution to the problem if there is no* $x \in X$ *such that* $f(x) < f(x^*)$.

Once the multi-objective problem is formed by combining the quantitative objectives with quantified intangible variables, the Pareto optimal space is generated. The Pareto optimal space represents the set of alternatives which are most favorable for the global supply network decision in consideration. Consequently, the preferences of the decision makers are determined by using utility theory and the final structure of the global supply network is established by selecting the Pareto solution that maximizes the total utility.

CONCLUSION

In today's environment of ever-increasing globalization, a major challenge for organizations is to implement an efficient strategy that can provide a cost advantageous global supply network. Over the years, scientists have established quantitative and qualitative models to support decisions that range from long-term to short-term and from those that are broad in scope to micro-decisions. Uncertainty and diversity of multiple objectives are the greatest challenges for these decision models. Quantitative methods deliver solutions by means of simulation, probabilistic models, and mathematical models, whereas qualitative decision methods imitate the functions of the human brain by transforming intangibles to numbers in order to compare and assess their magnitude. Most of these methods are supported by a strong theoretical framework and their relevance is accepted by researchers and scientists, yet many do not fulfill the specific needs for decision making in complex global environments.

A common and reliable approach in supply network decisions is to structure the decisions from a cost/benefit perspective and formulate mathematical models by numerical equations that reflect the utilities and monetary values of the related decision variables. However a major challenge here is the lack of intangible variables that cannot be expressed in terms of equations. On the other hand, other decision analysis techniques may lack the rationality and sensitivity of mathematical modeling approaches. An ideal decision model should combine the strengths of mathematical and qualitative models. Research clearly shows that integrated decision making models specific to global supply networks is a necessity simulated by the complexity and multidimensionality of the problem.

KEY TERMS

Decision Analysis: Formulation of models and interpretation of systems to generate the optimum set of choices that will lead to the best consequences.

Global Supply Network: Transnational network of retailers, distributors, transporters, suppliers, and manufacturers that participate in the process of production and/or service. The term "global supply chain" is used interchangeably.

Multi-Criteria Decision Making (MCDM): Methods that are designed to solve decision problems incorporating multiple-criteria whose solutions often result in conflicting objective values.

Multi-Objective Optimization: Optimization of mathematical models that share the same decision variables but differ in their objectives and constraints.

Outsourcing: Transferring an operation or operations to an outside vendor. Offshore outsourcing (offshoring) refers to the transfer of operations to a vendor overseas.

Chapter 1.17

Leveraging Supply Chain Management in the Digital Economy

Mahesh S. Raisinghani
TWU School of Management, USA

INTRODUCTION

A supply chain is a network of facilities and distribution options that performs the functions of procurement of materials, transformation of these materials into intermediate and finished products, and the distribution of these finished products to customers. In other words, supply chain encompasses all of the activities associated with moving goods from raw-materials stage through to the end user.

The information systems needed to monitor all of these activities are a critical part of the mix. Successful supply chain management (SCM), then, coordinates and integrates all of these activities into a seamless process. It embraces and links all of the partners in the chain. In addition to the key functional areas within the organization, these partners include vendors, carriers, third-party logistics companies, and information systems providers.

THE BUSINESS CASE FOR SUPPLY CHAIN MANAGEMENT

Improving supply chain management has become the major objective of the corporate world, because it represents an opportunity to resolve monumental problems that face corporations and create a mismatch between supply and demand throughout their supply chains.

For example, let us go back a few years to 1992, when a study of a major department store facing serious market-share troubles showed that 46% of the buyers who entered its stores that year did not buy anything! More than half of the empty-handed said it was not because they did not want something—they did, but the store did not have the product. The department store ended up with dissatisfied buyers and lost sales, plus a surplus of goods in stock that people did not buy, leading to mark downs. This is not a unique story. The number of markdowns among retailers have skyrocketed in the last decade, to the point where people refuse to buy unless goods are on sale and they totally distrust words like "suggested retail price".

This epidemic arises from a total mismatch of supply and demand. Customer and retailer and manufacturer alike are victims of "wrong product, wrong time, wrong place, and probably wrong price." It is a staggeringly costly problem. The retailer must support unwanted goods. The manufacturer must often deal with returns and a complex system of credits.

With constant markdowns, many retailers have faltered and ultimately gone out of business. The manufacturers have not been paid and there they sit with resources allocated to the wrong arenas. The mismatch between supply and demand ultimately arises from the inability of vendors and manufacturers, as their markets change, to make the right decisions about who they want to be. For instance, do the department stores want to be discounters, competing on the basis of commodity products? That is, all department stores would carry the same basic designer/manufacturing lines in clothing. Or do they want to differentiate themselves through such means as exclusive designers, private labels, and customer service?

Let us consider another example. Hewlett-Packard was historically known for high quality, high functionality products in computing and measurement that few, if any, could deliver. As these products became commoditized, customers expected HP to lower its prices, while maintaining a high level of functionality. In HP's case the transition has been from high quality and functionality at a premium price, to differentiation through a competitive combination of price, functionality, and delivery performance. The customer today is looking for a tradeoff: "Can you customize it for my requirements and can you deliver it reliably? And, oh, by the way, keep the price down" (http://www.internetsolutions.enterprise.hp.com/supplychain/library/articles/30000_feet.html).

The real challenge for companies, then, is to make the right decision about where they want to position themselves in cost, functionality, and delivery performance with respect to both their customers' requirements and their competitors' strategies and gambits (see Figure 1). Companies can achieve this with better supply chain management.

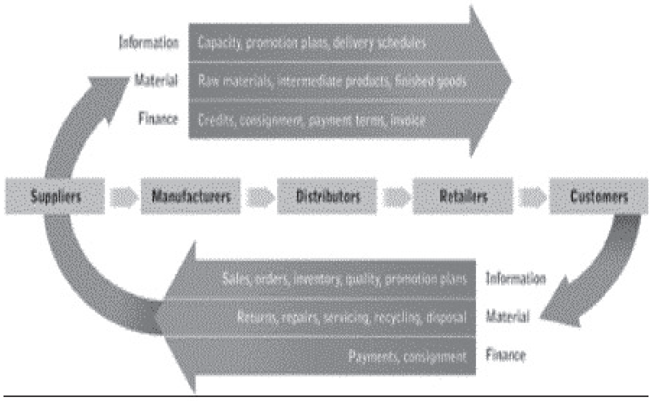
Supply chain management involves the flows of material, information, and finance in a network consisting of customers, suppliers, manufacturers, and distributors. (Figure 2 gives an overview.) Material flows include both physical product flows from suppliers to customers through the chain and reverse flows via product returns, servicing, recycling, and disposal. Information flows involve order transmission and delivery status. Financial flows include credit terms, payment schedules, and consignment and title ownership arrangements.

These flows cut across multiple functions and areas both within a company and across companies (and sometimes industries). Coordination and integration of these flows within and across companies are critical to effective supply chain management. However managing these flows effectively is a daunting task, particularly for global corporations. A global corporation's supply chain now usually consists of multiple enterprises lo-

Figure 1. Products and services differentiate on price, functionality, and delivery performance

(Source: http://www.internetsolutions.enterprise.hp.com/supplychain/library/articles/30000_feet.html. 2000)

Figure 2. The supply chain flows (Source:www.manufacturing.net/scl/scmr/scm0016/integration_1.html)



cated around the world. Furthermore, each of these enterprises is involved in a wide variety of supply chain activities—order fulfillment, international procurement, acquisition of new information technology, and customer service. There are complex relationships such as multiple suppliers serving multiple customers, or a supplier who may be a customer or even a competitor in different parts of the chain. This complexity is why some people refer to supply chains as "supply networks" or "supply webs" (http://www.manufacturing.net/scl/scmr/scm0016/integration_1.html).

Executives of the various companies are increasingly recognizing the tremendous payoff of truly integrated supply chains. They read about Wal-Mart's leveraging of the chain to achieve a dominant position in the retail marketplace. They hear of companies like Dell Computer reconfiguring the supply chain to respond almost immediately to customized orders. They are intrigued by the bold measures taken by M&M Mars to virtually eliminate standing inventory from the pipeline.

The supply chain payoff can come in many forms. It might reduce transaction costs by eliminating unnecessary steps in moving product to market. It could enhance customer service through closer coordination among vendors upstream and carriers, distributors, and customers downstream. Or may be it increases market share within better customer service or lower costs.

KEY CHARACTERISTICS AND PRINCIPLES OF SUPPLY CHAIN MANAGEMENT

The best supply chain management programs display certain common characteristics. For one, they focus intensely on actual customer demand. Instead of forcing into the market product that may or may not sell quickly (and thereby inviting high warehousing and inventory-carrying costs), they react to actual customer demand. And by doing so, the supply-chain leaders are able to minimize the flow of raw materials, finished product, and packaging materials at every point in the pipeline.

Andersen Consulting has encapsulated these qualities in what it terms the "Seven Principles" of supply chain management. When consistently and comprehensively followed, the consulting firm says, these principles lead to a host of competitive advantages—among them, enhanced revenues, tighter cost control, and more effective asset utilization. The seven principles are (http://www.ascet.com/ascet/wp/wpQuinn.html):

1. Segment customers based on service needs. Companies traditionally have grouped customers by industry, product, or trade channel and then provided the same level of service to everyone within a segment. Effective supply chain management, instead, groups custom-

ers by distinct service needs—regardless of industry—and then tailors services to those particular segments.

2. Customize the logistics network. Companies need to design their logistics network based on the service requirements and profitability of the customer segments identified. The conventional approach of creating a "monolithic" logistics network runs counter to successful supply chain management.
3. Listen to signals of market demand and plan accordingly. Sales and operations planning must span the entire chain to detect early warning signals of changing demand in ordering patterns, customer promotions, and so forth. This demand-intensive approach leads to more consistent forecasts and optimal resource allocation.
4. Differentiate product closer to the customer. Companies today no longer can afford to stockpile inventory to compensate for possible forecasting errors. Instead, they need to postpone product differentiation in the manufacturing process closer to actual consumer demand.
5. Strategically manage the sources of supply. By working closely with their key suppliers to reduce the overall costs of owning materials and services, supply chain leaders enhance margins both for themselves and their suppliers.
6. Develop a supply chain-wide technology strategy. Information technology must support multiple levels of decision making across the supply chain. The IT system also should afford a clear view of the flow of products, services, and information.
7. Adopt channel-spanning performance measures. Excellent supply chain measurement systems do more than just monitor internal functions. They adopt measures that apply to every link in the supply chain, incorporating both service and financial metrics.

To respond more accurately to actual customer demand and keep inventory to a minimum, leading companies have adopted a number of speed-to-market management techniques. The names by now have become part of the supply chain vernacular...Just in Time (JIT) manufacturing and distribution; efficient consumer response (ECR); vendor managed inventory (VMI); collaborative planning, forecasting, and replenishment (CPFR); cross docking; and more. These are the tools that help build a comprehensive supply chain structure.

The critical questions are: How do companies get to be supply chain leaders? What are the challenges involved in the process of implementation?

An essential first step is to integrate the key internal organizational functions that are involved in moving product to market. But, advancing from a highly segmented structure to a cross-functional team orientation can be a formidable challenge; people are inherently resistant to change. But, as the industry leaders have demonstrated, making that essential transition pays handsome dividends in terms of cost reduction, operational efficiency, and customer satisfaction.

Once the internal integration is underway companies can set their sights on the next challenge--executing the supply chain strategy and building the bridges to the external partners. This is not an easy task, even for the best-run organizations. It takes a dedicated effort and committed people who know the meaning of persistence.

A STRATEGIC SUPPLY CHAIN AGENDA: INTENT AND IMPLEMENTATION

The consulting firm of A.T. Kearney has developed an instructive framework for setting—and then implementing—a strategic supply chain agenda. The consultants recommend that a supply chain assessment team be created to spearhead the effort. Under the team's guidance, the agenda-setting process would proceed along four steps. (http://www.ascet.com/ascet/wp/wpQuinn.html)

1. **Assess the organization's supply-chain competitiveness.** The evaluation begins by comparing business objectives to existing capabilities and performance. This exercise typically reveals where the existing supply chain can achieve immediate competitive advantage (the "low-hanging" fruit) and where inefficiencies may be leaving the company vulnerable to the competition.
2. **Create a vision of the desired supply chain.** Through a series of "visioneering" sessions that include key customers and suppliers, the team considers how such trends as globalization, channel shifts, and new technology will affect the desired supply chain configuration. It addresses questions such as, what supply chain factors and performance levels drive customer buying decisions? What would make one supply chain a winner over others?
3. **Define those actions required to close the gap between tomorrow's vision and today's reality.** The team identifies possible re-engineering, restructuring, or other actions that could help narrow any gaps. At this stage, the team also works closely with management to assess the organization's readiness to pursue needed changes.
4. **Prioritize the action items identified and then commit the appropriate resources.** The end result of this task should be a unified commitment to a supply chain strategy and a clear agenda to achieve that strategy.

Subsequent actions to implement the supply-chain agenda typically fall into these broad categories:

- Designing the long-term supply chain structure to position the company in the right roles in the right supply chains with the right customers and suppliers.
- Re-engineering supply chain processes to streamline product, information, and funds flow internally and externally.
- Reinforcing the supply chain's functional foundation by improving quality and productivity within operational areas such as warehousing, transportation, and fleet management.

Ultimately, successful execution of this strategy will depend upon how effectively companies can integrate their operations with supply chain partners both upstream and downstream. As consultant James T. Morehouse of A.T. Kearney has pointed out in his writings and speeches, in tomorrow's market arena it will be supply chain vs. supply chain as opposed to company against company.

ANALYSIS OF PAYOFF OF SUCCESSFUL SUPPLY CHAIN MANAGEMENT

Given the extensive time, effort, and commitment of resources involved, is design and execution of a comprehensive supply-chain strategy really worth it all? An evaluation of the bottom-line numbers is the best way to respond to this question. According to A.T. Kearney's research, supply chain inefficiencies can waste up to 25% of a company's operating costs. With profit margins of only 3 to 4%, then, even a 5% reduction in supply-chain waste can double a company's profitability.

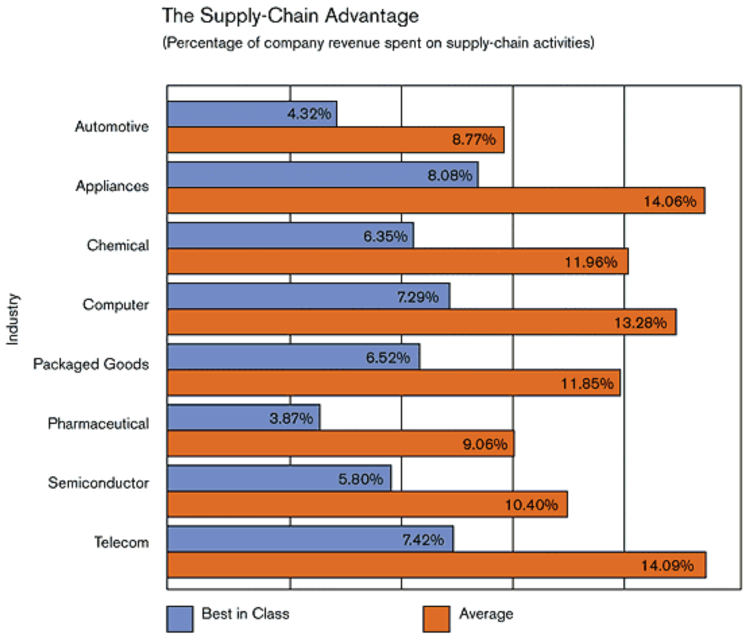
Through its comprehensive Integrated Supply Chain Benchmarking Study, Pittiglio Rabin Todd & McGrath (PRTM) found that best practice supply chain management companies enjoyed a 45% total supply chain cost advantage over their median competitors. Specifically, their supply chain costs as a percentage of revenues were anywhere from 3 to 7% less than the median, depending on the industry (see Figure 3).

Based on his experience with companies participating in MIT's Integrated Supply Chain Management Program, Prof. Metz has identified certain commonly reported bottom-line benefits. These center on cost reductions in such areas as inventory management, transportation and warehousing, and packaging; improved service through techniques like time-based delivery and make-to-order; and enhanced revenues, which result from higher product availability and greater product customization.

There are other payoffs as well. For example, the supply chain technique of optimizing the distribution network—that is, determining the best location for each facility, setting the proper system configuration, and selecting the right carriers—can bring immediate cost advantages of 20 to 30%. That's the number determined by IBM's Wholesale Distribution Industry Segment, based on consulting engagements in a wide range of industries. "This typically breaks down into transportation savings of 15 to 25 percent and improvements in inventory-carrying costs of 10 to 15 percent," says Mark Wheeler, national solutions manager for the IBM consulting unit. (www.ascet.com/ascet/wp/ wpQuinn.html)

Another supply chain technique with proven payback potential is cross-docking—the practice of receiving and processing goods for reshipment in the shortest time possible and with minimum handling. According to Maurice A. Trebuchon, a partner with PricewaterhouseCoopers, cross docking can produce savings of 25% or more over conventional warehousing. In a presentation made at the annual Council of Logistics Management meeting, Trebuchon cited one manufacturer that used cross docking to realize a net savings of $0.84 per ton of freight processed. The savings resulted from the elimination of putaway, picking, and storage costs.

Figure 3. The supply chain advantage



(Source:http://www.ascet.com/ascet/wp/wpQuinn.html)

CONCLUSION

In today's business world, one thing becomes strikingly clear: Supply-chain management is not just the wave of the future. For professionals working in this field, the issue is not so much whether to become expert in the art and science of supply-chain management, but rather how fast. This means becoming intimately familiar with the corporate mission and figuring out how supply chain processes can help achieve that mission. It means becoming an evangelist of the supply chain word—preaching both within the organization and externally to customers, suppliers, carriers, and third party logistics providers.

KEYWORDS

Collaborative Planning, Forecasting and Replenishment (CPFR): Aims at the enhancement of supply chain integration by supporting and assisting joint practices. It seeks for cooperative management of inventory through joint visibility and replenishment of products throughout the supply chain. Information shared between suppliers and retailers aids in planning and satisfying customer demands through a supportive system of shared information.

Efficient Consumer Response (ECR): The joint trading and industry working towards a more efficient and productive answer to consumer demand and the removal of unnecessary costs from the supply chain. It's characterized by the emergence of collaborative management in the supply chain.

Supply Chain: A network of facilities and distribution options that performs the functions of procurement of materials, transformation of these materials into intermediate and finished products, and the distribution of these finished products to customers.

ABSTRACT

Supply Chain Management (SCM) has proven to be an effective tool that aids companies in the development of competitive advantages. SCM Systems are relied on to manage warehouses, transportation, trade logistics and various other issues concerning the coordinated movement of products and services from suppliers to customers. Although in today's fast paced business environment, numerous supply chain solution tools are readily available to companies, choosing the right SCM software is not an easy task. The complexity of SCM systems creates a multifaceted issue when selecting the right software, particularly in light of the speed at which technology evolves. In this paper, we use the approach of Analytic Hierarchy Process (AHP) to determine which SCM software best meets the needs of a company. The AHP approach outlined in this paper can be easily transferred to the comparison of other SCM software packages.

INTRODUCTION

A supply chain represents the veins of a business; it is a network of facilities and distribution options that perform the functions of material procurement, the transformation of materials into intermediate and finished products, and finally the distribution of finished products to customers. Supply chains are not specific to any one industry; they are inherent in both manufacturing and service based organizations. Supply chains do however vary in complexity from industry to industry and even firm to firm. The process of managing supply chains is a multi-billion dollar software industry; the worldwide market for SCM software topped an estimated $6 billion in 2006 and is expected to reach $10 billion by 2010 (a compound annual growth rate of 8.6%) (Trebilcock, 2007).

Supply chains are evolving to meet the changing requirements of the companies trying to manage them. A few years ago simply having full visibility of your own supply chain was seen as extraordinary. Now that visibility is no longer enough; companies need to be agile in respect to their supply chain (Croom, Romano, & Giannakis, 2000; Bartels, 2006). Companies need to make educated business decisions based upon the information captured in their information systems.

SCM systems are used to coordinate the movement of products and services from suppliers to customers (including manufacturers, wholesalers, and retailers). The system's main objective is to manage warehouses, transportation, trade logistics and various other issues concerning facilities and the movement and transformation of materials en-route to customers.

The components of SCM include (but are not limited to) supply chain event management and optimization, warehouse management, radio frequency identification (RFID), transportation management, demand management, supplier relationship management, and service parts planning. Beyond the traditional elements, SCM software has also incorporated modules for international management; this is the direct result of the growing need for businesses to manage supply chains that include a mix of global suppliers, manufacturers, and company owned plants. In fact, the bursting demand for global SCM has led the upsurge in the worldwide market for SCM systems (Aksoy & Derbez, 2003; Das & Buddress, 2007; Hill, 2007).

Why Compare?

Research has found that the typical U.S. manufacturer is managing an average of more than 30 contract relationships (Trebilcock, 2007). Wholesalers are distributing to worldwide retailers and jobbers for resale; and retailers now staff virtual storefronts that service customers globally. The growing supply chain requires a management system that is efficient and caters to the needs of each enterprise. The benefits of implementing an appropriate SCM system include: Increased top-line profit growth through supplier teamwork; Reduced inventory carrying costs and stock-outs; Increased customer service; Supply chain visibility; Optimization of the value chain respective to cost reduction and bottom-line improvement; Reduced corporate-wide operating costs; Increased competitiveness; and Quick adaptation to changing markets without detriment to customers.

However, since SCM system implementation is typically not a small scale operation, there are inherent managerial risks. For example, within businesses with several facilities, partners, and departments etc., a legacy or manual SCM system can lead to bottlenecks. There are cases where the appropriate SCM application is chosen but it does not sufficiently integrate with the rest of the enterprise software applications. In some cases, the wrong SCM application is chosen (perhaps to cut costs or due to poor information); the result is that the whole business from sourcing to distribution is negatively affected. Efficient SCM provides immense benefits; a well-run value chain should positively impact an organization's profitability and success.

SUPPLY CHAIN MANAGEMENT SOFTWARE

While there are a number of SCM software providers, the major players have maintained their top positions. For example, in 2005 the top 5 ranked providers were Manhattan, RedPraire, SSA Global, Swisslog, and SAP AG (O'Neill, 2005); in 2007 the top 5 spots were manned by Manhattan, RedPraire, SAP, Oracle and Infor (who swallowed up SSA) (Trebilcock, 2007). In selecting SCM software vendors to compare for this study, the following criteria were utilized:

- Limited to those providers offering worldwide solutions
- Limited to vendors whose SCM systems include the following minimum components: Warehouse Management Systems (WMS), Transportation Management Systems (TMS) and Warehouse Control Systems (WCS),
- Limited to 7 software vendors in the study (use of Expert Choice limited us to 7 alternatives).

Based on criteria outlined above we have elected to compare the following 7 software vendors:

- Aldata – Aldata SCM
- HighJump - HighJump SCM
- Infor – Infor SCM
- Manhattan Associates – Integrated Logistics Solutions
- Oracle – Oracle E-Business Suite Supply Chain Management - R12
- RedPrairie – E2e
- SAP – SAP SCM

Decision Tool

To aid in the comparison of our selected SCM systems, we have relied on Expert Choice 11.5 (EC11.5). The key functions of EC11.5 are: to structure by identifying objectives and criteria for evaluating the decision at hand and the potential alternatives; to evaluate the objectives and alternatives; to synthesize by combining hard numbers and intuitive judgments (math and psychology) to value the alternatives via sensitivity analyses and exploring "what if" scenarios (Expert Choice Inc., 2007). By relying on EC11.5 we can understand the trade-off of weighing certain choice criteria differently.

It is possible to yield the best alternative via EC11.5 using the Analytical Hierarchical Process (AHP). AHP is based on mathematics and human psychology; the process deals with complex decision making by providing a framework for arranging the criteria, quantifying them, and relating the elements to the overall goal. The AHP method breaks down the decision into a hierarchy of more clearly stated sub-issues (where each issue is treated independently); once the hierarchy is built, the numerous alternatives are reduced to a series of pair-wise comparisons for synthesis. Those judgments are converted to numerical values that are processed, evaluated and compared over the whole scope of the issue. Because a numerical priority (weight between 0 and 1) is assigned to each element, AHP allows non-comparative elements to be compared in a consistent way. Finally, AHP produces numerical priorities and the choice of the best alternative simply becomes ranking the software packages in order of preference (Saaty & Vargas, 2006; Saaty, 1980; 1996; 2001; 2005).

In the following section, we briefly discuss features offered in each of our seven chosen software alternatives. Based upon this information, each alternative software package will be scored with respect to our evaluation criteria; these scores form the basis for pair-wise comparisons used in the AHP.

Aldata (Aldata SCM)

Aldata is one of the global leaders in supply chain software for retail, wholesale and logistics companies. The company's comprehensive range of SCM and In-Store solutions enable more than 300 customers across 50 countries to enhance productivity, profitability, performance and competitiveness. The majority of Aldata's customers are located in Western Europe; they primarily service small and medium size supermarket chains but also provide service to larger companies including Bosch and Merck. Aldata has won the IT Europa's European IT excellence award (General Business News, 2008).

Aldata invests heavily in research and development within the SCM unit. The G.O.L.D. product family is being further developed and the current version six of the software will remain the core platform for the coming years. Major launches were the new G.O.L.D. Track modules, a federation module for providing integrated traceability across business networks, and G.O.L.D. Mobile, a module providing mobility in the retail store and enabling store operations such as stocktaking, receiving and price control using PDAs or radio frequency terminals (IHL Group, 2006). The company does not provide any other enterprise management solutions.

HighJump (HighJump SCM)

HighJump, a 3M Company, offers standard functionality but leverages best practices in order to meet the clients' immediate operational disciplines while increasing efficiencies. HighJump software highlights its vertical-specific adaptability which enables solutions to fit a variety of customer requirements in industries that include aerospace, automotive, consumer goods, direct store delivery (DSD), discrete manufacturing, food and beverage, wholesale distribution/industrial production, document management, and publishing.

HighJump implants a best-practice advantage implementation methodology which focuses on budgeting and aligning clients' interests. HighJump offers in-depth training courses aimed at preparing clients to administer their software solutions and 24/7 staffed customer support. Furthermore, HighJump organizes an annual user conference where HighJump industry analysts, employees, partners and customers meet to brainstorm the latest trends in execution; customers get the opportunity to learn how to leverage SCM solutions to achieve increased efficiencies and maintain competitive advantage.

The software architecture and hardware platforms include the following: Main Languages: C++; .net; C-sharp; DMBS; SQL Server; Oracle; and a 4GL: HighJump adaptability tool set. The software pricing ranges from $100,000 to $250,000 and is dependent on the number of concurrent users. The target market for HighJump includes logistics/distribution, batch, repetitive, job shop, discrete, process, continuous flow, and project manufacturing which translates to industries that include health care, pharmaceuticals, automotive, grocery, food, apparel, 3PL, and audio.

HighJump integrates source-to-consumption solutions that contain four critical elements including rapid return on investment, a global execution platform that allows all applicants to work together seamlessly, ease of configuration to empower strategic competitive advantage, and best practices based functionality to solve core logistic challenges

Infor (Infor SCM)

Infor is a large size software developer that provides very strong management resource solutions. The company offers its products as separate modules for various enterprise functions, including: Manufacturing, Supply Chain Management, Financials, Project Management (PM), Human Resources, and Customer Relationship Management. Infor also offers an all-inclusive Enterprise

Resource Planning Suite (ERP). Their products are implemented worldwide.

Built on Open SOA (service-oriented architecture), Infor's logistics software provides advanced customization, which is not limited to any specific platform.

Due to high levels of customization, there are high setup costs in switching to the Infor's software. Due to high setup costs, Infor has historically targeted medium and large size businesses with sales in excess of $50,000,000. Recently, Infor announced a new ERP solution targeting small to medium size distributors (ERP FACTS). In targeting smaller firms, Infor has developed numerous industry specific basic modules that do not need costly customization; this has put them in a very cost advantage position when compared with their industry competition. Infor's SCM solutions range from $2,000 to $100,000+; solutions at the higher end of the price range tend to be solutions that have been extensively customized.

Manhattan Associates (Integrated Logistics Solutions)

Manhattan Associates is a leading supply chain solutions provider. The company's supply chain planning, supply chain execution, business intelligence, and business process platform capabilities enable its more than 1200 customers worldwide to enhance profitability, performance and competitive advantage. Unlike some of the other companies that provide SCM tools in addition to other non-SCM solutions, Manhattan Associates is engaged almost exclusively in the SCM solutions field. Much of their operational results company acquisitions.

Manhattan Associates targets companies in the retail, distribution, transportation, and manufacturing industries; their modules include warehouse, transportation, trading partner, distributed order, and reverse logistics management applications. Manhattan also offers performance management and radio-frequency identification tools designed to enhance the functionality of its other products. Manhattan's "Atlanta facility lets customers evaluate technology and equipment before adding RFID to supply-chain operations" (Malykhina, 2005, P.1). The company sells third-party hardware, including bar code scanners and printers, and also provides professional services. Manhattan Associates has been expanding their operations through new product offerings. According to Trebilcock (2007), "In 2001 Manhattan was the No.1 provider of warehouse management systems, with just more than $100 million in revenue. Today, Manhattan is a nearly $300 million company, offering transportation management, supplier collaboration and supply chain planning" (P. 47). Manhattan offers customer service on a 24 hour /7 days a week basis.

Oracle (Oracle E-Business Suite Supply Chain Management - R12)

With Oracle SCM (OSCM), companies can build and operate world class value-chains for profitable growth. The Oracle E-Business Suite Supply Chain Management (R12) family of applications integrates and automates all key supply chain processes, from design, planning and procurement to manufacturing and fulfillment, providing a complete solution set to enable companies to power information-driven value chains. Companies can anticipate market requirements and risks, adapt and innovate to respond to volatile market conditions, and align operations across global networks. A unified data model provides a single, accurate view of your entire supply chain. Companies can implement lean, demand driven principles and manage their increasingly complex, global supply chains.

OSCM consists of a variety of separate applications which are categorized by supply chain segments. Depending on a company's needs, a wide variety of applications are available. Some of the basic benefits of OSCM include real time supply chain measurements as a result of a direct connection with suppliers and customers, expense management for all categories of goods and services, analytical support to monitor the performance of a company's supply and the ability to make adjustments.

Oracle has been rapidly expanding its SCM software business, primarily through the acquisition of smaller, more specialized businesses. Oracle has adopted an acquisition strategy in order to accelerate its software innovations. Previous acquisitions include People Soft and Demantra. As a result of the acquisitions, Oracle is focusing its next generation of products on integration and the ability for these programs to communicate and share information with each other.

RedPrairie (E2e TM Suite)

E2e offers customers supply chain execution, store management, logistics, and warehouse management software that can assist or manage all facets of their business. E2e allows for monitoring and control from inbound logistics and inventory management to order fulfillment and transportation. Collaboration tools are included to assist in a company's daily efforts to collaborate or interact with trading partners.

Every industry is being challenged with increasingly complex multi-channel demands, especially from the end consumer of their products. The ability to respond to create perfect, customized, and timely orders is a critical competitive advantage to meet consumer expectations, reduce inventory and storage costs, and streamline operations (Report, 2006).

RedPrairie considers themselves unique in the SCM software industry in their effort to incorporate change management, learning management, interactive training, comprehensive online help, and customized learning and reference materials into their offerings. Companies implementing their suite of tools can leverage real ROI, minimize downtime due to obstacles, and move toward near 100% efficiency which increases companies core advantage. RedPrairie's support centers are located globally and offer full language capabilities in addition to leading-edge call tracking capabilities for reliability.

RedPrairie's ability to configure their software suites into practical groupings and components allows them to offer build-to-order manufacturing solutions that include sophisticated in-line sequencing which can lead to reduced cost and increased efficiency. The result is that all component levels can be tracked, revised and/or updated keeping all elements in synchronization. This capability is enhanced when used in conjunction with RedPrairie's warehouse management system (WMS).

SAP (SAP SCM)

SAP is the world's largest business software company and the world's third – largest independent software vendor. By building the strongest technology, services and development resources, SAP is positioned to deliver a superior business platform that can access valuable information resources, while improving overall process efficiencies and strong customer relationships including end users, suppliers and vendors. SAP's integrated packages allow customers' needs to be identified quickly and precisely while comprehensive and personal solutions are developed and rolled out.

SAP's services assists companies in maximizing their success through a combination of SAP experts, methodologies, tools, and certified partners. Users of SAP SCM can benefit with the following: Faster response to changes in supply and demand that will give customers the chance to quickly capitalize on new opportunity; Increased customer satisfaction- SAP SCM enables clients to better adapt to changes and meet customer demand; Compliance with regulatory requirements; Improved cash flow; and Higher margins- SAP SCM helps companies lower operational expenses with more timely planning for procurement, manufacturing and transportation. Using SAP

SCM companies can also improve their overall performance and quality through better order, product, and execution synchronization.

SAP SCM delivers a complete set of futures and functions for building adaptive supply chain networks. SAP SCM includes features and functions to support collaborative supply chain planning processes, including strategic, tactical, and operational planning as well as service parts planning. By using SAP SCM, a company can optimize a full range of planning activities including: demand planning, safety stock planning, supply network planning, distribution planning, and supply network collaboration. The company can also handle service parts planning activities, which includes: parts demand planning, parts inventory planning, parts supply planning, parts distribution planning, parts monitoring. With SAP SCM the company can manage order fulfillment activities, support end-to-end procurement, manage key transportation processes, manage warehouse activities, support all production processes including engineer-to-order, make-to-order, and make-to-stock manufacturing. SAP SCM also supports supply chain visibility design and analytics with features and functions that enable supply chain design and analytics processes. Planners and key decision makers can perform strategic and tactical business planning.

RELATIVE COMPARISON

Criteria Revisited

In order to conduct our analysis we will use selected quality criteria to assess software characteristics. With the help of Expert Choice software, we will first compare the relative importance of each of the criteria against each other.

- Ease of Integration: the ability to integrate with any third party software platforms (vendors, government clearance computers, ocean carriers, etc.) and any other proprietary software or legacy systems.
- Reliability and Stability: any warranties provided by the vendor in addition to the degree of completeness, accuracy, and consistency of the package. The availability of any templates or custom models available for specific aspects of the supply chain.
- Efficiency: the level of accessibility and efficiency; how well the software functions are aligned with the general business objectives as well as the number of tools available.
- Customization and Expansion potential: the degree to which the product supports the specific business goal assumptions and the tools available for SCM respective to the specific needs of the client company. Also, the degree of augmentation ability and the ability to evolve over time and expand as well as any expert options or limitations.
- Service and Support: the availability of support services coupled with the time it takes to have a technician to be available on site or on the network. The availability of technicians that are specialized in the particular industry the SCM is being utilized (transportation versus warehouse management, retail versus wholesale etc.). Any extra perquisites such as annual conferences.
- Mobility and Portability: is a measure of platform independence; the number of support platforms and supported architecture as well as any software requirements needed to run the software.
- Ease of Interface: shows how well the software communicates with the outside world, the quality of human machine interface, and how results are displayed.
- Pricing: the base price of the product, and/or range of the price for “basic” packaging respective to the SCM applications.

Evaluation Model

Our evaluation criteria, as entered in Expert Choice, are as follows:

- Ease of Integration – evaluated in terms of:
  - Time
  - Number of platforms supported
  - Support for open source developers
  - Reliability and Stability – evaluated in terms of:
  - What classes of models does the application support?
  - If the application allows custom model creation, templates or both.
  - The reputation of the vendor supplying the tool
- Efficiency – measured in relation to:
  - How well the software supports the general business objectives?
  - Data processing capacity and speed.
- Customization – evaluated in terms of:
  - How well the product supports the general business goal assumption?
  - Specific tools available respective to the specific needs of the client company.
- Expansion – evaluated in terms of:
  - The degree of augment ability
  - The ability to evolve over time and expand (i.e. available upgrades)
  - Any expert options or limitations
- Service and Support – evaluated in terms of:
  - Any available demos
  - Turnaround time for on site or network tech availability
  - Specialization of the techs in the respective industry
  - Any additional perks (i.e. annual conferences, 24/7 service etc.)
- Mobility and Portability – evaluated in terms of:
  - Hardware platform
  - Software architecture
  - Software requirements
- Ease of Interface – evaluated in terms of:
  - Simplicity of human machine interface
  - Result displays
  - Graphical layout
- Price (where available) – evaluated in terms of:
  - The price range provided – the lower of the range and the mean served as the rating criteria.

PROCEDURE OF EXPERT CHOICE: SHORT EXAMPLE

Providing an example of Expert Choice on a small scale helps to describe the method behind pairwising and making the best decision regarding which SCM Software to choose contingent on our criteria. To provide a small scale example we implemented five criteria against our objective and compared three SCM software applications.

The pair–wise weights were assigned to the criteria initially chosen; the decisions were based on available information and which criteria outweighed their pair. The result is the prioritized listing of criteria respective to the objective – in this case selecting the best SCM software. Expert Choice allows for normalization in order to better understand the weighting scheme – in other words these small scale results recommend that Pricing is more than twofold the importance of Portability. In addition, the inconsistency is very low at only 2%; the logic behind assigning weights (importance) to each criterion remained consistent within each pair-wise comparison.

We chose three alternative SCM Software packages (Infor, SAP & Oracle) for the short example to exhibit the functions of AHP relied on by Expert Choice. We proceeded to perform a pair-wise comparison of all our software solution

Figure 1. Presents the prioritized criteria after the initial weight assignments

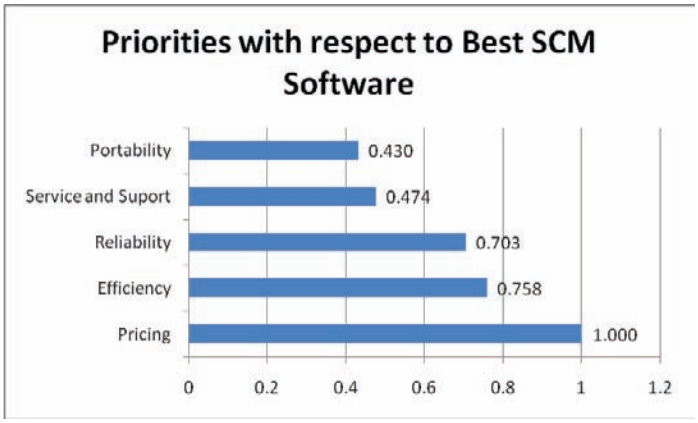

Figure 2. Presents the introduction of alternative SCM software packages analyzing pricing

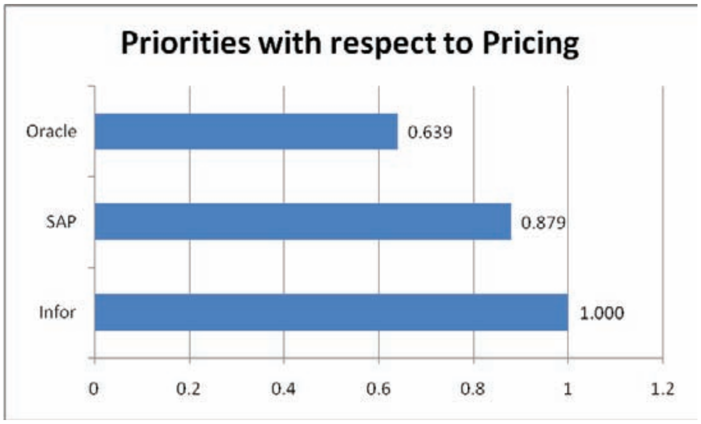

alternatives based on each established criteria. Based on strengths and weaknesses determined about each software; we analyzed the components of each criterion on a case by case basis. The detailed level of analysis allowed us to obtain informative results about each software solution tool. The logic provided a prioritized listing of the software packages according to the criteria which held the highest weight. As an example, Figure 2 displays results obtained from Expert Choice when analyzing Pricing criteria.

However, this is minimal information when making a decision – sensitivity analysis provides a technique for determining the outcome of a decision if a key prediction turns out to be wrong. The analysis is a tool for analyzing the impact of key criteria; sensitivity blocks are used to generate tables and/or plots of simulation results as functions of feed stream, block input, or other input variables. Since there are various criteria, the following charts demonstrate the outcome of each SCM package against the chosen criteria. Expert Choice offers a variety of alternatives which facilitates the decision making process and offers alternatives for assessing the outcomes according to user preference.

We found that the dynamic sensitivity analysis tool can prove to be very useful when trying to estimate overall impact of each criterion on the final decision. The program allows users to graphically manipulate the relative weight of each criterion against one another by simply clicking and dragging. Furthermore, the program would simultaneously change the graphically presented outcome. Thus, if for the purposes of presentation, we assigned an unrealistically high weight to the price criterion in the example above the overall outcome would change from SAP being the best option to Infor software as the ultimate solution.

SCENARIO ANALYSIS

In this section, we compare the seven chosen SCM applications based on the seven criteria previously defined. The decision of optimal software choice involves multiple-objectives and will vary among customers based upon individual needs. It is not often that one SCM application suits the expectations of every industry, institution, or customer; therefore the integration of scenarios is an important tool of the decision making process.

In order to make the simulation realistic, various scenarios were examined that altered the size, needs, and global presence (amongst other aspects) of potential customers for the available SCM applications. We proceed with the hypothetical situations and demonstrate techniques and procedures to establish the best available alternative based on our set of defined criteria. In examining the importance of various criteria, size stood out as a decision making factor. In order to emphasize the importance of size as a decision making factor, we went further to implement three specific scenarios that visit opposite ends of the spectrum; large global presence versus small regional existence. Note, however, that when the size was manipulated, only certain criteria proved to be dependent on that factor, therefore the results below exhibit how other criteria were weighted similarly, despite the variations in size.

The number of SCM applications compared coupled with the number of evaluation criteria results in a significant number of pair-wise comparisons used in the AHP process. The following table summarizes the relative weights of each criterion in addition to the direct relationship between the synthesized weights in each column with their respective criterion. The higher the synthesized weight, the more a particular sized company (Large vs. Small) views that particular SCM software alternative.

When comparing above scenarios, the notable changes were the relative weights of each criterion when the size of the company is accounted for in the scenario. It is important to take into consideration that a real business environment comprises many different industries, as well as an array of different company types with different needs, goals and business objectives; all of which would impact relative weights and the ultimate SCM software decision.

The selection of the best software for a specific company should be based on the individual needs of the organization making the choice. The same software package will not be the best choice for every buyer. Different SCM solutions will provide the best fit depending on the applicable situation or scenario. Creating different hypothetical scenarios can be useful in the selection process.

To illustrate this point, we have created different scenarios which demonstrate the relevance of the individual organization’s environment and objectives in the selection process. In addition to size, the best SCM software package for an organization can differ based on characteristics like industry or sector, geographic diversity of operations and vertical or horizontal integration of the supply chain. We found that sector can be a crucial factor in the decision making process; we believe that an organization’s sector will drive the decision for an optimal SCM software package.

In addition to a total of 144 basic pair-wise comparisons in order to compare all alternatives with respect to all of the criteria, each scenario also requires an additional 21 pair-wise comparisons. Once all pair-wise comparisons are made, Expert Choice is used to synthesize the weights of all the criteria with the weights of all the alternatives

Table 1. Synthesized weights with respect to criteria or goal

Synthesized Weights with Respect to Criteria	Pricing		Service & Support		Reliability & Stability		Customization & Expansion		Easiness of Interface		Mobility & Portability		Easiness of Integration

three alternatives for a business entity would be Oracle, Manhattan Associates and i2 Solutions. This was in line with our expectations. We had expected Oracle and Manhattan Associates to be prime solutions for business and government operations, since they were the software solution tools that excelled in the areas of Efficiency and Reliability.

Table 3 summarizes the overall results obtained through Expert Choice for our case scenario. We previously placed emphasis on efficiency and reliability for which the weights obtained were very close to each other when comparing the three top alternatives. However, when the rest of the criteria are considered, the weights obtained under each business entity change influencing the type of software solution that best suit each type of organization. For example: under a business entity Oracle obtained the highest weight of .202 overall, as opposed to .180 under a government entity. Picasso on the other hand, although obtained the lowest weight for both type of entities, it obtained a better rating from the government sector with a weight of .092 as opposed to .086 from the business sector.

As demonstrated by the tables previously shown above, different entities have different preferences and priorities which leads to differences in optimal software selection. The following scenarios will further support this conclusion.

Scenario 1: A&D Wholesale Distributors, Inc

Let us assume this is a mid-size distribution company that operates throughout the United States, with 550 employees and operations in 20 different states. A&D is looking for SCM software that will

Table 3. Summary of synthesized results for government vs. business entities

support a distribution intensive type of business and assist them in reducing transportation and inventory retention costs leading to increased revenue and customer satisfaction. Based on this company's goals and objectives, we decided that the criteria they would focus on would be: Customization Flexibility, they need a software solution tool that would be able to customize to support their specific needs and Efficiency, their main objectives are to reduce transportation costs and inventory retention time.

Scenario 2: Start Up Online Company

Let us assume this is a small retail oriented start up internet company with 10 partners, no fixed location, no fixed relationship with outside parties and limited knowledge on the industry. This is a company that would need a software solution alternative that would offer them a high level of support with relation to hardware platform and software architecture, and one that would be able to provide a high level of training and support, since they are new in the industry and have a flexible SCM structure. Based on this company's needs, we decided that the criteria they would focus on would be: Portability, because they need a software solution that would support their internet based business, across different platforms and operating systems and Training and Support, because they need a software solution that will provide them with intensive training about the software as well as with aids to gain a better understanding of their flexible supply chain structure and demands.

In the following tables, results for a number of additional scenarios are presented.

Scenario 2.

CONCLUSION

The SCM software industry is gaining an increasing amount of attention as companies try to maximize return on investment and gain a competitive edge in their markets. The increasing focus on the industry is resulting in greater investment in SCM software and fueling innovation. In order to choose the best alternative among all of the choices available, potential users must clearly identify and prioritize their needs and preferences.

Expert Choice's technology, which utilizes AHP analysis, allowed us to compare seven SCM software alternatives according to seven select criteria in order to determine which software best meets the needs of each scenario. All of the potential factors involved in the selection process must be determined by the organization making

a decision on an individual basis. We expect continuous improvements and competition from the companies we have examined as well as new entrants into the marketplace looking to fill niches. The natural caveat to all this software is from the human side; the software is only as good as the users who truly understand how to properly use the application. Most logistics professionals and senior level management lack the knowledge or training to fully exploit the potential of their systems (Hannon, 2005). This ties in to a recent emphasis in moving away from pure planning and focusing on the execution aspects of managing a supply chain (Parker, 2007).

Since problems, criteria, needs, alternatives and other variables will vary from one entity to the next, there is no universal solution. In order to support an optimal choice, all of the key factors in the decision process must be identified and quantified. The methods and processes relied on in our research transfer easily to the comparison of other SCM software packages. The future for SCM software solutions is endless.

Chapter 1.19

Negotiation, Trust, and Experience Management in E-Supply Chains

Gavin Finnie
Bond University, Australia

Zhaohao Sun
Heibei Normal University, China

ABSTRACT

This chapter reviews fundamentals of e-supplhy chain management and examines the transformation from the traditional supply chains to the e-supply chains (e-SC). This chapter applies experience management (EM) and experience-based reasoning (EBR) to intellegent agents in the e-SC and explores how to use experience in extablishing trust in other agents. The role of trust and deception in supply chains for real-time enterprises is discussed, and a logical framework for fraud and deception is explained in this chapter. EBR is considered as a way to manage trust in the supply network. This chapter explores cooperation and negotiation, trust and deception in e-supply chains by providing methodologies and intelligent techniques for multiagent trust, negotiation, and deception in an e-SC. Finally, a unified model is developed for integrating cooperation and negotiation, trust and deception in e-supply chains. Although primarily theoretical, the chapter highlights new areas of research which will impact supply chain management.

INTRODUCTION

Current supply chain management (SCM) is largely based on older information retrieval methods. It generally has not taken advantage of the 'dynamic' information that is now available due to developments in information and communication technology (ICT) and knowledge management (KM). The focus of SCM has also changed from a supply-side view of optimizing production efficiency to a demand-side view of consumers driving the process. Supply chains

(SCs) are developing into demand networks that adapt to consumer demand in almost real time (Silisque, Brito, Almirall, & Cortés, 2003). With moving towards real-time enterprises, there is an imperative need for rapid automated and intelligent response in the supply network. As discussed in this chapter, an e-SC can be considered as a form of agent society, with trust and negotiation between the intelligent agents as a significant issue.

Experience of suppliers and customers plays an important role in an SC. In particular, customer experience management (CEM) will become a major issue in e-SC because the latter is a customer-centered service in the Internet world (Sun & Lau, 2006). Further customer experience is a prerequisite for customer satisfaction in SC, which is highly dependent on the flexibility of the SC, such as its ability to respond to changes in demand. Because the selection and interaction space of customers in e-SC is theoretically infinite, how to manage customer experience in e-SC also becomes a significant issue for any e-SC providers.

Experience management (EM) is a new concept in information systems (IS) and information technology (IT), although KM has become well-established in business management and artificial intelligence (AI). However, experience has always played a similar rule to knowledge for organizations. Experience-based reasoning (EBR) is a reasoning paradigm using prior experiences to solve problems, and could be considered an advanced form of knowledge-based reasoning (Sun & Finnie, 2005a). This chapter will develop the concept of EM and EBR, and apply them to intelligent agents in the e-SC. In particular the use of experience in establishing trust in other agents will be explored. Any organization will have some history of dealing with problems relating to orders and perturbations in the network and the solutions applied, as well as some formal processes for dealing with these. To respond automatically, software must be capable of reacting, as one would expect a human agent to do. The information available to the agent can come from a variety of sources, including analysis of historical information/experience at the informational/planning level.

Multi-agent systems technology has been successfully applied in many fields such as e-commerce (Sun & Finnie, 2004a) and supply chain management (Finnie, Barker, & Sun, 2004). The trend for the future will be to increasingly autonomous behavior of agents. However, it is imperative that management considering relinquishing control of key aspects of the business to software systems be aware of the issues involved, in terms of how agents will need to operate and negotiate, as well as the potential for misuse of trust with adverse economic results. The increasing importance of strong IT governance and control procedures, and the possible criminal implications for failing to implement these, makes it essential that management be aware of developments in this area. The major contribution of this chapter is in establishing a basis for understanding the new field of experience management and the role it may play in the new supply chain environment. In addition the issue of trust and the role of experience in automating trust development should be appreciated. This chapter will resolve these issues by providing some methodology and intelligent techniques for multi-agent trust and negotiation in an e-SC based on EM. These include the use of EM to enable agents in an e-SC to learn from prior experience in dealing with suppliers and customers, and issues relating to trust and deception in the agent world of the e-SC.

The rest of this chapter is organized as follows: the next section examines fundamentals of e-SC management. We then review the concept of experience management, explore cooperation and negotiation in e-supply chains, and discuss trust and deception in e-supply chains. Finally this chapter proposes a unified model of integrating cooperation and negotiation, trust, and deception in e-supply chains, and the chapter ends with some concluding remarks.

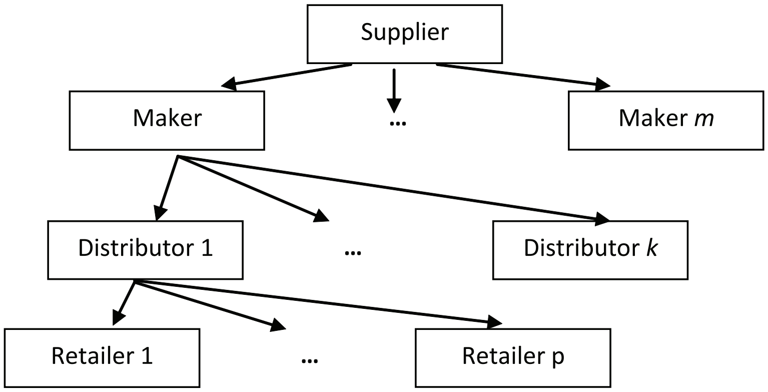
FUNDAMENTALS OF E-SUPPLY CHAIN MANAGEMENT

A supply chain can be broken into three parts: an upstream part, an internal part, and a downstream part (Turban, King, Viehland, & Lee, 2006). The upstream part encompasses all the activities involved in material and service inputs from suppliers, the internal part involves the manufacturing and packaging of products, and the downstream part involves the distribution and sale of goods to distributors and customers.

There are three different viewpoints for an SC: supplier viewpoint, intermediary viewpoint, and end-customer viewpoint. From a supplier viewpoint, the SC is a tree, the root of which is the supplier. We can consider this tree as a supplier-centered supply tree of the SC, as shown in Figure 1. The output degree of the root of this tree (supply flow) should be as large as possible from a supplier viewpoint in order to obtain the most number of orders from the SC. From an end customer viewpoint, the SC is also a tree, and the root of the tree is the customer. We call this tree a customer-centered source tree with respect to the SC. The input degree of the root of the customer-centered source tree should be as large as possible, in order to obtain the most satisfactory information and source from the SC. From an intermediary viewpoint, the SC is a double tree uniquely bridged by the intermediary. On the one side, the tree is the customer-centered source tree with its root being the intermediary, because it is the customer of the upper level supplier. On the other side, the tree is a supply-centered supply tree, also with its root being the intermediary, because it is the source and information supplier of the lower level customer. These three different trees co-influence the performance of the SC. In particular, the intermediary plays a vital role in any SC, because any inefficiency of the intermediary might lead to the breakdown of the SC.

The supply network integrates the value chain and the agent chain, and extends them into a complete graph-formed value-supply network (Sun & Finnie, 2004a). With the development of the Internet/Web technology, the traditional SC is being transformed into the e-SC. The e-SC brings together widely dispersed suppliers and customers to enhance coordination and knowledge sharing, and to manage upstream and downstream value chain channels (Poirier & Mauer 2001; Ross, 2003). e-SC enables firms to improve flexibility and move toward real-time operations by sharing information and collaborating dynamically among partners. e-SC management (e-SCM) can increase revenues or decrease costs by eliminating time-consuming steps throughout the online order and delivery process. It can also improve customer satisfaction by enabling customers to view detailed

Figure 1. A supplier-centered supply tree



information on delivery dates and order status. As an example, a mid-sized manufacturer of small loaders was reviewed. Materials management for loader assembly is extremely complex, with any shortage of required parts (e.g., pumps or engine blocks leading to significant additional costs in terms of unused labor, late delivery, possible disassembly of other components, etc.). By making the demand for specific types of loaders more visible to suppliers in an electronic form, it becomes increasingly efficient for suppliers to time the delivery of components when they are required. In addition, the manufacturer can look for alternatives if supply is impeded.

E-SCM has been a hot term for the past few years, but linking many business partners has been extremely difficult. Everyone from the raw material supplier to the ultimate seller in the chain must be able to get accurate information quickly and easily about orders, shipping, and customer responses to products and services. Business partners must decide which areas they will try to link first. Each partner then focuses on key internal groups that have the most to gain by adopting e-commerce.

Suppliers and customers in the traditional SC have been transformed into intelligent agents of suppliers or customers in the e-SC so that an e-SC can be considered as a form of agent society. Papazoglu (2001) provides a good typology of agents in such an e-business environment. Under this new situation, how to manage trust and negotiation between the intelligent agents within e-SC becomes a significant issue. This is because the trust and negotiation in the e-SC are based on interaction and communication between human suppliers and customers, between human suppliers (or customers) and their intelligent agents, and between intelligent supplier agents and intelligent buyer agents (Sun & Finnie, 2004). Experience management is also required for these activities in the e-SC.

EXPERIENCE MANAGEMENT

Experience is wealth for any individual or organization. Generally, experience can be taken as previous knowledge or skill obtained in everyday life (Sun & Finnie, 2004a, p. 13). Experience management (EM) has drawn increasing attention in IS and AI in the past few years (Bergmann, 2002; Sun & Finnie, 2005). This section will examine EM in some detail as it applies to intelligent agents in the e-SC. Although many managers are aware of the development in significance of knowledge management over the last few years, the role of experience management is still very new. Managers will be faced with a plethora of buzzwords in this area, and an intended contribution of this chapter will be to make managers aware both of experience management as a concept as well as its role in SCM. An example of experience in an organization may be in company buyers, for example, in retail who deal with a number of suppliers. Over time a buyer will learn from experience which suppliers are more reliable. This experience may be shared with other buyers, particularly inexperienced employees. In an automated environment in which suppliers and buyers are agents, the recording, management, and sharing of experience must also be automated.

Experience can be considered as a special case of knowledge. Methodologies, techniques, and tools for knowledge management (KM) can be directly reused for EM, because EM is a special kind of KM that is restricted to the management of experience. On the other hand, experience has some special features and requires special methods different from that of knowledge, just as a subclass Y of its superclass X usually possesses more special attributes and operations. Therefore, the following two issues are very important for EM:

- What features of EM are different from those of KM?
- Which special process stages does EM require?

In what follows, we will try to resolve these two issues. First of all, we define EM as a discipline that focuses on experience processing and its corresponding management (Sun, 2004), as shown in Figure 2. The experience processing mainly consists of the following process stages (Bergmann, 2002, pp. 1-14; Sun & Finnie, 2005):

- Discover experience
- Capture, gain, and collect experience
- Model experience
- Store experience
- Evaluate experience
- Adapt experience
- Reuse experience
- Transform experience into knowledge
- Use experience-based reasoning
- Maintain experience

Where management has permeated each of above-mentioned process stages.

It is significant to separate management functions from experience processing functions and then integrate them in EM (Sun, 2004).

The management of experience processing for each process stage includes analysis, planning, organization, support, collaboration (Sun & Finnie, 2005), coordination, and possible negotiation (Sun, 2004). Generally, management issues related to each or some of the experience processing stages include:

- Organization and control of experience
- Experience processing or management task assignment to specific person or teams

In the above experience processing stages, "maintain experience" includes updating the available experience regularly, while invalid or outdated experience must be identified, removed, or updated (Sun, 2004). Transforming experience into knowledge is an important process stage for EM, which is the unique feature of EM that is different from those of KM. In the history of human beings, all invaluable experience is gradually transformed into knowledge, which then is spread widely in the form of books, journals, and other means such as multimedia.

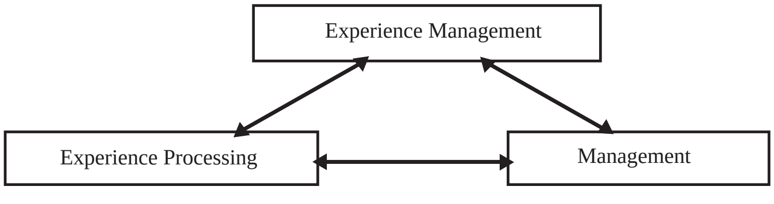
It should be noted that discovery of experience from a collection of knowledge or social practice is a significant issue for EM, just as knowledge discovery from a very large database (Sun & Finnie, 2005). Further, the processing of experience requires an experience base, where experience processing will be conducted.

EM research is providing a new way of looking at data, knowledge, experience, and its management for organizations and e-services (Sun & Finnie, 2005). This will include experience retrieval, experience similarity, and experience processing. Successful solution of these problems could provide the basis for new advances in both EM and e-SC.

As an application of EM, customer experience management (CEM) has been studied in business and commerce (Schmitt, 2003) and e-services (Sun & Lau, 2006).

Generally, CEM is the process of strategically managing a customer's entire experience with a product or a company (Schmitt, 2003, pp. 17-18). In this way, CEM changes traditional customer

Figure. 2. EM as an integration of experience processing and management



satisfaction from outcome oriented to process oriented. CEM also extends traditional CRM from recording transactions to building rich relations with customers and understanding the experiential world of customers, because it is imperative that organizations understand their customers' past experiences, current behaviors, preferences, and future needs (Brohman, Watson, Piccoli, & Parasuraman, 2003).

Schmitt proposes a framework to manage customer experience (Schmitt, 2003, p. 25) which targets the business managers or consultants. This framework consists of the following five steps:

1. analyzing the experiential world of the customer
2. building the experiential platform
3. designing the brand experience
4. structuring the customer interface
5. engaging in continuous innovation

The customer interface is one of the key implementation strategies for managing customer experience in e-SC, because it affects retention through the exchanges and interactions which further determine whether the customers are satisfied with the e-SC and whether they will buy the services again. Most CRM solutions merely record what can be easily tracked: the history and transactions of customer-company contracts (Schmitt, 2003, p. 141). However, this is not enough for managing customer experience in e-SC because the customer in e-SC believes that the interface of the e-SC is the agent of the e-SC, and s/he is communicating face to face with this agent. This is a new world, because the interaction between the customer and the agent of the e-SC is different from traditional face-to-face interaction or communication in traditional business or service. However, in such an interaction, the customer will still try to obtain human-like interaction with the interface agent in the e-SC.

Furthermore, humanizing and harmonizing the customer experience are important components for CEM. Humanizing the customer experience requires communicating with customers according to humanity rather than technology (Schmitt, 2003, p. 92). This is because the customer in e-SC hopes to experience a friendly human community in the virtual society such as the environment of e-SC. Harmonizing the customer experience allows the customers to increase their confidence in receiving the services or products from a company.

It should be noted that Schmidt's discussion of CEM is essentially based on his business consultation experience, in particular, in the traditional business sectors, without regards to any intelligent techniques. Sun and Lau (2006) argue that intelligent techniques can improve management of customer experience in e-services, just as had been done in other fields such as e-commerce. In the following sections we will argue that EM can facilitate cooperation, negotiation, and trust in e-SC.

COOPERATION AND NEGOTIATION IN THE E-SUPPLY CHAIN

Coordination among agents within e-SC has raised considerable interest, because cooperation across different entities is a central issue of SCM (Homburg & Schneeweiss, 2000). This is also because an agent cannot by itself just make a locally optimal decision, but must determine the effect its decisions will have on other agents and coordinate with others to choose and execute an alternative that is optimal over the entire SC (Fox, Barbuceanu, & Teigen, 2000). Therefore, agents within an e-SC should cooperate with other agents in finding a schedule or plan or a solution to a problem. A large number of tools facilitate collaboration and communication between two parties and among members of small as well as large groups (Turban et al., 2006, p. 283).

Negotiations within the SC have also drawn increasing attention in e-SCM. For example, Homburg and Schneeweiss (2000) propose a structure for a cooperative contract negotiation between the supplier and the retailer. Barker and Finnie (2004) examine cooperation and negotiation in supply networks based on multi-agent technology. Logistics agents will negotiate over contracts with the available contractors. In this case, several rounds of offers and counteroffers should be proposed before reaching an agreement (Fox et al., 2000). As an example, factors that might be traded off would be price, delivery times, quality, delivery costs, order quantities and discounts, and so forth.

The negotiation process might be affected by uncertain events. For example, failures in agents and communication channels can occur during negotiation (Walsh & Wellman, 1999). To optimize the performance, the agents within the e-SC should work in a coordinated manner. However, the dynamics of the enterprise, the market, and agents makes this difficult (Fox et al., 2000): materials do not arrive on time, or customers change or cancel orders and negotiation between intermediaries fails. Therefore, trust and deception have become an increasing issue in e-SC. Finnie, Sun, and Barker (2005) explore trust and deception in multi-agent trading systems including supply chains. Trust among the trading partners can generate speed, agility, and lower cost (Turban et al., 2006, p. 281).

In an e-SC there is a continuous process of planning, scheduling, and management of supply and demand which requires cooperation, coordination, and negotiation by human managers. Cooperation and negotiation are thus routine activities in the e-SC. Furthermore, in recent years, cooperation and negotiation with suppliers have become increasing important in order to establish an effective and efficient supply network (Schneider & Perry, 2001). However, delegating these responsibilities to an agent requires a great deal of autonomy and intelligence.

Any organization has some history of dealing with problems relating to orders and perturbations in the supply network and the solutions applied, as well as some formal processes for dealing with these. In order to automate the response to any stochastic event, the e-SC system must be capable of reacting as one would expect a human agent to do. In many cases, a human agent responds by working from and possibly adapting solutions to previously encountered situations similar to the present problem—that is, a process of reasoning from experience using prior cases such as case-based reasoning (CBR) (Finnie & Sun, 2003) or experience-based reasoning (EBR) (Sun & Finnie, 2005).

Multi-Agent E-Supply Chain Systems

Multi-agent systems (MASs) for e-commerce probably had their origins in the pioneering work of the Autonomous Agents group of the MIT Media Lab which resulted in the Kasbah and Market Maker (Chavez & Maes, 1996). Other simple online shopping agents followed, for example, shopping bots like “Ask Jeeves.” Applying multi-agent technology to e-SC has also been drawing attention since the end of the last century. Nissen and Mehra (1999) use ADE to develop a MAS for government supply chains. ADE is an integrated development environment to design, develop, debug, and deploy agents. Walsh and Wellman (1999) discuss some issues of using MAS to model supply chain formation, which is the process of bottom-up assembly of complex production and exchange relationships. However, agent interaction during SC formation might be complex, because agents do not generally have the incentive to truthfully reveal information. Papazoglu (2001) provides a good framework for intelligent agents in e-business. Singh, Salam, and Iyer (2005) describe an agent architecture for infomediary e-marketplaces which facilitates the flow of information among e-SC participants. The same group (Iyer, Singh, & Salam, 2005) further develop the concept of information exchange by agents to support collaborative business functions, using the concept of an agent-managed knowledge repository to maintain domain knowledge. This may include historical information on buyer experiences, "including the reliability and trustworthiness of the supplier." From a multi-agent viewpoint, an e-SC is composed of a set of intelligent agents, each responsible for one or more activities in the SC and each interacting with other agents in planning, bargaining, and executing their responsibilities (Fox et al., 2000). An agent is an autonomous, goal-oriented intelligent subsystem that operates asynchronously, communicating and coordinating with other agents as needed.

More and more multi-agent e-SC systems (MESC) are being developed in order to realize the transformation from conventional SC to e-SC, taking advantage of the Internet and e-commerce technology.

CBR-Based Cooperation in E-Supply Chain

Cooperation is an important characteristic of e-SC (Schneider & Perry, 2001). An agent with "perfect" knowledge and "complete" capabilities for a given task has no need to require the cooperation of other agents. However, normal agents do not have "perfect" knowledge and "complete" capabilities for a given task.

One approach to CBR-based cooperation is described by Martín, Plaza, and Arcos (1999). A cooperation mode establishes how two agents must behave to accomplish a particular task. Two cooperation modes between CBR agents are proposed in that research: Distributed CBR (DistCBR) and Collective CBR (ColCBR). The DistCBR cooperation mode is a class of cooperation protocols where a CBR agent is able to ask one or several other CBR agents to solve a problem on its behalf, and the ColCBR cooperation mode is a class of cooperation protocols where a CBR agent is able to send a specific CBR method to one or several CBR agents that are capable of using that method with their case base to solve the task at hand (Plaza, Arcos, & Martin, 1997). Therefore, the DistCBR cooperation mode enables an agent to share experiential knowledge acquired by an acquaintance by means of particular problem-solving methods, while the ColCBR cooperation mode allows a couple of CBR agents to share experiential knowledge.

CBR-Based Negotiation in E-Supply Chain

Negotiation in e-SC is a process where two parties (customers and suppliers) bargain resources for an intended gain. In order to adequately support customers, an e-SC system should possess negotiation capability. However, automated negotiation has had relatively little support to date because of the complexity of the negotiation process, which depends on the complexity of the product or service being negotiated.

The approaches to negotiation in e-SC can be classified into two classes: a cooperative approach and a competitive approach (Guttman, Moukas, & Maes, 1998). Competitive negotiation takes place if there is at least a conflict of interest between the buyer and seller/supplier. Consequently, there will be the minimum collaboration necessary between buyer and supplier to solve the negotiation problem, while cooperative negotiation tries to get as much collaboration as possible between the two parties. A competitive negotiation arises when an agent attempts to get the best deal possible, for example, to get goods at the lowest price. An example of cooperative negotiation between agents is in real-time load balancing of mobile cellular networks—all agents benefit from efficient network operation. In a supply chain environment, agents could cooperate in managing delivery across several companies to optimize utilization of trucks and so forth. However, both approaches present two extremes on a continuum of possible underlying problems. In practice, a negotiation usually lies between cooperative negotiation and competitive negotiation (Sun & Finnie, 2004a).

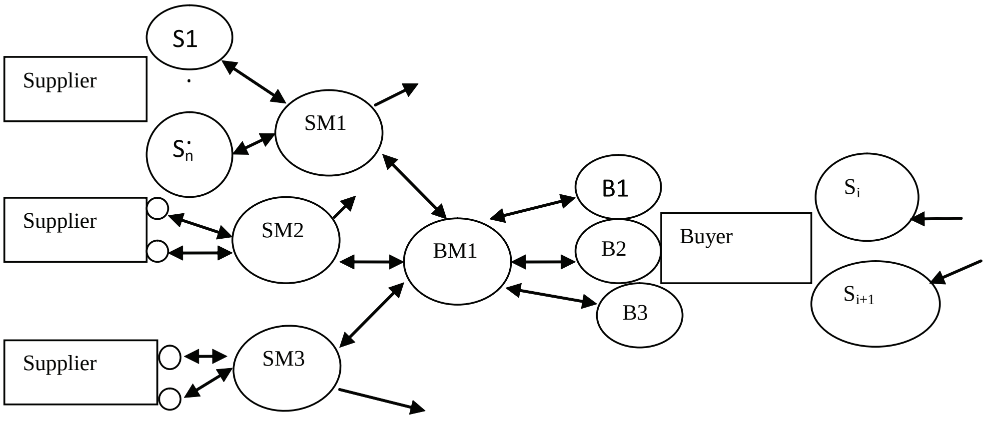
In the automated e-SC system, buyer agents search for a product that meets their demands. The goal of a CBR-based negotiation system is to identify these demands in cooperation with the supplier agents and to find a product that fulfils them (Sun & Finnie, 2004a, p. 186). During negotiation, the CBR-based negotiation system might suggest or even add some new demands or modify some weak demands for the purpose of finding an appropriate product. For configurable products, it is also possible for the CBR-based negotiation system to modify existing products during product adaptation to meet the customer's demands. Therefore, the task for the CBR-based negotiation system during the negotiation process is the combination of *iterative demand adaptation* and *iterative supply (product) adaptation*. The former is realized by making proposals for adjusting the demands from the buyer agent, while the latter is done by supply/product adaptation with the goal of finding an agreement point in the multidimensional demand/product space. During the negotiation, the agent or the CBR-based negotiation system is allowed to modify customer demands. If products in the product case base are configurable, it might also be possible to modify the products during negotiation.

An intelligent agent should be able to negotiate with the customer agents and to assist them during the search for an appropriate product in the e-SC. The buyer and supplier manager agents use CBR to negotiate; that is, they assess the similarity of the current negotiation to previous negotiation cases in their negotiation case base. Once a negotiation case is selected as the most relevant to the current negotiation, the agent might revise or adapt this case in order to meet any counter offer from the counterpart. Successful negotiation cases are kept in the case base for reuse in later negotiation case retrieval. These agents can use fuzzy rule-based adaptation to adapt the most similar negotiation case to the current negotiation situation (Sun & Finnie, 2004a, p. 207).

A MULTI-AGENT ARCHITECTURE FOR COOPERATION AND NEGOTIATION IN AN E-SUPPLY CHAIN

Based on the above discussion, we proposed a multi-agent architecture for cooperation and negotiation in e-SC, shown in Figure 3, in which S_i are supplier agents, SM_i are supplier manager agents, B_i are buyer agents, and BM_i is a buyer manager agent. The architecture is called MCNES (Multi-agent system for Cooperation and Negotiation in E-SC). In MCNES, CBR is used for intelligence

Figure 3. MCNES: Multi-agent cooperation and negotiation in an E-SC



at the buyer/supplier junctions within a specific supply network. A number of *buyer agents* control the interface between an organization and its suppliers, with each of the buyer agents using CBR to provide intelligent processing of supply needs on the basis of prior experience.

A *buyer manager (control agent)* coordinates and controls the activation and operation of the buyer agents utilizing CBR. It also uses CBR to select a suitable strategy for finding all components required for a particular product.

A *seller (supplier) agent* is at the supplier interface and is responsible for each product type. A request to purchase from an organization may itself trigger *adaptations* in the internal schedule for that organization and in turn cause its buyer agents to *negotiate* with its suppliers. To *coordinate* the actions of supplier agents, there is a supplier manager agent for each supplier which has responsibility for checking whether the product can be supplied. Each order processed for a specific customer forms part of the *case base* for that customer and provides a historical portrait of the relationship with the customer.

Each buyer agent has a local case (experience) base. Buyer and seller manager agents need more intelligence and have their own company case base. The supplier agents will check on the impact of an order which may in turn generate a procurement need. Agents will also need to have fallback positions—that is, if there is no suitable information in the case base, there must still be a response, either by appealing for human intervention or going to other forms of reasoning (e.g., rule based).

MCNES provides two levels of agent operation: the buyer/supplier manager agents at the enterprise level and the buyer/supplier agents at the logistics level. At the enterprise level, the agents are "middle agents" (Decker, Sycara, & Williamson, 1997) who "support the flow of information in e-commerce, assisting in locating and connecting the ultimate information provider with the ultimate information requester." At the logistics level, the supplier manager agents and buyer manager agents deal with product transfer and require learning cost-effective buyer/supplier dealings for specific products.

An agent in MCNES must be capable of reasoning and learning. The CBR approach is capable of reasoning and learning dynamically; for example, as new experience is gained, it will be added to the case base for that specific product in a specific company.

Agent Interaction in MCNES

As noted above, interaction between buyers and suppliers occurs at two levels in MCNES. At the buyer agent and supplier agent level (B_i, S_i), the interaction is product based with the focus on logistics/manufacturing. Buyer agents need to keep their production optimal while supplier agents need to determine the impact of re-scheduling.

At the supplier and buyer manager agent level (BM_i, SM_i), the interaction is inter-enterprise with the focus at the trading level. Both buyer manager agents and supplier manager agents are concerned with maintaining a good trading relationship to mutual benefit. For the buyer manager agent, this may mean retaining a range of alternative suppliers. For the supplier manager agent, this is customer relationship management (CRM). The supplier agent needs to have information on the likely impact of re-scheduling which it can feed into the CRM process so that any negative effects on a customer are minimized. In essence, this is using dynamic information for real-time CRM. Obviously in many situations this will only be part of the total picture and for some time to come will probably still require human intervention if any concerns are flagged. However, the need to incorporate the capability to gather and process dynamic information is obviously an issue that will need to be part of CRM, particularly in a virtual enterprise environment. Each order that is processed for a specific customer forms part of the case base for that customer and provides a historical portrait of the relationship with the customer. A key part of the knowledge capture relates to the formation of trust between a buyer and seller. As more experience is gained of a specific supplier or buyer, the more trust (or otherwise) can be established in the relationship.

Summary

The multi-agent system approach proposed in this section provides a suitable architecture for rapid and agile response to any event. MCNES is scalable, as there is no overall controller—each organization in the chain or network will have its own agent management structure.

The MCNES system requires further development and testing both in simulated and real environments. Although initial results are encouraging for the determination of a suitable supplier (Barker & Finnie 2004), the structure of supplier agents, their relationship to CRM, the use of profiling, and the development of negotiating capability needs to be explored.

It is to be noted that in current society, negotiation between the retailer and the end-customer is not common, in particular in the supermarket. However, negotiation between business and business still exists. In the MCNES, the negotiation usually occurs between supplier agent and manufacturer agent or retailer agent. For example, Homburg and Schneeweiss (2000) discuss a model for automated negotiation between a supplier and its retailer with supply chains.

TRUST AND DECEPTION IN E-SUPPLY CHAINS

Trust and deception have been of concern to researchers since the earliest research into multi-agent e-SC (MESC). Although much of the research in MESC assumes inherent benevolence, in practice a completely open agent society must allow for the possibility of malevolent behavior. In an open trading environment, trust can be established by external mechanisms (e.g., using secret keys or digital signatures) or by internal mechanisms (e.g., learning and reasoning from experience). As noted by Ramchurn, Huynh, and Jennings (2004), many current computer applications are following a distributed model with components available through a network like the semantic Web, Web services, and grid computing. The open multi-agent system with autonomous agents has been suggested as the logical computational model for such applications (Jennings, 2001). As a result, the implications of trust and deception have broader relevance than just e-SC systems.

This section will discuss MESC systems, explore how deceptions change the reasoning required in an MESC system/environment, and will illustrate several forms of logical reasoning that involve trust and deception in an MESC. It looks at a systematic classification of reasoning techniques which can be applied between buyers and sellers. As noted earlier, it is important that management understands the issues involved in autonomous agent systems. If agents have local control and act on behalf of the organization, then the need to understand and implement controls against deception is a management imperative.

Trust and Deception in MESC

As in any other form of society, agents can exhibit malevolent behavior in the MESC environment. With the focus moving to the distributed systems paradigm and the multi-agent programming model, the study of trust and deception in agent interaction has significant implications for the operation of these systems.

Ramchurn et al. (2004) provide an extensive review of research into trust in multi-agent systems. They define trust as follows: “Trust is a belief an agent has that the other party will *do what it says it will* (being honest and reliable) or *reciprocate* (being reciprocative for the common good of both), given an *opportunity to defect* to get higher payoffs." The authors conceptualize trust as (a) individual-level trust (agent believes in honesty or reciprocation of interaction partners) and (b) system-level trust (the agents are forced to be trustworthy by the system). They further characterize individual-level trust models as learning (evolution) based, reputation based, or socio-cognitive based. Learning models are based on interactions with other agents. Reputation-based models work by asking other agents of their opinion of potential partners, often based on some form of social network (Sabater & Sierra, 2002). Rather than relying on interaction with other agents, socio-cognitive models operate on subjective perceptions of opponents. Wong and Sycara (1999) address two forms of trust: trust that agents will not misbehave and trust that agents are really delegates of whom they claim to be. Vassileva, Breban, and Horsch (2002) consider the formation of long-term coalitions of customer and vendor agents using an agent trust model. Others have done research on agent learning in an untrustworthy environment—that is, agents who will attempt to deceive each other in trading. For example, Wu, Kimbrough, and Zhong (2002) show that trust can be established if agents learn which other agents exhibit poor behavior and hence which agents not to trust.

Trust and deception are twins in MESC. Trust in MESC can be sustained only if we can understand how agents commit fraud and deception in an MESC. Furthermore, how will agents in an MESC operate autonomously in such an environment, and what precautions will they need to take to protect their "owners" from fraudulent or malevolent acts? In traditional SC systems, "caveat emptor" or "let the buyer beware" is a well-known trading rule of thumb. Humans expect the possibility of fraud and deception in trades and accordingly take whatever precautions are possible. Less well known is the Latin maxim "caveat mercator" or "let the merchant beware." The latter is particularly relevant with the increase in Internet fraud, with online merchants carrying the cost of fraudulent transactions. If this is the norm in conventional trading systems, why should it be any different in multi-agent systems?

In business and social activities, fraud depends on deception, while deception is realized through fraud. Further, the aim of both fraud and deception is to get an advantage in an environment with conflicts of interest. Therefore, in what follows, we only refer to deception, rather than fraud and deception, if necessary.

With the development of the Internet, we find ourselves in hybrid artificial societies, where real-world assumptions and the whole range of possible behaviors including deception must be taken into account (Ramchurn et al., 2004; Wooldridge & Jennings, 1994). From an e-commerce viewpoint, there are three different kinds of deception in a hybrid artificial society: deception between humans, deception between humans and intelligent agents, and deception between agents in multi-agent societies such as MESC (Sun & Finnie, 2004b). In what follows, we focus on deception in MESC.

There are many agents operating in the MESC. Some agents are generally trustworthy, for example, market coordinators, search agents, transaction agents, and payment agents. All these agents are working as a lubricant for a healthy MESC. These agents work for buyer agents, seller agents, and others such as brokers and bidders in a neutral way in order to maintain the market trading order. However, the buyer agents, seller agents, and brokers may not be trustworthy. These agents may deceive other agents in the MESC in order to obtain the maximum advantage or profit, just as buyers, sellers, and brokers may use deception in a traditional house market, where the first house buyer is usually deceived to some extent by the real estate agent on behalf of the seller.

Furthermore, Internet technology provides new opportunities and ways to deceive, because intelligent agents will also participate in deception, and agents are and will be designed, selected, or trained to deceive in MESC, and people will be also deceived by intelligent agents (Sun & Finnie, 2004b). For example, e-sellers might use all the tricks to sell something and introduce new forms of deceptive advertising. Deception in the MESC can take a variety of forms, for example, pretending to be someone else, offering goods for sale which they do not have, and so forth. This is one of the reasons why some businesses fear using an e-SC. However, we would not stop driving because we saw a fatal car accident. Similarly, we cannot stop developing e-SC or MESC, although we find some cases of deception in them. The most important issue for us is recognizing and preventing fraud and deception in MESC. To this end, it is necessary to answer the question: What is the logical foundation of fraud and deception? The essence of fraud and deception depends on its logical foundation.

Finally, to detect and defeat fraud and deception requires a theory of deceptive communication, attitudes, and behavior (Castelfranchi & Tan, 2001). In what follows, we address this issue from a logical viewpoint.

A Logical Foundation for Fraud and Deception in MESC

This subsection will examine a logical foundation for fraud and deception, and then look at how the agents commit fraud and deception in the MESC from a logical viewpoint.

Inference rules play a fundamental role in any reasoning paradigm, because any reasoning is based on an inference rule or a couple of inference rules (Sun & Finnie, 2004b). For example, *modus ponens* and *modus tollens* are central to deductive reasoning. Sun and Finnie (2004, 2005) have proposed eight basic inference rules for performing experience-based reasoning (EBR) which are summarized in Table 1. These cover all possible EBRs and constitute the fundamental for all natural reasoning paradigms at the first level. The eight inference rules are listed in the first row, and their corresponding general forms are shown in the second row respectively.

Four of them, modus ponens (MP), modus tollens (MT), abduction, and modus ponens with trick (MPT) are well known in AI and computer science, but the other four need some clarification. First of all, we illustrate modus tollens with trick with an example. We may know that:

1. If Socrates is human, then Socrates is mortal.
2. Socrates is immortal.

What we wish is to prove is "Socrates is human." In order to do so:

Let $P \rightarrow Q$: If Socrates is human, then Socrates is mortal.

- ***P*:** Socrates is human.
- ***Q*:** Socrates is mortal.

Therefore, we have P: Socrates is human, based on modus tollens with trick, and the knowledge in the knowledge base (KB) (note that $\neg Q$: Socrates

Table 1. Experience-based reasoning: Eight inference rules

MP	MT	Abduction	MTT	AT	MPT	IMP	IMPT
P $\underline{P \rightarrow Q}$ $\therefore Q$	$\neg Q$ $\underline{P \rightarrow Q}$ $\therefore \neg P$	Q $\underline{P \rightarrow Q}$ $\therefore P$	$\neg Q$ $\underline{P \rightarrow Q}$ $\therefore P$	Q $\underline{P \rightarrow Q}$ $\therefore \neg P$	P $\underline{P \rightarrow Q}$ $\therefore \neg Q$	$\neg P$ $\underline{P \rightarrow Q}$ $\therefore \neg Q$	$\neg P$ $\underline{P \rightarrow Q}$ $\therefore Q$

is not mortal). From this example, we can see that modus tollens with trick is a kind of EBR.

Abduction with trick can be considered as a "dual" form of abduction, which is also the summary of a kind of EBR. Abduction can be used to explain that the symptoms of the patients result from specific diseases, while abduction with trick can be used to exclude some possibilities of the diseases of the patient (Sun & Finnie, 2004b). Therefore, abduction with trick is an important complementary part for performing system diagnosis and medical diagnosis based on abduction.

It should be noted that if one does not like to use trick or deception, he can use "exception" instead. The essence is that such kinds of inferences have not yet been examined in computer science and AI, although they are necessary for EBR.

Inverse modus ponens (IMP) is also an inference rule in EBR. The "inverse" in the definition is motivated by the fact that the "inverse" is defined in logic: "if $\neg p$ then $\neg q$," provided that if p then q is given (Sun & Finnie, 2004b). Based on this definition, the inverse of $P \rightarrow Q$ is $\neg P \rightarrow \neg Q$, and then from $\neg P$, $\neg P \rightarrow \neg Q$, we have $\neg Q$ using modus ponens. Because $P \rightarrow Q$ and $\neg P \rightarrow \neg Q$ are not logically equivalent, the argument based on inverse modus ponens is not valid in mathematical logic. However, the EBR based on inverse modus ponens is a kind of common sense reasoning, because there are many cases that follow inverse modus ponens. For example, if John has enough money, then John will fly to China. Now John does not have sufficient money, then we can conclude that John will not fly to China.

The last inference rule for EBR is *inverse modus ponens with trick* (IMPT). The difference between IMPT and *inverse modus ponens* is again "with trick"; this is because the reasoning performer tries to use the trick of "make a feint to the east and attack in the west"—that is, he gets Q rather than $\neg Q$ in the *inverse modus ponens*.

These eight inference rules provide a logical foundation for any EBR paradigms at the fundamental (or atomic) level, so that they can be applied to both benevolent and deceptive agent societies. In what follows, we give several examples to illustrate this view (Finnie & Sun, 2005).

We assume that in the MESC, the seller agent S will offer goods at a specific price, while the buyer agent B will agree to purchase a specific volume at a specific price. If the MESC provides a trustworthy trading environment, we can assume that conventional reasoning applies—that is, modus ponens, modus tollens, and possible abduction are used in the agents in MESC to conduct any trading activities. For the buyer agent B, his trustworthy reasoning could be as follows:

If a seller offers goods at a price, then those goods will be available at that price. We assume that G and D are propositions: G = goods offered at known price, D = goods are available for delivery.

Modus ponens is what the buyer agent or seller agent normally uses in the trading activities: bidding, brokering, and negotiation, because they believe that If G, $G \rightarrow D$ Then D. They also use *modus tollens* in the trading activities—that is, if goods are not available, then they will not be offered for sale by an agent.

If Not D (i.e., goods are not available), Then Not G (i.e., goods will not be offered for sale).

Abduction is another common sense inference rule underpinning the marketplace: if a seller agent S has goods available for delivery D, s/he will make them available for sale. That is:

D (Goods are available and will be delivered)
$G \rightarrow D$

Therefore, we have G (goods will be offered at a known price).

However, the environment provided by the MESC is not always trustworthy, because some agents (e.g., buyer agents, seller agents, bankers, solicitors, and brokers) may have a conflict of interests so that they will try to deceive their trading partners. In what follows, we look at several scenarios in the simple buyer/seller context where deception or fraud could apply and consider the variations on traditional logic, which could provide a logical basis for the deceptive reasoning. A number of scenarios will be proposed where the buyer agent is misled in their dealings with the seller agent in the MESC.

1. A seller agent may offer goods at a price *G*, but those goods are not available, which case is an obvious fraud. An example could be malevolent or fraudulent behavior by a competitor of the buyer company, for example, to delay production by ensuring that materials in the SC are not delivered. This could also apply to competitors of the supplier, for example, to reduce the chances that a competitor does not achieve the deal by offering goods at a lower price. This scenario could be described as *modus ponens with trick* (MPT) (see Table 1). It takes the form:

   G (goods at known price),
   $G \rightarrow D$
   Therefore, Not D (goods are not available for delivery).

   The essence behind this fraudulent behavior is that the seller agent has used MPT to deceive the buyer agent.

2. A second form of deception could arise in the MESC, if a seller agent does not offer goods at a price but the goods are in fact available at that price. This could arise if there are limited goods available and a seller wishes to preference another buyer (agent). This is referred to as *inverse modus ponens with trick* and takes the form:

   Not *G* (not offer goods at a price)
   $G \rightarrow D$

   Therefore, *D* (goods are in fact available at that price).

3. We could also have the situation where goods are not available but are offered at a specific price. This varies slightly from case (1) above in that the starting point is that the goods are not available. This could, for example, be a negotiating tactic if goods will be available within a short time. This is called *modus tollens with trick* and takes the form:

   Not *D* (goods are not available),
   $G \rightarrow D$

   Therefore, G (goods are offered at a specific price).

4. We could have the situation where goods are available for delivery but not at that price. This could be used to fool the buyer into intending to make a purchase—again as a possible negotiating tactic or delaying tactic. This could be termed *abduction with trick* and takes the form:

   D (goods are available for delivery)
   $G \rightarrow D$

   Therefore, Not *G* (goods are not offered at that price).

There are also a number of scenarios of deceiving the seller or seller agent in the MESC. As above, the seller assumes that if goods are purchased at a specific price, the seller will receive the amount in full. The most usual form of fraud and deception would be where goods are purchased, but the seller does not receive the full amount (or anything) (Finnie & Sun, 2005). This is theft or fraud and can be represented as *modus ponens with trick*. Other forms of inference rules do not apply easily to deceive the seller. *Inverse* *modus ponens with trick* or *abduction with trick* suggest that goods are not purchased at a specific price, but that the seller receives the full amount, which might be good for the seller but not that likely in practice.

EBR for Dealing with Trust in the E-Supply Chain

In conventional business practice, experience plays a key role in the selection of trading partners. We talk of learning from "bitter experience" when a disastrous mistake is made. Learning means that some record of past transactions together with success or failure must be made. As discussed earlier, CBR and EBR provide a practical approach to creating and manage an experience repository (Bergmann, 2002). All dealings with specific organizations would be recorded. These could then be analyzed over time to identify whether a partner is meeting the conditions of being a trustworthy collaborator.

From a buying viewpoint, buying a product in a marketplace, electronic or otherwise, can be an iterative bargaining process between an agent *S* acting on behalf of the seller and a buyer *B* initially. But it is not the only negotiation. It may also start an iterative bargaining process between *B* and bankers, delivery contractors, and so forth with the progress of the purchasing, as shown in Figure 4. First of all, *B* asks his informant (Internet agents, newspapers, acquaintances, and so forth) to search for the products for which he intends to buy. Then he will negotiate over the selling price with *S* for selling each of the products. This is also a trust and deception process between *S* and *B*, because *S* hopes to obtain the best interest by maximizing the price of the selling, while *B* also tries to obtain the best interest by minimizing the offer price to *S*. With the progress of the negotiation, the degree of deception of *S* to *B* becomes less, while the degree of trust of *B* in *S* becomes higher. If the deception degree of *S* and the trust degree of *B* can reach an equilibrium (like break-even point), as shown in Figure 5, then the price for the purchase will be fixed. Otherwise, the negotiation will be broken off and *B* will negotiate with another seller agent.

After the purchase price is fixed, *B* may ask his informant (Internet agents, newspapers, acquaintances, etc.) to search for suitable delivery contractors and then he will negotiate with each of these over the delivery price. However, *B* still uses negotiation to increase his trust in one of the contractors based on the knowledge and experience from his informant.

Although identifying partners who are not making the grade can be based on historical transactions, it would be preferable to be able to detect untrustworthy organizations fairly early in the trading relationship. One approach here relies on using data mining techniques to identify patterns of behavior which indicate possible difficulties. As one company on its own is usually

Figure 4. Bargaining process in marketplace

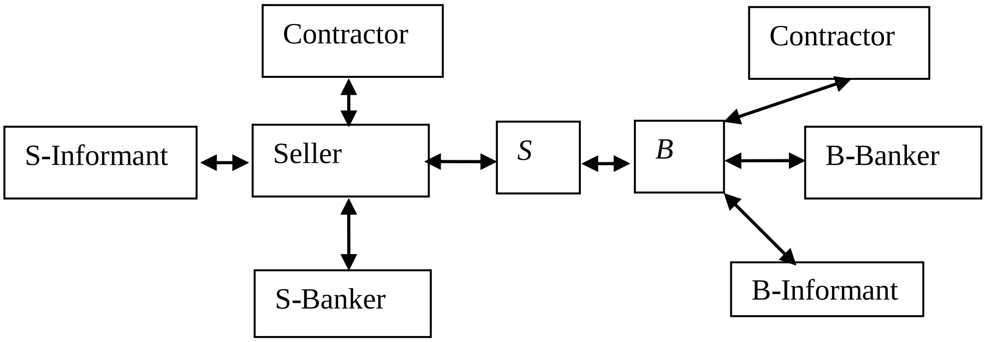


Figure 5. Trust and deception in negotiation

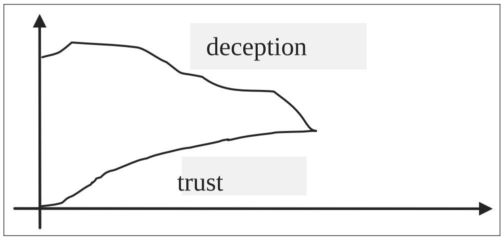


unlikely to have sufficient data for effective data mining, it is possible that some form of industry-level repository could be developed (e.g., in an industry marketplace) which could be used for analysis. Although collaborative filtering techniques could possibly be used to directly identify possible problem partners, it is likely that legal issues would limit the application of these techniques. However, an industry repository based on cleaned and anonymized information might provide a good basis for learning key features for identifying trustworthy partners. Management needs to be aware of the potential role of industry marketplaces in establishing suitable trust repositories.

Summary

In the e-supply chain (e-SC), most agent models and systems assume secure and reliable communication exists between them. This ideal situation may not hold in reality. This section examined agent behaviors, in particular trustworthy behaviors, and fraud and deception behaviors of agents in the MESC. Fraud and deception are an unavoidable phenomenon for engineering MESC. Failure to understand deception will lose the "biological" balance in MESC. Benevolent agent societies assume a fundamental basis of the conventional forms of reasoning (i.e., modus ponens). In situations with malevolent or fraudulent agents, it is useful to consider other forms of reasoning to better model the processes involved. Although heuristic techniques have been applied to learn which agents could be deceptive, this section looked at the underlying models of reasoning which might apply with such agents.

Recognition of deception in e-SC remains a big issue, because wherever negotiation exists, there are issues of deception, and any bargaining in negotiation implies some justifiable concealment and deception. IT can weaken trust relationships already holding in human organizations and relations, and aggravate problems of fraud and deception (Castelfranchi & Tan, 2001). The e-medium could make matters worse by weakening the usual bonds in social control. The habit or disposition to deceive will grow stronger, because the Internet is an anonymous medium. Agents in the e-SC will deceive the users or their delegated agents, for example, we have agents that bid on our behalf from a self-interested perspective. When our agent is bidding on something in an auction, we do not want it to honestly bid our reservation price for the good, if it could possibly get that good for less money.

Many techniques have been used over time to detect and prevent fraud and deception in human communications and e-SC, for example, increasing security by security protocols, authentication, cryptography, central control, and rigid rules. All these are useful and needed, but a technical solution to protect against deception and fraud in e-SC is unrealistic. Fraud and deception was a problem 2,000 years ago, it is a problem in e-SC today, and it will be a problem in another 100 years time. It is a game of chase, catch up, run ahead, and chase all over again. Therefore, exploration of the essence of fraud and deception is at least also crucial to solve these problems.

A UNIFIED MODEL OF COOPERATION, NEGOTIATION, TRUST, AND DECEPTION IN E-SUPPLY CHAINS

So far, we have explored cooperation and negotiation, trust, and deception in e-SC respectively.

These issues have drawn attention in multi-agent systems, e-commerce, and virtual society. Kraus (1997) explores cooperation and negotiation in multi-agent environments based on an intermedisciplinary approach. Sun and Finnie (2004a, 2004b) examine cooperation, negotiation, and deception in e-commerce. Weigand and van den Heuvel (2001) discuss trust, fraud, and deception in e-commerce. Castelfranchi and Tan (2001) investigate trust and deception in artificial agents and societies. However, no studies have been attempted to explore the interrelationships between communication, cooperation and negotiation, trust, and deception among the agents within the e-SC in a unified way. Without such attempts it is easy for the SC to be broken down by failures in agents, failure in communications, and intentional deception (Walsh & Wellman, 1999):

1. At least a link in an e-SC is broken or it is breakdown.
2. One part of an e-SC where many business partners involved is so weak that it is ignored.

The first case sometimes results in the bankruptcy of the lower level companies in the chain, because of delay of the materials' arrival to the company. Risk management can be used to avoid the occurrence of this case (Turban et al., 2006, p. 286).

The second case results from inefficiency of delivery of materials in the corresponding supply chain. The final results will affect the end products to end customers and negatively influence customer satisfaction.

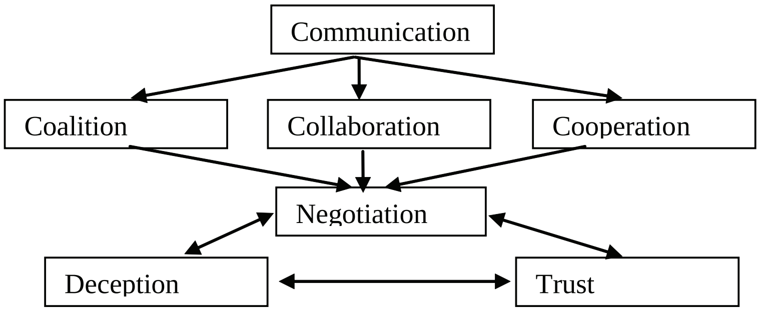
In what follows, we will propose a unified model of cooperation, negotiation, trust, and deception in e-supply chains, as shown in Figure 6, in order to explore the above-mentioned interrelationships.

In the e-SC, an agent first communicates with its adjacent agents. However, communication between agents is normally not transitive, because indirect communication between some agents (e.g, the buyer and the seller's solicitor) is illegal or unethical. However, the communication is fundamental for any activities such as collaboration, cooperation, and coordination in the e-SC.

Agents have to coordinate their activities and cooperate based on collaboration, coordination, and cooperation protocols (3C) in order to make materials and information flow in the e-SC effectively and efficiently. For example, product design and demand forecasting can be based on 3C among the business agents. The general case of these collaborations among the business partners constitutes collaborative commerce, which implies communication, information sharing, and collaborative planning done electronically through tools such as groupware and specially designed collaboration tools (Turban et al., 2006, p. 286).

Basically, agents work trustfully in order to form coalitions, collaborate, and cooperate with other agents. This is the reason why in the majority of cases, both traditional SC and e-SC run well. Sometimes, however, the coalition,

Figure 6. 3C, trust, and deception in e-supply chains



collaboration, and cooperation might terminate because one agent breaks the relevant protocols. Such a termination might lead to economic risk or breakdown of the e-SC. In this case, a negotiation mechanism has to be activated, in order to maintain effective communication, collaboration, and cooperation with the related agents. Negotiation is a bargaining process between two or more agents over prices or service items within the e-SC. In order to obtain the maximum benefit, one party in the negotiation usually hides some truths so that there are deceptions in any negotiation. Every party makes sufficient use of their knowledge and experience to avoid any possible deception in the negotiation. Any loss of benefit in the negotiation can be considered as a result of being deceived (Sun & Finnie, 2004b). Sometimes, negotiation is also a process of improving trust among the parties. The successful negotiation can bring new coalition, collaboration, and cooperation based on new 3C protocols with improved levels of trust. In other cases, the negotiation does not improve the trust among the parties, or create new coalitions, collaboration, and cooperation among them. One of the reasons is that at least one party has not shown sufficient compromise in the negotiation so that its deception strategy has not been successful. In this case, the negotiation is broken and the e-SC has to be relinked.

Coalition, collaboration and cooperation, trust, and deception comprise a dynamic process in the e-SC. They can be considered as a subchain (i.e., deception chain, negotiation chain, or trust chain) in the e-SC. In this subchain, any change in an entity will affect the activities of other items. Negotiation plays a pivotal role in this subchain, because it can improve the trustworthiness of other entities. Deception is a unavoidable part in this subchain. It can reduce the trustworthiness, coalition, cooperation, and coordination among the agents. However, removal of deception through negotiation can improve the trustworthiness, cooperation, coalition, and coordination among the agents.

CONCLUSION

This chapter first examined the transformation from the traditional SC to the e-SC and experience management. Then it explored multi-agent cooperation and negotiation, trust, and deception in e-SCs respectively. It also proposed a unified model of cooperation, negotiation, trust, and deception in e-supply chains. The approach will facilitate research and development of negotiation, trust, and planning in e-supply chains and multi-agent systems. The trend to the future will definitely lead to increasing autonomy for agents in the electronic supply chain. With such autonomy comes an increasing requirement for management to take responsibility for the actions of agents working on their behalf. Managers must be aware of the potential for fraud and deception in the supply chain and of research in this field.

Experience management is still a new concept for e-supply chains. How to manage experience of agents within the e-supply chain in order to improve cooperation, negotiation, and trust among agents, and to control deception, remains a significant issue in e-supply chains and one that decision makers in organizations need to be aware of. Experience management is currently where knowledge management was some five to ten years ago. A contribution of this chapter is to raise awareness of this developing field. In future work, we will develop algorithms and mechanisms of integrating cooperation, negotiation, and trust, taking into account deception in e-supply chains.

Chapter 1.20

Using SA for SAM Applications and Design:

A Study of the Supply Chain Management Process

Mahesh Sarma
Miami University, USA

David C. Yen
Miami University, USA

ABSTRACT

In order to maintain a competitive position in today's marketplace, companies must demand a greater level of enterprise efficiency. In today's rapidly changing market, experts argue that it is no longer about becoming a powerhouse but simply about remaining competitive. That is why automating and linking the supply chain has become so imperative. Supply chain management systems link all of the company's customers, suppliers, factories, warehouses, distributors, carriers, and trading partners. These systems integrate all the key business processes across the supply chain of a company. This chapter explains the objectives of supply chain management and how SAP's supply chain management system helps companies fulfill these objectives.

INTRODUCTION

Supply chain management is the delivery of customer and economic value through integrated management of the flow of physical goods and associated information, from raw materials sourcing to delivery of finished products to consumers (Viradix, 2005). There are many enterprise resource planning (ERP) and supply chain management (SCM) vendors in the market. Some of these vendors design ERP packages while some design SCM packages. However, looking at the definition of supply chain management previously given, it sounds a lot like what an ERP system does. However, the difference between ERP and SCM systems is in the detail. Usually, SCM systems provide companies with planning capabilities for their supply chain. SCM systems can not only plan the supply chain but it can optimize the whole supply chain so that all the business processes are linked together to form part of one single activity. It does so because it can look at the demand, supply and the constraints simultaneously and then find an optimal solution. Traditional ERP vendors have started developing and supplying SCM solutions in order to gain a foothold in the SCM market. This chapter will look at the details of a SCM system more specifically SAP's SCM system.

The purpose of this chapter is to study the different features and functionalities in an SCM system. Users of this chapter will be able to understand the various modules in a SCM system and how these modules are used across the supply chain by different departments. Users will also be able to understand the flow of data, the underlying business processes, how the data is stored and retrieved and how the same data can be used by both an ERP and an SCM system. The objective of this chapter is to focus on the business processes in the SCM system. People reading this chapter will be able to understand how the SCM process actually works. Integrated systems usually have centralized databases and this allows for the free flow of information. Any activity that takes place somewhere in the supply chain affects the other activities someplace else in the supply chain. This chapter will look at how these activities are linked together to form part of one big picture.

This chapter can be used by the users to start understanding the different parts of a supply chain management system and how this system can be used in different business activities. Usually, SCM implementations are very complicated because it involves integrating the business processes of more than one company. By understanding the business processes in one company, users will be able to better understand how the business processes work in other companies and how these processes can be integrated. They will also know the different data that is used in an SCM system. The best way to use this chapter is to understand the business process explained in this chapter and then try to implement it on an actual system. By doing this, users will be able to understand the important details of a SCM system. The intended audiences for this chapter are the faculty and students in schools interested in learning about a SCM system. People involved in implementing a supply chain management system can use this chapter as a starting point for understanding the business processes that take place in a supply chain. Most importantly, this chapter can be used by beginners just starting to work on the system as a reference in understanding the different departments involved in a supply chain. This chapter can be used in any course teaching the concepts of ERP and SCM systems. The SCM process is important for any company and users have to know what happens in an SCM process. Learning about an SCM system will give the users an idea of how business transactions occur within a company and how the data from these transactions is sent upstream and downstream to the company's suppliers and customers respectively.

Since there are many vendors who provide supply chain management systems, it is difficult to explain all the supply chain management systems in detail. So, this chapter will focus on SAP's supply chain management system. This chapter starts off with an introduction to supply chain management and SAP's SCM system. It explains the different modules in SAP's SCM system and then takes a look at the different business processes in an SCM system. It looks at the different departments involved in a supply chain and tries to explain how these departments can use SAP's SCM system to add value to the organization. In conclusion, it looks at the future trends in the industry and how these trends are helping companies change the way they do business.

From an academic point of view, this chapter can also be used as a case study for instructional purposes. Instructors can use this chapter to explain the concepts of supply chain management and to explain how the different operations in a supply chain come together so that companies can deliver the right products to the right customers at the right time. The supply chain management course can be conducted over the period of a semester with a class size of typically 35 students. These students should have a basic understanding of the different departments in a company and should have an idea of the business processes within a company. However, this knowledge is not essential as students should be able to pick up any details that they do not understand just by reading this chapter. A very important point to be noted is that this course covers the different parts of the supply chain and how all these parts are used together by companies to tighten their supply chains. This course does not go into the practical aspects of the supply chain (i.e., it does not explain how to actually use a supply chain management software). It is up to the discretion of the instructor to incorporate practical exercises using supply chain management software. Please note that the chapter explains the topics that are covered in the course but instructors may have to use additional readings or exercises to explain each module of the course in more detail. Another point to be noted is that there are many SCM softwares available in the market and this course primary uses SAP's supply chain management system to explain the concepts associated with a supply chain. Again, it is up to the discretion of the instructors to use any software that they think will explain the supply chain management concepts. Though it is possible to explain the concepts in supply chain management without the use of any softwares, SAP's SCM system is used here so that students have a better understanding of how exactly an information system is used to handle the supply chain of any organization. In most modules of the course, the course theory and the module itself are linked together, that is, the theoretical aspects of the course are linked and explained together with some of the systems used in SCM systems so that students have a better understanding of how supply chain management systems (information systems) are used in order to improve an organization's supply chain. Much of the concepts are explained using modules of an actual SCM system. However, students will be able to understand the theoretical aspects of a supply chain. They will learn about the different departments in a company involved in the supply chain and how these departments work together to create more efficiency. They will also be able to understand what the different tools are offered by software vendors to manage a company's supply chain. The different modules that are covered in the course are as listed below. Each module is explained in detail in the topics that follow. Each module explains in detail the theoretical aspects associated with the particular part of the supply chain and then tries to explain how students are able to benefit from this information.

1. Background Information
2. Concepts in Supply Chain Management
   a. Supply Chain Planning
      (i) Demand Planning
      (ii) Advanced Planning and Scheduling
      (iii) Transportation Planning and Vehicle Scheduling
   b. Business Procurement
   c. Warehousing and Distribution
3. The Business Processes in a Supply Chain
   a. Product Design and Development
   b. Sales
   c. Procurement

   e. Distribution and Logistics
4. Future Trends
   a. Suggestions to Learn the Supply Chain Management Process
   b. Lessons Learned
   c. Strengths and Weaknesses of a Supply Chain Management System
5. Conclusion

BACKGROUND INFORMATION

Supply chain management involves coordinating and integrating the business flows both within and among companies. Thus, supply chain management can be viewed as a pipeline for the efficient and effective flow of products/materials, services, information, and financials from the suppliers' suppliers through the various intermediate organizations/companies out to the customers' customers. The inbound and outbound logistics are very important components of the supply chain and this helps in making any company financially viable. Supply chain management (SCM) integrates marketing, sales, and manufacturing with logistics. The integration of each business function helps to reduce lead times, making companies with supply chain management systems more competitive in the marketplace. However, implementing supply chain management systems involves spending a lot of time and money. Companies have the option of creating their own SCM system, but it makes more sense for companies to buy an SCM system from a vendor and then get it customized according to their needs. Many companies offer complete supply chain management systems, which can be used by companies without too much customization.

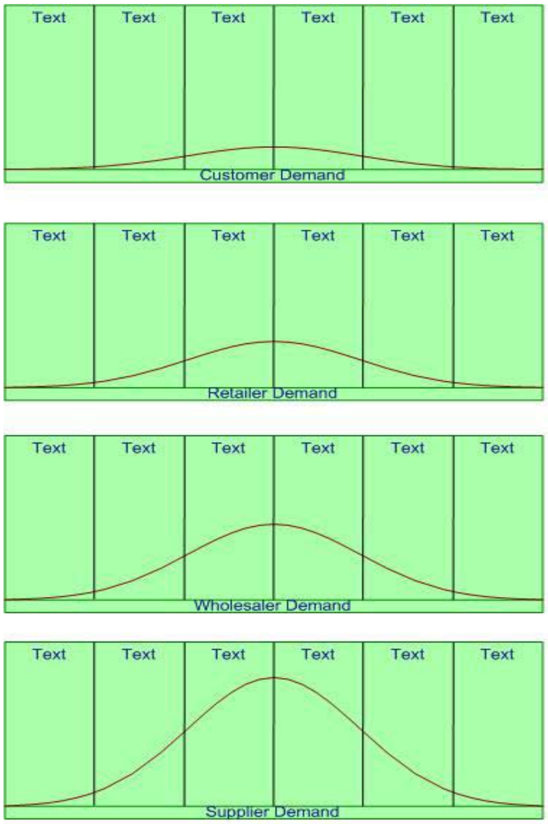
Though all these companies offer supply chain software, this chapter focuses on the supply chain management system offered by systems, applications, and products (SAP) in order to explain the different concepts associated with the supply chain. The advantage of SAP's SCM system is that it uses an adaptive supply chain network. What this means is that this network consists of many customer-focused companies that share resources and knowledge so they can better adapt to changing market conditions (SAP). These supply chain networks connect all the operations within a company like planning, manufacturing, distribution, etc and the data within these departments is visible immediately so decisions can be made and carried out immediately. The results are cost reduction, productivity gains, and higher profit margins. This chapter will focus on how a supply chain management (SCM) system helps companies fulfill its objectives. We will also look at some SCM components, look at the various business processes that can take place in a supply chain and see how these components fulfill those business processes. The main objective of SCM is to get the right product to the right place at the right time and at the right price. Some of the other broad objectives of SCM are to:

- Reduce lead times
- Increase customer satisfaction by providing products and services at the lowest possible cost
- Reduce operating expenses
- Understand the value chain and understand and eliminate those activities, which do not add value to the company's business processes
- Share information both up and down the supply chain in real-time
- Have accurate and flexible operations, which can be totally integrated with the suppliers' value chain

All these objectives can be achieved in a supply chain if information about product demand and service requirements is shared within the shortest possible time. These objectives arise out of the need to eliminate the "bullwhip effect." In the bullwhip effect, relatively small fluctuations in the actual demand among consumers is magnified through the supply chain which in turn has negative effects on the planning of transportation of the products and services and also on the production of the company's products.

Figure 1 explains how there is a distortion of demand information as this information passes up the supply chain and this is the bullwhip effect. The supply chain in the figure consists of customer, retailer, wholesaler, and supplier. The curve in the figure is the demand information that is received by each component of the supply chain.

Figure 1. The bullwhip effect — a distortion in demand



One of the main causes of the bullwhip effect is the break in the sharing of information between the different partners in the supply chain. Some of the solutions for reducing the bullwhip effect are to have real-time data up and down the supply chain, have just-in-time supply, reduce lead times, and so forth. Companies have come up with many solutions to reduce the bullwhip effect and to share information between the different partners of their supply chain. One of the solutions is to have an efficient and responsive supply chain system, which will integrate the different parts of the company's supply chain. However, just knowing that there is a bullwhip effect taking place is not the most important thing. Companies have to understand and change their business processes in order to reduce or eliminate this effect. Though it is important to understand the ramifications of the bullwhip effect and its possible solutions, it is more important to understand how supply chain management works within a company. There are many business processes, which take place when a company receives an order or wants to purchase an item from a supplier. In order to understand how supply chain management works, it is necessary to look at the various business processes within a company because it helps users understand how the flow of information takes place up and down the supply chain.

This is the background information that is explained to the students over the first week of the course. This helps the students understand the objectives of the course, that is, understanding how a company manages its supply chain. This background information helps the students to understand what the objectives of a supply chain management are and why companies decide to implement supply chain management systems.

Please note that the topics in the rest of the chapter covers the theoretical aspects of the course (i.e., the topics that are taught to students).

CONCEPTS IN SUPPLY CHAIN MANAGEMENT

As previously explained, the main use of a supply chain management system is to link all of the company's customers, suppliers, factories, warehouses, distributors, carriers, and trading partners in one virtual enterprise. By doing this, a company can use an SCM solution to achieve a competitive advantage and broaden its profit margin. By providing greater visibility throughout the supply chain — from planning and procurement to point-of-purchase — businesses can reduce expenditures, improve operational efficiency, and respond more quickly to customer demands (Borck, 2001). A supply chain management system should have the capability to plan, implement and control any strategy that is necessary to advance the company's objectives. What this means is that the system should be able to respond to the corporate strategy (i.e., the SCM plan should be in sync with the plans of all the other departments in the company). The system should be good enough to put the plan into action (i.e., implementation should not be too much of an effort). The system should also be able to carry out checks of the processes and inform the personnel whether the plan was good or not and whether it was properly implemented.

Supply Chain Planning

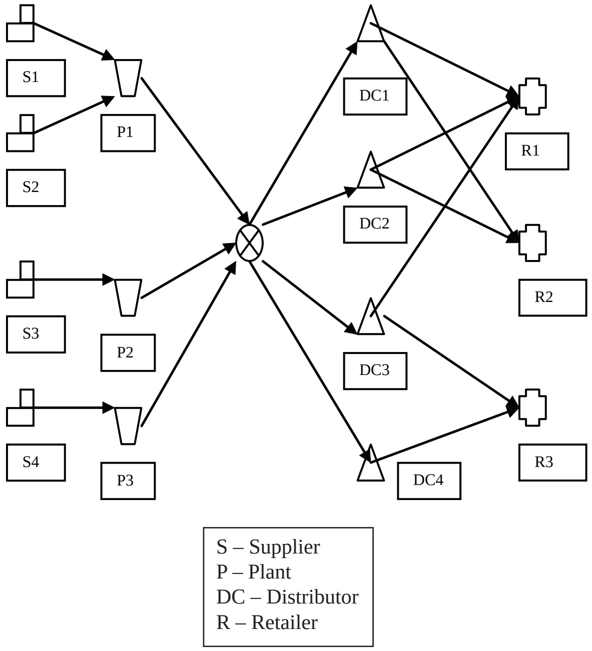
The first thing to be done in any supply chain system is to have the capability to plan the supply chain functions. A supply chain planning system should house the functionalities to schedule and monitor all the processes that are necessary in the planning phase. It should also have a single common database and several modules that share this common database. It should also provide the visualization capabilities for planning the inter- and intra-company logistical networks. All this is explained to the students using SAP's advanced planning and optimizer (APO). The different modules used in supply chain planning softwares are explained using SAP's software. The graphical user interface for SCM planning softwares in the SAP environment is explained to the students as given next:

- **Supply chain cockpit (SCC):** The SCC module is like the graphical user interface of SAP's SCM initiative. It consists of built in algorithms that can be used to optimize company networks. With the help of these algorithms, modeling of any logistics network [based on nodes (locations) and arcs (transportation lanes)] can be carried out and different business scenarios can be evaluated. It also has pre-defined exception conditions. When these conditions occur, the SCC sends a message to the workers or managers informing them of the problem in the business scenario. Since the SCC can be used to model a logistics network using advanced algorithms, managers can use these algorithms to access demand forecasts and to create business plans based on the supply and demand in each individual business unit (node). The detailed version of the SCC can be used for scheduling and control of products, which can then be assigned to specific locations.

Figure 2 explains a supply chain cockpit with locations and transportation lanes. It shows how the different parts of a supply chain are linked together. It also shows that information and materials can be passed through any part of the supply chain.

Supply chain planning consists of demand planning, advanced planning and scheduling and transportation planning and vehicle scheduling.

Figure 2. A supply chain cockpit with locations and transportation lanes (Knolmayer & Zeier, 2002)



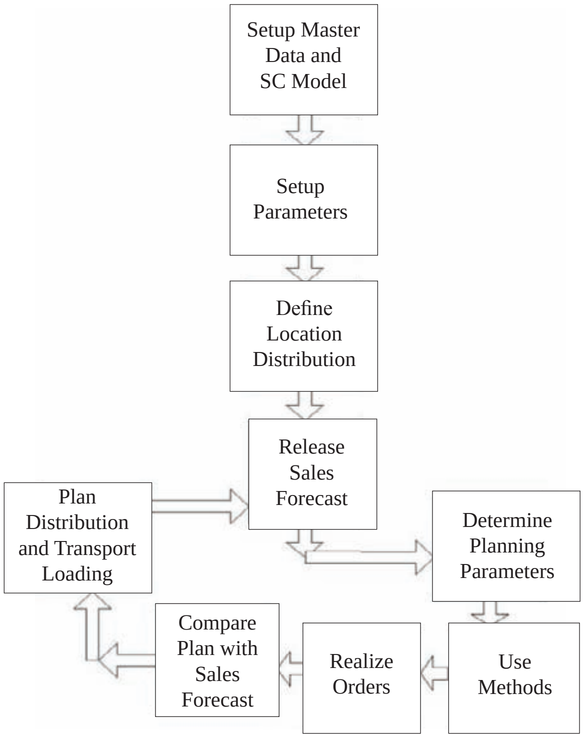
- **Demand planning:** Given the constraints within each company, the ability to forecast demand is one of the key functions in any SCM system. The demand planning sub-module in a supply chain is used to forecast the products that will be sold in the market. Then a sales plan is generated for any particular market. This forecasting and sales plan creation may be based on historical data collected over the years. This data can be taken from a business warehouse, point-of-sale systems, or online analytical processing servers providing the users with functionalities of data analysis. The demand planning is done based on the collaborative planning, forecasting and replenishment (CPFR) model. This model and in turn the demand planning sub-module is based on the idea of reducing the bullwhip effect (i.e., the effect of any problem at one end of the supply chain felt at some other end of the supply chain). If companies in the supply chain improve coordination and avoid multiple administration and repeated use of planning methods and databases, they can reduce the bullwhip effect. This increases the coordination between the different partners of the supply chain and helps them to make decisions which can benefit the whole chain. With demand planning systems in place, the supply chain partners are able to develop an outline plan in which core process activities can be assigned to the participating companies. These companies then jointly prepare a forecast of the consumers' demands. This forecast serves as a basis for the schedules to be agreed on. Finally, the partners try to avoid inappropriate schedules in the material flow.
- **Advanced planning and scheduling (APS):** This sub-module contains functions by which different planning methods for different time zones can be examined and appropriate steps taken. It consists of sup-

ply network planning which determines the procurement, production and distribution schedules. It also determines the optimal quantities that can be shipped and the advantages of using external suppliers. The APS also consists of deployment functionalities which can be used to determine the optimal usage of existing distribution and transport resources taking into account all the constraints. Finally, it contains the production planning and detailed scheduling system which is used to plan the sequence of the production and the scheduling of orders. This can be done with a very high amount of accuracy usually with accuracies as high as 99% (Morris, 2000).

Figure 3 explains the different parts of the advanced planning and scheduling cycle. It starts off with a company planning their supply chain model and setting the limitations and constraints. The company then defines its different locations for supplying products. It then prepares a sales forecast, that is, deciding the amount it plans to sell. It then determines the parameters for its sales plan, that is, the limitations for sales and distribution, then it looks at the orders that it gets and then compares the actual orders to its sales forecast. It then executes its orders. By comparing its actual and forecasted orders, it is then able to fine-tune its supply chain so that the next time around, it is able to try and equate demand and supply for its goods and services.

- **Transportation planning and vehicle scheduling (TP/VS):** The TP/VS sub-module helps in the simultaneous consideration of transportation constraints using the company's transport fleet or using external carriers. This module allows different

Figure 3. APS cycle (Knolmayer & Zeier, 2002)



members of the supply chain to design their transportation activities in such a way that everybody benefits because of the optimal use of transport loads, routes and carriers.

- **Available-to-promise (ATP):** The ATP sub-module can be used to investigate whether a promised delivery can be made. It can be used to determine whether an existing order can be fulfilled accurately. It takes into account all the market forces and determines the most favorable result for both the company and the customer. It works on the principle that the customer is always right and that the customer has to be satisfied under any circumstances.

By learning about the different aspects of supply chain planning, students are able to get an idea of the different terms factors involved in supply chain planning. They are able to grasp the fact that just to plan a supply chain; a company has to plan many different factors like demand and transportation. They are also able to understand the fact that implementation of a supply chain management system involves understanding the factors involved in the demand of a product. They understand that in order for a product to reach the customer the company has to start the supply chain in the planning stage and then move over to the execution stage.

Business Procurement

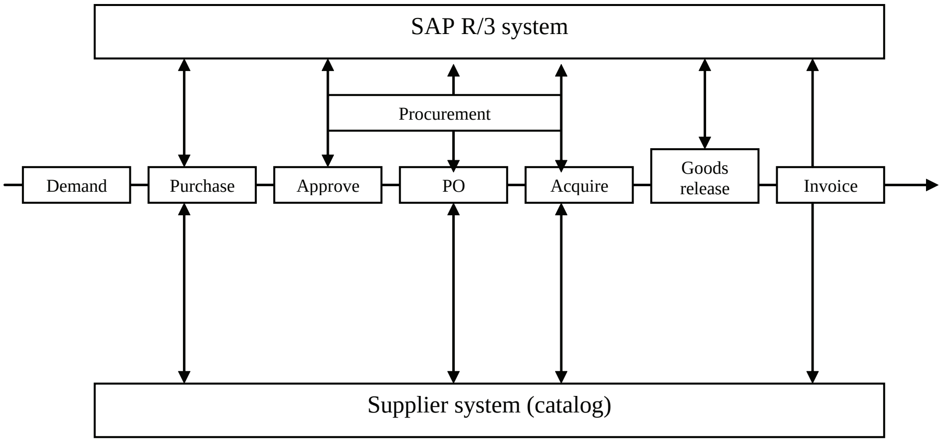
In today's business world, companies need to get raw materials at the right time so that they do now have to maintain excess inventory. Companies are realizing the importance of linking their processes to those of their suppliers so that there is free flow of information. By doing this, suppliers will be able to supply materials needed by the company at exactly the time that the company needs those materials. This concept is explained using SAP's business-to-business procurement module. The business-to-business module takes care of the electronic support for the procurement of goods and services and helps in integrating the purchasing process into the overall flow of goods and information. The advantage of this module is that purchases can be made by individual members of the company using the Internet from their own workplace. Since these tasks can be carried out by individual members of the company, the actual purchasing department can use their time on making strategic decisions beneficial to the company. This module can be used to control and monitor the purchasing process. Since the purchase orders are made by individual members without involving the purchasing department, the receipt of goods is streamlined. This also helps in making the invoicing and payment tasks simpler. It can also be used to connect various product catalogs so that there is a direct interaction between a purchasers and suppliers. This is based on the principle of free market economy where the order is one by the company, which offers the lowest price and the best quality product.

Figure 4 depicts a sales order process from demand of the product to the invoice. This sales order is fulfilled by the company by ordering products from its suppliers using and online catalog on the Internet. This is again linked to an internal ERP system within the company so that there is free flow of information between the different departments of the company.

Warehousing and Distribution

Once the company receives the raw materials and produces finished goods, it has to supply those goods to the customers where and when they need it. The company needs to have a good inventory management system in its warehouses and logistics system so that it does not have to maintain excess inventory while at the same time is able to supply its products to customers at the right time. This is the concept that is explained using SAP's logistics execution system (LES). The logistics execution system helps in efficient

Figure 4. Procurement of parts using the Internet (Knolmayer & Zeier, 2002)



warehousing and distribution using the warehouse management system (WMS) and the transport management system (TMS). The warehouse management system supports the use of various warehouse equipment like rack storage areas. This system is used to monitor the movements in the warehouse and for the management of warehousing activities like unloading, packing, dispatching loading vehicles to the appropriate ramps and the printing of necessary documents. It is also used to maintain the inventory in the warehouse. When dangerous materials have to be handled, this system can be used for creating the regulations and circumstances for the handling of these materials. Warehousing technologies include the use of wireless terminals and mobile barcode scanners. SAP R/3 provides a tool called the radio frequency component which uses radio frequency terminals with scanning devices attached so that the data can be accurately and immediately transferred. These radio frequency terminals have the advantage that they can be mounted almost anywhere and that they receive the data directly from the SAP R/3 system.

The transport management system uses the plans and ideas developed in the transport planning and vehicle scheduling (TP/VS) system and using these ideas helps in providing the functionalities for scheduling, shipping, route planning, calculating freight charges and handling of the products. The transport management system also helps in selecting the best transport companies, determines the best possible routes for transporting materials and helps in scheduling the shipping of the materials. This system takes into account the various constraints imposed on the transportation process because of the nature of the goods being transported and gives the user the best possible solution. It takes into consideration the fact that transportation costs signify the largest portion of costs in any logistical system and so calculates the transportation costs in such a way that these costs are always minimized. It relies on the Internet to communicate with the suppliers and the customers and so can be used to transfer appropriate data in the minimal time possible.

Though the section above gives the user an idea of the different components that can be utilized to effectively fulfill some supply chain objectives, it is still not sufficient. It is more important to understand the flow of business processes within a company. The flow of business processes within a company can be integrated with the help of an enterprise resource planning (ERP) system. Though the ERP system will help to link the different departments within a company, the necessary information has to be transmitted to the company's supply chain partners so that there is a smooth flow of information to suppliers and customers. A company can have all the resources and systems but a system that is implemented on top of a flawed business process is bound to fail and in the long run, create even more problems for the company. In order to implement a good supply chain system, a company has to know which business processes can be improved and then think about how to go about it.

THE BUSINESS PROCESSES IN A SUPPLY CHAIN

The first step to study the company's business process is to understand the company's value chain. The value chain can be seen as a necessary tool for identifying the areas where a company can gain a competitive advantage over its rivals (Porter, 1985). Every firm can be broken down into a series of activities or categories that start at the design of the product and ends with customer support. By looking at each and every detail in terms of the value chain, a company will be able to understand its business process and identify potential sources where it can gain an advantage over its competitors.

Figure 5 depicts the value chain for a company with primary activities that process inputs and produce outputs and the support activities which support the primary activities.

A company's value chain can be divided into primary and support activities. The primary activities are concerned with manufacturing, sale and distribution of the product and can be divided into five categories viz. inbound logistics concerned with inventory, transportation, product returns etc, operations concerned with manufacturing etc, outbound logistics concerned with orders, deliveries etc, marketing and sales concerned with marketing the product or service and service concerned with customer service activities. The support activities support the primary activities and consist of procurement, human resources, technology, and procurement. These activities are again broken down further into different business processes and by understanding these business processes, a company can focus on the area it wants to improve.

Figure 6 illustrates the different departments within a company and the various activities that take place in each department. It depicts how information flows from one department to the other in order to fulfill the sales order. This shows the value chain thinking in action.

Using all the components of a supply chain management given above, a company will be able to design its network and supply chain effectively. However, the design part has to be followed by proper execution of the design. In order to maintain a competitive advantage, a company has to be able to improvise depending on the fluctuations

Figure 5. Porter's generic value chain (Porter, 1985)

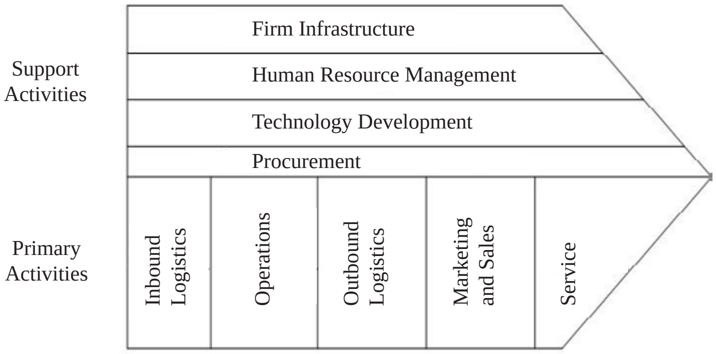


Figure 6. Value chain thinking (Curran, 2000)

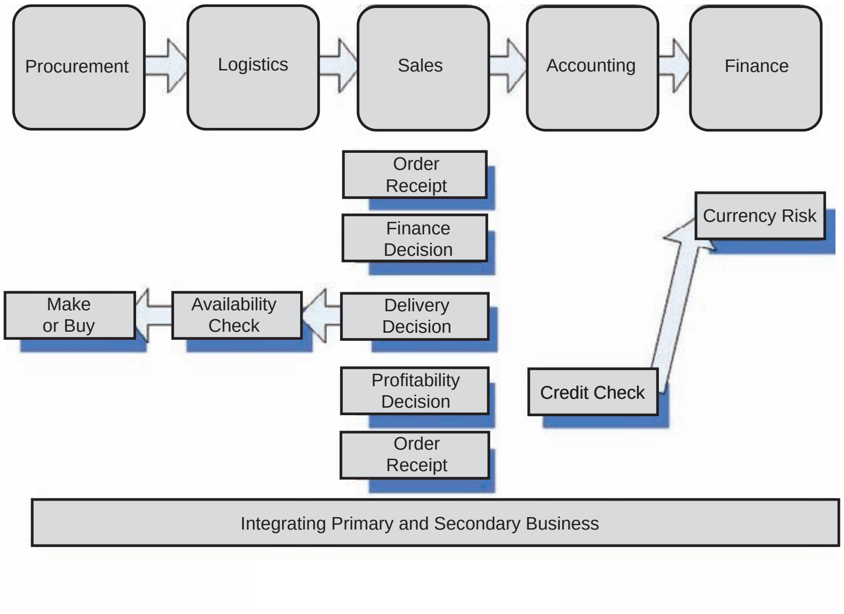


in demand for its products and services. In order to understand how the supply chain works, let us look at the different departments that process the sales order and which ends with the delivery of the products to the customer. By looking at this process, students are able to understand the different processes within a supply chain and also have a general overview of different departments and its functions within a company and how the different SCM and ERP modules help these departments do their job more effectively and efficiently. Logistics, scheduling transportation and materials, procurement from external suppliers, warehousing, inventory management, production, and so forth are some of the areas in a supply chain. But the supply chain also includes areas like product design, sales, procurement, production and distribution.

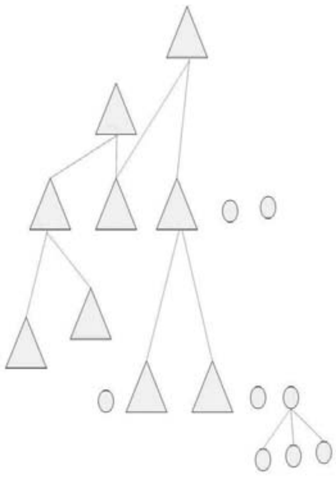
Product Design and Development

Product design and development is one of the most important activities carried out within a company. This includes research and development (R&D), design of the product and so forth. The reason why this part is so important because the data developed initially is sent to different systems to be used. For example: the bill of material (BOM) is sent to the materials resource planning (MRP) module, design data is sent to the computer aided design (CAD) systems and so forth. It is always better to have people from different companies and if possible employees from supplier and customer firms to work together in the design and development of a product. Having different people from different companies and departments in the development stage is beneficial because it will save the company time and money on the modifications of the products, if and when it comes up. Customers have their own preferences for products and this is always the main concern for the sales and marketing teams. Therefore, it is necessary to introduce a few variations in the products so that the customer is fully satisfied. However, by introducing variations in the product, the cost for the companies increases. This happens because it is difficult to forecast the demand for the products with variations, there may be differentiations in the logistics part and so forth. So it is always better to introduce these variations as late in the production process as possible. This concept is explained using SAP's product variant structure (PVS). Students are able to understand the importance of having standardized products as far as possible so that companies are able to cut down on their expenses and as a result, increase their profits. "In SAP, the Product Variant Structure (PVS) can be used to describe the different types of variants. PVS provides filter mechanisms to define function specific variants of products and structures" (Knolmayer & Zeier, 2002).

In Figure 7, each triangle is a part produced by the company and the circles next to the triangles represent the variations in the product. It shows how even though different products can be linked together during design and manufacturing, the variations are separate and may require a separate assemble line which in turn costs the company additional time and resources.

"Every triangle represents a part and points placed next to triangles indicates an alternative" (Knolmayer & Zeier, 2002). In addition to product variations, computer aided design (CAD) systems are used to develop the product. For product design, students are introduced to the CAD interface so that they understand that an SCM system contains not only the planning and execution components of the supply chain but also the design components of the supply chain. The SAP system includes an open CAD interface. It can be used to link different CAD systems so that the data needed to design the product and materials can be taken directly from the SAP system. After the design part of the system, students are explained that an SCM system also has components for documentation and project management. This is explained using SAP's product data management (PDM) sub-module. This sub-module helps in administering the documentation, master data for product classifications and project management.

Figure 7. Visualization of the product variant structure (Knolmayer & Zeier, 2002); triangle — part, point — alternative



Sales

Sales is another area which is very important to optimizing the supply chain. Among other things, sales include the pre-sale activities, the actual sales order, delivery, and customer relationship management.

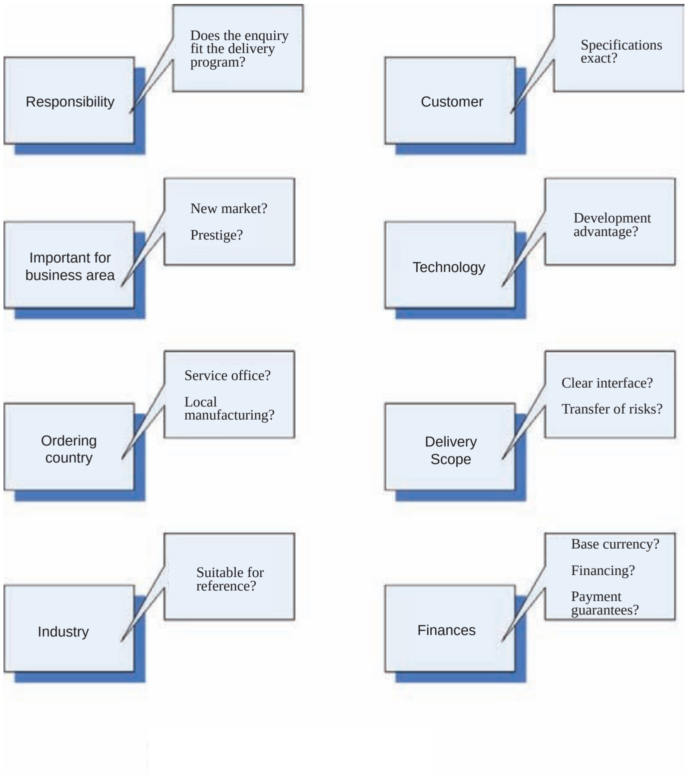
The aim of marketing is to increase the customer base and at the same time reduce the costs of marketing the products to customers. This can be done by targeting specific customers, which reduces the costs of customer visits. The best way to do this is to tap into a large database and select customers to be targeted. Data mining can be used to create customer groups and identify patterns of customers within existing groups. It can also be used to forecast marketing strategies by looking at patterns between complimentary products. For example: companies selling furniture will be able to forecast future sales by looking at customers who purchase a house based on the fact that people who buy a house may at some time in the future decide to purchase furniture. Companies can target these customers for specific marketing strategies. SAP has included many marketing strategies like one-to-one marketing, data mining etc in its mySAP customer relationship management (CRM) module. Data mining can be run on a data warehouse for better results.

Depending on the number of customers in a company, recording a customer enquiry and processing customer quotations may be very important from the company's point of view. This is so because there are many quotations that may have to be processed every day and if the company can use standard quotation elements for processing quotations, it will be able to save a lot of money. Since the quotations involves taking data from materials management, customer master data and inventory management, it is important for the company to have a good system in place for developing quotations. This forms an important part of knowledge management. A data warehouse can contain data from many different sources and this data can be drawn upon to create new quotations.

In Figure 8, each box represents a factor to be considered for a sales quotation while the boxes above the original boxes represent the data within the different factors. This figure explains how data is drawn from different sources within the company to create new quotations.

Large, multinational corporations have a range of products and some of these products are designed even if there is no customer demand for these products or if the customer is not willing to pay enough for these products. In such cases, companies use something called product costing which depends on the maximum price a customer is willing to pay for a product rather than the costs of manufacturing the product. Depending on the market requirements, the products are designed and the maximum price that the customer is willing to pay is taken into account. Since the customer is not willing to go beyond

Figure 8. Checklist for quotation selection (Knolmayer & Zeier, 2002)



a specific price, the company and its suppliers have to come up with ways to reduce the costs of developing and transporting the product. This involves a high degree of coordination between the different parts of the supply chain. Product costing can be carried out with the help of SAP's project system (PS) (Knolmayer & Zeier, 2002). Depending on the maximum allowable limits for the costs in the different business processes, the system generates messages when these limits are exceeded. This system is customized according to the customer requirements which help in building the customer base. Another way of providing total customer satisfaction is to introduce the concept of mass customization. Mass customization can take place successfully only when there is a free flow of information between the suppliers, the company, and the customers. If this happens, as soon as the customer places the order, it triggers an assemble-to-order process and by doing this, companies will be able to satisfy even the smallest customer demand thereby increasing its customer base. SAP provides the "Order Entry with configuration" system in which data is directly entered into the SAP system using the Internet and which triggers the production process immediately (Knolmayer & Zeier, 2002).

When an order is received from a customer, there are many checks that have to be performed before the order can be processed. If the customer requires a customized product, then checks have to be performed to see whether the company can manufacture the product on time and deliver it to the customer. Credit checks have to be performed in order to see whether the customer has a good credit standing with the company. SAP has credit management functionalities in the sales and distribution (SD) and the financial accounting (FI) modules. Also, these modules contain functionalities by which the customer can pay for the order using different kinds of payments. The important part here is that these systems are integrated with many different kinds of customer-centric systems and all the data is stored in a central database. Another check that has to be performed is whether the company will be able to meet the customers' required delivery date. If it does not, then the company has to schedule the production process and inform the customer accordingly of the new delivery date. In order to do this, it has to coordinate fully up and down the supply chains so that the production process and the logistics process can work simultaneously in tandem with each other. SAP permits the planned delivery time to be calculated depending on the availability of a product by calculating the inventory, production capabilities, resources, and so forth. It does this using the available-to-promise (ATP) module of the advanced planning and optimizer (APO) system. With the advent of the Internet, communication between different companies has become a lot easier and if a company has business customers (B2B e-commerce), then it can use the Internet to communicate with its business partners. Electronic trading exchanges and portals are one of the best ways to interact with business partners. SAP has developed the business-to-business procurement solution which uses the Internet for communication (Knolmayer & Zeier, 2002). "The Internet helps companies in the obtaining the raw materials, processing sales orders, the billing process, and so forth. In addition to this, e-commerce has grown on a large scale and has become a widely used form of selling products and services. Online stores are a predominant way of getting in touch with the customers and making a sale. This involves credit card transactions online and security measures like secure socket layer (SSL) and digital signatures are of paramount importance" (Knolmayer & Zeier, 2002). The SAP online store can be used to create an online product catalog on a company's Web site on the Internet (Knolmayer & Zeier, 2002). The data entered by customers on the Web site is transferred to a transaction server and this in turn is transferred to the SAP database where these orders are processed (Knolmayer & Zeier, 2002).

After the order is processed, it is necessary to have a good customer service system which involves the products to be stocked in stores and how much space to allocate to each item, good replenishment systems, good marketing and promotion systems and efficient new product introduction systems (Knolmayer & Zeier, 2002). Value can be added to the value chain only when all these things can be implemented correctly and this can occur only when there is total trust between the suppliers, the company, and the customers and when there is free flow of information in all parts of the supply chain. This can take place when the vendor manages the inventory so that any fluctuations in customer demand are directly visible in the vendor systems and by which the vendor can take immediate action to satisfy customer demand. The SAP APO system provides the tools for vendor managed inventory (VMI) and which is a very popular and efficient way of satisfying customer needs. In order to take care of customer needs, SAP offers tools to the sales people in a company as part of its mySAP customer relationship management (CRM) system. The sales people are able to retrieve to customer data anywhere from the data warehouse. They are also able to configure products based on a customer's needs and run queries and reports on the data warehouse in order to extract the exact data that they want.

Procurement

Procurement is an important part of the supply chain because only when the raw materials arrive on time is the company able to start producing the products. In procurement, it is very important to have a close relationship between the sales departments and the purchasing department. By sharing information, the demand can be anticipated by the sales department and this can be transmitted to purchasing which can take the necessary steps to procure the materials needed to complete an order. Just-in-time procurement and vendor managed inventory (VMI) are two methods by which companies can cut down on procurement lead times and fulfill customer orders. The advent of the Internet has greatly enhanced the way companies procure raw materials from its suppliers. By having a direct line of communication with its suppliers, a company is able to share demand information with these suppliers. By using procurement portals over the Internet, a company is able to provide a single point of access for its suppliers and at the same time share information cheaply using the Internet. The SAP business-to-business (B2B) component allows all the procurement tasks and activities to be conducted over the Internet. It also allows product catalogs to be offered over the Internet.

Figure 9 explains how users use Web browsers to access and search a company's online store. This search is done using a search engine on the company's online store and this search engine is linked to the company's product catalog and the company's online database in order to retrieve customer queries in the shortest possible time.

Good procurement techniques come into effect when all the parts of the supply chain including all the systems are linked together to form part of a big, cohesive system. This will allow the free flow of information between all parts of the supply chain and will go a long way in adding value to the value chain of a company.

Figure 10 shows how the different components of an information system are linked together right from an online store to the company (its value chain) and the different components of its SCM system. This results in a free flow of information up and down the supply chain.

Production

Once all the materials are available, the production process has to be started. The main goals of production are to reduce the lead times, to manage inventory in the production process and utilize all the resources efficiently (Knolmayer & Zeier,

Figure 9. Use of the Alta Vista search engine in the SAP online store (Knolmayer & Zeier, 2002)

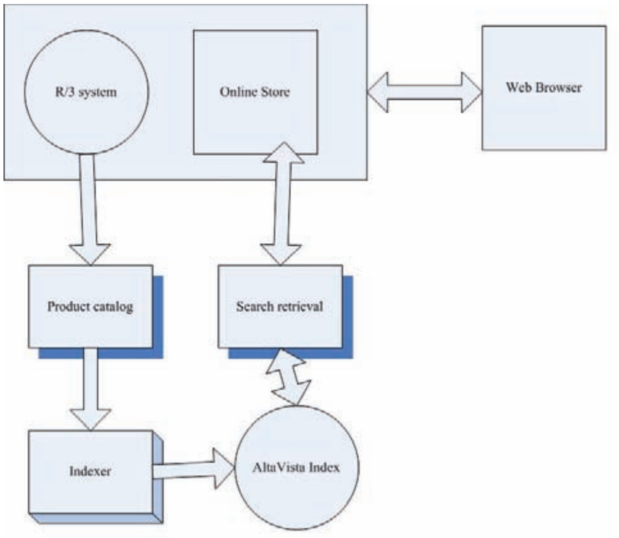


Figure 10. Cooperation of SAP components (Knolmayer & Zeier, 2002)

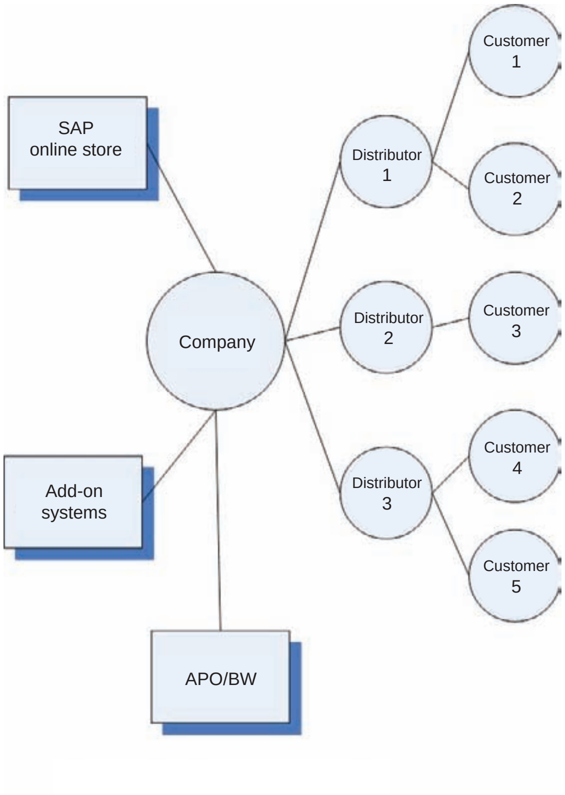


2002). This can be achieved using the materials requirements planning (MRP) functionality in the production planning (PP) module. Projects can be managed using the project management (PS) system. It may so happen that a company may have different manufacturing facilities in different parts of the country or the world and it is necessary for the distribution of production to be partially or fully centralized. This will allow the company to get all the data required for production without the need to worry about where the data and materials are stored. However, MRP within standard ERP systems is used to plan the production within a company while SAP's advanced planning and optimizer (APO) provides algorithms that can be used to support the entire supply chain (Knolmayer & Zeier, 2002). The advanced planning and scheduling (APS) module provides much different functionality that can overcome the shortcomings of standard MRP systems. Production can also be improved using the Kanban and just-in-time systems. The production planning (PP) module in the SAP system supports the Kanban principle and this allows the external and internal procurement, production and supply from a warehouse (Knolmayer & Zeier, 2002). The

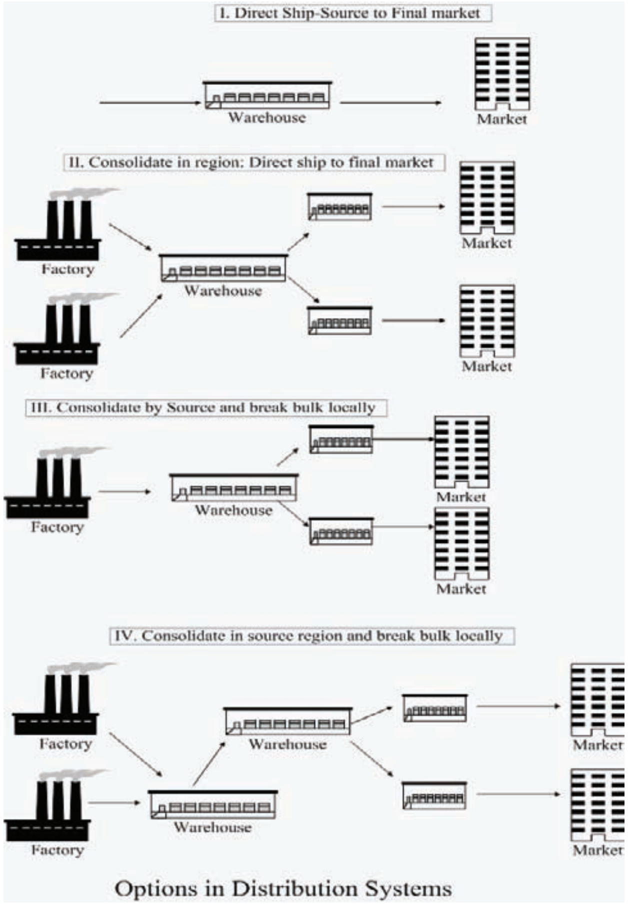
SAP APO uses mathematical models which takes into account the problems in capacity planning, constraints in production, material stock-outs, inventory levels etc and tries to come up with an optimal solution that will allow the company to streamline its production process.

Distribution and Logistics

Once all the products, materials, and services are ready, it is necessary to package and distribute them to the company's warehouses and outlets and from there transport these products to the customers. Usually, products are supplied to the customers either from a central warehouse or from local warehouses. A systems called cross-docking distribution tries to combine the advantages of both these types of distribution (Knolmayer & Zeier, 2002). This works in such a way that even though goods are transported to warehouses, they pass through as fast as possible because these goods have already been assigned spaces in the warehouses and storage locations and the picking and delivery parts have already been decided. "This concept has been developed by Wal-Mart. The warehouses use laser-controlled transportation systems where barcodes indicate to which trucks the incoming goods have to be routed" (Knolmayer & Zeier, 2002).

Figure 11 explains the different options that a company has in order to distribute its products from its production facilities to its markets using different components like wholesalers and retailers who make up the supply chain.

Figure 11. Options in planning of distribution systems (Knolmayer & Zeier, 2002)



The distribution systems include transport models which look at the optimal transportation techniques and route planning models which look at which vehicles should be used to satisfy demand. The SAP logistics execution system (LES) is an important component of the SCM system. Route planning is the trigger point in LES and by selecting the mode of transport; the resulting routes are calculated by the system. It also provides a graphical display of the planned routes on the screen for better visualization. It also includes distribution requirements planning systems, fleet management systems and shipment tracking systems. To determine where a company's vehicle is on the road at a given time, the fleet management systems are linked to global positioning systems (GPS). Using satellite technology, the exact location of a vehicle can be determined and this information is passed on to the customer using shipment tracking systems so that the customers know exactly where their ordered products are and the expected time of arrival of the products. For customer service, SAP also has a SAPPhone interface to provide data to call center personnel (Knolmayer & Zeier, 2002). "In addition, a help desk can be organized using SAP Call Center Components" (Knolmayer & Zeier, 2002). Logistics and distribution also involves reverse logistics by which goods that are damaged or not required by the customers can be returned back to the company. These goods travel up the supply chain and the system makes sure that this is done in the least possible time and at the minimum possible cost. The system automatically updates the data in all the modules of the ERP and SCM systems.

FUTURE TRENDS

The Internet is changing the way companies do business by providing a cheap and efficient form of communication. One of the most important trends to be noted is the convergence of ERP, SCM and CRM systems. Customers always like to have systems that compliment their existing systems for example; customers with SAP's ERP system prefer to have a supply chain management system developed by SAP so that they can be sure that both their systems will be compatible. So, ERP vendors are providing SCM and CRM solutions while SCM and CRM vendors are developing ERP solutions. In order to contain supply chain costs, it is necessary for companies to look beyond their existing borders and try and collaborate with different supply chain partners (Srikanth RP, 2003). Outsourcing has become very common in today's business world and companies look at ways to cut labor costs with outsourcing. Since companies outsource their business processes to different countries throughout the world, it has become all the more important to have an efficient and responsive supply chain to satisfy customer demand. Most companies have stand-alone business solutions for certain departments. However, companies are now realizing the benefits of having an integrated approach in which all the different software solutions are part of the same package. The Internet has made sure that geographical boundaries do not exist anymore and companies are able to track the cheapest suppliers anywhere in the world and also reach a customer anywhere in the world. This has led to a significant increase in the number of suppliers and also the number of customers. An increase in the number of suppliers and customers has led to an increase in the number of transactions carried out everyday. In order to maintain these transactions and gain a competitive advantage over their rivals, companies are investing in supply chain planning and supply chain execution systems. These systems not only help a company develop its customer base but also help in maintaining it over an extended period of time.

SUGGESTIONS TO LEARN THE SUPPLY CHAIN MANAGEMENT PROCESS

There are many details, which the user can use in order to successfully learn the business processes involved in a supply chain. Some of these suggestions are:

1. In order to understand how a supply chain works, users should try and understand the business processes in a supply chain.
2. To understand the business processes in a supply chain, users can look at the business processes that take place within a company and try and understand those business processes. After understanding the business processes within a company, it will be easier to understand the processes that take place between two or more companies.
3. There are many similarities in the transactions in an ERP system and an SCM system. If users are able to understand the transactions in an ERP system, they will also be able to understand the processes in an SCM system.
4. A good way to learn how the system works is to actually work on the system. Users should try to implement what they learn in this chapter on an actual system.
5. Another good way to learn about the SCM process is to create many companies within the system and carry out transactions between those companies.
6. Before carrying out the transactions, users should try to use the design part of an SCM system. By using the different modules of a supply chain management system, users will be able to design their own supply chain between suppliers and customers.
7. Once the supply chain is designed, users will be able to visualize how an actual supply chain looks like and how a change in one part of the supply chain affects all the different parts of the supply chain.

LESSONS LEARNED

There are many things that a user should be able to follow after going through this chapter. Users should:

1. Understand the different modules in a SCM system and know how each module helps create an efficient supply chain
2. Have an understanding of the business processes in a supply chain
3. Understand how the SCM process and the processes within an ERP system are linked together
4. Know how to fix the errors that may come up. By fixing these errors, users will be able to better understand the flow of data within the system
5. Know the different departments that can be involved in a company's supply chain and how these departments can use the modules of an SCM system

STRENGTHS AND WEAKNESSES OF THE SYSTEM

Each system has its own strengths and weaknesses. Some of the strengths and weaknesses for a SCM system are listed next:

Strengths

1. The main purpose of a training SCM system is that users can make mistakes and learn from the system rather than making a mistake during an actual implementation which can prove to be very expensive for the company.
2. By understanding the different departments that can be involved in a supply chain, users will be able to grasp the significance of each department and focus on the business processes that interest them the most.

3. By understanding the business processes, users can create their own companies and carry out transactions between those companies. Users will be able to learn the importance of having an efficient supply chain and know how a small change at one end of the supply chain is reflected at the other end.

Weaknesses

1. The main problem with an SCM system is that users should have access to such a system. The design modules form an important part of the SCM system and users should be able to access those modules to learn how a supply chain can be designed from scratch.
2. Another problem that the users can face is the lack of technical support or technical documentation. But by going through this chapter, users will have a basic understanding of how a supply chain works and this may help them in overcoming technical difficulties.
3. Some users may encounter errors while going through the SCM process in the system. This happens because in a supply chain management process there are many different companies involved and users have to learn to coordinate between different departments.
4. For users who are new to the system, getting familiar with the system may be time consuming. However, by going through this chapter, users should be able to understand the system better.

CONCLUSION

Companies are changing the way they do business by moving from vertically integrated enterprises to horizontally integrated enterprises. They do so by increasing the number of suppliers and procuring products and services from may different suppliers rather than produce everything in-house. This is achieved by having good supply chain management systems, which help in reducing waste between the company and its suppliers and the company and its customers. By having good supply chain management systems, companies can focus on their core competencies and improvise on it. This chapter looked at some SCM initiatives and how it can be used by companies to satisfy customer demand. However, though all these things are important from a broad perspective and though we have looked at the different components in a SCM system and studied their importance, it is always better to work on an actual implementation to gain a thorough understanding of how an SCM system operates. This will help the user to implement the theoretical knowledge and will go a long way in making certain that the user has totally understood the different internal and external business processes that take place in a company.

ABSTRACT

Supply chain risk management has increasingly becoming a more popular research area recently. Various papers, with different focus and approaches, have been published since a few years ago. This paper aims to survey supply chain risk management (SCRM) literature. Paper published in relevant journals from 2000 to 2007 are analysed and classified into five categories: conceptual, descriptive, empirical, exploratory cross-sectional, and exploratory longitudinal. We also looked at the papers in terms of the types of risks, the unit of analysis, the industry sectors, and the risk management process or strategies addressed. The literature review will provide the basis for outlining future research opportunities in this field.

INTRODUCTION

The practitioners and scholars believe that the effective supply chain management has become an important enabler to improve organization performance and valuable way of securing competitive advantage (Chirderhouse et al, 2003; Li et al, 2006). The intensifying business competition since 1990s has forced companies to improve efficiency in many aspects of their business. On the other hand, the increasing uncertainty requires them to spend more resources to anticipate for demand, supply, as well as internal uncertainties for better sustainability of their supply chain. Interestingly, such an increasing uncertainty is not solely induced by the external business environments, but also due to increasing complexity of the supply chain structure and varying mechanism initiated by the supply chains in their business. The trend of companies outsourcing their activities to outside parties has certainly created a new source of uncertainty. The chance of having a delay in raw materials delivery is increasing if a company relies to outside parties to do most of the inbound logistics activities. Likewise, the trend of supply base reduction has exposed some companies to more risks than the associated benefits.

Risk and uncertainty has always been an important issue in supply chain management. Earlier literature consider risks in relation to supply lead time reliability, price uncertainty, and demand volatility which lead to the need for safety stock, inventory pooling strategy, order split to suppliers, and various contract and hedging strategies (see Tang (2006a) for an excellent review of various quantitative models considering supply chain risk). Although supply chain management has always had a strong emphasis on risk, the notion of supply chain risk management has gained an increasing popularity in recent years due to increasing supply chain complexity, including the use of global contract manufacturers and suppliers. Faisal et al.(2006b) and Tang (2006a) believe that effective supply chain risk management (SCRM) has become a need for companies nowadays. Companies like Ericsson (Norrman and Jansson, 2004) and Nokia (Li et al, 2006), have long realized the need for an effective risk management in their supply chain operations.

According to Chopra and Sodhi (2004), the supply chain risks could be in the form of delays of materials from suppliers, large forecast errors, system breakdowns, capacity issues, inventory problems, and disruptions. Another classification is provided by Tang (2006a) who categorized supply chain risks into operations and disruptions risks. The operations risks are associated with uncertainties inherent in a supply chain, which include demand, supply, and cost uncertainties while disruption risks are those caused by major natural and man-made disasters such as flood, earthquake, tsunami, and major economic crisis.

Numerous articles on supply chain risk management have been published in the last 20 years, the oldest being the article by Kraljic in 1983 (Paulsson, 2004). An attempt to review articles on supply chain risk management was done by Paulsson (2004). The author classified the articles using three dimensions: the unit of analysis, type of risk, and risk handling. From our observation, there are many more SCRM articles published since the appearance of Paulsson's review, making it beneficial to provide a more up to date review to include more recent articles. Tang (2006a) reviewed SCRM articles, but he focused on quantitative models. The author classified articles according to four basic supply chain areas: supply management, product management, information management, and demand management. The purpose of this article is to provide an extensive literature review on supply chain risk management. In particular, we aim to:

- Classify SCRM articles according to their approach and methodologies
- Discuss opportunities for future research

REVIEW METHODOLOGY

Search Methodology

In this review, we did exhaustive search of the articles related to supply chain risk management. We collected articles published from 2000 to 2007, focusing on risk management issues pertinent to manufacturing and supply chain management. There are two reasons for not including papers published prior to 2000. First, although traditionally risk and uncertainty have always been an important issue related to supply chain management literature, the term “supply chain risk” is relatively new to the literature. Our search in two major literature databases (Science Direct and Emerald Online) using a keyword “supply chain risk” revealed no result for papers published prior

2000. Second, the issue of supply chain risk management has gained much attention after a series of events having major impacts on supply chain, including fire in one of the Ericsson's supplier in New Mexico in 2000 that led Ericsson to a loss of about 400 million Euros, insolvency of one of Land Rover's supplier in 2001 causing this company to lay off 14000 workers, and certainly the tragic terrorists attack on the World Trade Center on September 11, 2001 causing major supply chain problems to the world (Norrman and Jansson, 2004; Paulsson, 2004; Tang, 2006b).

The literature search was done through various electronic databases, including Science Direct, Emerald Fulltext, EBSCO, ABI/INFORM Global Pro-quest, and Inderscience. The keyword used for the search was "supply chain risk". This search revealed nine articles in Science direct (abstract, title, and keywords), 30 articles in Emerald, 5 articles in EBSCO (abstract, title, and keywords), 10 articles in Inderscience, and 154 in ABI/inform Global Pro-quest academic database (full text documents and scholarly journals, including peer-reviewed) in August 2007. A total of 208 articles were found. After looking at the types of articles, we discarded those not belong to refereed journal articles such as prefaces, editorial notes, book review, and interview. Finally, we ended up with 82 relevant articles to be reviewed in this article.

Classifications

A total of 82 articles (from 39 journals in 5 journal databases) have been reviewed. Thirty eight percent of the SCRM articles have been published in the following four journals.

- International Journal of Physical Distribution & Logistics Management
- International Journal of Production Economics
- European Journal of Operations Research
- Production and Operations Management

It is interesting to note here that the SCRM articles are published in so many different journals, indicating the multi-disciplinary nature of the problem. In table 1, the distribution of articles published in various years and the publishing journals are shown. The International Journal of Physical Distribution & Logistics Management has much more articles on SCRM than other journals as it published two special issues (volume 34 (5) and volume 34 (9), both in 2004), covering this issue. Other well known journals, such as the Journal of Operations Management, have also called papers for a special issue on SCRM, suggesting that the distribution of SCRM papers among relevant journals would be more even in the future. As depicted in figure 1, the number of articles is generally increasing during the period of 2000 – 2006 and there is a big jump from 2004, indicating that the research on SCRM attracts attentions of many researchers.

ANALYSIS OF RESULTS

Methodologies

Different methodologies used by various researchers are divided into five categories, according to Malhorta and Grover (1998) which include conceptual, descriptive, empirical, exploratory cross-sectional and exploratory longitudinal. The distribution of supply chain risk management papers according to the various methodologies is shown in Figure 2. As it is shown, almost half of the papers applied the descriptive approach in their methodology. In the second place is the empirical research, and is by far lower than the two are conceptual and exploratory researches. The descriptive and empirical researches together account for 80% of the methodologies used.

The conceptual is meant to represent a research methodology that describes basic/fundamental concepts on supply chain risk management. In this classification, most papers propose a conceptual

Figure 1. Number of articles of supply chain risk management in 2000-2007 periods

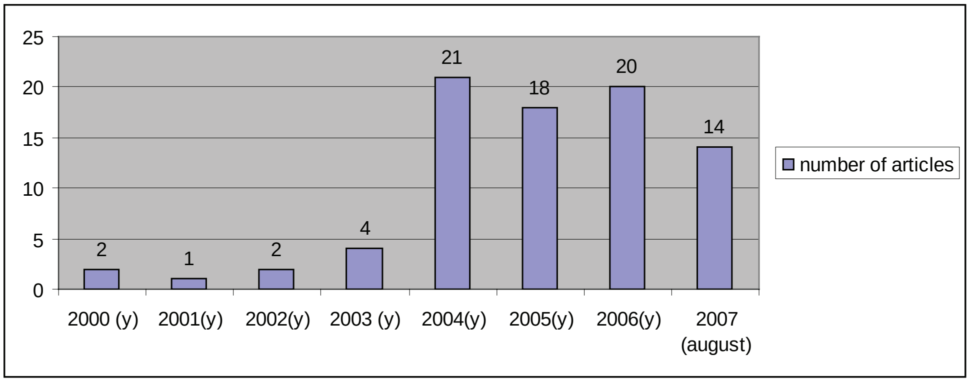

Figure 2. Research methodology used in SCRM articles

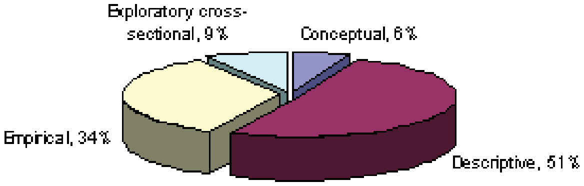

methodology for managing supply chain risks. For example, Cucchiella and Gastaldi (2006) developed a framework for the management of uncertainty in the supply chain in order to minimize firm risks. The authors employed a risk option approach to increase firm's flexibility as a means for dealing with uncertainty within a supply chain. Some papers in this category also clarify some matters related to supply chain and supply chain risk management, including their definition. Peck (2006) examined the term supply chain, supply chain management, and then the fusion of supply chain management with risk. The author then argued that the supply chain risk should not be addressed solely within a functional SCM perspective, but required cross-functional concerns.

Descriptive is a methodology that descript, formulates, and develops model in supply chain risk management. For example, there are models that have been developed as a supply chain management framework that include identification, analysis, and prioritizing mitigation actions. Some popular tools such as failure mode and effect analysis (FMEA) and analytical hierarchy process (AHP) have been used for this purpose. Wu et al.(2006) and Gaudenzi and Borghesi (2006) for example applied the AHP model, Sinha et al. (2004) applied the FMEA approach, and Cucciella and Gastaldi (2007) applied the real option model. Some authors also developed mathematical models to analyse risk behaviour in supply networks (for example Nagurney and Matspura, 2005; Nagurney et al, 2005).

Empirical is a methodology in which the data for study is taken from existing database, case study, literature review, and taxonomy or typology approaches. Some of the studies in this category are in the form of a survey study involving practitioners as respondents. Zsidisin and Ellram (2003) did a survey involving respondents of purchasing professional associated with the Institute for Supply Management ^{TM} (ISM). The authors investigated the concept of agency theory within the context of supply risk management.

Juttner et al. (2003) conducted a field research involving interviewees from manufacturing companies, retail sectors, and logistics service providers. The researchers first interviewed the companies' representatives separately for each company and then they were invited for a focus groups discussion. The study seek to identify future research agenda and then to clarify the concept as well as to propose a working definition for supply chain risk management.

Exploratory cross-sectional is a methodology where the information is collected at one point in time. Peck (2005) proposed a framework, based on the results of the exploratory study, for analyzing the scope and dynamics of supply chain risks. The framework is consisted of four levels of supply chain elements, i.e., value stream / product / processes, asset and infrastructure dependencies, organizations and inter-organizational networks, and then the environment. The author argues that a robust or resilient supply chain can not be done by merely good design and management of supply chain processes, but should also taking into account the system more widely to include the other three levels.

Exploratory longitudinal is a survey methodology where the data collection is done at two or more points over time in the same organizations. We found no paper applying this methodology. The fact that the supply chain risk management has just received much attention quite recently could be an explanation for why this methodology has not been applied in this field.

Industry Sectors

SCRM articles appear to be spread over many industrial sectors. Most of the applications have been in the electronics and aerospace sectors. It is understandable that the supply chain risk management has been mostly applied to the electronic sector. As suggested by Sodhi (2005), the electronic industry is prone to risk due to short product life cycle and high demand uncertainty. Ericsson supply chain risk management model (Norrman and Jansson, 2004) which was developed after a fire at its sub-supplier is one of the mostly discussed cases in the supply chain risk literature. The aerospace on the other hand is exposed to risk due to its complexity. The product complexity as well as the supply chain structure complexity brings much risks and uncertainty to the aerospace sector. Sinha et al. (2004) developed a framework for mitigating supply chain risks in an aerospace industry. The authors suggest that such risks as lack of common terminology among supply chain players, conflict in OEM requirements, and lack of raw materials are examples of risks that could happen in this sector. To a lesser extent, supply chain risk management have also addressed the automotive, telecommunication, semiconductors, machinery and machine tools, metal industry, and other sectors. Table 2 presents the classification of the papers according to the industry sectors where they are applied. Based on scale of the companies, the SCRM are mostly biased toward large rather than small and medium enterprises.

Unit of Analysis

We also categorized the papers from the perspective of the unit of analysis following Norrman and Lindroth (2004). The unit of analysis describes the complexity of the entities from which the supply chain risks are viewed. This article uses the level of complexity from a single logistic activity to a supply network. Logistics is that part of SCM process that plans and control between the points of internal company such as: traffic and transportation, warehousing and storage, industrial packaging, etc (Coyle et al, 1992). Thus, risks can be evaluated from a single supply chain function such as procurement, planning, transport, warehouse, etc. Dyadic relations represent a relationship between two organizations within a supply chain. For example, the relationship between a manufacturing company and one of its suppliers can be considered as a dyadic relation. The supply

chain, on the other hand, is considered here as a set of three or more entities which work together to produce and deliver products from sources to customers (Mentzer et al, 2001). The most complex unit of analysis is the supply network. Choi and Krause (2006) define supply networks is “all inter-connected companies that exist upstream to any one company in the value system”.

Our categorization shows that most SCRM literature addresses a supply chain as a unit of analysis followed by a dyadic relationship in the second place. We found only one article which exclusively looking at risk from solely a single logistic activity, i.e., Wilson (2007). The author investigates the effect of transportation disruptions on supply chain performance using system dynamics simulation. Although there are many articles, which looked at only one side of the supply chain (e.g., supply risk or inbound risks), we consider them to fall within a dyadic relationship as some risk sources are from other organizations (e.g. from supplier). On the other extreme, we also found only limited articles looking at risks within a supply network. The complexity of the structure and relationships obviously prevents ones to be able to capture a network when addressing supply chain risks. Table 3 shows the categorization of papers according to the unit of analysis, excluding those papers which do not use any unit of analysis in their study.

Types of Risks

There are various types of supply chain risks. Chopra and Sodhi (2004) categorized supply chain risks into disruptions, delays, systems, forecast, intellectual property, procurement, receivables, inventory, and capacity. In the aerospace industry, Sinha et al. (2004) classified four areas of risks which include standards, supplier, technology, and practices. In each of these four areas, there is a number of supply chain risks that could happed. Finch (2004) classified risks into three broad categories which include the three levels of coverage: application level, organizational level, and inter-organizational level. At the application level, the risks include natural disasters, accidents, deliberate acts, data/information security risks, and management issues. At the organizational level, such risks as legal and strategic changes in decisions could happen, while at the inter-organizational level, there are possible uncertainty from the outside of the organization which could pose risks. Other classification of risks can be found in other articles, including for example Mason-Jones and Towill (1998), Juttner et al.(2003), Peck (2005).

Following the classification in Norrman and Lindroth (2004), we categorize the type of risks addressed in the SCRM papers into operational accidents, operational catastrophes, and strategic uncertainty. The operational accidents are those

affecting the operational process or resources related to logistics / supply chain, such as fires, truck accidents, machine failures, labor strikes, etc (Norrman and Lindroth 2004). Most companies are facing day-to-day operational accidents, but the frequency of those risks happening depends on how good they manage supply chain risks. Operational catastrophes are risks associated with rare and difficult to predict events, but once occurred; they have severe impacts on the company. Such risks as natural disaster, socio-political instability, economic disruptions, and terrorist attacks are examples of operational catastrophes. Finally, the strategic uncertainties are the type risks that are generally difficult to address and affect the company not at the operational level, but strategically. The strategic uncertainty could be in the form volatile demand, supplier default/bankruptcy, increasing competition, market constraint, and technology change.

Certainly, each company would have a different set of typical risks. In aggregate terms, there is a common pattern in the types of risks the companies/supply chains are facing. For example, the operational catastrophes are less likely to happen compared to the other two types. However, recently the operational catastrophes are happening with an increasing rate, making it a necessity for companies to have well prepared mitigation strategies for this type of risks. We witness increasingly more frequent natural disasters, which cause operational catastrophes in recent years, including for example the earthquake, tsunami, floods, etc. Table 4 shows the types of risks addressed in the SCRM literatures.

As table 4 shows, operational accidents and strategic uncertainty are discussed in about the same number of papers, while the operational catastrophe has received relatively less attention. Interestingly, only 7 papers addressed all three types of risks (Juttner et al. (2003), Zsidisin

(2003a), Christopher and Peck (2004), Norrman and Jansson (2004), Peck (2005), Wagner and Bode (2006), Wu et al.(2006)). Certainly, it would be interesting to develop more analysis to see if different types of risks are associated with different industry sectors. For example, one would think that the strategic uncertainty could be very much a concern of innovative industries as product life cycles are becoming shorter and shorter with rapid technology development. On the other hand, operational accidents could be associated with low awareness of internal risks which is often attributable to weak management systems. The future studies should attempt to look at a more detailed level the typical risks each industry sector is facing.

Risk Management Process or Strategies

Risk management processes refer to the stages a supply chain or a company could follow to reduce the supply chain risks. It normally involves such activities as identifying supply chain risk events, assessing the probabilities and the severity of impacts, prioritizing the risk event to be dealt with and developing actions for mitigating risks or planning for backup actions. In the identification stage, one may use various techniques or tools to list various risk events that possibly occur in the supply chain. Most of the techniques at this stage are qualitative in nature. Brainstorming within the research team or which include experts from industry are common practices that have been used at the identification stage (see Hallikas et al., 2002; Zsidisin, 2003b; Norrman and Jansson, 2004; Sinha et al. 2004; Wu et al, 2006 for examples of articles using brainstorming). Some models have also been used to assist in identifying supply chain risks at this stage, such as IDEF0 (Sinha et al, 2004) and AHP (Wu et al, 2006). Some other tools such as Fault Tree Analysis (FTA) and Event Tree Analysis (ETA), which have been used in technical areas such as maintenance, have not been popularly used in the supply chain risk management.

In the assessment stage, a number of approaches are possible including brainstorming, process mapping, risk impact analysis, and scenario planning. A popular model used in the assessment stage is the failure mode and effect analysis (FMEA) where we can assign a priority list to each risk based on the multiplication of the probability of occurrence and the severity of the impact caused. Some authors have developed an innovative model for supply chain risk management where assessment is a critical stage within it. For example, Norrman and Jansson (2004) described a model called ERMET (Ericsson Risk Management Evaluation Tools). Brun et al.(2006) described another model called SNOpAck (Supply Network Opportunity Assessment Package).

In assessing supply chain risks, authors use different scales. Some authors (Hallikas et al, 2002; Norrman and Jansson, 2004) use a 1 – 4 scale while Hallikas et al.(2004) use a 1 – 5 scale. Each number corresponds to a verbal definition. For example, in defining the magnitude of impacts (severity), the values of 1, 2, 3, 4, and 5 represent low, medium, high, very high, catastrophic impacts respectively. Zsidisin (2003b) and Sheffi and Rice (2005) only use two levels, i.e., high and low, to assess the magnitude of risks.

Mapping the risks into a graph or a matrix could be useful in the analysis stage. Such visualization is particularly desirable to assist management in a company communicating risks internally as well as to other parties within the supply chain. The traffic light analysis such as the one presented by Norrman and Jansson (2004) is a good visualization of risks. They use colors to highlight the different magnitude of risks and hence, prioritization can be easily judged from the colors.

The risk management involves the course of actions to consider in order to reduce the risks. This can be done by reducing the probability of occurrence, the severity of impacts, or both. Generally, risk management involves such options as transferring it to or sharing it with other parties, accepting it as it is, or avoiding the risks. Transferring risk to other parties is a common supply chain management practices nowadays. An example would be the outsourcing / subcontracting practices where some types of supply chain risks are transferred to the parties providing the products or services. Some global players outsource the whole production processes to outside parties which automatically means that such a company does not need to deal with labor and production facility problems. Risk sharing maybe developed in terms of a joint collaboration for risks involving two or more parties in a supply chain. Juttner et al.(2003) suggested that cooperation with supply chain partners is one of the mitigation strategies for supply chain risks. The cooperation can be in terms of joint efforts to improve supply chain visibility and understanding, joint efforts to share risk related information, and joint efforts to prepare supply chain continuity plans. Dropping specific products, geographical markets, suppliers, or customers can be considered as a way to avoid risks.

One major action that each company should do is to develop an alternative plan or contingency plan to mitigate the supply chain risks. Such an alternative, which is also called as business continuity management (Juttner et al, 2003), is developing well in the area of supply chain risk management recently. According to Norrman dan Lindroth (2004), business continuity planning / business continuity management (BCP/BCM) cover wider scopes than the supply chain risk management. BCP/BCM includes crisis management, disaster recovery, business recovery, and contingency planning which are often not considered to be the main focuses of supply chain risk management.

As presented by table 5, the SCRM articles address the four general risk management processes well.

CONCLUDING REMARKS AND OUTLINES OF FUTURE STUDIES

We have presented a classification of articles on supply chain risk management (SCRM) published in recent journal papers based on the classification methodology of Malhorta and Grover (1998). The review shows that SCRM is a rapidly grow-

ing area since a few yeas ago. Papers on supply chain risk management address various types of supply chain risks and authors developed various risk classifications. In this article we follow the classification of Norrman and Lindroth (2004) where the supply chain risks are categorized into operational accidents, operational catastrophes, and strategic uncertainty. Understanding the types of risks and their probability of occurrence as well as the associated impacts is a starting point for companies to develop effective risk management strategies. From methodological point of view, most published papers were based on empirical and descriptive, while very few based on exploratory research.

Since supply chain risk management is still in the infancy stage and the need for better supply chain risk management is high, this field will continue to be placed on top list of future research agenda. We discuss here a number of possible research opportunities in this area.

The first agenda is related to the use of technology in relation to supply chain risk management. As suggested by several authors (Atkinson, 2004; Giunipero and Eltantawy, 2004; Tang, 2006a; Wilson, 2007), the use of technology such as RFID and ERP will become an important facet of supply chain risk management. More research should be conducted to learn how technologies could be used to mitigate risks in a supply chain. In general, the use of information technology could improve information visibility across the supply chain. Certainly, with better ability to see what is happening in the upstream and downstream stages of the supply chain, each player would be able to anticipate for delay in delivery of materials, swings in demand, act of competitors, and even for some disruption risks. How technology could contribute to the management of supply chain risks, would technology also pose other supply chain risks, how technology can be used to monitor supply chain risks are among interesting questions to answer in future studies.

Zsidisin (2003b) suggests that managerial perception of risk from different perspectives is an area for future research. It is indeed important to understand what different people in an organization or across different organizations within a supply chain perceive about supply chain risks. Different perception about supply chain risks from marketing and from operations could pose a conflict in deciding what mitigation actions to choose in an organization. Likewise, as suggested by Zsidisin (2003b), if sales representatives perceive risks in a similar manner than the purchasing professionals in a supply chain relationship, then strategies to manage the risk in that link could be created within the dyadic relationship and may be easier to implement due to the similar perception from both sides. Certainly, it would be interesting to explore differences and similarities in perceptions toward supply chain risks inside an organization and across organizations in a supply chain.

Another fertile area of research is decision making process related to supply chain risk management. Risk management process is a complex issue that could involve risky decision making processes. Some papers suggest that risk management may involve such decision as risk transfer (for example using outsourcing), risk sharing (through joint collaboration for risks), and risk avoidance (through, for example hedging currency). From our observation, there is no paper that has a focus on decision making process for selecting the best course of action in dealing with supply chain risk management. Deciding which options to choose among various possible alternatives such as risk transfer, risk sharing, or any types of risk mitigation strategies could be a difficult decision making problem within a supply chain. Cucchiella and Gastaldi (2006) present a real option model for risk management. Application of other decision making models for making risk management decision is an interesting research topic for the future. As Juttner et al.(2003) suggest, guiding supply chain trade-off decision making is an important agenda for future research in supply chain risk management. Standard decision making models such as the AHP or ANP could be further explored for decision making application in supply chain risk management.

To the best of our knowledge, there is no paper that specifically addresses collaborative risk management in the supply chain. In contrast, the discussions on collaborative planning and forecasting (for example through CPFR initiatives) or other collaborative schemes (such as in the context of quality control as presented in Tapiero 2007) are gaining more attention in the literature. Future research should then be expanded to explore how collaborative risk management between companies in a supply chain could work. The possible research could be the design of a framework for collaborative risk management and various possible schemes for collaborative risk management between organizations in a supply chain.

Research on supply chain risk management that attempts to compare strategies to manage risk or to create a robust supply chain across different sectors is still limited. Juttner et al.(2003) also suggest that it is important to develop risk management approaches for specific supply chains / industries. To enable this, it is necessary to first understand different types of risks that are dominant in different supply chains / industry sectors. Generally, it is conceivable that the types of risks, and then the appropriate mitigation actions, vary with supply chains / industry sectors. For example, in the electronic sectors, the competitions due to many players and the rapid development of technology force products to have shorter life cycle. These pose various supply chain risks such as forced markdown prices and inventory obsolescence. In the pharmaceutical industry, on the other hand, long product development time (time to market) could be a major issue related to supply chain risk management. Thus, it would be important to expand supply chain risk management research into these issues.

Chapter 1.22

Implementing Supply Chain Management in the New Era:

A Replenishment Framework for the Supply Chain Operation Reference Model

ABSTRACT

Combining with the collaborations between business customers and suppliers, traditional purchasing and logistics functions have evolved into a broader concept of materials and distribution management, namely, supply chain management (SCM) (Tan, 2001). This chapter reviews the literature of SCM from several paths that can be the basis of a proposed framework for SCM within academic and managerial contexts. In addition, it includes the approaches of supply chain operations reference (SCOR) model, which was developed by the Supply Chain Council and is recognised as a diagnostic tool for SCM worldwide. This chapter also summarises the literature of performance control and risk issues in SCM and the SCOR Model and discusses a proposed framework for the future research.

INTRODUCTION

A supply chain is established when there is an integration of operations across its constituent entities, namely, the suppliers, partners, and business customers (Narasimhan & Mahapatra, 2004). It is an observation that individual firms compete as integral parts of supply chains in the global markets. Moreover, the evolution of information technology (IT) has particularly generated growing attention on searching for ways to improve product quality, customer services, and operation efficiency and remaining competitive by supply chain collaboration. As noted by Strader, Lin, and Shaw (1999), ". . .there has been a general movement towards organizing as partnerships between more specialised firms or business units as IT enables the costs of coordination decrease" (p. 361), implying the impact of IT and potential advances of supply chain management (SCM). A number of researchers and practitioners have, therefore, devoted their efforts to various approaches to manage the constituents and activities of a supply chain since the early 1980s. Yet conceptually, the management of supply chains has not been well organised or understood. Academia has continuously highlighted the necessity for clear definitional constructs and frameworks on SCM (Croom, Romano, & Giannakis, 2000; New & Mitropoulos, 1995; Saunders, 1997).

However, SCM research, which draws on industrial economics, information systems, marketing, financing, logistics and interorganisational behaviour, has a fragmented nature and lacks a universal model. Hence, what we set out to construct in this chapter are the general theoretical and managerial domains of SCM, thereby, attempting to contribute to the development of such discipline. The literature is surveyed to identify the cognitive components of the current subject, as it is a key question for any applied social research that concerns the strategic approach taken to its mapping (Tranfield & Starkey, 1998).

Theoretical models are needed in order to inform the understanding of the supply chain phenomena. An illustration of industrial dynamics in Forrester's (1958) model in fact instantiates the possibility of such applications that aid the comprehension of material flows along the supply chain. Further, it has remarkably laid the foundation for subsequent advancement of supply chain analyses and understandings (e.g., Min & Zhou, 2002; New & Payne, 1995; Sterman, 1989; Towill, Naim, & Wilker, 1992). SCM is not only concerned with the extraction of raw materials to their end of useful life, it also focuses on how firms utilise their suppliers' processes, technology, and capability to enhance sustainable competitive advantage (Farley, 1997). When all organisational entities along the supply chain act coherently, operation effectiveness is achieved throughout the systems of suppliers. Cooper, Ellram, Gardner, and Hawk (1997) advocate such a concept, and further indicate that much of SCM literature is predicated on the adoption and extension of extant theoretical concepts.

Our chapter is not so much a critical review of the literature as a taxonomy with which to map the subsequent research. In this context, it is our intention to try to provide a framework for conducting a project of supply chain management.

This chapter is organised into five sections corresponding to the initial idea of the book layout. In the first section, the supply chain operations reference (SCOR) model is introduced (SCC, 2001), underlying the common aspects and approaches, as it has gradually become a widely accepted standard of supply chain management in industry from its initial launch in 1996. One of the goals in this chapter is to identify the limitations of the SCOR Model and, therefore, to suggest a framework and supply chain implementation. Aligning with the SCOR model, we map the possible research areas by proposing a framework as a domain of research in supply chain design and for the managerial concerns in a project of supply chain management. The next section considers the bodies of literature associated with the stakeholder theory and network theory in organisational studies, which are applied to the interorganizational context (e.g., Premukumar, 2000; Rogers, 2004; Windsor, 1998). Then, we focus on the how to bridge the gaps towards the integration of the supply chain. We further explain the elements for facilitating transformation of the supply chain associated with business processes, organisation structure, and performance control in the following section. The chapter concludes with a summary with some conclusions that can be drawn from the content in terms of moving towards a coherent approach to supply chain management.

FINDING THE SUPPLY CHAIN CHALLENGES WITH THE SCOR MODEL

There is a profusion of literature related to the landscape of supply chain management. Various aspects can be found as the constituents of this subject, which leads to a confusion of meaning (New & Payne, 1995), thus causing difficulty in laying out the scope and content of supply chain design. The term *supply chain management* has not only been associated with logistics activities in the literature but also with the planning and control of materials and information flows of an enterprise, both internally and externally. Additionally, strategic issues, resources, interorganizational relationships, and even governmental intervention have been addressed in extant studies (e.g., Thorelli, 1986; Wang & Heng, 2004), and others discuss the effects of network externality (e.g., Gulati, 1999). These research domains are indeed relevant to the understanding of supply chain context; however, in this chapter, we consider the direct challenges that an enterprise may encounter in order to implement supply chain management. Therefore, the issues in the subsequent discussion follow the logical sequences of SCOR that have been widely adopted by industries such as AT&T, Boeing, and ACER for supply chain diagnosis and design.

The Supply Chain Operations Reference Model

Developed in 1996, SCOR is a standard model of supply chain processes and is used similarly to International Organization for Standardization (ISO) documents for intra-enterprise processes. The SCOR model also builds on the concepts of business process reengineering (BPR), performance measurement, and logistics management by integrating these techniques into a configurable, cross-functional framework. It is a model that links business processes, performance indicators (metrics), and suggested actions (best practice and the features). It was developed to be configurable and aggregates a series of hierarchical process components that can be used as a common language for enterprises to describe the supply chains and communicate with each other (Huang, Scheoran, & Keskar, 2005; SCC, 2001).

The SCOR model follows a set of "top-down" procedures, commencing from the corporate-level strategy that the procedures can help to identify thousands of business activities inside an organisation and spanning across the boundaries of the supply chain entities. The document of the SCOR model includes the following elements as a communicative platform among enterprise owners, project leaders, and corporate consultants of the supply chain planning activities:

- Standard descriptions of each business process along the supply chain that are categorised as "Plan," "Source," "Make," and "Delivery." There are also other two categories defining the product return as "Return"[1] and the supportive activities as "Enabler."
- Key performance indicators (KPI) are defined and classified by the attributes accompanying with each of the business processes; for example, "Total Source Cycle Time to Completion" is a KPI in the attribute of "Supply Chain Responsiveness" of Source activities.
- Best practices are brought up in the SCOR model as recommendations if the diagnosis of certain processes by KPI shows the necessity for improvement.

- Identification of the associative software functionalities that can enable the best practices for business processes reengineering.

This SCOR model consists of four levels as the analytical stages leading to the implementation of an effective SCM strategy. The five distinct business processes, Plan, Source, Make, Deliver, and Return, are within the Level 1 stage and should be further decomposed into processes categories pending on the activities involved. Hence, Level 2 defines the core process categories that can be found in an actual and idealised supply chain around an enterprise. For example, the "source" category includes "source stocked products," "source made-to-order (MTO) products," and "source engineered-to-order (ETO) products" (Table 1). These different types of channel activities derive from the three major customer demands. Making stocked products corresponds to the situation of unknown demand quantities and expects easily procurement of the raw materials, while making MTO and ETO products requires the accuracy of demand forecasting and transparent market estimation.

Because of the customer-oriented nature, the delivery processes actually affects the associated Make and Source activities, and hence the SCOR model spans at least the interactions of information and material flows from the understanding of aggregate demand to the fulfillment of each order. To portrait the business processes by recording down the Level 1 and Level 2 activities of current supply chain is also called "As-Is" stage, which requires the project team to canvas the business environment of an enterprise that should normally include two ties from the core firm (the centre of a supply chain, definition can be seen in Banerji & Sambharya, 1998, and Wang & Heng, 2002), that is, "the customer's customer" and the "supplier's supplier."

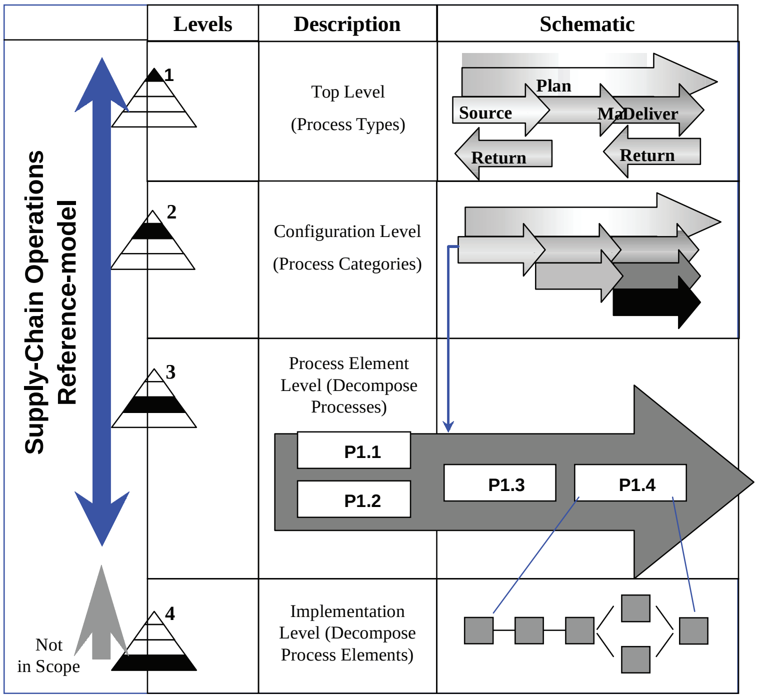
To begin with, it suggests an analysis to prepare the Level 1 document as to geographical context so as to reveal the transportation costs and trading relationships between the legal entities. Then, the diagram at Level 2 can be developed to describe the information flows of forecasts/orders and the material flow with the types of goods produced and delivered by connecting the business processes involved. Software has recently been developed to computerise the SCOR elements in enacting the interrelations of the processes, for example, ScorWizard, IBS Business Intelligence (BI), and i2 Enterprise Resource Planning (ERP) solutions. These are relatively helpful in simulating different scenarios based on the business strategies.

The SCOR model at Level 1 and Level 2 reveals the supply chain in a simplified way, thus enhancing its overall flexibility (Huang et al., 2005). Level 3 represents the decomposition of Level 2 processes in an interrelated way. For instance, there are four Level 3 components

Table 1. Supply chain activities based on SCOR level 1 & 2 (Adapted from SCC, 2001)

Plan		**Source**		**Make**		**Deliver**	
P1	Plan Supply Chain	S1	Source Stocked Product	M1	Make-to-Stock	D1	Deliver Stocked Product
P2	Plan Source	S2	Source MTO Product	M2	Make-to-Order	D2	Deliver MTO Product
P3	Plan Make						
P4	Plan Deliver	S3	Source ETO Product	M3	Engineering-to-Order	D3	Deliver ETO Product
Source Return				**Deliver Return**			
SR1	SR2	SR3		DR1	DR2	DR3	
R1: Return Defective Product			R2: Return MRO Product			R3: Return Excess Product	

Figure 1. The "top-down" approach in implementing the SCOR model (Adapted from SCC, 2001)



Notes: P1.1—Identify, prioritize, and aggregate supply-chain requirements; P1.2—Identify, assess, and aggregate supply-chain requirements; P1.3—Balance production resources with supply-chain requirements; P1.4—Establish and communicate supply-chain plans

decomposed from P1 (Plan Supply Chain), as shown in Figure 1:

- P1.1 – identify, prioritize, and aggregate production requirements
- P1.2 – identify, assess, and aggregate supply chain resources
- P1.3 – balance supply chain resources with supply chain requirements
- P1.4 – establish and communicate supply chain plans

To accomplish the Level 3 activities, the "To-Be" (future) processes model is developed to support strategic objectives that should work within the new supply chain configuration at Level 2. At this level, all SCOR processes are interconnectively designed and running as an operation cycle of planning, execution, and enabling by certain frequency. The supply chain components at Level 4 are acting as the work statement that is expected to be set up by the project team without standardised documents. Eventually, the completed four levels become the guidelines for implementing supply chain management.

The SCOR model has become a topical issue, attracting not only the interest of enterprises themselves, but of industrial associations and government. Contrary to the industrial emphasis, there is a scarcity of academic literature regarding the application, adoption, benefits, and limitations of SCOR model, except for very few reports such as Huang et al. (2005) and Wang, Ho, and Chau (2005). The aspects of the framework that are of interests for further study in the literature are discussed in the subsequent sections.

THE PARTICIPANTS' ROLE IN SUPPLY CHAIN MANAGEMENT

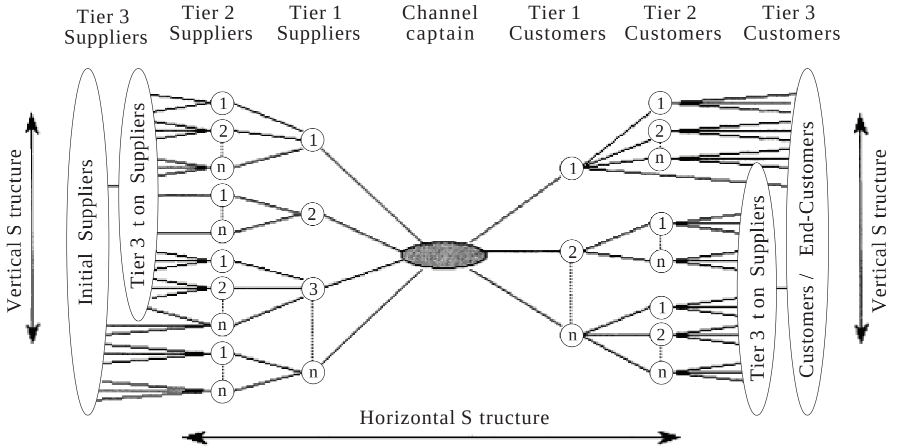
When configuring a supply chain, it is necessary to identify who the stakeholders within the channel context are. However, an inclusion of all potential partners might complicate the analysis of the complete supply chain, since it may explode the number of partners added from one tier to another (Cooper et al., 1997; Min & Zhou, 2002). The key is to target the supply chain entities that are critical to the value-added processes and are manageable by the core firm, that is, the centre of a supply chain targeted and is influential and powerful to its affiliate firms (Banerji & Sambharya, 1998; Wang & Heng, 2002).

As noted by Lambert, Cooper, and Pagh (1998), marketing research has contributed to identifying the members in a supply chain context, describing the needs for channel coordination, and drawing a marketing network. There are also studies with similar aspects from the area of strategic alliances and business network (e.g., Liu & Brookfield 2000) that are concerned about the germination of channel structure and participants. Lambert et al. (1998) further claim that the extant literature has not built on early contributions to put an emphasis on the complete supply chain from suppliers, manufacturers, distributors, and product brand owners. Indeed, one of the major weaknesses of SCM literature is the assumption that everyone knows the participants within the scope of SCM.

In a complete supply chain, there are primary stakeholders of SCM who actually perform operational and managerial activities in the channel processes and secondary stakeholders playing the roles of supporting entities such as the banks and freighters (Lambert et al., 1998). Although such classification may not be clear in all cases, it helps to identify the key customers who trigger the supply chain flows from demands and the major suppliers for value-added activities. From this starting point, the current SCOR model that only spans two tiers of the core firm becomes insufficient for analytical purpose, since the channel structure is quite often not a linear type and the supporting participants are not included in the analysing scope of the SCOR model.

Understanding the structural dimension of supply chains is a prerequisite for analysing and configuring the process links among channel members (Min & Zhou, 2002). The supply chain is derived from the interrelationships of its stakeholders that actually cause a multidimensional structure. Lambert et al.'s (1998) supply chain

Figure 2. Supply chain network structure



network indicates that there are two structural dimensions: horizontal and vertical, as shown in Figure 2. The horizontal structure represents the numbers of tiers along the analytical scope of a supply chain, and the vertical structure represents the number of partners within each tier.

Based on such aspect, a change of channel partners will alter the dimension of the supply chain. For example, the horizontal spectrum may become narrower when some entities merge with others. Outsourcing decisions may further change the scope and structure of supply network. In fact, some outsourcing firms can form various network formations other than the tier structure, such as rings, stars, or fans (Liu & Brookfield, 2000; Wang & Heng, 2002). The shifting of the supply chain scope (or, in some literature, the boundaries of the business network), which is normally caused by the strategic moves toward channel partners, eventually affects existing design and current managerial performance of SCM. A recent example is the case of the ACER Group which is associated with the shifting of channel structure that is reported by Wang and Ho (2005).

Despite a delicate design and implementation of global SCM and ERP systems, the ACER Group has suffered from a low retention rate of IT professionals of ERP systems and a lack of patterns for business processes reallocation in new manufacturing bases. These challenges are actually due to insufficient ante-consideration of potential business reallocation. When a sudden rundown occurred at several subordinates with reduced production volume in The Philippines and operation scale in Canada, it was somehow too late to adjust the plans of SCM. Therefore, it is necessary to identify the proper scope for a SCM project with the entities involved and then determine which aspects (e.g., geographical ranges and time period) of the supply chain network should be configured (Min & Zhou, 2002). Comparing the SCOR model, there are at least three limitations that can be found; they are:

- SCOR can only present business flow in between legal or geographical entities, not any matrix organisational structure or the concept of "virtual enterprise".
- SCOR is limited to the presentation of one single supply chain, while most enterprises may be associated with multiple channels of markets and products.
- The activities of collaborative design and customer relationships management are not defined in SCOR.

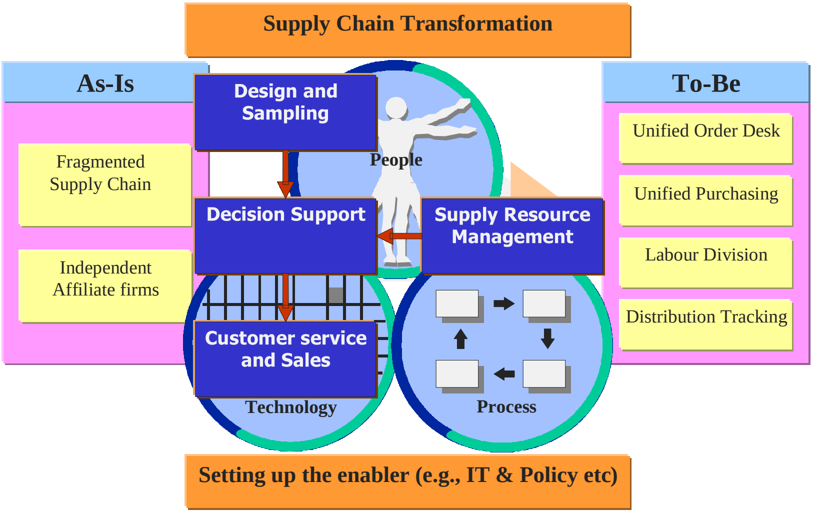
In brief, modeling a supply chain requires the analysis of relationships among channel participants and the structures formed. Thus, a clear picture for defining the scope of a SCM project can be presented. Moreover, these processes may connect multitiered supply chains as the core firm is actively involved in tier one and a number of other links beyond it. The direct involvement of a core firm may not only allocate physical resources but also interorganizational powers, technology, and knowhow to its trading partners. There is also indirect involvement from non-integral parts of the supply chain structure, but it can influence the operations of channel participants. Those different characteristics of trading relationships affect the firms' decisions regarding resource allocation that lead to the concerns in supply chain configuration.

IMPLEMENTATION OF CHANNEL INTEGRATION

The Transformation toward the "To-Be" Stage

Subsequent to the right analysis and design of supply chain management, this section discusses issues in the implementation of SCM. Using the terminology of the SCOR model, it is the "To-Be" stage. Figure 3 shows the most common goals and components of the transformation that

Figure 3. The components of implementing SCM projects from As-Is to To-Be



involves human factors, business processes, and the technology, so as to build up a unified order desk, purchasing channels, delivery tracking, and so on, for the support of supply chain decision. Although the SCOR model is a widely adopted industrial standard—and possibly the only one—it has not successfully addressed a transforming framework from the stages of "As-Is" to "To-Be" for SCM projects. In particular, it merely handles the components of business processes and technology without tackling any social factors or human issues.

The previous section has portrayed the "top-down" approaches by utilising SCOR model as a standard. That approach requires the team of a SCM project to lay out existing business processes and use the suggested SCOR metrics to diagnose current problems for the implementation of ideal SCM. At least the Level 1 and Level 2 business processes should be confirmed so that hundreds of metrics can be then applied to measure the current operation excellence along the specific supply chain, such as "day of inventory" (Level 2) in the category of cash-to-cash cycle time (Level 1) and "supplier on time and in full delivery" (Level 2) in the category of delivery performance (Level 1). The step of measuring KPI of the supply chain activities belongs to the second stage of SCOR, namely "gap analysis," which underpins the design of "To-Be" processes. In other words, the differences between current status and ideal performance are actually the opportunities for improvement based on the expectation of target firms and on the comparison with competitors.

Nevertheless, such a way of bridging the gap between "As-Is" and "To-Be" might not be applicable to many circumstances. There are at least two reasons, as discussed below. First, the KPI analysis, which depends on recording operation outcomes, is actually a measuring tool from a basis of productivity, efficiency, and profitability. There is a myth that the figures of operation excellence and actual responsibility can and should be combined in an ideal business situation. However, it is clear that they are at least partially contradictory.

First, on the one hand, the business units within a supply chain must try to achieve operation excellence for survival, and each of the enterprises has the pressure and duty to earn a higher return on its shareholders' equity than occurred before the SCM project. The KPI figures that are made create trust on the part of investors and are usually reflected in short-term operation efficiency, making it easier to project to an image of corporate success. These indicators are not only a sort of management result, but also a source of enterprise competitive health and wealth at a supply chain context.

On the other hand, supply chain participants are networks of parties that work together by trading relationships toward both a shared goal and individual interests without being merely economic machines. Although an SCM initiator (mostly the core firms) represents a major role of the value of channel participants, it does not necessarily have enough power to force its partners to follow the integration contents. Likewise, it is also important for trust to develop between the SCM initiator and its external partners and other interest groups. Such trust can only be built up from ensuring that the perceived value of all entities and stakeholders along the supply chain are taken into account. However, it may be difficult to have a unique standard of KPI measurement across the boundaries of enterprises.

Second, the KPI of SCOR is not always available in the SCM initiator, particular when it involves the sharing of interorganizational information. It may be caused by lack of information readiness in other trading partners (Iacovou, Benbasat, & Dexter, 1995; Lee, Clark, & Tam, 1999; Wang et al., 2005). For instance, the calculation for the indicator of "Complete Manufacture to Order Ready for Shipment Time" might need the information of several tiers of suppliers and collaborative manufacturers, since there are usually several working segments before the delivery of final products. As such, the SCM initiator must gather operation information from various suppliers in time for a precise estimation of this KPI. Unfortunately, in the brick-and-mortar world, it is not easy to ensure equal systems readiness between an SCM initiator and its trading partners, albeit even the headquarter may find it difficult to obtain confidential information from its subordinators because their interests are potentially contradictory.

Last but not the least, KPI analysis has a limitation in corresponding to the strategic choices. For example, a SCM initiator may consider "Perfect Order Fulfil Rate" to be the most important target in the very beginning, when the distributors have equal or much more power than it does. This occurs in the supply chain of the Taiwanese IT industry (e.g., Wistron, Accton, and Asus); many of them initiate their projects of global logistics management with the major players such as Dell and IBM. They have to give in to the benefits of reducing inventory level for channel competency. Only when they ensure the higher bargain power with their customers would they adjust the ratio of some KPI evaluations along the supply chain.

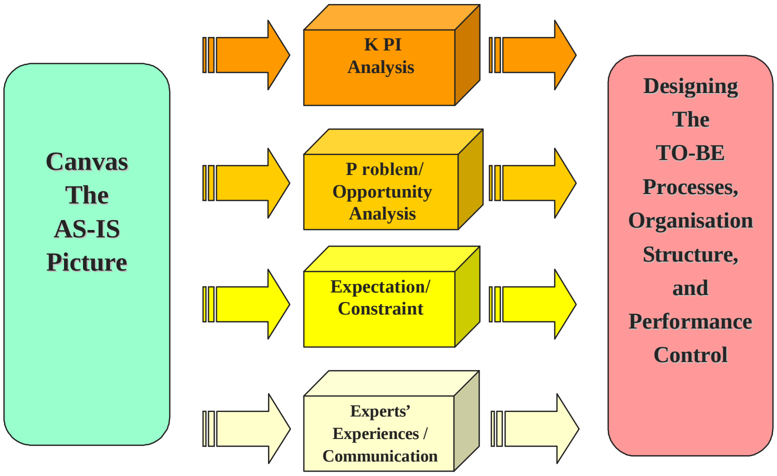
Major Approaches of the Transformation

In a matrix of two-dimensional content analysis, Croom et al. (2000) highlight four major categories of supply chain elements for trading exchanges by summarising the extant literature. These categories are assets, information, knowledge, and relationships. In Croom et al.'s (2000) framework, SCM elements are further divided into three levels of dyadic, chain, and network forms. These elements are much richer than those defined in the SCOR model, which are very limited in the categories of assets and information and still less than the two-dimensional framework just mentioned. For example, SCOR does not include the analysis of total cost ownership (asset), business network redesign (information), human resource planning (knowledge), or trust/power/commitment (relationship). However, there is, in particular, a scarcity of research on knowledge elements for SCM that lead to their unclear and inconsistent presence in the literature. The few examples are the subjects of knowledge with time-based capabilities in production activities (Handfield & Nichols, 1999) and configure-to-order for customised sales (Ton & Liao, 2002). The last category of Croom et al.'s (2000) framework is associated with "soft" elements, since relationship is a social tie existing among the supply chain entities. Although there have not been any widely accepted methods in industry (nor in SCOR) for managing the supply chain relationships, some scholars have considered it to be the most important figure in SCM. For example, Handfield and Nichols (1999) indicate that the efforts of other elements for implementing SCM in managing the flows of information and materials are likely to be unsuccessful if there is not a solid foundation of effective relationships in the channel context.

In order to mark up the insufficiency of the SCOR model and to map the Croom et al.'s (2000) elements, we propose a method in bridging current gaps for the SCM transformation processes. As shown in Figure 4, there are four major approaches, namely, KPI analysis, problem/opportunities analysis, expectation/constraints, and the experts' opinions, which can be amended to the SCOR model as explained next.

- **KPI analysis:** This approach follows the typical "top-down" SCOR analytical processes and is relevant when most operation figures are recorded and updated regularly. Since it requires information across the boundaries of firms, the SCM adopters may often encounter difficulties by merely using such an approach. It is even true in the situation in which most channel participants are subordinates or in joint ventures of a particular adopter because of unequal readiness of IT infrastructure or conflictions of management interests.
- **Problem/opportunity analysis:** When identifying the processes "gaps" by KPI information becomes less achievable, it is possible to find out the existing problems and difficulties by interviewing the employees from both upstream and downstream of the supply chain. Contrary to the KPI analysis that starts by enacting the supply chain strategy and comparing existing performance and the targets, problem/opportunity analysis is rather a "bottom-up" approach. It is suggested that the SCM project participants record various feedback and then map them into the different levels of SCOR processes. For instance, the KPI of "day sales receivable outstanding" in the Delivery element of SCOR Level 2 is related to the processes performance of the sales department. The same goal of identifying the SCM gaps can thus be achieved by directly finding problem/opportunity through individual interviewing and observation.

Figure 4. Bridging the gap of the supply chain transformation



- **Expectation/constraint:** One of the successful key factors in implementing an SCM project is the participants' attitude with commitment to collaborative improvements. It will affect the information gathering for KPI and problem analyses and the subsequent actions for supply chain modification that is sometimes accompanied by the adjustment of existing benefits among channel members. For example, the delivery routes, supply chain policies of pricing and return of goods, and requirements of forecasting between buyers-suppliers may be altered after the SCM implementation. It is, therefore, necessary to find out the expectations/constraints of channel participants so as to avoid the potential conflictions among supply chain entities.

Another example is that examining the demand management processes of the SCM initiator might lead to a tentative solution of implementing collaborative planning, forecasting and replenishment (CPFR) systems as suggested by SCOR model. However, doing so might require the adoption of new IT infrastructures and cause changes to the existing demand management processes in some of the suppliers. It is inevitable that compromises will have to be made in order for the transformation to happen in upstream and downstream of a supply chain. There are a few points should be considered when identifying the expectations and constraints of the supply chain stakeholders:

- Enterprise as a participant in a business ecosystem and supply network
- Cluster of firms that gradually evolves as a group—the coevolution effects
- Gradual development of shared vision—centred around a product or product group
- Further, the role of clusters in competitiveness

The experts' experiences/communication: The last approach for the supply chain transformation is to adopt an expert opinion from a third party. A SCM project covers the areas of channel collaboration in material management, production planning, sales/distribution, quality control, assets management, and cost controlling, and requires the knowledge of a business processes enabler, such as the adoption of information systems. Acquiring expert opinions is vital to the successfulness of any SCM project, not only because of the need for the above expertise, but also in the pre-selection adoption methods, business processes design, training, and customised IT systems. That means, most likely, that firms have to get the help of consulting companies to enact the proper adoption methods and learn from others' successful experiences. Nevertheless, the SCM project owners have to interact with outside consultants who are not always familiar with the "know-how" of a particular industrial context.

Quanta Computer Inc., one of the major players in the IT industry of global market, has a sales volume of USD 10 billion in 2004. Its implementation of SCM has become a legendary story in the Taiwanese IT industry, as Quanta Computer Inc. accomplished the supply chain processes redesign with its trading partners and established its ERP systems (a modified version of SAP) in only half a year. It is a monumental SCM implementation project, not only because of such a short period of time, but also because of the success of building up the global supply network to dramatically achieve the target of cost cutting through low-level inventories. An interesting thing was, although the consultants for the SCM project of Quanta Computer Inc. had a strong background in SAP systems, only the project manager was initially conversant with the production line of IT products. Communication and exchange of ideas thus played a significant role before the commencement of SCM adoption. In addition, Quanta Computer Inc. and its trading partners have cooperated with consultants from various global regions throughout the adoption period.

In short, the transformation of existing supply chain processes and structure relies on identifying the gaps and opportunities for improvement. Both "top-down" and "bottom-up" approaches are keys to the success of supply chain configuration now and in the future. Moreover, it is necessary to discreetly survey the stakeholders' expectations from the standpoint of various supply chain entities in order to ensure substantial benefits and learn from the anatomy of successful/failed cases via the experiences of the experts from the third party.

Combining the Performance Control into SCOR Analysis

The important leverage gained from the supply chain integration is the mitigation of risk by certain control (Min & Zhou, 2002). It is generally believed that the implementation of an SCM project consumes considerable resources of human labour, materials, and time. It will definitely have an impact on the enterprise and its trading partners. Therefore, a part of reasonable performance control is to ensure that the supply chain operates right on track.

For such consideration, there are hundreds of KPI (metrics) mapping the levels of business processes defined in the SCOR model. Whether the KPI information of the supply chain entities is available for calculation or not, it is possible to find out the existing problems and difficulties of supply chain configuration, as suggested in previous section. The recorded "As-Is" process, as illustrated in Figure 5, can be labelled in the format of normal flowchart.

Then, each of the codified processes should be analysed by a set of SIPOC diagrams (Pyzdek, 2003), which were originally used as quality control tools and can detail the information deliver (supplier), data sent (input), data generated (output), and information receiver (customer) for the purpose of systems development. This instrument allows us to see the opportunities for improving current communication interfaces among departments and trading partners. The previously identified "gaps" should be then codified, grouped, and prioritised, since some of them may cause similar problems, affect related business processes and supply chain entities, or be overcome by integrated solutions. The grouped and prioritised "gaps" thus

Figure 5. Example of current processses coding in the flowchart

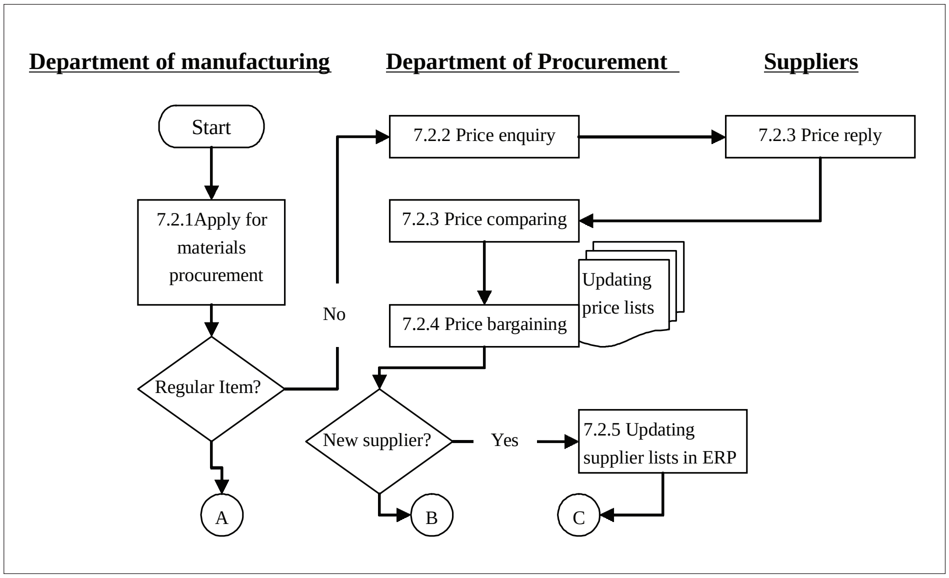


Figure 5. The sequence of SCM implementation

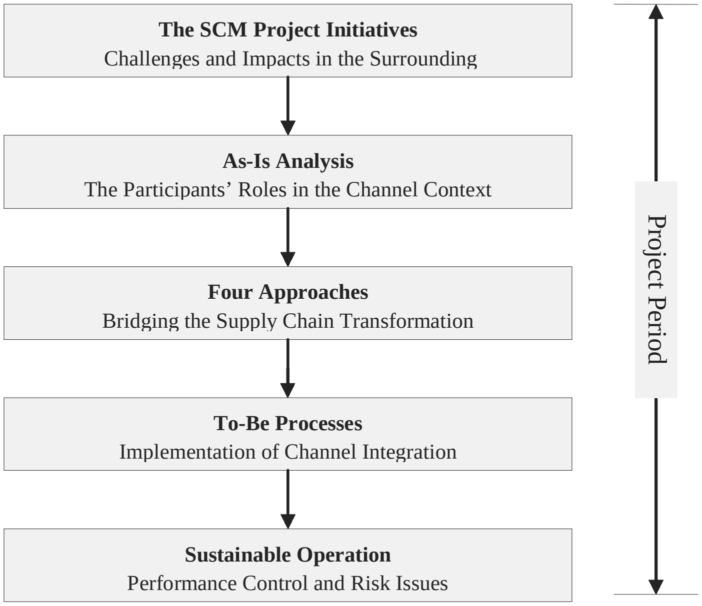

become the basis for creating "To-Be" scenarios that are associated with the adjustment of corporate policies, organisation structures, business flows, and information systems.

As previously discussed, most of the KPI items are naturally related to existing business processes because of their formulas for calculation. For instance, the KPI "day sales receivable outstanding" in the D element of SCOR Level 2 is related to the processes performance of sales department. As most of the SCOR metrics are related to the business processes of a single organisation, we recommend an extended table to map the cross-functional channel activities for performance monitoring encompassing the supply chain entities within the scope of an SCM project.

Formulated in another way, the business processes can be divided into two types—the planing and coordinating activities owned by the supply chain group and the operational activities of individual firms. Staff in the department of procurement in one firm might often play the role of directly and indirectly taking care of the purchasing decisions of other collaborative participants in the supply chain structure. The supply chain coordinating team may also negotiate with the customers' team to manage the suppliers' inventory level (Lambert & Pohlen, 2001). Ideally, it means that they should be evaluated both by the KPI of their original firms and the KPI of the suppliers and customers, based on certain percentages in order to monitor the two types of business processes. A control panel is thus generated in Table 2 for designing the KPI measurement and monitoring the supply chain performance.

Table 2 is an example of the control panel for planning and decision-making activities that maps the existing processes and "To-Be" processes in a project with four companies. It entails the information of how to control the supply chain functions across the boundaries of firms based on the selected KPI that are predefined by the SCOR standard. More importantly, this table contains the implications that the "gaps" between the current and future infrastructures of information exchange might be overcome by combining the current business processes codes that are embedded with SIPOC analyses and

Table 2. The control panel of planning and decision-making activities

Collaborative activities I			**ndividual Supply Chain Entities**				
Business Processes	SCOR Code	'To-Be' SCOR KPI	Core firm (SCM initiator)	Distributor	Supplier 1	Supplier 2	Current Business Processes Code
Supply Chain Planing	P1	Provided by SCOR documents (should be further selected based on the top managers' opinion).	V				Recorded in 'As-Is' analysis and should be mapped into the planning processes.
Plan Sourcing	P2		V	V			
Plan Making	P3		V		V V		
Plan Delivering	P4		V	V			

Notes: The level 3 SCOR code and the related departments of each supply chain entities should be shown on a real control panel. They are omitted in this table because of consideration of simplicity.

the responsible supply chain entities. One of the benefits is, for example, this joint process-metrics analysis of customer, supplier, and distributor will capture how the repositioning of inventory control improves total supply chain performance, whereas the information of inventory turns does not reflect any of the trade-offs that occurred in the channel links (Lambert & Pohlen, 2001). Consequently, it amends the insufficiency of using current SCOR metrics in the dyad and network supply chain structure.

CONCLUSION

We have stated in the foregoing sections that SCM plays a role in influencing the economic behaviour by the way business processes are managed. This, in itself, is certainly a very significant point, as it influences the costs of inventory holding, goods delivery, and manufacturing processes. In particular, it affects performance in customer fulfillment and cash-to-cash cycling, which are vital to enterprise survival (Garrison & Noreen, 2003). Achieving effectiveness of SCM does not only rely on process tuning, but also just-in-time communication and decision making through the enablers as performance measurement and information systems. Despite its importance, however, there is not much literature on the implementing framework, and most of the existing reports are individual case studies (Croom et al., 2000).

The SCOR model has been the most widely adopted standard and may be the only one for the analysis of SCM implementation. It has been modified several times since its first announcement by the Supply Chain Council in 1996. There is yet another point deserving the attention of academia and practitioners, namely, it is not a complete framework for implementation of an SCM project, but merely a referential tool for assigning business processes and associated factors of performance measures. It may actually be dysfunctional without considering the stakeholders' value/expectation and embedding the mutually owned processes into performance measurement. Therefore, we have amended its weakness by discussing the supply chain configuration and transformation and the implementation procedures.

Future research is required to test the proposed framework in actual business settings, including different industries and regions. Other barriers and limitations to SCM implementation and how they shall be overcome need to be further identified. These may consist of the demand up-size and down-size from order changes, for example, emergent orders or order cancelling, and the calculation of KPI for nonfinancial figures from the operation activities. To the extent that similar difficulties and solutions are identified in various supply chain context, it is possible that a refined framework can be developed for practitioners. Finally, progress should be tracked over time to prove the long-term benefits derived from implementing SCM based on such a framework.

ABSTRACT

This article traces past research on the application of the systems approach to information systems development within the disciplines of information systems and software engineering. Their origins historically are related to a number of areas, including general systems theory. While potential improvement of software development practices is linked by some leading experts to the application of more systemic methods, the current state of the practice in software engineering and information systems development shows this is some way from being achieved. The authors propose possible directions for future research and practical work on bringing together both fields with systems thinking.

INTRODUCTION

Information technology (IT) articles often include statements along these lines: "systems development continues to be challenging. Problems regarding the cost, timeliness, and quality of software products still exist" (Iivari & Huisman, 2007, p. 35). This recognition justifies the continuous search for improvement of Information Systems Development (ISD).

Glass, Ramesh, and Vessey (2004) provide an analysis of the topics covered by the three computing disciplines—information systems (IS), software engineering (SE), and computer science (CS)—and show overlaps between them all in the area of systems/software concepts. They also demonstrate that CS has only minor regard of the issues and concerns of systems/software management. Sommerville (2007) states that CS is concerned with the theories and methods that underlie computers and software systems rather than the engineering and management activities associated with producing software. Whilst acknowledging that CS, SE, and IS do have a considerable overlap, the practices of both IS and SE have to deal with common matters such as the management of huge development projects, human factors (both software developers and software end users), organisational issues, and economic aspects of software systems development and deployment (Van Vilet, 2000).

For the reasons stated above, we will concentrate here only on SE and IS and their links to systems thinking. We will consider as a starting point the reality that the whole computing field has evolved historically as several "stovepipes of knowledge": CS, SE, and IS (Glass et al., 2004). Whether the separation or integration of computing disciplines will prevail is a complex issue. Integration has yet to be achieved as a consequence of the sets of values central to each area. We believe, along with others, that a systems approach may lead to improvement of the development and management of software systems and to a greater integration of computing. One might expect that the use of the word "system" in various contexts today leads to more "systems thinking," but is this true?

A reflective history of the IS field is presented in Hirschheim and Klein (2003, pp. 244-249). According to them, because of its roots in multiple disciplines, "such as computer science, management, and systems theory, it is hardly surprising that the field of IS cast a wide net when defining its boundaries, sweeping in many themes and boundaries" (Hirschheim & Klein, 2003, p. 245). In that light, it is somehow striking to note the conclusion about a lack of a systems approach in IS research according to Lee (2004, p. 16). Alter (2004) is even more specific, claiming that "the information systems discipline is ostensibly about systems, but many of our fundamental ideas and viewpoints are about tools, not systems" (p. 757).

The systems approach has been acknowledged in the SE literature as providing an insight into the factors that influence the success or failure of computer technologies (Mathieu, 2002, p. 138). It is symbolic that the 2006 special issue of the *IEEE Computer* magazine on the 60th anniversary of the IEEE Computer Society is dedicated to the past and future of software engineering. A brief examination of the papers in that issue shows that four of them are dealing with some systems features and the other three give examples of tool thinking. None of the seven papers in the issue had a reference to any source from the field of systems thinking and only one paper (Baresi, Di Nitto, & Ghezzi, 2006) had references to several classic SE sources dealing with fundamental systems ideas. This does not advance the ideas suggested by Boehm (2006a) and Sommerville (2007) that there is a need to integrate SE with systems engineering, a branch of systems thinking (see Jackson, 2003).

The contribution of this research is in the identification of areas where a systems approach would lead to improvements in ISD within a point of view that favors implicitly the integration of the IS and SE disciplines. The article will proceed with an analysis of how links between software development and systems thinking were perceived in the fields of IS and SE. This is done predominantly with the intention of exploring the application of systems ideas to software development separately in the two fields, outlining the success stories and the open problems. At the end, we will propose possible directions for future research in software development within SE and IS associated with the systems approach.

ON INFORMATION SYSTEMS DEVELOPMENT AND SYSTEMS THINKING

A review of the history of various IS development methods is presented in Avison and Fitzgerald (2003). Iivari and Huisman (2007) point out, however, that the research literature on IS development has been scarce. This is most evident for the period after 1990. Prior to that point, the origins of IS research were associated more strongly with issues on building information systems. However, one sub-area of IS development grew significantly in the U.K. and elsewhere over the last 20 years: incorporation of Soft Systems Thinking (SST) into IS.

Soft Systems Thinking, Social Science, and Their Influence on IS

Stowell and West (1996) argued in the mid-1990s that practices of IS design had not appeared to have progressed since 1979; despite attempts in several proposals to embrace the social aspects of an information system, most seem to be based upon a functionalist view. Stowell and West (1996) explored the shift towards antipositivism in the mid-1980s, which resulted in a number of suggested methodologies that focused upon the social implications of computer systems design. As examples, they point out Soft Systems Methodology (SSM) (Checkland, 1999), the MULTIVIEW approach (Avison, 2000), participative systems design, and others (see also Avison & Fitgerald, 2003).

SSM evolved originally from experience within interventions in various management problems in public administration and industrial companies. However, subsequently it evolved more towards the field of IS (see Checkland & Holwell, 1998). Stowell (1995) presents a collection of papers analysing various aspects of the contribution of SSM to IS. SSM seems to be the most well researched interpretive systems approach used in the field of IS (see Holwell, 2000, for a detailed account of the literature on SSM, and Checkland & Poulter, 2006, for a contemporary presentation of SSM ideas).

The relevance of SSM to the field of IS has been explored in two directions. One way is to apply SSM on its own in some IT related aspect, for example, extend the standard SSM method to specify the information requirements of the system (see Wilson, 1990). The use of SSM in data modeling is explored by Lewis (1995). A further application of SSM for improvement of software quality is presented in Sweeney and Bustard (1997). A second direction of using SSM in information systems is through the linking of SSM to existing design methods. An overview and detailed analysis of using SSM with structured analysis and design is provided by Mingers (1995). Several authors have covered aspects of combining the Unified Modeling Language (UML) with SSM. A recent paper by Sewchuran and Petkov (2007) analyses the related theoretical issues and shows a practical implementation of a combination of UML and SSM within a Critical Systems Thinking (CST) (see Jackson, 2003) framework justified by Multimethodology (see Mingers, 2001).

On Critical Systems Thinking, Multimethodology, and IS

Multimethodology is a metatheory for mixing methods from different methodologies and paradigms in the same intervention (Mingers, 2001). It seems to be an attractive vehicle for further research in systems thinking and IS research.

Further refinement of the ideas on pluralist interventions can be found in a recent paper on Creative Holism (Jackson, 2006). Details on three cases, illustrating how Multimethodology and CST were practiced in separate systemic interventions in the Information and Communications Technologies sector, can be found in Petkov, Petkova, Andrew, and Nepal (2007).

In his paper on the links between CST and IS research, Jackson (1992) demonstrates the power of an integrated critical approach in the IS field. However, there have been relatively few subsequent publications on the practical application of CST in IS. Some of them are surveyed in Ngwenyama and Lee (1997), a paper demonstrating the significant relevance of CST to IS. Another interesting example, exploring how Triple Loop Learning (Flood & Romm, 1996) can be applied to the complexities during systems development is given in Finnegan, Galliers, and Powell's (2002) work. Further papers on systems thinking and IS can be found in proceedings of several meetings on the philosophical assumptions of IS research that took place after 1997, including the U.K. Annual Systems Conference, the European Conference on Information Systems, the Australasian Conference on IS, and Americas Conference on Information Systems (AMCIS).

CST provides both theoretical sophistication and practical directions for future research that are applicable to IS. Jackson (2003) cautions that whatever argument is made in favour of pluralism, it is bound to run up against objections from those who believe in the incommensurability of paradigms. The latter notion is linked to the assumption that if paradigms have distinct and opposing philosophical foundations, applying them together is impossible. This issue has been addressed by several authors in the past (see Jackson, 2003). Zhu (2006), however, questioned recently the relevance of concerns about paradigm incommensurability from a practical point of view, another issue for possible further research. His view on paradigm incommensurability is similar to that of the pragmatic pluralism approach. This is based on the assumption that we are witnessing the end of a particular reading of theory and that there is no single truth and no single rationality (White & Taket, 1996, p. 54).

Both pragmatism and functionalism are often criticised in systems thinking (see Jackson, 2003). However, an interesting and relevant new systems approach in IS, the work system method (Alter, 2007), has emerged recently that may be linked to the pragmatic school of thought.

The Work System Method and IS

Alter (2006) stresses that past dominance of single ideas like Total Quality Management and Business Process Re-engineering are not sufficient to influence the IS field profoundly. The work system method provides a rigorous but nontechnical approach to any manager or business professional to visualise and analyse systems related problems and opportunities (Alter, 2006). This method is more broadly applicable than techniques "designed to specify detailed software requirements and is designed to be more prescriptive and more powerful than domain-independent systems analysis methods such as soft system methodology" (Alter, 2002). We may note that making comparisons between the work system method and soft systems methodology requires a broader investigation of their philosophical assumptions and scope. A possible starting point for comparing their areas of applicability could be the classification of strategies for doing systems analysis provided by Bustard and Keenan (2005). SSM has been attributed by them to the situation when the focus is on development of a long term vision of the environment in which a computer system is to be used with identification of appropriate organisational changes (see Bustard & Keenan, 2005). Where Alter's approach stands in the Bustard and Keenan (2005) classification is an open question for research requiring both theoretical work and field experimentation. We consider the systemic nature of the work system method and its applicability to understanding business and IS problems to be its most distinctive and important characteristics. Though the work system method has a relatively short history and a small group of followers for now, the multifaceted scale of Alter's work, bringing together systems ideas with methods for deeper understanding of work systems and IS, has strong appeal.

On Sticking to a Single Research Tradition in IS

Bennetts, Wood-Harper, and Mills (2000) provide an in-depth review of combinations of SSM with other IS development methods supporting multiple perspectives along the ideas of Linstone (1984). Thus, they brought together two distinct traditions in IS research: the former practiced in U.K./Europe/Australia where SSM has found significant acceptance, and the latter was pursued predominantly in the U.S. Linstone's ideas are strongly related to the influence of Churchman whose analysis of Inquiring Systems was a starting point for some significant IS research that followed (e.g., Vo, Paradice, & Courtney, 2001).

It is interesting to note that Bennetts et al. (2000) have examined sources not only from IS but also from the CS and SE literature. This raises a question that is hard to answer in a simple way. We observe that often authors of SE articles belong to CS or IS departments, rather than engineering schools (Aurum & Wohlin, 2005; Dietrich, Floyd, & Klichewski, 2002). On the other hand, it seems that publications on IS development written by U.S. scholars often use references only from IS or from SE disciplines, depending on the field of the authors; a refreshing exception is a series of articles written over many years by R. Glass and I. Vessey with several collaborators (Glass et al., 2004). The reason could be the lack of communication between CS, SE, and IS (see Glass, 2005). Another possible reason is the growing concern within the separate computing fields for promoting and protecting their own paradigms (Bajaj, Batra, Hevner, Parsons, & Siau, 2005).

Maybe similar paradigmatic concerns have led Allen Lee to formulate his first idea from an advice to IS researchers: "practice paradigm, systems thinking and design science" (Lee, 2000). These are seen as a recipe to address the three dilemmas that are as relevant today as they were in 2000: the rigor vs. relevance debate in IS research; the "reference discipline" vs. "independent discipline" dilemma; and the technology vs. behaviour as a focus for IS research dilemma.

So far, we have considered the second of Lee's ideas and its relevance to IS development over the last 15 years and to a lesser degree some issues related to scientific paradigms in terms of Kuhn (1970). Further details on earlier contributions of Systems Science in the 1970s and 1980s can be found in comprehensive reviews related to the fields of IS research (see Xu, 2000), Decision Support Systems (see Eom, 2000), and Information Resources Management (see McLeod, 1995). Mora, Gelman, Forgionne, Petkov, and Cano (2007) presented a critique and integration of the main IS research paradigms and frameworks reported in the IS literature using a systems approach. We briefly comment below on design science, a more recent trend in IS research.

On Design Science As One of the Directions to Resolve the Three Dilemmas in IS

According to Hevner, March, Park, and Ram (2004), IS related knowledge is acquired through work in behavioural science and design science paradigms. They point out that "behavioral science addresses research through the development and justification of theories that explain phenomena related to the identified business need, while design science addresses research through the building and evaluation of artifacts designed to meet the particular need." Another relevant detail is the differentiation that Hevner et al. (2004) make between routine design and system building from design science. The former is associated with application of existing knowledge to organisational problems, while the latter is associated with unique (often wicked or unresolved) problems that are associated with the generation of new knowledge. The latter idea is similar to the main thesis in Hughes and Wood-Harper (1999). Hevner et al. (2004) laid the foundation for a significant boost in IS research on issues related to IS development, including systems analysis and design science. The journal *Communications of AIS* started a series of articles in 2005 on this topic; the first of which was Bajaj et al. (2005). We may note that in spite of progress in applying action research in IS in theory (see Baskerville & Wood-Harper, 1998) and in practice (see the IbisSoft, n.d., position statement on environment that promotes IS research) the dominant IS research trend has been of a positivist behavioural science type which is another challenge for the proponents of a systems approach.

A substantial attempt to provide suggestions towards resolving the three dilemmas in IS research mentioned by Lee (2000) is discussed in Hirschheim and Klein (2003). They identify a number of disconnects between various aspects of IS research and outline a new body of knowledge in IS development (Iivari, Hirschheim, & Klein, 2004). They suggest there are five knowledge areas in ISD: technical knowledge, application domain (i.e., business function) knowledge, organisational knowledge, application knowledge, and ISD process knowledge. Further, according to Hirschheim and Klein (2003):

> *ISD process knowledge is broken down into four distinctive competencies that IS experts are suggested to possess: (1) aligning IT artefacts (IS applications and other software products) with the organizational and social context in which the artefacts are to be used, and with the needs of the people who are to use the system as identified through the process of (2) user requirements construction…(3) organizational implementation from which (4) the evaluation/assessment of these artefacts and related changes is factored out …. These competencies are … at best weakly taken into account in the ten knowledge areas of SWEBOK.* (see for comparison SWEBOK, 2004)

Hirschheim and Klein (2003) present comprehensive proposals for strengthening the IS field. Their work was partly motivated by a widely discussed paper by Benbasat and Zmud (2003) on the identity crisis in the IS discipline. Both papers provide important background details about the IS research environment in which one may pursue the main ideas of this article. The next section will explore the relevance of systems thinking to SE.

ON SOFTWARE ENGINEERING AND SYSTEMS THINKING

Software engineering has a primary focus on the production of a high quality technological product, rather than on achieving an organisational effect, however increasing emphasis in SE is being given to managerial and organisational issues associated with software development projects. Cornford and Smithson (1996) observe that SE "can never encompass the whole range of issues that need to be addressed when information systems are studies in the full richness of their operational and organisational setting".

Weinberg (1992) writes about systems thinking applied to SE. It is an excellent introduction to systems thinking and quality software management dealing with feedback control. It has a close kinship with the concepts of systems thinking and system dynamics in Madachy (2007), even though it is almost exclusively qualitative and heuristic. Weinberg's main ideas focus around management thinking about developing complex software systems, having the right "system model" about the project and its personnel.

Systems thinking in the context of SE, as described in Madachy (2007), is a conceptual framework with a body of knowledge and tools to identify wide-perspective interactions, feedback, and recurring structures. Instead of focusing on open-loop event-level explanations and assuming cause and effect are closely related in space and time, it recognises the world really consists of multiple closed-loop feedbacks, delays, and nonlinear effects.

Lee and Miller (2004), in their work on multi-project software engineering, advocate a systems thinking approach as “in general, we are able to make better, more robust, and wiser decisions with systems thinking, since we are considering the problem by understanding the full consequences of each feasible solution”.

Other details on systems thinking with links to other books and articles can be found through practitioner’s Web sites such Weinberg (2007), Developer (2007), or Yourdon (2007). The interest of software practitioners in systems ideas is a significant fact, in light of the previously mentioned debate about relevance in the IS literature. However, systems thinking is not mentioned by Reifer (2003) in his taxonomies of the SE theory state-of-the-art and SE state of practice. In relation to that, we will discuss below whether systems ideas are promoted in SE education.

Software Engineering Education and Systems Thinking

The coverage of systems concepts in leading SE textbooks is possibly another indicator about the way the systems approach is perceived within the SE community. We considered books by several well established authors: Sommerville (2007), Pressman (2001), and Pfleeger (2001), amongst many. Table 1 shows a summary of findings related to the treatment of several typical systems notions in those books.

Table 1 shows that the systems concepts covered in the three widely used textbooks are mostly related to introductory notions from systems thinking. There is nothing about open

Table 1. Systems features covered in popular software engineering textbooks

Notions covered	**Author**		
	Sommerville	Pressman	Pfleeger
System definition	Yes	Yes	Yes
Boundary	Implied	Yes	Yes
Open vs Closed systems	No	No	No
Relationships	Implied	Implied	Yes
Inter-related systems	Implied	Implied	Yes
Emergent property	Yes	No	No
Decomposition	Yes	Yes	Yes
Coupling	No	Yes	Yes
Cohesion	No	No	Yes
Hierarchy	Yes	Yes	Yes
System behaviour	Yes	Yes	Yes
Law of requisite variety	No	No	No
Sociotechnical systems	Yes	No	No
Systems engineering	Yes	To some extent	To some extent

and closed systems, about the law of requisite variety or any other aspect of cybernetics, very little about sociotechnical systems, and nothing about soft systems methodology or CST. In our opinion, these are unexploited notions that have some potential to introduce fresh ideas in SE after further research.

Crnkovic, Land, and Sjogren (2003) question whether the current SE training is enough for software engineers. They call for making system thinking more explicit in SE courses. They claim that "the focus on modifiability (and on other non-functional properties) requires more of a holistic and system perspective" (Crnkovic et al., 2003). Similar thoughts are shared more recently by others in engineering like Laware, Davis, and Perusich (2006).

The narrow interpretation of computing disciplines is seen as a contributory factor to the drop in student enrolments in the last five years. Denning (2005) hopes that students will be attracted by a new educational approach promoted by the ACM Education Board that relies on four core practices: programming, systems thinking, modeling, and innovating. It has now been four years since those ideas were stressed by ACM, but there is little evidence that systems thinking has become a core practice emphasised in teaching in any of the three computing disciplines.

In the U.K., the Quality Assurance Agency (which monitors and quality assures all U.K. university programmes) recently published the updated version of the computing benchmark statement (encompassing IS, SE, and CS) on the content and form of undergraduate courses (QAA, 2007). Although not intended to be an exhaustive list but "provided as a set of knowledge areas indicative of the technical areas within computing," it fails to make explicit reference to systems thinking or systems approaches and makes only one reference to "systems theory" under a more general heading of "systems analysis and design". Perhaps the answer is to explore how to introduce these concepts earlier in pre-university education or to continue to try to convince the broader academic community of the importance of systems thinking.

One promising systems approach used for education of software engineers is the Model-Based System Architecting and Software Engineering (MBASE) framework being used at USC, and also adapted by some of their industrial affiliates. According to Boehm (2006c), MBASE integrates the systems engineering and SE disciplines, and considers stakeholder value in the system development. The MBASE framework embodies elements of agile processes and teaches students to "learn how to learn" as software development will continue to change. Valerdi and Madachy (2007) further describe the impact of MBASE in education.

On Software Engineering and Systems Engineering

Systems Engineering is concerned with all aspects of the development and evolution of complex systems where software plays a major role. Systems engineering is therefore concerned with hardware development, policy and process design, and system deployment, as well as software engineering. System engineers are involved in specifying a system, defining its overall architecture, and then integrating the different parts to create the finished system. Systems engineering as a discipline is older than SE, as people have been involved in specifying and assembling complex industrial systems such as aircraft and chemical plants for more than 100 years (Sommerville, 2007).

A thought provoking comparison of SE culture vs. systems engineering culture is presented by Gonzales (2005). This work points out to where we should strive to change the perceptions of the SE student entering the IT profession. We agree with Gonzales (2005) that we "must continue the dialogue and ensure that we are aware of strides to formalise standard systems engineering approaches and generalise software engineering approaches to capturing, specifying and managing requirements" (p. 1). We would also suggest that this dialogue should be supported by more work on the application of a systems approach to SE, stimulated by journals such as IJITSA.

Boehm (2006b) concludes that "The push to integrate application-domain models and software-domain models in Model Driven Development reflects the trend in the 2000's toward integration of software and systems engineering". Another reason he identifies is that other surveys have shown that the majority of software project failures stem from systems engineering shortfalls. A similar thought is expressed by Boehm and Turner (2005), who state that there is a need to move towards a common set of life-cycle definitions and processes that incorporate both disciplines' needs and capitalise on their strengths.

Boehm (2006a) points out that "recent process guidelines and standards such as the Capability Maturity Model Integration (CMMI), ISO/IEC 12207 for software engineering, and ISO/IEC 15288 for systems engineering emphasise the need to integrate systems and software engineering processes". He further proposes a new process framework for integrating software and systems engineering for 21st century systems and improving the contractual acquisition processes. Another issue is how to capitalise on the new developments in SE over the last decade which will be discussed in the next section.

The Evolution of Plan-driven and Agile Methods in SE and System Thinking

The traditional software development world, characterised by software engineering advocates, use plan-driven methods which rely heavily on explicit documented knowledge. Plan-driven methods use project planning documentation to provide broad-spectrum communications and rely on documented process plans and product plans to coordinate everyone (Boehm & Turner, 2004). The late 1990s saw something of a backlash against what was seen as the over-rigidity contained within plan-driven models and culminated in the arrival of agile methodologies, which rely heavily on communication through tacit, interpersonal knowledge for their success.

Boehm and Turner (2004) quote Philippe Kruchten (formerly with IBM Canada and now a professor at UBC in Vancouver) who has likened the Capability Maturity Model (CMM)—a plan-drive approach—to a dictionary:

> *'that is, one uses the words one needs to make the desired point; there is no need to use all the words available' (p. 23). They conclude that processes should have the right weight for the specific project, team, and environment. Boehm and Turner (2004) have produced the first multifaceted comparison of agile and plan-driven methods for software development. Their conclusions show that neither provides a 'silver bullet' (Brooks, 1987). Some balanced methods are emerging. We need both agility and discipline in software development.* (Boehm & Turner, 2004, p. 148)

Boehm (2006b) presents a deep analysis of the history of SE and of the trends that have emerged recently. These include the agile development methods: commercial off-the-shelf software and model driven development. The same author points out that the challenges are in capturing the evolving IT infrastructure and the domain restructuring that is going on in industry. In our opinion, it is necessary to investigate further if systems thinking may play a role in integrating agile and plan-driven methods (see Madachy, Boehm, & Lane, 2007, as an application of systems thinking to this problem). It has also been speculated that systems thinking could be relevant to Extreme Programming (XP) as it supports building relevant mental models (see Wendorff, 2002).

A recent paper by Kroes, Franssen, van de Poel, and Ottens (2006) deals with important issues in systems engineering such as how to separate a system from its environment or context. They conclude that the idea that a sociotechnical system can be designed, made, and controlled from some central view of the function of the system has to be given up, as many actors within the sociotechnical system are continuously changing (redesigning) the system. This is an important issue deserving further investigation in light of software systems and the methods implied by agile development frameworks.

Systems Dynamics and SE

A widely publicised idea is modeling software development processes through systems dynamics (see Abdel-Hamid & Madnick, 1991; Madachy, 2007; and others). The differences and relationships between systems dynamics and systems thinking are detailed in Richmond (1994) and others. Systems dynamics is a tool that can assist managers to deal with systemic and dynamic properties of the project environment and can be used to investigate virtually any aspect of the software process at a macro or micro level. It is useful for modeling sociotechnical factors and their feedback on software projects. The systems dynamics paradigm is based on continuous systems modeling, which has a strong cybernetic thread. Cybernetic principles are relevant to many types of systems including software development systems, as detailed in Madachy (2007).

The primary purposes of using systems dynamics or other process modeling methods in SE as summarised from Madachy (2007) are strategic management, planning, control and operational management, process improvement and technology adoption, and training and learning. Example recent work by Madachy (2006) focuses on the use of systems dynamics to model the interaction between business value and the parameters of a software process for the purpose of its optimisation. Another application of systems dynamics to assess a hybrid plan-driven and agile process that aims to cope with the requirements of a rapidly changing software environment while assuring high dependability in Software-Intensive-Systems-of-Systems (SISOS) is presented in Madachy, Boehm, and Lane (2007).

On Other Methods of Systems Thinking Applicable to SE

The development of understanding of a particular software project for making better judgments about the cost factors involved in cost and effort estimation is supported also by the work of Petkova and Roode (1999). They implemented a pluralist systemic framework for the evaluation of the factors affecting software development productivity within a particular organisational environment. It combines techniques from several paradigms: stakeholder identification and analysis (from SAST, see Mason & Mitroff, 1981), from SSM (Checkland, 1999), Critical Systems Heuristics (Ulrich, 1998), and the Analytic Hierarchy Process (Saaty, 1990).

While we could not find any specific earlier accounts of the use of SSM in the mainstream SE literature, it is significant that Boehm (2006a) has recognised its potential as he quotes its originator in a recent paper:

> Software people were recognising that their sequential, reductionist processes were not conducive to producing user-satisfactory software, and were developing alternative SE processes (evolutionary, spiral, agile) involving more and more systems engineering activities. Concurrently, systems engineering people were coming to similar conclusions about their sequential, reductionist processes, and developing alternative "soft systems engineering" processes (e.g., Checkland, 1999), emphasising the continuous learning aspects of developing successful user-intensive systems.

One does not need always to have a systems philosophy in mind to generate an idea that has a systemic nature or attempts to change the current thinking in SE. Thus, Kruchten (2005) presents, under the banner of postmodernist software design, an intriguing framework for software design borrowed from architecture. One may investigate how such an approach is different from a systemic methodology and what are their common features. Starting from a language-action philosophy point of view, Denning and Dunham (2006) develop a framework of innovation based on seven practices that are inter-related in their innovation model—every element is in a relationship with all others, thus fulfilling the criterion for "systemicity" by Mitroff and Linstone (1993). We need more analogical examples of systemic reasoning or even just of alternative thinking related to every aspect of the work of a software engineer and IS developer demonstrating the power of innovative interconnected thinking. The analysis so far allows us now to formulate some recommendations in the following section.

CONCLUDING RECOMMENDATIONS ON THE NEED FOR MORE RESEARCH LINKING SOFTWARE ENGINEERING, INFORMATION SYSTEMS DEVELOPMENT, AND SYSTEMS THINKING

We may derive a number of possible directions for future work from the analysis of research and practice in ISD and systems thinking within the fields of IS and SE. Alter (2004) has produced a set of recommendations for greater use of systems thinking in the IS discipline which incorporate various aspects of the work system method. We believe that Alter's proposals are viable and deserve the attention of IS and SE researchers.

Boehm and Turner's (2005) suggestions to address management challenges in integrating agile and plan-driven methods in software development will be used by us as an organising framework for formulating directions for research on integrating IS, SE, and the systems approach. The five main points below are as defined originally by Boehm and Turner (2005) for their purpose, while we have provided for each of them suggestions promoting such integration along the aims of this article:

1. **Understand how communication occurs within development teams:** There is a need to continue the work on *integrating systemic methods promoting organisational learning* (see Argyris & Schon, 1978) like systems dynamics, stakeholder analysis, soft systems methodology, critical systems thinking, and others to identify the advantages of using specific methods and their limitations when dealing with uncovering the microclimate within a software development team. Most of the previously mentioned applications of systems methods for this purpose have had limited use and little experimental evaluation. *More case studies need to be conducted in different software development organisations to validate the claims for the applicability of such methods and to distil from the accumulated knowledge best practices and critical success factors* relevant to flexible, high quality software development teams. We may *expand further the boundary of investigations with respect to what is happening at the level of systems-of-systems* (see Sage, 2005). An example of related relevant ideas on cost estimation for large and complex software projects can be found in Lane and Boehm (2007). Another direction is to *explore information systems development as a research act*, as suggested by Hughes and Wood-Harper (1999) and Hevner et al. (2004), as well as the philosophy of integrating practice with research in the field of software and management, promoted by IbisSoft (n.d.).

2. **Educate stakeholders:**This is probably the most difficult task of all. It needs to be addressed at several levels:

- *Implement changes in educational curricula*—it is essential to introduce the systems idea in relatively simple forms at the undergraduate level and in more sophisticated detail at the masters' level. There is *a need to create the intellectual infrastructure for more doctoral dissertation projects in IS or SE involving systems thinking*. Teaching could be supported by *creating an accessible repository for successful utilisation of systems ideas in IT education*. Amongst the many examples we may mention here the use of SSM in project-based education at a Japanese university (Chujo & Kijima, 2006), on integrating systems thinking into IS education (see Vo, Chae, & Olson, 2006), or the use of MBASE in student projects (see Boehm, 2006c; Valerdi & Madachy, 2007).
- *Broaden the systems knowledge of IS and software engineering educators*—the current situation in some of the computing disciplines can be compared to a similar one in Operations Research (OR) in the 1960s, which had evoked a sharp critique by Ackoff (1999) in his famous paper "The Future of Operational Research Is Past." published originally in 1979. Ackoff (1999, p. 316) points that survival, stability, and respectability took precedence over development and innovativeness in OR in the mid-1960s and its decline began. The *challenge however is not just to bring systems thinking to IS and SE education beyond several elementary concepts of general systems theory but to keep up to date with the latest body of knowledge in the systems field*. For a comprehensive overview, see Jackson (2003) and, for recent developments in systems science, see Barton, Emery, Flood, Selsky, and Wolstenholm (2004).
- *Empower IT developers to practice systemic thinking*—a significant role here needs to be played by research on the most *suitable forms for continuing professional education on IT and the systems approach*, *supported by professional meetings and journals for mixed audiences* like this one, that are oriented to academia and industry practice. Ackoff (2006) underlines that one of the reasons why systems ideas are adopted by few organisations is that "very little of the systems literature and lectures are addressed to potential users" (p. 707). Further, he stresses the need to analyse management failures systemically, pointing out that there are two types of failures: errors of commission and errors of omission. In spite of publications analysing software failures like Glass (2001), *there is still room for systemic analysis of IT failures and there are very few accounts of errors of omission* in software projects.
- *Change the attitudes of clients in managerial and operational user roles*—viable research and practical activities in this direction could *use the work system method* (Alter, 2006) and other relevant methods to develop better understanding of organisational problems and to improve their communication with software developers.

3. **Translate agile and software issues into management and customer language:** We may suggest several possible directions here:
    - *Investigate in a systemic way the existing agile and plan-driven models* for software development and continue with the work started in Boehm (2006a) on creating new process models integrating not just SE and systems engineering ideas but other applicable systems concepts as well.

- *Explore the applicability of "Sysperanto"* (see Alter, 2007) to foster a common language for all stakeholders in software development.
- *Build methods and tools to facilitate the communication process between software developers, customers, and supporting multiple perspective* representations of problem situations as proposed by Linstone (1984).

4. **Emphasise value for every stakeholder:** Design science research and agile methods place high emphasis on this idea. There is a *need for more research on systemic identification of stakeholder values.* Further, there is a need for research on methods to model and help the effective analysis and *better systemic understanding of all aspects of software development*, related to the technical product attributes, the project organisational attributes, the developers attributes, and the client features in a particular project or system-of-projects.
5. **Pick good people, reward the results, and reorient the reward system to recognise both individual and team contribution:** These suggestions can be categorised as human resource management issues and hence are also suitable for *investigation through suitable systemic approaches and problem structuring methods, including multicriteria decision analysis, promoting evaluation, and decision making.*

One of the limitations of the scope of our proposals is that we have provided suggestions reflecting only on the above five ideas by Boehm and Turner (2005). A systemic investigation of all aspects of ISD could lead to a much broader set of considerations integrating SE, IS, and systems thinking. We believe, however, that the examples we have provided here can lead to easier adaptation and development of other relevant ideas serving a similar purpose. Another possible limitation is that we have produced our suggestions for future research on integrating SE, IS, and the systems approach by assuming that the current state of the art and practice in SE and IS are known and we have focused rather only on identifying examples of the use of a systems approach in IS or SE. As we have pointed out earlier, we have relied on the comprehensive analysis of the state-of-the-art of the IS discipline provided by Hirschheim and Klein (2003). We have also reflected on trends in SE (see Reifer, 2003; Boehm, 2006a, b; Boehm & Turner, 2004) and on the comparative analysis of research in the three computing disciplines by Glass et al. (2004). It would be interesting to conduct a further investigation of IS implementation as a whole that goes beyond the existing disciplinary boundaries and takes a systems approach as an organising viewpoint.

Most of our recommendations on integrating IS, SE, and systems thinking relate to issues of organisational learning where contemporary systems methods have a significant history of achieving improvement. The challenge for IS and SE practitioners, researchers, and educators is not just to investigate the issues we discussed in this article but also to practice what was learned for improved ISD.

ACKNOWLEDGMENT

The authors are very grateful to D. Bustard and I. Bider for their very insightful comments that helped improve the article and to the editors of IJITSA for their encouragement.

Chapter 1.24

Software Engineering and the Systems Approach:

A Conversation with Barry Boehm

Jo Ann Lane
University of Southern California Center for Systems and Software Engineering, USA

Doncho Petkov
Eastern Connecticut State University, USA

Manuel Mora
Autonomous University of Aguascalientes, Mexico

INTRODUCTION

IJITSA is honored by the fact that this issue presents an interview with probably the most significant figure in the field of software engineering since its inception and one of its founders, Professor Barry W. Boehm. He has published many seminal books and papers that have shaped the foundations of software engineering. We have included in the references just a small sample of his numerous publications addressing some of the fundamental issues in this field in recent years. They cover diverse topics ranging from a comparison of agile development methods and software engineering (Boehm & Turner, 2004) to reflections on enhancing software engineering education (Boehm, 2006c). A thought-provoking review of the evolution of software engineering and its current challenges is presented in Boehm (2006b), while his thoughts on the need to integrate more closely software and systems engineering are reflected in Boehm (2006a) and Boehm and Lane (2006). The questions we asked Professor Boehm relate to his significant contributions to software engineering and enhancing its links to the systems approach.

Dr. Barry Boehm is the TRW Professor of Software Engineering and Director, Center for Software Engineering, University of Southern California. He received his B.A. degree from Harvard in 1957 and his M.S. and Ph.D. degrees from UCLA in 1961 and 1964, all in mathematics.

He also received an honorary Sc.D. in computer science from the University of Massachusetts in 2000. He served within the U.S. Department of Defense (DoD) as Director of the DARPA Information Science and Technology Office, and as Director of the DDR&E Software and Computer Technology Office. He worked at TRW from 1973 to 1989, culminating as Chief Scientist of the Defense Systems Group, and at the Rand Corporation from 1959 to 1973, culminating as Head of the Information Sciences Department. He was a Programmer-Analyst at General Dynamics between 1955 and 1959.

Professor Boehm's current research interests focus on value-based software engineering, including a method for integrating a software system's process models, product models, property models, and success models called Model-Based (System) Architecting and Software Engineering (MBASE). His contributions to the field include the Constructive Cost Model (COCOMO), the Spiral Model of the software process, the Theory W (win-win) approach to software management and requirements determination, the foundations for the areas of software risk management and software quality factor analysis, and two advanced software engineering environments: the TRW Software Productivity System and Quantum Leap Environment. He has served on the boards of several scientific journals, including the *IEEE Transactions on Software Engineering*, *IEEE Computer*, *IEEE Software*, *ACM Computing Reviews*, *Automated Software Engineering*, *Software Process*, and *Information and Software Technology*. He has served as Chair of the AIAA Technical Committee on Computer Systems, Chair of the IEEE Technical Committee on Software Engineering, and as a member of the Governing Board of the IEEE Computer Society. He has also served as Chair of the Air Force Scientific Advisory Board's Information Technology Panel, Chair of the NASA Research and Technology Advisory Committee for Guidance, Control, and Information Processing, and Chair of the Board of Visitors for the CMU Software Engineering Institute.

Professor Boehm was the recipient of numerous honors and awards, which include among others the ACM Distinguished Research Award in Software Engineering (1997) and the IEEE Harlan D. Mills Award (2000). He is a Fellow of the primary professional societies in computing (ACM), aerospace (AIAA), electronics (IEEE), and systems engineering (INCOSE), and a member of the National Academy of Engineering.

THE CONVERSATION

IJITSA: Professor Boehm, thank you for agreeing to this interview for IJITSA. You have noted in your previous writings the need for integration of systems engineering and software engineering. Please could you provide your opinion on why the systems approach is useful to software engineering?

Professor Boehm: I think the most convincing reason for that is most of the analyses of the root causes of failed software projects. They tend not to be whether you got your algorithms and data structures correct. They tend to be failures in doing the systems engineering. Getting the wrong requirements, or getting incomplete requirements, or getting the wrong stakeholders to give you requirements, or not understanding the feasibility of the requests, or being able to estimate cost or schedule, or tradeoffs in performance and reliability. So, most of the projects that fail seem to be failing because of failures in doing a good job of systems engineering. As we've tried to teach software engineers here at USC, we find that what we end up doing in the whole first semester of a two-semester course is getting them to learn how to systems engineer the operational concepts, the prototypes, the requirements, the architecture, the plans and get those right before they start doing a lot of detailed programming.

IJITSA: How would you assess the current level of information technology professionals practicing a systems approach? Would you say that the IT community faces a challenge to include more systems thinking in the state of the practice and state of theory in software engineering, information systems or systems engineering?

Professor Boehm: I think there is a bit of a gap in that there are some information technology professionals who are good at business workflows and things like that, but do not have a really deep computer science background as far as knowing whether the COTS products that they rely on are scalable or able to be tailored in ways that are necessary for the application. And on the other hand, there is a bunch of people who major in computer science who know all of that stuff, but don't know much about the business workflows. I think what's really valuable is when you get information technology professionals who have enough depth to do both of those things. And so, with the business-intensive people that do IT in the business school, we have just set up a joint Master's Program where you can get a master's in the management of software engineering that says that you need to know what the Business School people know about management and business applications, but you will also need to know what software engineers do about the algorithms, data structures, object-oriented methods, architectures, and those kinds of things.

IJITSA: What would be your recommendations for a better introduction of systems ideas in the software engineering and information systems curriculum at undergraduate and postgraduate levels?

Professor Boehm: This is easier to do for the post-graduate level. At the undergraduate level, it is hard to get people up to speed in both these things that are needed to understand information systems and computer science. So at USC, we find you can teach them a principles course in the junior year and they sort of get it and a small project course in the senior year and they get it a bit more. But where it all seems to come together best is really at the master's degree level. If they are well-enough grounded in one or the other, they can learn what they need to learn about the counterpart things: systems engineering if they are more in software engineering, software engineering if they are more systems oriented.

Actually, this is the direction that the current software engineering body of knowledge group is going. The previous body of knowledge was fairly heavy on computer science aspects. The more recent one is more appreciative and reflective of systems analysis, economics, business cases analyses, and things like that. Also, there is a similar activity to define a body of knowledge that is not just driven by academics, but really driven by a balance of academic and industry people that I think will have even more emphasis on the systems engineering and the management aspects.

IJITSA: You have pioneered and inspired significant research in software cost and effort estimation over many years. How would you characterize the role of the systems approach for the more recent evolution of the body of knowledge in that area?

Professor Boehm: Well again, as we saw with software engineering, it really needed to adapt more to the practices that are involved in systems engineering and software engineers needed to know more about the aspects of the rest of the system like the hardware, the facilities, and things like that. So what that means is that where our previous cost models really focused on defining and designing and developing the software, we've gone more into looking at models that estimate the cost of doing systems engineering, integrating systems of systems, integrating commercial-off-the-shelf (COTS) products, or things like that. A lot of the systems approach has been valuable in providing things like system engineering standards such as ISO 15288 and EIA 632 that give you representative work breakdown structures that you can relate to in doing these estimation models.

IJITSA: You indicate in some 2006 papers (Boehm, 2006a; Boehm & Lane, 2006d) that there is a need for considering alternative soft approaches such as those embodied in the ideas of Peter Checkland. Why do you think that a variety of systems approaches from different paradigms would improve our understanding of important software engineering activities?

Professor Boehm: Let me turn the question around a little bit. I think the software people really had to understand the role of people in systems more rapidly than some of the traditional system engineers who were engineering bridges and buildings and various kinds of physical artifacts. So, a lot of the soft systems engineering was necessary for software engineers to adapt as far as what they did with the front end of the life cycle. As I got more involved in doing this, I started seeing a lot of this really good work that John Warfield, Peter Checkland, and Eberhart Rechtin were doing in trying to take a more holistic approach to "what is a system?" There are still definitions of systems in the systems engineering field that say they do not include the people. But it's hard these days to exclude the people from being part of the problem and part of the solution when you are trying to engineer a system that has software in it.

IJITSA: What do you think of the potential of the systems approach to address some unresolved research challenges in the disciplines of information systems, software engineering or systems engineering?

Professor Boehm: I think that it's really been extremely valuable. As we have tried to do this in what we do in teaching computer science people how to do a systems approach, it has been very valuable. I was recently on a National Research Council study that was trying to come up with better ways in integrating human factors into the system development process, and again, the system approach had an appropriate framework for doing this, particularly if you included people as part of the system. I think it has been good to see that the "systems approach" has broadened enough to so that it does account for all of those kinds of things. There are still a lot of devils in the details about how do you come up with systems approaches that fit all of the different possible configurations of systems that need to be built these days. But I think the framework is going to be strong enough to help address those.

IJITSA: Could you give us, please, a final message related to the systems approach movement in IT in general and in software engineering more specifically?

Professor Boehm: Well, I think we were approaching that in the previous question which is that the systems that we are trying to engineer these days are getting a lot more complicated than the ones that were done before in that they are trying to pull together existing systems that have different owners and are operating on different timescales, different objectives, and different management chains. And somehow we need to make these things come together and operate as some kind of unified whole. At the same time these things are becoming more software intensive, so the software needs to be brought more up front. The pace of change in the system means that you have to do the systems engineering very rapidly or the system will be obsolete by the time you build it. And these things need to be much more resilient than they used to be because they are now driving the whole world's financial systems, the whole world's emergency services, and all the things we rely on in preserving and having a good quality of life.

IJITSA: Thanks very much for sharing your knowledge and wisdom with the IJITSA readers and us.

Information and Knowledge Perspectives in Systems Engineering and Management for Innovation and Productivity Through Enterprise Resource Planning

Stephen V. Stephenson
Dell Computer Corporation, USA

Andrew P. Sage
George Mason University, USA

ABSTRACT

This article provides an overview of perspectives associated with information and knowledge resource management in systems engineering and systems management in accomplishing enterprise resource planning for enhanced innovation and productivity. Accordingly, we discuss economic concepts involving information and knowledge, and the important role of network effects and path dependencies in influencing enterprise transformation through enterprise resource planning.

INTRODUCTION

Many have been concerned with the role of information and knowledge and the role of this in enhancing systems engineering and management (Sage, 1995; Sage & Rouse, 1999) principles, practices, and perspectives. Major contemporary attention is being paid to enterprise transformation (Rouse, 2005, 2006) through these efforts. The purpose of this work is to discuss many of these efforts and their role in supporting the definition, development, and deployment of an enterprise resource plan (ERP) that will enhance transformation of existing enterprises and development of new and innovative enterprises.

Economic Concepts Involving Information and Knowledge

Much recent research has been conducted in the general area of information networks and the new economy. Professors Hal R. Varian and Carl Shapiro have published many papers and a seminal text, addressing new economic concepts as they apply to contemporary information networks. These efforts generally illustrate how new economic concepts challenge the traditional model, prevalent during the Industrial Revolution and taught throughout industry and academia over the years. In particular, the book *Information Rules* (Shapiro & Varian, 1999) provides a comprehensive overview of the new economic principles as they relate to today's information and network economy. The book addresses the following key principles:

- Recognizing and exploiting the dynamics of positive feedback
- Understanding the strategic implications of lock-in and switching costs
- Evaluating compatibility choices and standardization efforts
- Developing value-maximizing pricing strategies
- Planning product lines of information goods
- Managing intellectual property rights
- Factoring government policy and regulation into strategy

These concepts have proven their effectiveness in the new information economy and have been fundamental to the success of many information technology enterprises introducing new ideas and innovations into the marketplace. Paramount to an enterprise's success in reaching critical mass for its new product offering is the understanding and implementation of these new economic concepts.

Economides (1996) has also been much concerned with the economics of networks. He and Himmelberg (1994) describe conditions under which a critical mass point exists for a network good. They characterize the existence of critical mass points under various market structures for both durable and non-durable goods. They illustrate how, in the presence of network externalities and high marginal costs, the size of the network is zero until costs eventually decrease sufficiently, thereby causing the network size to increase abruptly. Initially, the network increases to a positive and significant size, and thereafter it continues to increase gradually as costs continue to decline. Odlyzko (2001) expands on the concept of critical mass and describes both the current and future growth rate of the Internet and how proper planning, network budgeting, and engineering are each required. He emphasizes the need for accurate forecasting, since poor planning can lead to poor choices in technology and unnecessary costs.

Economides and White (1996) introduce important concepts with respect to networks and compatibility. They distinguish between direct and indirect externalities, and explore the implications of networks and compatibility for antitrust and regulatory policy in three areas: mergers, joint ventures, and vertical restraints. They also discuss how compatibility and complementarity are linked to provide a framework for analyzing antitrust issues. Strong arguments are made for the beneficial nature of most compatibility and network arrangements, with respect to vertical relationships, and policies are set forth to curb anti-competitive practices and arrangement. Farrell and Katz (2001) introduce concepts of policy formulation in preventing anti-competitive practices and, in addition, explore the logic of predation and rules designed to prevent this in markets that are subject to network effects. This work discusses how the imposition of the leading proposals for rules against predatory pricing may lower or raise consumer welfare, depending on conditions that may be difficult to identify in practice.

Research conducted on these economic concepts establishes a solid foundation and baseline for further research in the area of enterprise resource planning and new technology innovations (Langenwalter, 2000). In this work, he extends the traditional enterprise resource planning (ERP) model to incorporate a total enterprise integration (TEI) framework. He describes TEI as a superset of ERP and also describes how it establishes the communications foundation between customer, manufacturer, and supplier. Each entity is linked internally and externally, allowing the TEI system to enhance performance and to provide process efficiencies that reduce lead times and waste throughout the supply chain. This work illustrates how ERP is uniquely integrated with customers and suppliers into the supply chain using TEI and how it significantly improves customer-driven performance. The model for this includes five major components: executive support, customer integration, engineering integration, manufacturing integration, and support services integration. These components are essential for integrating all information and actions required to fully support a manufacturing company and its supply chain. TEI presents a strategic advantage to an enterprise, rather than just improving operating efficiencies. The TEI framework provides the enterprise a competitive edge by:

- Maximizing speed and throughput of information and materials
- Minimizing response time to customers, suppliers, and decision makers
- Pushing decisions to the appropriate levels of the organization
- Maximizing the information made available to the decision-makers
- Providing direct integration into the supply chain

In addition to the technology, TEI also incorporates stakeholders. People are empowered at all levels of the enterprise to improve the quality of their decision-making. One result of this is MRP II (Manufacturing Resources Planning) systems. MRP II evolved from MRP (Material Requirements Planning), which was a method for materials and capacity planning in a manufacturing environment. Manufacturing plants, to plan and procure the right materials in the right quantities at the right time, used this method. MRP became the core planning module for MRP II and ERP. MRP was later replaced by MRP II, which expanded the MRP component to include integrated material planning, accounting, purchasing of materials for production, and the shop floor. MRP II integrated other functional areas such as order entry, customer service, and cost control. Eventually, MRP II evolved into enterprise resource planning (ERP), integrating even more organizational entities and functions such as human resources, quality management, sales support, and field services. ERPs became richer in functionality and involved a higher degree of integration than their predecessors MRP and MRP II.

Another very well-known contributor to the field of enterprise resource planning is Thomas H. Davenport (2000). In *Mission Critical: Realizing the Promise of Enterprise Systems*, the need to take a customer or product focus when selecting an operational strategy is emphasized. To enable this, a direct connection should exist between the daily operations and the strategic objectives of the enterprise. This is made possible through the use of operational data, that is used to enhance the operational effectiveness of the enterprise. Operational data is defined by the organization seeking to measure the operational effectiveness of its environment. Operational data may be defined in terms of various parameters such as cycle time (CT), customer response time (CRT), or MTTR (mean time to repair). These are only a few of the parameters, and they are contingent on the operational strategy the organization is seeking to adopt. For example, an organization that seeks to reduce cycle time (CT) for processing orders in order to minimize cost may look to capture CT in its operational data. This data is captured over time as process efficiencies are instituted within the existing order process. Operational effectiveness is then determined by comparing the future CT state of the order process with that of its initial CT benchmark. For example, if cycle time to process an order was originally 15 minutes, and after the process efficiencies were instituted, CT was then 5 minutes, then operational effectiveness improved by 10 minutes. Now it takes fewer resources to process orders, thus reducing operational costs.

Davenport (2000) introduces a data-oriented culture and conveys the need for data analysis, data integrity, data synthesis, data completeness, and timely extracts of data. Data is used across organizational boundaries and shared between the various entities in an effort to enhance operational effectiveness. For example, transaction data must be integrated with data from other sources, such as third-party vendors, to support effective management decision-making. One's ability to interpret and analyze data can effect the decisions that are made and the confidence management has in pursuing particular ongoing decisions. Davenport believes that a combination of strategy, technology, data (data that is relevant to the organization), organization, culture, skills and knowledge assist with developing an organization's capabilities for data analysis. When performing data analysis, various organizations may have similar results, but with different meanings. He indicates that a typical corporation may have divisions that have a need to store customer data in different customer profile schemes. Therefore, a common shared master file between the divisions may not be feasible. This approach takes on more of a distributed approach versus a centralized approach to data management. The operational effectiveness of each of these divisions will vary based on the benchmarks and target improvements they have set for themselves.

Christopher Koch (2006) supports Davenport's data concept and elaborates on the value of an ERP and how it can improve the business performance of an enterprise. He demonstrates the value of an ERP by integrating the functions of each organization to serve the needs of all stakeholders. The associated framework attempts to integrate all organizational entities across an enterprise onto a single-systems ERP platform that will serve the needs of the various entities. This single platform replaces the standalone systems prevalent in most functional organizations such as human resources, finance, engineering, and manufacturing, thereby allowing people in the various organizations to access information not only in the most useful manner but also from their own perspectives. This information may be the same shared data used between the organizations or may vary, based on the need of each of the organizations. Each organization in the enterprise and its stakeholders will have their own set of requirements for accessing, viewing and manipulating their data. Data management may even take on a hybrid of a centralized and distributed approach. Some organizations may need a view of the same data, while others may have their own unique data requirements. Koch (2006) indicates that there are five major reasons why an enterprise adopts an ERP strategy:

1. Integrate financial information
2. Integrate customer order information
3. Standardize and speed up manufacturing processes
4. Reduce inventory
5. Standardize human resources (HR) information

Each organization within an enterprise has its own requirements for an ERP. They may share the same ERP solution; however, the ERP may be designed to support the specific business need of each organization. Some organizations may have a need to view the same data. For example, a sales and customer care-focused organization may need to view the same customer profile data to access customer contact information. In comparison, a human resources-focused organization may not need to be privy to this same information. They may be more interested in accessing internal employee personnel records for employee performance monitoring. The senior executive level of an enterprise will also have its own unique data requirements in order to make key strategic and tactical decisions. This executive level may need the capability to access data from each of the organizational units in order to effectively manage the operations of the business. The organizations, within an enterprise each have their own instances of an ERP with respect to accessing data and implementing processes. Some organizations may share a common process such as the order fulfillment process. For example, this process may be shared between organizational entities such as sales, operations, and revenue assurance. Sales would complete a service order, operations would deliver the service, and revenue assurance would bill the customer. However, there are processes that are only unique to a particular organization. For example, the marketing organization may not be interested in the escalation process used by operations to resolve customer issues. This process is unique to operations and, as a result, the ERP would be designed for such uniqueness. The design of an ERP should, of course, take organizational data and process requirements into account and support management of the enterprise and its inter-workings in a transdisciplinary and transinstitutional fashion (Sage 2000, 2006).

William B. Rouse had produced very relevant and important popular work surrounding new technology innovation with respect to the enterprise. In *Strategies for Innovation*, Rouse (1992) addresses four central themes to introduce strategies for innovation in technology-based enterprises. Rouse discusses the importance of strategic thinking and how some enterprises fail to plan long term. This is based on the notion that "while people may want to think strategically, they actually do not know how(p. 3)." He emphasizes the need for stakeholders to understand the solutions offered as a result of new innovation, and how strategies are critical for ensuring successful products and systems. Most importantly, these strategies must also create a successful enterprise for developing, marketing, delivering, and servicing solutions, thus leading to the need for human-centered planning, organization, and control. These are among the approaches needed to stimulate innovation in products and services (Kaufman & Woodhead, 2006).

Rouse (1992) describes the need for applying a human-centered design methodology to the problem of enhancing people's abilities and overcoming their limitations. In the process of planning, organizing, and controlling an enterprise, he illustrates how technology-based enterprises differentiate themselves from each other based on their core product technologies. This strategic strength is based on the unique value that the core product can provide to the marketplace. He indicates that the enterprise should continuously analyze the market and measure core product value to determine the benefits that can be provided. Assessing and balancing the stakeholders' interests will be necessary to ensure success of the core product. Stakeholders consist of both producers and consumers. Each may have a stake in the conceptualization, development, marketing, sales, delivery, servicing, and use of the product. The three key processes highlighted in this work are: strategic planning, operational management, and the engineering/administration, vehicles used by the enterprise to assist stakeholders with pursuing the mission of the enterprise.

Rouse further addresses strategic approaches to innovation in another one of his books. In *Essential Challenges of Strategic Management* (Rouse, 2001), he illustrates the strategic management challenges faced by all enterprises and introduces best practices for addressing these challenges. He disaggregates the process of strategically managing an enterprise into seven fundamental challenges. The essential challenges he describes, which most enterprises are confronted with, are: growth, value, focus, change, future, knowledge, and time. Growth is critical to gaining share in saturated and declining markets and essential to the long-term well-being of an enterprise. A lack of growth results in declining revenues and profits, and, in the case of a new enterprise, there is the possibility of collapse. He describes value as the foundation for growth, the reason an enterprise exists. Matching stakeholders' needs and desires to the competencies of the enterprise, when identifying high-value offerings, will justify the investments needed to bring these offerings to market. While value enhances the relationships of processes to benefits and costs, focus will provide the path for an enterprise to provide value and growth. Focus involves pursuing opportunities and avoiding diversions, that is, making decisions to add value in particular ways and not in others are often involved. For example, allocating too few resources among many projects may lead to inadequate results or possible failure.

The focus path is followed by another path called change. An enterprise challenged with organizational re-engineering, downsizing, and rightsizing often takes this change path. The enterprise will continue to compete creatively while maintaining continuity in its evolution. As the nature of an organization changes rapidly during an enterprise's evolution, managing change becomes an art. According to Rouse (2001), investing in the future involves investing in inherently unpredictable outcomes. He describes the future as uncertain. The intriguing question is, "If we could buy an option on the future, how would we determine what this option is worth(p. 6)?" A new enterprise will be faced with this challange when coming into the marketplace.

The challenge of knowledge is transformation of information from value-driven insights to strategic programs of action. Determining what knowledge would make an impact, and in what ways, is required. This understanding should facilitate determining what information is essential and should provide further elaboration on how it is to be processed and how its use will be supported. The most significant challenge identified is that of time. A lack of time is the most significant challenge facing best use of human resources. Most people spend too much time being reactive and responding to emergencies, attending endless meetings, and addressing an overwhelming number of e-mails, all of which cannibalize time. As a result, there is little time for addressing strategic challenges. Carefully allocating the scarcest resource of an organization is vital to the future of an enterprise. Some of the best practices Rouse (2001) has presented in addressing the seven strategic challenges may be described as follows.

- **Growth:** Buying growth via strategic acquisitions and mergers; fostering growth from existing market offerings via enhanced productivity; and creating growth through innovative new products and brand extensions.
- **Value:** Addressing the nature of value in the market; using market forces in determining the most appropriate business process; and designing cost accounting system to align budgets and expenditures with value streams.
- **Focus:** Deciding what things to invest in and those things to be avoided or stopped; and linking decisions or choices to organizational goals, strategies, and plans.
- **Change:** Instituting cross-functional teams for planning and implementing significant changes; and redesigning incentive and reward systems in order to ensure that people align their behaviors with desired new directions.

- **Future:** Employing formal and quantitative investment decision processes; and creating mechanisms for recognizing and exploiting unpredictable outcomes.
- **Knowledge:** Ensuring that knowledge acquisition and sharing are driven by business issues in which knowledge has been determined to make a difference; using competitive intelligence and market/customer modeling to provide a valuable means for identifying and compiling knowledge.
- **Time:** Committing top management to devoting time to challenges; and improving time management, executive training, and development programs, in addition to providing increased strategic thinking opportunities.

Gardner (2000) takes a complementary approach to the enterprise and to innovation by focusing on the valuation of information technology. He addresses the difficulties of defining the value of new technologies for company shareholders using integrated analytical techniques in his book *The Valuation of Information Technology*. Gardner presents methodologies for new enterprise business development initiatives and presents techniques for improving investment decisions in new technologies. This 21st-century approach to valuation avoids making investment decisions on an emotional basis only, in favor of predicting shareholder value created by an information technology system before it is built. Determining the contribution an information technology system makes to a company's shareholder value is often challenging and requires a valuation model. Gardner suggests that the primary objective of information technology systems development in business is to increase the wealth of shareholders by adding to the growth premium of their stock. The objective of maximizing shareholder wealth consists of maximizing the value of cash flow generated by operations. This is accomplished by generating future investment in information technology systems. As an example, this could be a state-of-the-art enterprise resource planning system, which could easily maximize what we will call operational velocity and, as a result, maximize shareholder wealth. The process that Gardner suggests using would be to first identify the target opportunity, align the information technology system to provide the features the customer wants in a cost-effective manner, and then to accurately measure the economic value that can be captured through this.

Some of the techniques Gardner uses to compute economic value are net present value (NPV), rate of return (ROR), weighted average cost of capital (WACC), cost of equity, and intrinsic value to shareholders of a system. Each of these techniques may be used to determine aspects of the shareholder value of an information technology system. The results from computing these values will assist an enterprise with making the right decisions with respect to its operations. For example, if the rate of return on capital is high, then time schedule delays in deploying an information technology system can destroy enormous value. Time to market becomes critical in this scenario. Gardner suggests that it may be in the best interest of the company to deploy the system early by mitigating the potential risk and capitalizing on the high rate of return. A risk assessment must be performed to ensure that the customer relationship is not compromised at the expense of implementing the system early. If the primary functionality of the system is ready, then the risk would be minimal, and the other functional capabilities of the system may be phased in at a later time.

If the rate of return is low, however, schedule delays will have a lesser effect on value and deployment of a system does not immediately become crucial to the success of the enterprise. This approach to predicting value takes a rational approach to decision making by weighing the rewards and risks involved with an information technology system investment. The author suggests moving away from the more intuitive approach of valuation often practiced in the high-tech industry, which is said to be very optimistic, spotty, and driven by unreasonable expectations from management. Gardner describes this intuitive practice as a non-analytical approach to assessing the economic viability of an information technology system. This practice primarily ignores the bare essentials that management must consider in assessing whether the economics of an information technology system are attractive. Gardner has established an analytical framework for analyzing the economics of information technology systems. His process is comprised of the three following steps:

1. Identify the target customer opportunity.
2. Align the information technology system to cost-effectively provide the features the customer wants.
3. Measure the economic value that can be captured.

The result of utilizing the framework is the quantification of the shareholder value created by an information technology system.

Boer (1999) also has much discussion on the subject of valuation in his work on *The Valuation of Technology*. He illustrates links between research and development (R&D) activity and shareholder value. In addition, he identifies the languages and tools used between business executives, scientists, and engineers. The business and scientific/engineering communities are very different environments and are divided by diverse knowledge and interest levels. Bridging the gap between these communities is made possible through the process of valuation, which fosters collaboration and communication between both communities. Boer identifies the link between strategy and value and addresses the mutual relationship between corporate strategy and technology strategy. He introduces tools and approaches used to quantify the link between technological research and commercial payoff within the value model of an enterprise.

This value model is comprised of four elements: operations, financial structure, management, and opportunities. The opportunity element is most critical to the future growth of an enterprise. The options value of an enterprise and how it is addressed strategically will determine the fate of an emerging enterprise. Boer illustrates how productive research and development creates options for the enterprise to grow in profitability and size. He views R&D as a component of operations, since this is the point at which new technology is translated into commercial production. In the competitive marketplace, the enterprise evolves in order to generate opportunity and growth. R&D serves as the vehicle for converting cash into value options for the enterprise. Boer introduces R&D stages (conceptual research, feasibility, development, early commercialization), where the level of risk, spending, and personnel skills vary. Each stage of the R&D process allows management to make effective decisions regarding the technology opportunity and perform levels of risk mitigation. R&D can be instrumental in decreasing capital requirements with results of a very high rate of return on the R&D investment. The art of minimizing capital requirements requires good and effective communication between the scientific/engineering and business communities. This will allow both communities to share their views and foster the need for driving this essential objective.

Some of the methods Boer uses for asset valuation are similar to Rouse's methods. Boer uses discounted cash flow (DCF), NPV, cost of money, weighted average cost of capital, cost of equity, risk-weighted hurdle rates for R&D, and terminal value methods for assessing valuation. In accelerated growth situations, as in the case of an emerging enterprise, Boer emphasizes that the economic value is likely to be derived from the terminal value of the project, not from short-term cash flows. A lack of understanding of terminal value can compromise the analysis of an R&D project. R&D can be a cash drain, and the outcomes are difficult to predict. Boer's techniques provide a vehicle for converting cash into opportunity and creating options for the enterprise.

Another work that addresses valuation is entitled *The Real Options Solution: Finding Total Value in a High-Risk World* (Boer, 2002). Here, the author presents a new approach to the valuation of business and technologies based on options theory. This innovative approach, known as the total value model, applies real options analysis to assessing the validity of a business plan. All business plans are viewed as options. These plans are subject to both unique and market risks. While business plans seem to create no value on a cash flow basis, they do become more appealing once the full merit of all management options is recognized. Since management has much flexibility in execution, the model offers a quantifiable approach to the challenge of determining the strategic premium of a particular business plan. Boer defines total value as "the sum of economic value and the strategic premium created by real options (p. vii)." He presents a six-step method for applying this model in a high-risk environment for evaluating enterprises, R&D-intensive companies, bellwether companies, capital investments, and hypothetical business problems. His method reveals how changes in total value are driven by three major factors: risk, diminishing returns, and innovation.

Boer's option theory efforts provide the enterprise with a vehicle for computing the strategic premium to obtain total value. This six-step method to calculate total value is comprised of:

1. Calculation of the economic value of the enterprise,
2. Framing the basic business option,
3. Determining the option premium,
4. Determining the value of the pro forma business plan,
5. Calculating the option value, and
6. Calculating total value.

Options theory approached to valuation leverage on elements of uncertainty such as these afford enterprise managers major investment opportunities. This was not common using more traditional valuation methods such as NPV- and internal rate of return (IRR)-based calculations. As Boer (2002) illustrates, the new options theory emphasizes the link between options, time, and information. Boer states: "Options buy time. Time produces information. Information will eventually validate or invalidate the plan. And information is virtual (p. 106)." This theory and its extensions (Boer, 2004) may well pave the way for a new generation of enterprise evolution and enterprise innovation.

Rouse (2005, 2006) is concerned with the majority of these issues in his development of systems engineering and management approaches to enterprise transformation. According to Rouse, enterprise transformation concerns change, not just routine change but fundamental change that substantially alters an organization's relationships with one or more of its key constituencies: customers, employees, suppliers, and investors. Enterprise transformation can take many forms. It can involve new value propositions in terms of products and services and how the enterprise should be organized to provide these offerings and to support them. Generally, existing or anticipated value deficiencies drive these initiatives. Enterprise transformation initiatives involve addressing the work undertaken by an enterprise and how the work is accomplished. Other important elements of the enterprise that influence this may include market advantage, brand image, employee and customer satisfaction, and many others.

Rouse suggests that enterprise transformation is driven by perceived value deficiencies due to existing or expected downside losses of value; existing or expected failures to meet promised or anticipated gains in value; or desire to achieve new, improved value levels through marketing and/or technological initiatives. He suggests three ways to approach value deficiencies: improve how work is currently performed; perform current work differently; and/or perform different types of work. Central to this work is the notion that enterprise transformation is driven by value deficiencies and is fundamentally associated with investigation and change of current work processes such as to improve the future states of the enterprise. Potential impacts on enterprise states are assessed in terms of value consequences.

Many of the well-known contributors in the field of enterprise resource planning presented had developed their own unique model. Each had established a strategy to address the evolution and growth of the enterprise. Differences between the models varied based on the challenge presented and the final objective to be achieved by the enterprise. A comparison of the ERP models presented is illustrated in Table 1.

Fundamentally, system engineering and system management are inherently transdisciplinary in attempting to find integrated solutions to problems that are of a large scale and scope (Sage, 2000). Enterprise transformation involves fundamental change in terms of reengineering of organizational processes and is also clearly transdisciplinary as that success necessarily requires involvement of management, computing, and engineering, as well as behavioral and social sciences. Enterprises and

Table 1. Comparison of ERP models

ERP Models				
Contributor	**Model**	**Strategy**	**Challenge**	**Objective**
Gary A. Langenwalter	Total enterprise integration (TEI) framework	• Integrates customer, manufacturer, and supplier • Provides competitive edge by: maximizing speed of information, minimizing response time, pushing decisions to the correct organizational level, maximizing information available to decision-makers, and direct integration of supply chains	• Establishing seamless communication • Multi-functional integration	• Incorporate all stakeholders • Empower people at all levels of the organization • Improve quality of decision-making
Thomas H. Davenport	Operational data model	• Introduces data-oriented culture • Supports a customer and product focus • Uses operational data to measure operational effectiveness	• Defining organizational boundaries • Enhancing operational effectiveness	• Define operational performance parameters • Measure operational effectiveness • Support effective decision-making
Christopher Koch	Business performance framework	• Supports data sharing • Integrates financial information • Integrates customer order information • Standardizes manufacturing process • Reduces inventory • Standardizes HR information	• Centralized and distributed approach to data management • Establishing requirements for accessing, viewing, and manipulating data	• Integrate all organizational entities across a single systems platform • Manage enterprise in transdisciplinary and transinstitutional fashions

continued on following page

Table 1. continued

William B. Rouse	Strategic innovation model	• Introduces a strategic approach to innovation • Focuses on the need for human-centered planning, organization, and control • Differentiating from the competition based on core product technologies	• Enhancing people's abilities and overcoming their limitations • Essential challenges: growth, value, focus, change, future, knowledge, and time	• Support strategic planning, operational management, and engineering • Ensure the successful innovation of products and systems
Christopher Gardner	Valuation model	• Presents methodologies for new enterprise business development initiatives • Determines the contribution an enterprise system makes to a company's shareholder value	• Defining the value of new technologies • Mitigating the potential risk and capitalizing on the high rate of return	• Increase shareholder wealth • Maximize the value of cash flow generated by operations
Peter F. Boer	Options model	• Bridges the gap between the business and scientific/engineering communities • Introduces research and development that creates options for the enterprise to grow in profitability and size	• Identifying the link between corporate strategy and technology strategy • Minimizing capital requirements • Understanding terminal value of a project	• Introduce research and development stages for assessing technology opportunities • Determine strategic premium created by real options

associated transformation are among the complex systems addressed by systems engineering and management. Rouse's efforts (2005, 2006) provide a foundation for addressing these issues and the transdisciplinary perspective of systems engineering and management provide many potentially competitive advantages to deal with these complex problems and systems.

Network Effects and Their Role in Enterprise Resource Planning

In today's information economy, introducing new technologies into the marketplace has become a significant challenge. The information economy is not driven by the traditional economies of scale and diminishing returns to scale that are prevalent among large traditional production companies. It has been replaced by the existence of network effects (also known as network externalities), increasing returns to scale and path dependence. This is the core economic reality, and not at all a philosophy, which has revolutionized traditional economic theories and practices, resulting in a new approach to economic theory as it pertains to the information economy.

There are a number of market dynamics or external variables that impact the success of any new technology entering the market. The most common variable is the element of network effects. A product exhibits network effects when its value to one user depends on the number of other users. Liebowitz and Margolis (1994) define network effects as the existence of many products for which the utility that a user of them derives from their consumption increases with the number of other agents that are also utilizing the product, and where the utility that a user derives from a product depends upon the number of other users of the product who are in the same network. Network effects are separated into two distinct parts, relative to the value received by the consumer. Liebowitz and Margolis (1994) denote the first component as the autarky value of a technology product, the value generated by the product minus the other users of the network. The second component is the synchronization value, the value associated when interacting with other users of the product. The social value derived from synchronization is far greater than the private value from autarky. This social value leads the way to increasing returns to scale, by creating path dependence (also known as positive feedback) and influencing the outcome for network goods. These efforts and others are nicely summarized in Liebowitz (2002) and Liebowitz and Margolis (2002).

Path dependence is essential for a company to reach critical mass when introducing new technologies into the market. As the installed customer base grows, more customers find adoption of a new product or technology of value, resulting in an increase in the number of consumers or users. Consumer choices exhibit path dependence for new products as others realize their value, eventually leading to critical mass. Path dependence is simply an effect whereby the present position is a result of what has happened in the past. The path dependence theory demonstrates that there are a number of stable alternatives, one of which will arise based on the particular initial conditions. Path dependence is evident when there is at least persistence or durability in consumer decision-making. Decisions made by early adopters can exhibit a controlling influence over future decisions or allocations made by late adopters. These product decisions are often based on the individual arbitrary choices of consumers, persistence of certain choices, preferences, states of knowledge, endowments, and compatibility. The outcome may depend on the order in which certain actions occur based on these behavioral determinants.

Network effects, increasing returns, and path dependence can be better illustrated when applied to the concept of a virtual network. The virtual network has similar properties to a physical or real network, such as a communications network. In such networks, there are nodes and links that connect the nodes to each other. In a physical network, such as a hard-wire communications network, the nodes are switching platforms and the links are circuits or telephone wires. Conversely, the virtual network nodes may represent consumers and transparent links represent paths, as driven by network effects and path dependence, that impact consumer behavior. The value of connecting to the network of Microsoft Office users is predicated on the number of people already connected to this virtual network. The strength of the linkages to the virtual network and its future expansion is based on the number of users who will use the same office applications and share files.

Path dependence can easily generate market dominance by a single firm introducing a new technology. This occurs when late adopters latch onto a particular virtual network, because the majority of users already reside on this infrastructure and have accepted the new technology. As more consumers connect to the virtual network, it becomes more valuable to each individual consumer. Consumers benefit from each other as they connect to the infrastructure. The larger network becomes more attractive to the other consumers who eventually become integrated. A communications network can best illustrate this concept. For example, additional users who purchase telephones and connect to a communications infrastructure bring value to the other users on the network, who can now communicate with the newly integrated users. This same concept applies to the virtual network and has the same impact. Real and virtual networks share many of the same properties and, over time, are destined to reach a critical mass of users.

New and emerging startup enterprises seeking to take advantage of network effects and path dependence when launching a new technology or innovation in the marketplace must have a reliable and operationally efficient enterprise resource planning (ERP) solution in place. The ERP solution must be capable of attaining operational velocity to address market demands. Miller and Morris (1999) indicate that traditional methods of managing innovation are no longer adequate. They suggest that as we make the transition to fourth generation R&D, appropriate complex timing for innovations remains a significant challenge. These authors assert that as new technologies and new markets emerge, management must deal with complexity, enormous discontinuities, increasing volatility, and the rapid evolution of industries. The challenge becomes that of linking emerging technologies with emerging markets through methods such as an ERP solution to bridge this link and to allow new emerging enterprises, or established mature enterprises seeking to transform themselves, to adapt quickly to the dynamics of the marketplace. The solution supports both continuous and discontinuous innovation as defined by Miller and Morris (1999). This form of innovation works well when customer needs in a competitive environment can be met within existing organizational structures.

In contrast to this, discontinuous innovation may bring forth conditions emanating from fundamentally different new knowledge in one or more dimensions of a product or service, and offer significantly different performance attributes. Discontinuous change potentially brings about change in a deep and systematic way. It offers a potential lifestyle change to customers that can be dramatic. Miller and Morris (1999) note, for example, the transition from typewriters to personal computers for producing written documents. In part, this occurred because customers no longer were satisfied with the existing framework of capability offered by the typewriter. New knowledge, organizational capabilities, tools, technology, and processes changed the behavior and desires of the customer. In addition to this change was also the change resulting in supporting infrastructure. Miller and Morris (1999) emphasize that discontinuous innovation affects not only products and services but also the infrastructures integral to their use, as well as extensive chains of distribution that may involve a plethora of affiliated and competing organizations.

As the threat of unexpected competition surrounds any new enterprise entering the market, the risk associated with technology shifts and the compression of the sales cycle make successfully managing discontinuous innovation a necessary challenge for success. We must be able to gauge how the market is evolving and what organizational capabilities must exist to sustain competitiveness as a result of this evolution. Because innovation usually requires large capital infusions, decreasing the time for appearance of a positive revenue stream is critical to the success of the enterprise. This decrease in time is made possible through operational velocity attainment, which requires changes in existing implementation strategies and organizational capabilities. This requires a collaborative effort between the various involved organizations to understand what is needed to support new innovations. Responsibility for supporting new innovation is not only supported by internal organizations but by such external organizations as suppliers, customers, and partners. Organizational structure, capabilities, and processes are fundamental to an evolutionary ERP model and serve as the framework for supporting new technology adoption in the marketplace.

The information economy is driven by network effects (also termed demand-side economies of scale or network externalities). Network effects support path dependence and are predicated on Metcalfe's Law, which suggests that the value of a network goes up as the square of the number of users (Shapiro & Varian, 1999), or on recent suggested modifications to this (Briscoe, Odlyzko, & Tilly, 2006). Positive effects occur when the value of one unit increases with an increase in the number of the same unit shared by others. Based on this premise, it is possible to create an enterprise resource planning model that influences positive feedback from human behavior in adopting new technologies and accelerates critical mass early in the deployment phase of the product development lifecycle, by attaining operational velocity. Operational velocity is defined in terms of speed in delivering products or services to market, meeting all customer expectations in a timely manner, and decreasing the time for appearance of a positive revenue stream as much as possible. This ERP model would support the integration of data, standardization of processes, order fulfillment, inventory control, supply-chain management, and customer relationship management (CRM) as critical drivers to result in enterprise transformation.

William B. Rouse, in his work *Strategies for Innovation* (Rouse, 1992), states "A prerequisite for innovation is strategies for making stakeholders aware of enabling technology solutions, delivery of theses solutions in a timely fashion, and providing services that assure the solutions will be successful. These strategies must not only result in successful products or systems, they must also create a successful organization—an enterprise—for developing, marketing, delivering, and serving solutions" (p. 2). His philosophy encompasses the human-centered design approach that takes into account the concerns, values, and perceptions of all stakeholders during a design initiative. This approach entertains the views of all the stakeholders, balancing all human considerations during the design effort.

Traditionally, when designing an enterprise resource planning solution, very few enterprises are easily able to think strategically. Most are only concerned with today's products and services and the financial profits and revenue growth realized in the short term. They often fail to properly forecast future growth and to properly scale their ERP in order to meet the potential consumer demands of the future. An enterprise must be able to plan for and respond to future demands by analyzing the market and evaluating the impact that their core product technologies will have in the marketplace. Market demand will drive consumer needs and desire for these core product technologies, as well as the type of ERP that will be used to support these products. An effective ERP must be capable of assessing and balancing all stakeholders' interests consciously and carefully. The market share that an enterprise is able to acquire for its core product technologies can be tied to how well an ERP is developed, deployed, and implemented in order to provide the operational support infrastructure needed. Many of the traditional success factors for an enterprise have been their position in the marketplace, achievements as innovators, productivity, liquidity and cash flow, and profitability. In order for an enterprise to grow and mature, it must be able to respond to market demand in a timely manner. Responding to market demand includes timely delivery of products and services, immediate attention to customer problem/resolution, and continuous process improvements. Operational velocity attainment becomes the focus and the critical success factor in the execution of an evolutionary ERP strategy, thus supporting the long-term vision of the enterprise by ensuring a strategic advantage for the enterprise.

A well-thought-out ERP strategy will require advanced planning to determine how each of the organizations will be integrated in supporting the long-term objective. Critical to the success of an enterprise is how well its associated organizations can adapt to organizational change, as the company begins to mature and demand increases for the new innovative products and services. Change may include the type of culture that is fostered, tools used, and level of knowledgeable resources required to make the organizational transitions. Most importantly, customer experiences becomes the focus. How fast an enterprise can service customers to meet their expectations may determine how soon it meets revenue expectations. The quality of on-time customer service could impact the number of future sales. A good product or service, combined with excellent customer service, may drive more business to the enterprise, decreasing the time taken to meet revenue forecasts. The mechanism used to drive customer on-time service becomes what we call an evolutionary ERP model. In order for new core technology products to become acceptable to a newly installed base of customers, service delivery and customer response times must be minimized as much as possible. True enterprise growth and profitability can be made possible through this model for emerging enterprises delivering new innovations to the marketplace. The model takes into account the long-term vision of the enterprise, which is a key to its consistent success. Rouse (1992) states this well when he says that many technology-based startup companies are very attracted to learning about new technologies, using these to creating new products, and hiring appropriate staff to accomplish these. Such activities may get the product, resulting from the enterprise vision, into the marketplace. Initial sales and profit goals may be achieved. He appropriately notes that without a long-term vision, plans for getting there, and an appropriate culture; no amount of short-term oriented activity will yield consistent long-term success.

The strategic advantages that a well-defined, developed, and deployed ERP brings to the enterprise are: integration across the enterprise, communication, operating efficiencies, modeling, and supply chain management. These effective strategies assist with bridging the overall corporate strategies with the organizational objectives. Integration across the enterprise supports the following organizational objectives:

- Maximization of speed and throughput of information,
- Minimization of customer response times,
- Minimization of supplier and partner response times,
- Minimization of senior management response times,
- Decision-making authority pushed to the appropriate levels within the organization, using work flow management,
- Maximization of information to senior management,
- Direct integration of the supply chain,
- Reduction of inventories,
- Reduction in order-to-ship time,
- Reduction in customer lead times, and
- Total quality integration.

Communication links the enterprise to both the suppliers and the customers. Good communication between supplier and the enterprise can help reduce design errors, foster good supplier and enterprise relationships, reduce enormous costs, reduce the supplier's time to respond to the enterprise, and improve performance and market adoption of a new core technology product.

Langenwalter (2000) indicates in his work on enterprise resource planning that integrating the design process with customers can surface customer responses with respect to their true needs. He emphasizes the voice of the customer (VOC) as a proven methodology that addresses the true needs and expectations of the customer. VOC serves as basic input to the evolutionary ERP model. Key customer considerations in achieving operational velocity using this model are ranked customer expectations, performance metrics, and customer perceptions of performance.

In *The Valuation of Technology*, Boer (1999) is also concerned with these customer considerations by including the concept of the value proposition from the customer's viewpoint. He emphasizes that stakeholders must find useful ways to determine the value added in every step of the business process from the viewpoint of the customer. The enterprise must exist to deliver value to the extent that it improves operational performance and/or lower costs through new or enhanced products, processes and services. For example, the operations of an enterprise will focus on procuring equipment and materials from vendors and suppliers to produce products on time and within budget. The operations objective is to meet customer demand through scheduling, procurement, implementation, and support, to meet the ever-changing needs of the customer environment. These changes must be measured so that the operations of the enterprise may be able to meet the needs of the marketplace. Such flexibility of operations in the marketplace is essential in keeping up with the dynamic needs of the customer.

In the new technology age, markets are moving much faster than traditional predictive systems suggest. Flexibility therfore becomes an essential and necessary element in achieving operational velocity. To achieve this, Langenwalter (2000) introduces a new measurement system that recognizes the ever-changing dynamics of products, customers, workers, and processes. His approach is based on the assumption that all products have life cycles and should have four key metrics: profitability, time, quality, and company spirit. Encompassing this approach would be the execution of a continuous process improvement initiative, with respect to the operational component of the product lifecycle. He proposes that the enterprise measure each organizational contribution to profit for the entire lifecycle of the product. An ERP can effectively measure the contribution to margin that a sales organization may make on new product releases. Unprofitable products can be immediately identified and retired. In comparison, an ERP can also track the total lifecycle cost that a manufacturing organization incurs when producing a product. Total profit and loss (P&L) responsibilities can be tracked and material procurement and cost strategies can be evaluated to enhance profitability to the extent possible. Other organizational facets such as engineering and marketing can increase profits, by accessing customer profile information from an ERP and trending product demand for various new features and functionality. Incorporating new design considerations in future product releases may also increase potential profitability, as more high-end products are released.

The element of time is an important metric and is truly a measure of process, although process efficiencies can also translate into cost savings. Langenwalter (2000) describes three key time dimensions: time to market, time to customer, and velocity. Each is a component of operational velocity. In achieving operational velocity, time to market is critical for new technology adoption. It is crucial for new enterprises to launch their core technology product(s) on time, in order to sustain long-term product profitability. This is especially true if new technology is involved. Langenwalter (2000) indicates that a study performed by the McKinsey Consulting Group reflects that a six-month delay in entering a market results in a 33% reduction in after-tax profit over the life of the product. In addition, the six-month delay is five times more costly than a 50% development-cost overrun and approximately 30% more costly than having production costs 10% over budget.

An ERP should be capable of monitoring product development and manufacturing processes to ensure timely delivery of products to market. Such items as customer requirements, technical viability, manufacturing costs, production volumes, staffing levels, work order priorities, material requirements, and capacity requirements can be accessible via the ERP, and allow both the engineering and manufacturing components in an organization to respond to product demands quickly. The ERP supports time to market in that these two organizations are able to ensure efficient product development manufacturing processes and organizational communication in launching new products to market. The ERP, so enabled, becomes the common domain and communications intermediary between engineering and manufacturing.

Time to customer is the next most critical dimension, or aspect, of time as described by Langenwalter (2000). This time dimension is focused on reducing lead times to customers. For example, manufacturers look to reduce the lead-time it takes to produce a product, component, or assembly. Although it may have taken weeks to produce a particular component, improved manufacturing capabilities may now enable this process in only two days. This may have been accomplished through the use of an ERP, which made it possible to track performance metrics of the various manufacturing processes. As a result of isolating various inhibiting manufacturing processes and improving these processes, time to customer was reduced significantly, thus supporting the operational velocity objective of the enterprise.

Another good example is customer care, achieved by responding to a product fault scenario and providing technical support capability to the customer for fault resolution. Response to a customer call may have originally taken 72 hours to resolve the problem due to the lack of an effective scheduling tool for the timely dispatching of technical support field resources. With the integration of a resource-scheduling tool within ERP, customer care can now respond perhaps within four hours and provide timely customer support. Velocity, the final dimension that Langenwalter presents, is defined as the total elapsed time consumed by a process divided by the actual value-added time contributed by the same process.

The quality metric of the product life cycle, as described by Langenwalter, focuses on continuous improvement. Quality metrics are very much tied to what may be called an evolutionary enterprise resource planning architecture framework. Operational velocity is only as good as the product and the service that is delivered. Any compromise in quality may translate to potential customer attrition and/or the degradation of market share. A good ERP should be capable of tracking product component failure rates and product design flaws, so that immediate action may be exercised on the part of the enterprise. Speed without quality only becomes a formula for failure. Product failures are not the only inhibitors of quality. A lack of knowledgeable and skilled resources can compromise quality, and this describes Langenwalter's last critical metric – company spirit. He emphasizes the fact that people are the ones who develop relationships with customers and suppliers, eventually leading to new products and processes. This metric goes outside much traditional thinking. However, during the enterprise startup technology revolution, company spirit is generally the most important element of survival and success among enterprises. This leads to a greater sense of ownership and responsibility among the people involved. An enterprise without a healthy team spirit and aggressive workforce has little chance of success.

Rouse (1992) introduces yet another interesting growth strategy that further supports the concept of operational velocity for new technology adoption. He describes a strategy for growth via enhancing productivity through process improvement and information technology. This approach leads to higher quality and lower cost of products and services and, eventually, to greater market share and profits. Enterprise performance is not as visible as product performance, so the money and time saved on process refinements often go unnoticed. Each approach has its own value. Rouse describes product value as the foundation for growth and indicates that the challenge of value concerns matching stakeholders' needs and desires to the enterprise's competencies in the process of identifying high-value offerings that will justify investments needed to bring these to market. Value to the customer is dependent on the particular market domain. The most noticeable form of value comes in the form of new innovations that meet a customer's economics or needs. Customers quickly realize the benefits of a new technology product; however, the real value is determined at the enterprise level, where customer support becomes critical. Technology products are sophisticated and require a high level of customer support when potential problems arise. After the sale of the product, the relative performance of the enterprise becomes the focus of the customer. Lack of timely and quality support can erode consumer confidence and eventually erode market share for an enterprise.

After the launch of its first product, an enterprise is immediately under the scrutiny of the public. Often, early adopters of new technologies can either make or break an emerging enterprise. Early adopters will assess the enterprise on product quality, delivery, and customer support. If the product is reliable and performs well, then delivery and customer support become the two most critical criteria that a customer will evaluate. It is usually the shortfalls in these two areas that diminish consumer confidence and challenge the credibility of a new enterprise. An enterprise that has an ERP strategy to address these criteria is better positioned for success. If the ERP is designed well, it will allow the enterprise to ensure quality delivery and customer support to the end users. The true value to the customer is realized in enterprise performance as opposed to product performance. Historically, customers have been prone to pursue other vendors because of lack of customer support, moreso than with average product performance. The result of a well-executed ERP strategy enables the enterprise to react immediately and consistently, enabling the organizational components to focus their human and financial capital in the right areas.

Rouse describes the challenge of focus as deciding the path whereby the enterprise will provide value and grow. Rouse (2001) introduces some common challenges in and impediments to an organization's decision making, including:

- Assumptions made,
- Lack of information,
- Prolonged waiting for consensus,
- Lack of decision-making mechanisms,
- Key stakeholders not involved, and
- Decisions made but not implemented.

An enterprise is capable of addressing these challenges if it institutes an ERP solution during its evolution. The ERP solution will bridge many of the communication gaps common among enterprises that are often organizationally disconnected. A good ERP solution will support information sharing, track performance metrics, and archive information, thus providing methods and tools in supporting rapid decision making and furthering the concept of operational velocity. Many times, senior management is unable to focus on key areas due to lack of information and decision-making tools. This problem can be overcome by integrating these capabilities with the ERP. An ERP can scale easily to meet the business needs. The enterprise that plans for growth through its evolution can scale more easily and adapt to change.

Rouse (2001) states that "given a goal (growth), a foundation (value), and a path (focus), the next challenges concern designing an organization to follow this path, provide this value, and achieve this goal" (pp. 5-6). The climate of the enterprise changes rapidly and dramatically throughout its evolution. As new core technology products are launched, the environment is subject to change. Enterprises find ways to scale their infrastructures to meet growth, fend off competition, restructure, reengineer, and support virtual organizations. The objective of change is to improve quality, delivery, speed, and customer service. All of this is made possible through a well-integrated ERP. An ERP capable of facilitating change allows the enterprise to foster new opportunities for growth and reward. As an enterprise evolves over time into a major corporation, business practices change and a paradigm shift occurs over several phases of maturation. The ERP can assist an enterprise in transitioning new business philosophies and practices and to help pave the way for future growth. There is a major need to anticipate future opportunities and threats, plan for contingencies, and evolve the design of the enterprise so that the plans are successful.

The value of the future is difficult to estimate; this realization has lead to another interesting concept, the option value of an enterprise. As previously mentioned, Boer (2002) is a major proponent of options value as applied to the enterprise. This concept explores investment decisions based on buying an option on the future and determining what that option is worth. An enterprise must plan for future growth and weigh the various investment alternatives available. These include looking at the following:

- Strategic fit,
- Financial payoff,
- Project risk and probability of success,
- Market timing, and
- Technological capability of the enterprise.

The above factors weigh into the decisions made to invest in the future. It is through investments in education, training and organizational development that the enterprise is enabled to meet future objectives through resource allocation.

Other investments in research and development technology make decision-making much more complex. However, they may yield promising future results if planned well and integrated with other decisions taken. Investments in R&D require knowledgeable resources that can influence the abilities of an enterprise to provide value. Knowledge management becomes a key element in the overall ERP strategy. Rouse (2001) indicates that knowledge management and knowledge sharing (Small & Sage, 2006) will promote an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets. This may be achieved by applying knowledge management concepts to the ERP strategy. A sound return on investment (ROI) model for an ERP should assess the dynamics of the enterprise, changes needed, and projected savings from these changes. The changes themselves should be measurable. An ERP must be planned carefully and, most importantly, well-executed with all resource considerations made during its evolution. The benefits derived from a well-executed ERP should reveal improvements in task management, automation, information sharing, and process workflow. Each of these components improves the most scarce resources that people face within the enterprise, that of time.

Time is a key ingredient for gaining organizational control. An ERP system with integrated tools and methods for communicating and modeling assists human resources with time management. Time management can be a critical problem and human resources can easily find themselves becoming reactive versus proactive in their day-to-day activities. Rouse (2001) emphasizes that it is important to increase the priority given to various long-term strategic tasks, especially since they too often suffer from demands for time from the many near-term operational tasks. A well-integrated ERP supports time management and allows human resources to gain control of their time and allocate it across the appropriate tasks. It further supports the need for long-term planning by supplying various tools and methods for enhancing strategic thinking. The tools and methods integrated within the ERP should improve both the efficiency and effectiveness of time allocation to tasks. An ERP that is incapable of handling the challenge of time diminishes the true value of the ERP. Time management is a crucial component in achieving operational velocity and must be controlled, in order for the enterprise to respond quickly to customer demands.

The seven challenges to strategic management of Rouse (2001) are all critical elements that need to be considered when designing an ERP. A well-designed ERP helps position the enterprise well in the market and gives it a strategic advantage. The true gauges of success of an enterprise, with a successfully executed ERP, will be reflected in how it is positioned in the marketplace. Rouse (1992) has identified five gauges of success:

1. Standings in your markets,
2. Achievements as an innovator,
3. Productivity,
4. Liquidity and cash flow, and
5. Profitability.

Each of these gauges of success is tied to shareholder value. Gardner (2000) also raises a major consideration about designing an ERP in his book *The Valuation of Information Technology*. He asks the questions:

> *What contributions will an information technology system make to a company's shareholder value? How can an information technology system be constructed to create shareholder value? In other words, not just determine the effect of a system on shareholder value but guide the activities involved in its construction in the first place.* (p. 63)

He emphasizes the need to predict the shareholder value that will be created by an information system before it is actually built. In the context of an ERP, the objective is to increase the wealth of shareholders by adding premium growth to their stock. An ERP can improve the asset utilization of an enterprise by allowing shareholders to increase their returns on invested capital. The traditional approach to increasing shareholder wealth consists of maximizing the value of the cash flow stream generated by an operational ERP. The cash flow generated from the ERP is allocated among the shareholders and debt holders of the enterprise. Shareholder value is traditionally measured by using the DCF method, which is central to the valuation of assets and the return they generate in the future. Boer (1999) addresses the DCF method well in his book *The Valuation of Technology*. He defines the premise of the DCF method "as a dollar received tomorrow is worth less than one in hand today" (p. 63).The question that arises from this premise is how much should one invest today in order to earn a dollar tomorrow. To address this, Boer presents one of the common DCF methods known as net present value.

The NPV method can be used to compute the value of tomorrow's dollar. Boer properly defines NPV as "the present value of a stream of future cash flow less any initial investment (p. 98)." NPV addresses the time value of money, which is essential for developing an ERP strategy, with the objective of attaining operational velocity. Gardner (2000) illustrates how this has a significant effect on the management of ERP systems. If the rate of return is high, schedule delays in deploying an ERP can erode value, which makes time to market critical; and since short product life generates as much value as long product life, there should be little resistance in replacing legacy systems. In comparison, if the rate of return is low, delays have little effect on value, and a longer product lifecycle is feasible, thereby allowing for a more thorough systems development effort. Gardner extends the NPV method to an ERP system and illustrates how shareholder value is created by changes in the present value of the cash flow to shareholders due to the use of the ERP system.

The DCF method illustrated here focuses solely on the economic value of the enterprise. Boer (2002) introduces a concept known as the options value of the enterprise in his book *The Real Options Solution: Finding Total Value in a High-Risk World*. The options method is presented as a means to value the strategic capital of an enterprise. This method is known as the total value model and combines the economic value and strategic value of the enterprise, and also takes into account three major drivers that affect value: risk, diminishing returns, and innovation. Enterprises satisfactorily releasing new technologies into the marketplace normally increase their strategic value if consumers adopt these new technologies to meet their needs. New technology adoption in the marketplace can vary based on need, price, standards, and other related factors. Once the need is recognized, operational velocity becomes critical to answering the customer's needs. How fast customers can be served and cared for will drive the strategic value of the enterprise. A well-designed and executed ERP can assist with operational velocity attainment by improving efficiencies, speed, and time to market. Boer's total value model uses a six-step approach to computing the total value of an enterprise. His practical six-step approach encompasses the following:

Step 1. Calculate the economic value of the enterprise, where free cash flow (FCF) is defined as the actual cash flow minus the amount of cash that must be reinvested: *Economic Value = FCF / (Cost of Capital – Growth Rate).*

Step 2. Frame the basic business option and identify strategic options. For example, leasing space at another site and expanding the enterprise may yield additional future revenue. Here, investment in an ERP system may yield future revenue, as a result of enhancing operational velocity.

Step 3. Determine the option premium, which is the premium paid or expenditures incurred to make the plan actionable. For example, this may include the option cost of technology, people, partners, financing, systems, and R&D.

Step 4. Determine the value of the pro forma business plan, where NPV is computed to determine valuation of the enterprise

Step 5. Calculate the option value. Here, the Black-Scholes option formula is used using five key elements: value of the underlying security, strike price, time period of the option, volatility, and risk-free rate.

Step 6. Calculate total value according to *Total Value = Economic Value + Strategic Value*.

Boer's model computes the true value of the enterprise taking options thinking into consideration, thus reflecting real life and the strategic payoff that can result if an enterprise is successful. To clarify the concept, Boer makes an interesting analogy by illustrating the strategic value of a common family with a low standard of living. The family's principal economic activities concern the income produced. Costs such as mortgage, utilities, and gas are set against this revenue. Any savings are stored away as additional income. The income and expenses mentioned thus far only reflect the economic value of the family. The potential strategic value lies in the education of its children. Education could pay off in the long term and increase the family's standard of living. However, there are also significant market risks. Once the children are educated, the marketplace may not demand their skills, or they may not meet the various job requirements of their profession. In comparison, an enterprise may have potential strategic value in a new technology that it develops. The enterprise may have sufficient venture capital to cover R&D expenses for the next few years. Once the technology goes to marketplace for the first time, the enterprise has first mover advantage in the market if it attracts enough early adopters to build market momentum. Critical mass can be achieved as momentum for the product accelerates. However, there could be the risk of competitors with a similar technology that may go to market during the same time frame. In addition, the competitor may have a similar product with different performance standards, which adds to the competitive nature of the situation. This leads to a race for market share and ultimate establishment of the preferred technology standard between the products.

Strategic value is not always predictable, and the dynamics of the market change constantly. A negative impact on strategic value could result in zero return; this results in a loss of venture capital to cover the R&D expenses. There is evidence during the past five years that a number of startup technology enterprises never arrived at fruition in strategic value. The strategic value represents the potential revenue that could be realized if market conditions are ideal for the enterprise. Gardner (2000) estimates the revenue opportunity for an enterprise using *Annual Revenue = ;Annual Market Segment Size x Annual Likelihood of Purchase x Annual Price*. The terms in this relation are time dependent and are critical to new technology adoption in the marketplace. Forecasting potential annual revenue requires understanding the purchasing decisions and patterns customers will make. Decreasing the time for appearance of a positive revenue stream for an enterprise, a new technology into the marketplace is highly desirable. The mechanism for achieving this objective is the evolutionary enterprise resource planning architecture framework, which will accelerate critical mass early in the deployment phase of the product development lifecycle by achieving operational velocity. Thus , the work established by the early pioneers of ERP and technology valuation methods has laid the foundation for a new ERP paradigm to evolve and support operational velocity attainment.

Network Elements Influencing Path Dependence and Network Effects

Consumers who become completely satisfied with a new technology product or innovation realize the value proposition derived from this new creation. For example, the value of a digital subscriber line (DSL) at home brings value to the home PC user who now has high-speed access to the Internet. The home user is no longer confined to the limiting speed capability of a 56 Kbps dial-up modem. As more users adopt DSL, due to its broadband capabilities, increasing returns to scale and path dependence are achieved. The economy has shifted from the supply-side economies of scale, based on the traditional industrial era of mass production driven by unit costs, to increasing returns to scale (also known as demand-side economies of scale) driven by consumer attitudes and expectations. Strategic timing is vital with respect to demand-side economies of scale. First, introducing an immature technology into the marketplace may result in negative feedback from potential consumers. For example, potential design flaws, functional limitations and constrained feature sets may overshadow the true value of the technology, making it less attractive to potential consumers. In addition, moving too late in the market means not only missing the market entirely but also the opportunity to acquire any significant market share. Moving without an effective ERP strategy compromises new customer acquisition and customer retention.

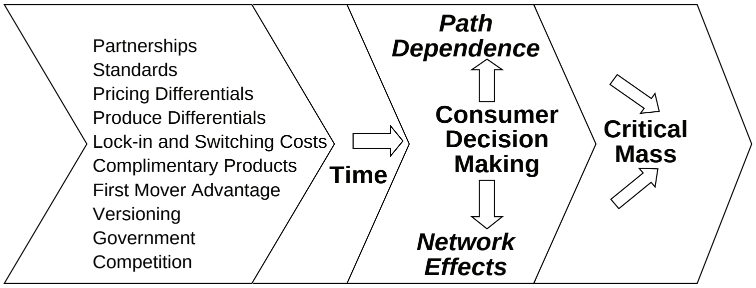
The marketplace is subject to various network elements that influence path dependence and network effects of new technology adoption. These network elements directly impact consumer decision-making and lead to the formulation of consumer perceptions and expectations of new technology. Network elements can be defined as economic, business, regulatory, market, and technological influences that impact consumer decision making relative to new technology adoption. Understanding what drives consumer behavior and how it can be controlled allows innovators and technologists to achieve better success in launching new products while gaining market acceptance.

In *Information Rules*, Shapiro and Varian (1999) identify 10 primary network elements that influence consumer decision-making. They describe how these network elements impact consumer decision making with respect to new technology adoption. The network elements described are: partnerships, standards, pricing differentials, product differentials, lock-in and switching costs, complementary products, first mover advantage, versioning, government, and competition. Figure 1 reflects these 10 primary network elements that influence consumer decision making over time. These network elements will shape consumer choice, based on the degree of consumer confidence, need, desire, satisfaction, and comfort with adopting a new technology. The degree that these human traits will vary among consumers will determine the speed with which a new technology will be adopted. Consumers will most likely fall into three categories of adoption: early, evolving, and late. As a technology becomes popular, consumer decision-making becomes positive with respect to new product acquisition. Early adopters of the technology will begin to generate demand for the product.

Based on the success of the initial product, more consumers will see and understand the value proposition realized by the early adopters. A large number of consumers begin to evolve connecting to the network of users. At this stage, consumer choice begins to exhibit path dependence and network effects. As the network of users begins to accelerate, critical mass is realized. Critical mass occurs when a large enough customer-installed base is established, as a result of positive feedback derived from the growing number of adopters. The network continues to expand until these late adopters eventually interconnect and the product reaches maturity in the marketplace. Network elements are also critical to consumer decision-making and can impact the destiny of a new technology if unrecognized. A good illustration of this was the competition between Beta and VHS in the 1970s. Beta was believed by most to be clearly superior to VHS in quality; however, VHS was the de-facto standard among consumers due to its compatibility. Operational velocity is one of the most fundamental critical success factors influencing adoption of new technology the presence of network elements. Operational velocity is a factor that needs the most attention and the one that can easily be controlled by implementing an effective ERP model. Since understanding the influence network elements have on achieving critical mass is essential, a narrative follows describing each one of the elements shown in Figure 1.

The first network element reflects partnerships, which provide a strategic advantage. New technology enterprises, possessing a leading-edge niche product in the marketplace, may find that one or more partnerships, with major players offering a complementary product suite, may be the answer to acquiring critical mass early in the game. An emerging enterprise would have the opportunity to immediately sell its new product to the existing installed customer base of its partner. This existing installed customer base may have taken the partner years to establish and grow, thus offering an advantage to a new enterprise, which has not yet established customer relationships or gained brand name recognition. An opportunity to sell into an existing installed base of customers, by gaining the visibility and credibility via a strong

Figure 1. Network elements



strategic partner, can shorten the sales cycle and accelerate critical mass. Alliances can even be established through suppliers and rivals as a means of accelerating critical mass attainment. It would also be advantageous for the enterprise to offer incentives when possible. Consumer confidence may be won, along with new customer acquisitions, by allowing customers who are undecided over a new technology to sample or test the new product.

The next element reflects standards. Standard setting is one of the major determinants when it comes to new customer acquisitions. Consumer expectations become extremely important when achieving critical mass, especially as each competitor claims they have the leading standard. Standards organizations try to dispel any notions or perceptions as to which company drives the predominant standard; however, most of these standards groups are comprised of industry players, each of whom attempts to market their own agendas. Most will try to influence the direction of standards setting for their own best interests. Standards are necessary for the average consumer, who wants to reduce potential product uncertainties and lock-in (defined as consumers forced to use a non-standard proprietary product). The product that consumers expect to be the standard will eventually become such, as standards organizations and large industry players begin to shape and mold consumer expectations. Standards increase the value of the virtual network and build credibility for new technologies introduced into the market.

One strategy often used among new and aggressive companies in order to gain market momentum is that of pricing differentials. This network element can ignite market momentum by under-pricing competitors and targeting various consumer profiles. Some enterprises may use various pricing strategies to offer incentives to new customers. As a result, this may be an effective strategy, since some customers may be more price sensitive and may not be as influenced by factors such as standards. A common pricing strategy is differential pricing; this may take the form of personalized or group pricing. Personalized pricing takes the form of selling to each consumer at a different price. The focus is in understanding what the consumer wants and tailoring a price to meet the consumer's needs. Group pricing will set targets for various consumer profiles and group them accordingly. This affords flexibility to potential consumers and takes into account various price sensitivities that may impact decision-making. Consumer lock-in may be achieved through pricing strategies by offering incentives such as discounts, promotions, and the absorption of consumer switching costs.

Making product differentials available is another strategy that is very common in the technology industry and that can effectively influence consumer decision-making. Product differentials offer consumers a choice across several product derivatives. By designing a new product from the top down, the company can easily engage any potential competition by introducing the high-end solution first. Once the high-end consumers have been acquired, a low-end solution can be made available to capture the low end of the market. The low-end product also may be used to position the high-end product, when using an up-selling strategy. When introducing a new technology to the market, the market should be segmented based on several factors such as user interface, delay, image resolution, speed, format, capability, flexibility, and features. These factors help target and span various consumer profiles.

As various pricing schemes, product features, and functionality are offered to the consumer, the fears of lock-in and excessive switching costs enter into the decision-making. This network element is one of the most common ones that can halt adoption of a new technology, especially if consumers only deal with one vendor. Most consumers want to deal with two or more vendors in order to maintain a level of integrity among the suppliers offering the product or service. This alleviates the possibility of lock-in with any one particular vendor, as long as they share the same standard. Consumers who deal with only one supplier may face the possibility of lock-in and high switching costs should they decide to select another vendor later. If the existing supplier has not kept up with standards and new technology trends, the consumer may be bound by old legacy infrastructure, which could result in complications if the consumers can no longer scale their environment to meet their own business needs. Some enterprises may absorb the switching costs of a consumer to win their business, if it is in their own best interest, and also if they need to increase their customer base and market share to gain critical mass. New enterprises gaining minimal market momentum with cutting-edge technology product introductions may be more willing to take this approach.

A common competitive strategy used by many high-technology organizations is the selling of complementary products to their installed base of customers. These complementary product offerings can arrive internally within a company by entering new product domains, or externally by offering a partner's complementary product and leveraging on its core competencies.

One of the most challenging network elements that an enterprise faces is having time to market a new innovation, better known as first-mover advantage. First-mover advantage is the best way to gain both market momentum and brand name recognition as the major provider of this new technology. Microsoft, Sun Microsystems, and Netscape serve as good examples of companies that have succeeded in gaining first mover advantage and that have become leaders in their industries (Economides, 2001). An early presence in the market place has allowed these companies to secure leadership positions throughout the years. We note, however, that Netscape has lost considerable market share to Microsoft's Internet Explorer for reasons that are also explainable by this theory.

Over the years, versioning has become a common practice among technology companies. The network element of versioning offers choices to consumers. Companies will offer information products in different versions for different market segments. The intent is to offer versions tailored to the needs of various consumers and to design them to accommodate the needs of different groups of consumers. This strategy allows the company to optimize profitability among the various market segments and to drive consumer requirements. The features and functions of information products can be adjusted to highlight differences and variations of what consumers demand. Companies can offer versions at various prices that appeal to different groups.

As observed with the Microsoft antitrust legislation proceedings, the government can impact the direction of new technology, whether it attempts to control a monopoly or fuel demand for new technologies (Economides, 2001). This network element can be the most restrictive in achieving critical mass. The government, in efforts intending to ensure that there are no illegal predatory practices that violate true competition, scrutinizes mergers and acquisitions involving direct competitors. There is every reason to believe that it will continue to focus on controlling genuine monopoly power and take action where necessary. All mergers and acquisitions are subject to review by the Department of Justice and the Federal Trade Commission. In addition, the government can serve as a large and influential buyer of new technologies. It can become a catalyst by financing, endorsing and adopting new technologies in order to accelerate their development, adoption, and use. Federal government IT spending on emerging technologies over the next several years can potentially aid those enterprises that are struggling for business and survival as a result of downturns in the economy.

Another network element that can restrict critical mass attainment is competition. Competition in the marketplace will continue as new enterprises are entering the market and presenting a challenge to some large established companies that are plagued by inflexibility and bureaucratic challenges. Companies will compete on new innovations, features, functionality, pricing, and, more importantly, standards. Information products are costly to produce but inexpensive to reproduce, pushing pricing toward zero. Companies that are challenged with a negative cash flow, and have limited venture capital, will need to devise creative strategies to keep themselves in the game. Margins begin to diminish as pricing reaches zero; a complementary set of products or services may be necessary or required to maintain a level of profitability. Knowing the customer, owning the customer relationship, and staying ahead of the competition are the major keys to survival.

Operational velocity is the critical success factor, making a much more profound impact on revenue and profit than the individual network elements described and illustrated in Figure 1. This critical mass determinant, which is the key to the success of an enterprise, is often given very little attention due to the organizational dynamics that take place. Operational velocity, as defined earlier, is speed in delivering products or services to market, meeting all customer expectations in a timely manner, and decreasing the time for appearance of a positive revenue stream as much as possible. This may appear to be a simple concept; however, it is very difficult to master. Without an evolutionary ERP approach, it will be quite challenging to scale a business to meet aggressive future customer demands. There exists a direct relationship between an effective evolutionary the ERP model and operational velocity attainment that allows an enterprise to scale its business accordingly while meeting customer demand in a timely manner. More importantly, there is a unique organizational process lifecycle and key behavioral influences that are essential to implementing an effective ERP model. Without these, the model becomes ineffective, in that ERP has not been implemented in an appropriate and effective manner.

Many enterprises lack any initial operations plan or back-office infrastructure to support new product launches in the marketplace. This is a major challenge in the commercial world, where time to market is critical and development of an effective ERP may be neglected in favor of seemingly more pressing and immediate needs. The primary focus of a new technology company is to amass customers immediately at minimal cost. Often a number of senior executives hired to manage a new enterprise come from sales backgrounds and have very little experience in running a company from a strategic IT, operations, and financial perspective. They sometimes lack the associated fundamental technical and nontechnical skill sets, which can easily compromise the future of the business. This often stems from senior executives who come from large corporations but who lack the entrepreneurial experience necessary to launch new businesses. For example, they may fail to see the value of hiring a chief operating officer (COO) who has the required operations background and who understands how to run a business in its operational entirety. The importance of the COO role is later recognized, but many times it is too late as much of the infrastructure damage has already occurred.

Many of the chief executive officers (CEO) hired to lead new enterprises are prior senior vice presidents of sales. It is believed that they can bring immediate new business to the enterprise and begin instant revenue-generating activity. The sole focus becomes revenue generation and new customer acquisitions. The common philosophy is that the company will resolve the back-office infrastructure later. This is usually a reactionary approach to developing a back-office versus a proactive approach. The lack of a sound evolutionary approach in developing an ERP from concept to market maturity for new products can result in missed customer opportunities, customer de-bookings, loss of market share, lack of credibility, competitive threats and, most importantly, bankruptcy of the business.

Other potential plaguing factors that can impact implementation of an effective ERP strategy are undefined, or at least under-defined, organizational requirements, sometimes termed business rules, and lack of business process improvement (BPI—also known as workflow management) initiatives and strategies. Organizational requirements and BPI for supporting new product launches should be addressed early in the development phase of the new technology. How a product is supported and the relationship and communication between the respective support organizations will be vital to the success of the product. Quite often, organizational requirements and BPI are lacking due to limited understanding and use of contemporary IT principles and practices. Many of the savvy technologists who have started the enterprise may lack knowledge in formal methods, modeling, systems development, and integration. They may be great internal design engineers who have come across a new innovation or idea; however, they lack infrastructure knowledge for commercializing the new technology. This had been a common problem among a number of new enterprises. Most new enterprises that have succeeded with these challenges have first mover advantage, a positive cash flow to continue hiring unlimited human resources, and, although reacting late in the process, have implemented an infrastructure that could support the business. The infrastructure was a splintered systems environment lending only to a semi-automated environment. The systems migration strategy occured too late in the product launch phase to allow for a seamless automated process.

Another factor that often plagues the enterprise is the lack of IT personnel who have business-specific skills. Personnel in the IT organization who lack business skills in the various vertical markets such as engineering, manufacturing, healthcare, financial, legal, and retail may have a difficult time eliciting internal customer requirements when developing and implementing an ERP. They may also lack the various business skills internally, if they are unfamiliar with the business and technical requirements of the other functional organizational elements such as sales, marketing, finance, operations, engineering, logistics, transportation, manufacturing, human resources, business development, alliances, product development, legal, along with any other relevant enterprise elements.

Finally, not all employees hired into an enterprise come with an entrepreneurial spirit. Some still have a corporate frame of mind and do not become as self-sufficient as is necessary to keep up the pace. They have a tendency to operate in closed groups and do not interact well with other business units. A team philosophy and aggressive work ethic is essential in order to succeed in an enterprise environment.

The approach, suggested here, to achieving operational velocity is to develop an ERP model that meets the following 15 performance criteria:

1. Reduces service delivery intervals;
2. Maintains reliable inventory control;
3. Reduces mean-time-to-repair (mttr);
4. Enhances customer response time;
5. Establishes timely and effective communications mechanism;
6. Automates processes;
7. Creates tracking mechanisms;
8. Maintains continuous business process improvement;
9. Supports fault management through problem detection, diagnosis, and correction;
10. Manages customer profiles;
11. Monitors business performance;
12. Establishes best practices;
13. Creates forecasting tools;
14. Supports supply chain management; and
15. Integrates all systems within the ERP model such as sales tools, order entry, CRM, billing, and fault management.

These performance attributes are ones that companies have adopted to monitor, manage, support, and measure success of their operational environment. Companies are also continuously challenged with developing and implementing an effective model to support these attributes. The challenges stem primarily from a lack of knowledge and limited use of contemporary IT principles and practices. Enterprises must realize the need for appropriate performance metrics in order to measure success criteria and to plan for future growth and expansion.

Of all the network elements impacting the adoption of new technology, operational velocity is the most compelling, since it will influence customer expectations based on how quickly customer needs can be serviced. These needs may consist of rapid customer service response time, product delivery, problem resolution, and maintenance. Operational velocity, like the network elements, will influence consumer decision making on new technology adoption. If a new technology product has long delays in service delivery or lacks customer support, new customer acquisition and retention eventually become compromised. Under these circumstances, it is possible to lose business to the competition, which may be introducing a similar product into the marketplace. Consumers become disappointed, less patient and quickly begin to look for alternatives. The lack of a reliable operational infrastructure would have been the result of a poorly executed ERP. An effective ERP must be automated, capable of tracking, serve as a communications mechanism, and support various tools. If these criteria are recognized and controlled by the core team of an enterprise, the ERP can provide many benefits as the business begins to scale and the product begins to meet customer expectations. Network elements can influence the outcome of a new technology or the destiny of the product. Understanding the impact that the various network elements have on the enterprise can help position the business in taking on the challenges that prevail. The market timing of the product and the influence on customer decision making will determine the end result of critical mass attainment. An enterprise that prepares and develops strategies, and which takes into account the large number of potential network influences, will accordingly realize this end result. There are a number of complex adaptive system challenges associated with these, and these must be explored as well.

Many of the enterprise resource planning efforts cited in this article can be traced to the three basic core elements of an ERP: people, process, and systems. Each of these elements were addressed in the various models and frameworks identified by early contributors in the field. As an ERP architecture evolves, each of the ERP elements goes through a maturity state. The evolution of a fully developed and integrated ERP architecture can be inferred from the phases of a basic systems engineering lifecycle. Table 2 illustrates this inference through a framework of key systems engineering concepts that can be applied to the development of an enterprise resource planning architecture.

This suggested framework could be used to develop an enterprise architecture using six key system engineering concepts. To support the ERP development effort, this 6x3 matrix of Table 2 could be used with the six general system engineering concept areas as rows and the three columns depicting the core components of an ERP. This defines the structural framework for systems engineering concepts and their relevance in developing, designing, and deploying an enterprise architecture. ERP maturity states are represented in each of the quadrants of the 6x3 matrix. As an ERP matures, each of the maturity states is realized and can be directly correlated to its respective systems engineering concept. It can be seen from the framework that the phases of the systems engineering lifecycle can be applied to ERP development. The various ERP models presented in this article revealed that a systems engineering paradigm may be inferred. The SE concept framework clearly illustrates a systems engineering orientation with respect to ERP.

Table 2. Key systems engineering concepts framework

Framework of key systems engineering concepts			
Concept Area	ERP Core Components		
	People	Process	Systems
Requirements definition and management	Organizational requirements elicited	High-level operational processes defined	System functions identified
Systems architecture development	High-level architecture developed by team	Architecture supports organizational processes	Systems defined to address organizational requirements
System, subsystem design	Unique data and functionality criteria addressed for each organization	Operational processes at the organizational level are developed	Organizational system components are designed
Systems integration and interoperability	Shared/segmented data and functionality is designed	Operational processes are fully integrated, seamless, and automated	All organizational system components and interfaces are fully integrated and interoperable
Validation and verification	Organizations benchmark and measure operational performance	Operational process efficiencies and inefficiencies are identified	System response time and performance are benchmarked and measured
System deployment and post deployment	Team launches complete and fully integrated ERP architecture	Operational readiness plan is executed and processes are live	Systems are brought online into production environment and supporting customers

SUMMARY

In this article we have attempted to summarize the very important effects of contemporary issues surrounding information and knowledge management as they influence systems engineering and management strategies for enhanced innovation and productivity through enterprise resource planning. To this end, we have been especially concerned with economic concepts involving information and knowledge and the important role of network effects and path dependencies in determining efficacious enterprise resource planning strategies. A number of contemporary works were cited. We believe that this provides a very useful, in fact, a most-needed, background for information resources management using systems engineering and management approaches.

Chapter 1.26

The Role of Systems Engineering in the Development of Information Systems

Miroljub Kljajić
University of Maribor, Slovenia

John V. Farr
Stevens Institute of Technology, USA

ABSTRACT

In this article, the inter-relationship between information systems (IS), systems engineering (SE), and information system development (ISD) is discussed from past, present, and future perspectives. While SE is relatively a well-established discipline based upon an interdisciplinary approach to enable the realization of successful systems, ISD has evolved to a variant of SE applied mainly for the development of IS. Given the growth in complexity and cost and schedule over-runs associated with software centric systems, well-established methodologies are needed for the development of good IS. Similarities and differences of methodology as well as their evolution and perspectives are also presented herein. We found a positive trend in the evolution of research methodology in SE and its use in IS towards a system's approach as a holistic methodology.

INTRODUCTION

The title of this article seems like tautology or at least a redundancy, but was conceived to support the vision of the new International *Journal of Information Technologies and the Systems Approach*. Applying a system approach (SA) and its interaction with systems engineering (SE) for a better understanding and development of the information systems (IS) disciplines is one of main goals of the new journal and also this article. Our task is twofold: to analyze the significance of IS for SE and its methods as well as the relevance of SA and SE for the development of IS. Both of them are important and distinct. It is impossible to utilize SE and SA methods without proper IS, and conversely you cannot develop cost effective and efficient IS without disciplined SE or SA approaches. However, there has historically been a difference in the methods used for the IS development and other sociotechnical systems using SE. These differences in methods were caused by user experience and established practices although economic and technical developments will lead to their convergence. Our aim in this article is to generalize and highlight these different methodologies and their relevance for research of the vast variety of processes where IS and system's methodologies are essential conditions.

The word "system" can broadly be defined as an integrated set of elements that accomplish a defined objective (INCOSE, 2004). Simply put, a system is a whole consisting of parts and is more than sum of its parts. That was an axiom of ancient philosophers, which accurately anticipated the contemporary definition of systems. Only order, structure, and behavior were added to the meaning of systems in cybernetics and general systems theory. Complex systems are usually understood intuitively, as a phenomena consisting of a large number of elements organized in a multilevel hierarchical structure where elements themselves could represent systems (Mesarović & Takahara, 1989). The word "complex" is used only to indicate that the problem treated here cannot be expressed only in hard (quantitative) relations, and those many relevant characteristics are qualitative. With a conception of complex systems, we think about a system within which a main role is played by a complexity of control and information processes. Undoubtedly, existing SE methodology is applied to small, medium, large scale, and complex process but with complex systems, SE moves to a SA methodology. Fortunately, these same SE techniques that have been successfully applied to complex systems are also being applied to systems of systems (SoS) and large enterprises.

A paradigm of SE has played important rules in the dealing with different aspect of human activity. In the beginning, it was based on empirical knowledge and heuristics in the building of human-made objects like pyramids, fortifications, tools, and so forth. Industrial production and scientific organization began with Ford Motor and F.W. Taylor who contributed to work specialization, planning, and control. The result was mass production, standardization, and higher productivity at defined quality levels. This period of worldview in science and production was known as the Machine Age and was marked by its use of classical analysis for problem solving (Ackoff, 1999). Systems engineering was subsequently born in the telecommunications industry of the 1940s and nurtured by the challenges of World War II (WWII), when project managers and chief engineers with the assistance of key subsystem leads oversaw the development of aircraft, ships, and so forth. The post-WWII creation of more complex systems, mainly in defense and communication systems, led to the formalization of SE as an engineering discipline. Its relevance became indispensable after WWII, when systems—technical, production, and organizational—became highly complex. A landmark for systems philosophy was founded in General Systems Theory (Bertalanffy, 1968) and Cybernetics (Wiener, 1948) and continued to be adapted to the different contexts and tools, taking new meaning and significance with successive ages as indicated by Ackoff (1999). The history of civilization development and growth is closely related to the history of working methodology and organization.

Although modern definitions of SE are of a later date, there are several books and papers on this topic, which discuss SE and the system engineer in great detail (e.g., Martin, 1996; Sage, 2000; *Thomé*, 1993). Some examples of modern SE definitions are shown in Table 1. This explanation is derived from the root of two words: "engine" and "systems." An engine is a device consisting of different parts. Engineers are those who construct

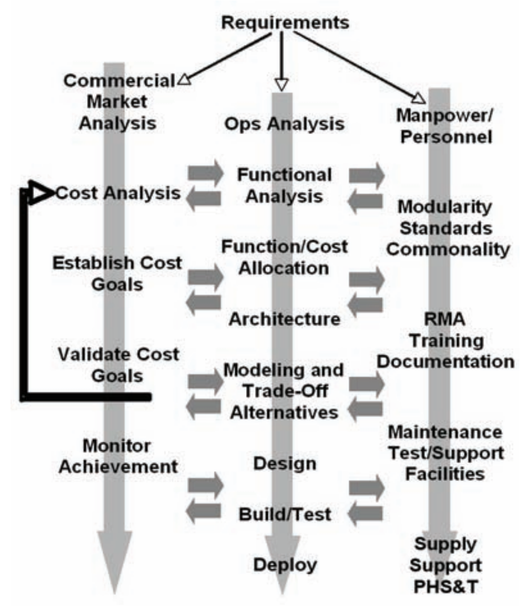
Table 1. Standard definitions of systems engineering

International Council on Systems Engineering (INCOSE, 2004)	Systems engineering is an interdisciplinary approach and means to enable the realization of successful systems.
Military Standard on Engineering Management 499A (United States Air Force, 1974)	The application of scientific and engineering efforts to: (1) transform an operational need into a description of system performance parameters and a system configuration through the use of an iterative process of definition, synthesis, analysis, design, test, and evaluation; (2) integrate related technical parameters and ensure compatibility of all related, functional, and program interfaces in a manner that optimizes the total system definition and design; (3) integrate reliability, maintainability, safety, survivability, human, and other such factors into the total technical engineering effort to meet cost, schedule, and technical performance objectives.
Department of Defense (2004)	Systems engineering is an interdisciplinary approach or a structured, disciplined, and documented technical effort to simultaneously design and develop systems products and processes to satisfy the needs of the customer. Systems engineering transforms needed operational capabilities into an integrated system design through concurrent consideration of *all* life cycle needs.
NASA (1995)	Systems engineering is a robust approach to the design, creation, and operation of systems.

engines according to their knowledge of natural sciences and economic law. "Systems" means a whole consisting of parts. Systems engineering is a methodology of how to "construct" purposeful systems in their surroundings. It is obvious that the meaning of SE has changed with the complexity of the man-made systems and social changes in its surroundings. As a comprehensive definition of SE as methodology for this article, we use *Thomé*'s (1993) definition: "Systems engineering consists of applying a System Approach to the engineering of systems." Figure 1 shows a graphical representation of what might constitute a SA to the engineering of a system. Its domain is the engineering of solutions to systems problems independent of employing a certain technology for realizing systems functions and properties. In this definition, SE was understood as the composition of SA and engineering of solution for systems problems independent of type of process. However, a SA could be considered also as enhanced SE for complex problem solving, taking into accounts not only stakeholders' requirements but also the environments requirements. That means considering a complex system from all relevant points of view in its environment during developing, maintaining, and functioning. The similarity and difference of methodology titles were discussed in Lazanski and Kljajić (2006), where the triadic principle of C.S. Peirce (1998) was used to explain the meaning of methodology in a context of problem solving. According to Peirce (1998), princliple of C.S. Peirce meaning is a triadic relation between a sign, an object, and an interpretant. A general meaning can always be found in genuine triadic relations, but can never be found in degenerate triadic relations. Only a subject gives real value and meaning to the model and methodology in a frame of a context of the problem. Basic principles and requirements for SE and its translation to practice as well as for systems engineering education are described in Martin (1996) and Sage (2000).

The relevance of SE and its variation for complex problem solving and its management could be clarified by a number of articles published in the last decade. Our Internet research results from the Engineering Village (Engineering Village, 2007)

Figure 1. Relationship between the traditional SE functions (center column), cost (left column), and supportability and logistics (right column) (Stevens Institute of Technology, 2007)



and the Web of Science (WoS Expanded, 2007) are shown in Table 2. The Engineering Village database is large and represents all articles from conference proceedings, journals from Journal Citation Records (JCR), secondary databases, and doctoral dissertations. Different results were observed from the Web of Science (WOS) database since it covers only journals from JCR.

Although SE and SA represent just methodologies and IS real systems, we compare their portions in order to see how frequently IS has been used besides established methodology. As shown in Table 2, the relative frequency of SA and SE is 77% and IS = 23% from the Engineering Village database. Our primary interest is IS and its associations with research methodologies like ISD, SE, SA. Simulation and its combination, within the IS database, n1 = 442,767 articles were found: ISD = ISD&IS = 29%, IS&SE = 47%, IS&SA = 18%, IS&SE&SA = 6%, and for IS&SE&Simulation, only three articles. Regarding ISD or ISD&IS, the answer was 29% in both cases. It means that the ISD methodology was used exclusively with IS and is between IS&SE = 47% and IS&SA = 18%. The result of IS&SE&SA is 5.8% while IS&SE&Simulation had only three articles.

Because our primary interest is the use of research methodology like ISD, SE, SA, and its combination with IS from IS database of n = 18,055 articles for the WoS database, the following result has been obtained: IS&SA at 0.4%, IS&SE at 0.4%, ISD at IS&ISD at 2%, IS&Simulation at 3.5%, and for IS&SE&SA and IS&SE&Simulation, only two and five articles were found, respectively. From these findings, only 6% of articles use established methodology with regard to IS; all other (94%) articles do not use labels like ISD, SE, and SA or similar. This finding does not mean that methodology is not used at all but perhaps not explicitly.

This research clearly shows two different trends in publications. In the broader Engineering Village database, the majority of publication content keywords is by SE at 58% and then IS at 23% followed by SA at 19%. From the WoS database, with the journals from JCR most dominant, keywords are IS at 80% followed with SA at 15% and SE at 5%. Keeping in mind that articles in journals from JCR are usually representing finished research, we can analyze the WoS database where IS = 80% (n1 = 18,055) as meaning that these articles considered topics where information systems play dominant roles like Production IS, MIS, Medical IS, Educational IS, and so forth.

Table 2. Engineering village and web of science subject searches

	Engineering Village	Web of Science
Articles in Database (1969 to 2007) Keywords IS, SE, and SA	1,926,146	22,615
% SE	58	5
% IS	23	80
% SA	19	15

SA at 15% could mean that articles also consider, besides SA methodology, another process or just methodology with SA dominant.

We have summarized key concepts for SE and SA and presented an overview of the research trends in SE, SA, and IS as reflected by the two established research databases. The remainder of this article is divided into three sections. The second section contains an overview of some theories and methods relevant for SE. The third section deals with the anticipative concept of SE. This is followed by the simulation approach to SE. Finally, the fourth section provides some concluding remarks and ideas for further research.

OVERVIEW OF SOME THEORIES AND METHODS RELEVANT FOR SE

Even though methodologies do not belong directly to systems theory, they are its products in searching for the means of complex problem solving. The diversity of systems phenomena created a variety of concepts and theories to describe them. The description of a system depends on the describer's point of view, interests, culture, and time (Koizumi, 1993). Experience, learning, knowledge, and motives influence an individual's consciousness and consequently society's awareness, which results in a certain choice of action. A social reality, which is a consequence of a compromise, is an organization and is measurable by its goals and means for achieving these goals. This is an objective matter, although there is a problem of measurability, scale ordering, and subjective understanding of an individual and the individual's values. The objective exists in time and place and is not separated from them, even though it is only partly described. *Awareness that partial description is not wholeness and the fact that we can more or less get close to this wholeness requires a SA* (Kljajić, 1994). *In this way,* Miller's (1978) Living Systems represent a comparative analogy among the structures, functioning and processing energy and information of different living phenomena. A comparative scheme is just an analogy without the power for deeper understanding of the phenomena. Even though we can find some useful similarities among an organism, an organ, and an organization, we can say that these are actually different systems with regards to their behavior. This approach can be partly useful as an analogy with organizational science. Organizational systems are complex goal-oriented systems (Ackoff, 1999) designed to achieve certain purposes. As such, organization is a function of the past, present, and future state and represents an anticipatory system. Therefore, the basic principles of systems development are essentially anticipatory as consequences of decision making based on anticipated and feedback information. To estimate the consequence of decision making, the decision maker needs a model of the system and the environment. System Dynamics (Forester, 1961) and System Thinking (Senge, 1994) are equivalent and can be unified within the systems concept (Kljajić, 1994). Some relevant paradigms for analysis were described in Flood and Carson (1988) and Rosenhead (1989), including soft systems analysis, hard systems analysis, critical thinking, and strategic options development and analysis. It is not surprising that a number of works have been dedicated to these topics. There are almost no differences among them; different names are a result of the complex context and the author's point of view. As Forrester (1994) states, all these titles have one and only one aim "to emphasize that this is the wish following an integral research of complex phenomena through its feedback connections." It is the eternal wish of a human being for the complete yet never-ending description of his surroundings. The cybernetics and general system theory expose these wishes even more. We can accept a SA or systems point of view as being proper. More so, thinking and rethinking is the mental process of a human being. It can be true or false in relation to a matter of thinking. If taken terminologically, it is a metaphor, with which we would like to expose a working method for mathematics (mathematical thinking) or philosophical method (philosophical thinking). This is the reason that the basic concept of General System Theory was the interdisciplinary work for complex problem solving. It is obvious that we cannot find an actual solution with just formal methods. Abstract matters need concrete ones and vice versa. The philosophy of SA is typical for complex problem solving and can be expressed with two words: interdisciplinary methodology + context problem solving = SA. Its openness and transparency satisfy Popper's (1968/1973) requirements for provability: "Within a methodology we do not define only a problem and search for a solution, but also set conditions for verification of solutions and validation of alternatives" (p. 131). All complex phenomena are systems in their essence, whose methodology derives from Cybernetics and GST.

In order to illustrate the interconnection of the above theory, ISD methodology relevant for IS and its evolution, the articles (Jan & Tsai, 2002; Xu, 2000; Zhu, 2000;) will be analyzed. As a good example of Miller's living systems analogy and Ackoff's (1999) lucid systems classification (Jan & Tsai, 2002), a three-stage ISD has been analyzed: methodology for the IS as machine, methodology for the IS as part of an organization, as well as IS as part of a social system. The study investigates the changing roles and missions of IS for the three stages and explores the evolution of ISD strategies. In the early phase of IS development for the organization as machine, IS was developed by information specialists. The role of the IS is to support transaction processing systems and operational control. In the organic stage, the IS role is to support transaction processing systems at all organization and management levels. In the social stage, the IS role is to support organization as a social system, and its mission should take account of organization as part of larger systems, even ecological ones. Similarly, in Xu (2000), the author reviewing the contribution of systems science to information systems research stressed how concepts and findings in systems science have to be applied, extended, and refined in IS research.

In Zhu (2000), the author presents "WSR: A Systems Approach for Information Systems Development," which is derived from traditional oriental thinking and contemporary practice in that sociocultural setting. As a philosophical framework, WSR (wuli-shili-renli) contends four principles: seeing ISD as a differentiable whole, treating ISD methods as complementary opposites, conducting ISD as a spiral bubble-management process, and searching for ISD methodologies in a form not independent from that of general management approaches. In this way, ISD researchers should develop methodologies in a form familiar to users and, at the same time, incorporate the best aspects of various methods, which nicely coincide with Ackoff's (1999) classifications. Samaras and Horst's (2005) SE perspectives on the human-centered design of health information systems are described. With human-centered design, the authors require that the SE method take into account human ergonomics (although cognitive aspects would be better), which in other words mean SA. An example of an IS for community nursing is presented in Šušteršič, Rajkovič, Leskovar, Bitenc, Bernik, and Rajkovič (2002). The goal of IS, in this case, is to reduce the workload with modern information and communication technologies and to improve the quality of nurses' work. It relies on an integrated and structured information picture, with special emphasis on transparency and interpretability. In Mouratidis, Giorgini, and Manson (2003), the security of information systems is considered as an integral part of the whole system development process. The above-mentioned articles, dedicated mostly to IS and its developing methodologies, clearly show the evolution of ISD to a systems approach methodology.

ANTICIPATIVE NATURE OF SA AND SE METHODOLOGIES

Many problem-solving methodologies are roughly similar regardless of the type of the process or purpose of the article. Three types of articles could be found on SE topics: SE Methodology, SE Application, and SE Education. This triad of methodology, application, and education are interrelated; each methodology is context dependent as well as dependent on education curricula. Therefore, common bases of all articles are also at high levels. Within this rough classification, there are large variations and combinations of methods. The best example of that is the fact that almost 94% of articles devoted to IS do not use in the keywords ISD, SE, or SA. With respect to the keywords in these 94% of articles, some implicit methodology has to be used.

The most common terms used with respect to SE can be divided into three stages: the initiation stage, the growth stage, and the maturity stage, which correlate to Jenkins' four phases cited in Flood and Carson (1988): Systems Analysis, Systems Design, Implementation, and Operation. Each of these phases could have several subphases for detail analyses. Thus, in Martin (1996), SE is defined with three parts:

A. SE Management Plan (organizes, controls, and directs the technical development of a system or its product)
B. Requirements and Architecture Definition (defines the technical requirements based on the stakeholders requirements)
C. System Integration and Verification (integrates the components at each level of the architecture and verifies that the requirements for those components are met)

The relevance of concurrent engineering in order to reduce design changes in the developing phase is stressed in Martin (1996). Similarly, in Sage (2000), the problem of SE education was dealt with from the point of view of SE as method, process, and management. In the context of education of SE, Sage (2000) elaborates three groups of knowledge: a natural science basis, an organizational and social science basis, and an information science and knowledge basis. This curriculum was further elaborated (Shenhar, 1994) into courses: mathematics and statistics, technical and engineering disciplines, economic and financial disciplines, management and organization theory, and SE procedures. Asbjornsen and Hamann (2000) approach unified SE education from a systems theory concept appealing to the SA concept to define the ratio between theory and applicative knowledge in curricula.

Perkins (2002) presents an educational program in which an industrial process SE was analyzed. His analyses show what is common in SE education curricula as well as differences caused by the specifics of the chemical process. Finally, Brown and Scherer (2000) compare SE programs in the United States. They note that there are relatively small numbers of students in SE and that none of the associations covering SE have a successfully defined core body of SE knowledge embraced by academic institutions. INCOSE (2007) has developed a standard reference for graduate programs. However, SE programs can range from operations research, control theory, information systems engineering, to industry standards of SE. Yet in the future, the first concerns of the "integration of information technology subject into the SE curricula" must be addressed. Similarities in these diverse processes suggest that there is a general process that might be closely related to human thinking (Bahill & Gissing, 1998). Bahill and Gissing defined these procedure swith the acronym SIMILAR which means: State the problem, Investigate alternatives, Model the system, Integrate, Launch the system, Assess performance, and Re-evaluate.

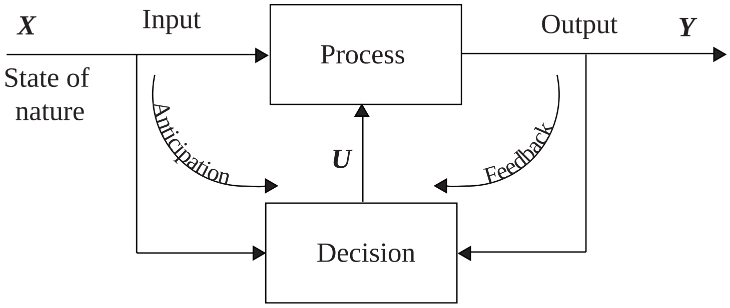
From a decision point of view, the systems approach to systems engineering as described by SIMILAR could be unified as in Figure 2. As portrayed, the process represent the progress of problem solving at anticipated systems performance in environment ***X*** (systems requirements on Figure 2), decision means action ***U*** according chosen methodology while feedback means interactive control and adaptation of realized task ***Y*** in phases of design, development, and deployment. Figure 2 clearly shows the interdependence of problems to be solved (process), users as decision makers, and methodologies used. Yet the simulation method for dynamic testing of alternatives for the anticipated system performance could be a very useful tool within SE.

SIMULATION METHODS AS A PART OF THE SA METHODOLOGY

The role of the simulation methodology in understanding x systems is constantly evolving and increasing. Today, in modern organizations, two words are dominant: change and learning, from which are derived change management and learning management. Human knowledge, the simulation model, and decision methodology combined in an integral information system offer a new standard of quality in management problem solving (Simon, 1967). The simulation model is used as an explanatory tool for a better understanding of the decision process and/or for defining and understanding learning processes. An extensive study on using the simulation method in enterprises can be found in Gopinath and Sawyer (1999). Information systems and decision support are important areas in Management Information Systems (MIS) as the part of complex SE. That could be clarified by number of articles associated with IS and Simulation: 3.5%. The majority of them discuss IS related to decision assessment. For example, in Mora, Forgionne, Gupta, Cervantes, and Gelman (2003) and Mora, Forgionne, Cervantes, Garrido, Gupta, and Gelman (2005), a new framework of identifying and classifying the support capabilities provided by the full range of decision-making support systems is posed with special regards to the information and knowledge representation and processing capabilities. However, only a few papers were used for simulation methods and SE in IS research. In Gao and Li (2006), business process re-engineering (BPR) is regarded as a revolution of enterprise management. Advances in modeling languages, such as the Unified Modeling Language (UML), is an industry standard that is used in modeling business concepts when building software systems in an object-oriented manner has also become mainstream for most SE organizations. Recently, XML has gained ground in becoming a key enabler of these systems in terms of transport of information and commands. All of this demonstrates the growth in tools and languages needed to describe and model a system.

Using a hybrid simulation model, decision assessment of BPR was analyzed in Kljajić, Bernik,

Figure 2. General model of a goal oriented system

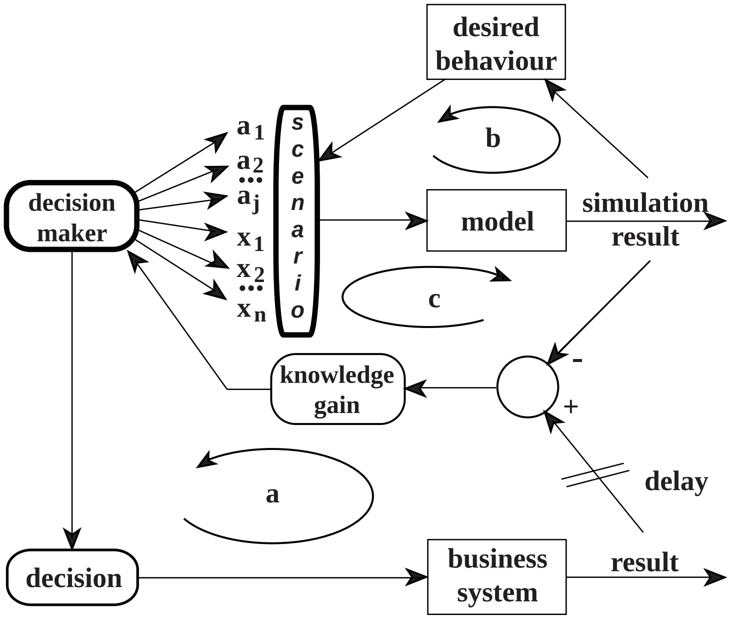


and Škraba (2000). The decision assessment has been organized at two hierarchical levels. The model at the upper level is used for the assessment of an enterprise's strategy (continuous simulation). At the lower level, the model is used for discrete event simulation, necessary for operations planning and testing production performance. The simulation approach seems to be an appropriate methodology for obtaining anticipative information for decision making as shown in Figure 2. Roughly speaking, this involves the concepts of state, goal, criteria, alternative, and the state of nature combined in a dynamic model interacting with decision-making groups. In both of these, simulations interacted with human experience create a new quality. The representation of the proposed approach is shown in Figure 3, adapted according to Kljajić (1994).

Figure 3 shows the interaction between the user, simulation model, and scenario in the process of seeking a solution to a managerial problem as decision support in a business system. The following three basic loops are emphasized:

a. The causal, or the feedback loop, representing the result as a consequence of former decision making, and as a part of management experience and history of the system. From the learning point of view, this loop could be named "learning by experience."
b. The anticipative or intellectual feedback loop, which provides the feed forward information relevant to the formulation of the system strategy. This loop consists of the simulation model of the system, criteria function, and scenarios. The simulation scenarios consist of two subsets: a subset of input x_i that anticipates the state of nature (or exogenous scenarios) and a subset of alternatives a_j (or endogenous scenarios). The generation of scenarios of the simulation system that responds to the *what-if* is based on different scenarios anticipating future impacts of the environment and desired performance of the system. They usually represent the extrapolation of past behavior and an expert evaluation of development targets employing the brainstorming method. The

Figure 3. The principle diagram of simulation approach for decision support in enterprises



most delicate part of this circle is above all (principally) the methodology of the system simulation that facilitates "experimenting" on the system model and the model of the process itself.

c. The *a posteriori* information concerning model applicability and former decision making. This loop represents the pragmatic validation of the model. The comparison of the prior information concerning the impact of the selected strategy on the system behavior with the achieved results allows us to gain knowledge and evaluate the value of the model and improve it. In this way, learning is facilitated on the basis of *a priori* assumptions on the model and not just on the basis of empirical experiences, which is usually delayed.

Loops a and c are the basic ones for the knowledge generation and experience for learning and quality decision making. Loop b represents the knowledge validation. In literature, major attention has been paid to the methodology of design, testing, and evaluation of the model. As such, a simulation could be very useful in testing alternatives in the SIMILAR methodology or merely SA. The user is, however, the key element of the three circles because the user is the one who makes decisions. As most of simulation projects necessitate teamwork, considerable attention should also be paid to the presentation of findings in the decision-making process. The advantage of the simulation method application for decision support is proved by the laboratory experiment on the business simulator (Škraba, Kljajić, & Leskovar, 2003; Škraba, Kljajić, & Borštnar Kljajić, 2007). The authors tested the efficiency of decision making (DM) (value of criteria function and its variation) at three different conditions: (a) DM-based on problem understanding, (b) DM-based on problem understanding and using simulation model as feedback, and (c) DM, which in addition to individual feedback, also uses information of group decisions. The best results were achieved for condition c over b and the worst at group a.

Advantage of the simulation model as part of SA lies in the fact that the problem defined in natural language could be easily transformed in a directed graph convenient for qualitative analysis and then transformed in a computer program. In this case, the user can always check the correctness of the stated problem within a certain theory and further its translation to computer programming. This is important, especially in case of a complex problem, where the feedback loop and stochastic relation are present, no matter if the process is a continuous or discrete event. Rich graphic presentations and 3D animation of the simulated process make this technique unique for testing systems performance in the phase of system design and deployment.

Modeling and simulation (M&S) have become ever more central to the development of modern systems. Unprecedented advances in digital processing have made high fidelity representation of systems and subsystems in computer models possible from the simplest of our systems to the most complex. This has made it possible to examine the projected performance of systems over wide excursions of design and environmental assumptions very early in the development process when key resources are committed. Today's M&S tools make it possible to perform extensive SoS and enterprise-wide simulations and evaluate alternate architectures at affordable cost and early enough to make a difference.

SUMMARY AND CONCLUSION

In this article, the relationship among information systems, SE, SA, and ISD was discussed from past, present, and future perspectives. While SE is a well-established methodology for developing different kinds of man-made objects from components to enterprises, ISD is a variant of SE applied for IS development. Based on a library study, it is possible to see a positive trend in the evolution of research methodology in IS and the use of IS for SE implementation toward the SA methodology. All classical methods initially developed for specific problems and processes converge with the development of IT and society into one holistic methodology colored with specific problems (context) and user preferences. A common name for SE or ISD could be SA or more precisely SA to SE and SE with SA as a holistic methodology for complex problem solving. A core substance for the management of all these methods is IS. Conversely, when IS itself should be developed and deployed in such a complex situation as the Internet, intranet, e-everything, GIS, e-market, and MIS of complex global environment, then ISD have to move to SA combining with principles of SE but combined with different methods and tools for dynamic testing of IS in all phases of SE by means of system simulation. One cannot imagine how to test reliability, stability, functioning, and behavior of global (complex) systems, where IS represents the backbone and Central Nervous Systems, after disaster impact without SA methodology combined with systems simulation.

No matter how we call a certain methodology for complex systems managing—systems thinking, system approach, soft systems methodology, critical systems methodology, or dialectic systems (that remains the preference of authors)—the essence of such methodology has to be intent to cope with the wholeness of the process in its environment. Or more precisely, the environment is a relevant part of the tangible problem solving local or global. Nanotechnology, computer science, and software systems offer new possibilities in developing information technology for more complex IS. In that case, a working methodology, more than ever, has to be holistic and user friendly. It means that it has to contain all existing particular methodologies (context oriented) in one working methodology where the user has to be in the first plan—anthropocentric orientation.

In our opinion, the systems approach, as a worldview on the systems dynamic originated from GST and systems engineering with its tradition in the production process, is a proper candidate for that. It can unify all methods dealing with complex systems like ISD, SE, software engineering, operations research, and especially, modeling and simulation. SA, in a natural way, provides synthesis of structure, behavior, and utility via goal, state, criteria, and feedback control as an anticipated property of the complex systems.

Chapter 1.27

Enterprise Resource Planning Systems in a Global Environment

Paul Hawking
Victoria University, Australia

ABSTRACT

Companies around the world are placing increasing emphasis on strategy development and implementation. Some argue that this increased emphasis is in response to market forces of increased competition and globalization, and the need to be flexible and adaptive to the business environment. Strategy development and implementation is a multifaceted task reliant on a number of interdependent factors. One of these is the role of information technology which in recent times has become an integral part of most companies' strategies. This chapter discusses the role of strategy development and the importance of the alignment of business and IT strategies in a global environment. It discusses the role of enterprise resource planning systems on strategy development and how these systems underpin many strategic objectives companies strive for in a global environment.

STRATEGY DEVELOPMENT

There is a plethora of articles, books, and presentations on the importance of strategy in today's companies (Mintzberg, 1994; Porter & Miller, 1985; Kaplan & Norton, 1996). But even with this emphasis, companies struggle with their strategy development and implementation. This is reflected by a much cited reference to a *Fortune* magazine article which stated: "Less than 10% of strategies effectively formulated are effectively executed" (Kaplan & Norton, 1996). In other words more than 90% of companies that are able to create an effective strategy struggle to implement it.

A possible reason for this finding may be the diverse views of what a strategy is. The increased focus on strategy has resulted in the word "strategy" and its derivatives being concatenated with a broad range of terms in an attempt to imply a higher level of importance—for example, strategic planning, strategic learning, strategic thinking, strategic leadership, corporate strategy, business strategy, and functional strategy. This is further reinforced in Mintzberg's (1994) landmark article "The Rise and Fall of Strategic Planning," where he argues the virtues between strategic planning and strategic thinking. In terms of what a strategy actually is, Minztberg (1992) defined strategy as:

> *A plan—some sort of consciously intended course of action, a guideline (or set of guidelines) to deal with a situation. By this definition strategies have two essential characteristics: they are made in advance of the actions to which they apply, and they are developed consciously and purposefully.*

He further attempted to define strategy from the perspectives of being a plan, a ploy, a position, a pattern, and a perspective (Ikavalko & Aaltonen, 2001). Porter's (1996) definition of strategy focuses more on the outcome: "the creation of a unique and valuable position, involving a different set of activities." He believes that a strategy is a way an organization seeks to achieve its vision and mission, and that a successful strategy allows a company to capture and sustain a competitive advantage.

The emphasis on the effective development and implementation of strategies has resulted in a number of methodologies being developed to facilitate this process. Two of the more accepted methodologies are Porter's Value Chain (1985) and Kaplan and Norton's (1996) Balanced Scorecard. Both methodologies adopt a multifaceted approach involving a number of perspectives to strategy development and implementation. This assists in identifying the interrelationships between the various facets that impact upon strategy and facilitates the devolution of the strategy to operational terms.

The Balanced Scorecard (Kaplan & Norton, 1996) views strategy development and implementation from four interrelated perspectives:

- Financial
- Customer
- Internal
- Learning and growth

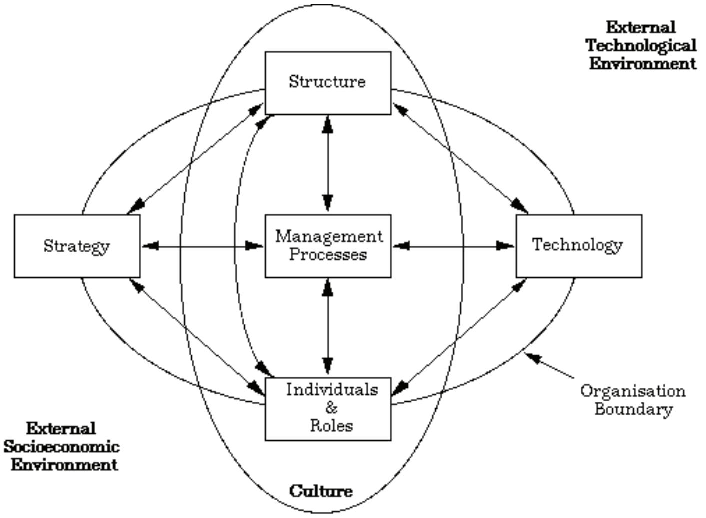
Within each of these strategic perspectives, a number of objectives are developed, and for each objective, key performance indicators (KPIs) are identified and targets determined. The methodology then encourages companies to identify initiatives whereby these targets can be obtained (BSC, 2003). For many companies this has involved the adoption of information technology solutions. Porter and Millar (1985) proposed an information intensity matrix to assist in identifying where information technology could be used strategically in the value chain. Somogyi and Galliers (1987) supported this concept by identifying how information technology could be used to assist companies in attaining competitive advantage in the various strategic focuses across the value chain.

Over the last three decades, companies have increasingly identified the importance of information technology in the achievement of strategic objectives. Scott Morton (1991) identified five interrelated factors that influence the attainment of strategic objectives. One of these factors was information technology (see Figure 1).

INFORMATION TECHNOLOGY ALIGNMENT

Even though the role of technology in strategy development and implementation has been identified, one of the major issues facing companies is the alignment of information technology (IT) strategy with their business strategy (CSC, 2000; Price Waterhouse, 1996). A recent survey of more than 300 CEOs and CIOs identified the alignment of IT and business strategy as their number one priority (Beal, 2003). The importance of this alignment has been identified as a priority for

Figure 1. Scott Morton's (1991) five forces influencing strategic objectives



companies for the past 20 years (Brancheau, Janz, & Wetherbe, 1996). Bakos and Treacy (1986) argue that the increased attention being paid to the role IT has in the corporate strategy is mainly due to the publicity received by companies who have gained significant advantage due to their IT utilization.

Researchers have validated the value to be gained from the alignment of IT and business strategies (Chan & Huff, 1993). Tallon and Kraemer (2003) in a survey of 63 companies found there was significant value gained from the alignment of these strategies. However lack of alignment can result in failure to gain value from IT investments (Gerstein & Reisman, 1982). Factors that have been identified and that have contributed to this lack of value realization include: lack of understanding of the potential of IT by senior management, lack of communication between IT managers and business managers, change management issues, lack of focus on opportunities for competitive advantage, and lack of availability or use of instruments to quantify possible business benefits (Gerstein & Reisman, 1982).

Broadbent and Weill (1993) define this IT-business alignment as "the extent to which business strategies were enabled, supported, and stimulated by information strategies" (p. 164). An alternative definition is: "the degree to which the information technology mission and objectives, and plans support and are supported by the business mission, objectives, and plans" (Reich & Benbasat, 2000, p. 82).

Both definitions involve a bi-directional alignment whereby other than the IS/IT strategy supporting the overall business strategy, it also can be a catalyst for the business strategy. Knoll and Jarvenpaa (1994) believe that this bi-directional reciprocal relationship is important for a company's competitive advantage—a view also supported by other researchers (Oesterle, 1991; Tallon & Kraemer, 2003).

Teo and King (1997) proposed four different scenarios or degrees of integration between the business and IT strategies. These included:

- **Administrative integration:** This is where there is littler relationship between the business and IT strategy.
- **Sequential integration:** This is where the business strategy is developed firstly in isolation to the IT strategy. The IT strategy

is then developed to support the business strategy.

- **Reciprocal integration:** This is where a reciprocal and interdependent relationship exists between both strategies. The IT strategy is used to support and influence business strategy.
- **Full integration:** This occurs when both strategies are developed concurrently in an integrated manner.

This increased need for closer alignment has resulted in companies focusing on strategic information systems planning (SISP) and the development of methodologies to support this (Pant & Hsu, 1995; Hackney, Burn, & Dhillon, 2000). Hackney et al. (2000) identified the assumptions which underlie SISP and discussed their validity. They identified the main assumptions as:

- Business strategies must exist as a precursor to SISP.
- Business strategies are different from IT strategies.
- IT and business strategies can be aligned.

They argue that as business strategies evolve, it is often difficult for IT strategies to respond. They believe that IT applications often require an environment of stability and predictability to enable their development and that the maintenance or modifications to developed applications are often expensive and sometimes impossible. This requirement of stability and predictability may be at odds with the iterative approach to business strategy development. Accordingly, a business strategy may be constrained by the existing legacy IT systems which were developed and implemented in accordance with a previous business strategy. Another premise which underlies SISP is that IT is a source of competitive advantage. For many organizations their IT systems make up a standard infrastructure to support generic information processing. Carr (2003) in his seminal article on the value of IT would argue that as IT solutions become generic and commoditized, there is no competitive advantage to be gained. He makes the analogy with the introduction and diffusion of electricity, whereby companies who initially adopted this technology gained a competitive advantage, but as other companies increasingly introduced the technology, the competitive advantage dissipated.

It can be argued that the technology in itself does not provide the competitive advantage, but how it is used to support business activities. From a different perspective Vitale (1986) proposed that rather than achieving a competitive advantage from the use of IT, IT can be used to avoid a competitive disadvantage. This is where a competitor has achieved a competitive advantage through the use of technology and a company rather than being disadvantaged by this adoption implements the same technology. Hackney et al. (2000) refer to Mintzberg's reasoning for strategic planning being an oxymoron and apply the same reasoning to SISP.

He further highlights the flaws in SISP when it is applied to the impact that enterprise resource planning (ERP) systems have had on business strategy (Hackney et al., 2000). ERP systems are widely adopted in a diverse range of organizations and define the business model on which they operate. For many companies they were relieved that an ERP system could help them define a business strategy and provide the IT infrastructure to support it (Davenport, 2000). Hackney et al. (2000) believe that ERP systems can provide a "dynamic stability" to the alignment of business and IT strategies. These systems can provide a stable predictable environment of which their usage can evolve in accordance with a company's business strategy.

ENTERPRISE RESOURCE PLANNING SYSTEMS

The term 'ERP systems' did not appear until the early 1990s. These systems evolved from material requirements planning (MRP), manufacturing resource planning (MRP II), computer integrated manufacturing (CIM), and other functional systems responsible for the automation of business transactions in the areas of accounting and human resources (Klaus, Rosemann, & Gable, 2000). The attempt to integrate all these systems coined the term 'ERP systems'.

Due to the purported benefits of ERP systems, many companies consider them as essential information systems infrastructure to be competitive in today's business world and provide a foundation for future growth. A survey of 800 top U.S. companies showed that ERP systems accounted for 43% of these companies' application budgets (Somer & Nelson, 2001). The market penetration of ERP systems varies considerably from industry to industry. A report by Computer Economics Inc. stated that 76% of manufacturers, 35% of insurance and healthcare companies, and 24% of federal government agencies already have an ERP system or are in the process of installing one (Stedman, 1999). The ARC Advisory Group (2006) estimated that the worldwide market for ERP systems was $16.67 billion in 2005 and is forecasted to surpass $21 billion in 2010. The major vendor of ERP systems is SAP with approximately 56% of the market.

Researchers believe the growth in the uptake of ERP systems is due to several factors: the need to streamline and improve business processes, and better manage information systems expenditure; competitive pressures to become a low-cost producer; increased responsiveness to customers and their needs; the need to integrate business processes, and provide a common platform and better data visibility; and as a strategic tool for the move towards electronic business (Davenport, Harris, & Cantrell, 2003; Hammer, 1999; Iggulden, 1999; Somer et al., 2001; Markus, Petrie, & Axline, 2001).

For many companies, underestimating the impact the system would have on their organization caused them initially to struggle with their ERP implementation. For some the barriers associated with the lack of skilled resources and inexperience with projects of this scope became insurmountable (Calegero, 2000). Davenport (2000) believes that ERP systems by their very nature impact on a company's strategy, organization, and culture. The move to become process rather than functionally focused and the resultant need for business process integration can result in a loss in competitive advantage in particular areas. However the potential benefits across the entire organization often outweigh the losses in individual areas (Holland & Light, 2001). The lack of understanding of the role ERP systems play within an organization often leads to conflict and hinders benefit realization of the ERP system implementation.

As mentioned previously, for many companies their business strategy is now being influenced by the existence of an ERP system. This is reflected in the views of researchers who believe that a bi-directional reciprocal relationship between the business strategy and the IT strategy is important for a company's competitive advantage and that the IT strategy can act as a stimulus for the overall business strategy (Oesterle, 1991; Tallon & Kraemer, 2003; Knoll & Jarvenpaa,1994; Teo & King, 1997). Companies have made a significant investment in their ERP system and realize that it has the potential to support new strategic directions. This contention is reflected in the landmark Deloitte study (1998), where 49% of the sample considered an ERP implementation to be a continuous process, as they expect to continually find value propositions from their system. This was also the finding of other researchers (Davenport et al., 2004). They surveyed 163 organizations in Europe, the United States, and Australia who had implemented an ERP system and found that no company had finished implementing the system to support all business processes. Over time the benefits companies expect to achieve from their ERP system changes in accordance with their business strategy and the improved functionality provided by the ERP vendors.

Accordingly ERP vendors added increased functionality and "bolt on" solutions to extend the reach and penetration of the ERP system, while at the same time increasing its strategic value. In 2000, the Gartner Group coined the term ERPII to describe such offerings and defined the term as a "business strategy and set of industry domain specific applications that build customer and shareholder value by enabling and optimizing enterprise and inter-enterprise collaborative operational and financial processes." They considered that ERPII would have a global focus and would extend the current ERP systems by incorporating customer relationship management (CRM), supply chain management (SCM), and other strategic solutions (Mohamed, 2002).

ERP Usage Models

Many researchers and analysts have attempted to develop models to illustrate the evolution of ERP benefits and ERP usage. Five main models have been identified from the literature: Deloitte (1998), Holland and Light (2001), Cap Gemini Ernst and Young (2002), Davenport et al. (2003), and Nolan and Norton (2000). These models are based on the premise that companies initially implement a functional component of their ERP system. After a period of time this component's usage is accepted and becomes part of normal work practices. This stabilization results in companies learning from its usage and investigating how to extend this functionality across the company and/or implement other functionality. In other words there is a significant learning curve associated with ERP usage and capabilities.

All the ERP usage models identify the evolutionary nature of how companies use these types of systems to gain greater business value. The use of these systems moves from automating transactional processing to more strategic analytics and forecasting to assist in improved decision making. This is reflected in the two major studies that investigated the drivers and benefits of ERP usage (Deloitte, 1998; Davenport et al., 2003). The earlier study identified the key drivers/benefits of an ERP implementation as operational factors: Y2K compliancy, and disparate systems limiting information integration. Davenport et al. (2003) identified more strategic drivers/benefits in terms of improved management decision making and financial management. The different models and previous research indicate that there is a strong interdependent relationship between business and IT strategies, especially in companies that adopted ERP systems. ERP vendors accordingly have evolved their product offerings from a transactional focus to a more analytical strategic focus. This has created an extremely complex ERP environment where solutions are interdependent of each other. Many of the solutions such as customer relationship management, supplier relationship management (SRM), business intelligence (BI), and supply chain management extend the transactional focused ERP system while at the same time they are reliant on its existence. This means that the implementation of an ERP system could be considerably different from company to company due to the range of functionality and solutions available. This evolution of ERP systems has seen the increased usage of the term "enterprise wide systems."

The usage models reflect the evolutionary nature of ERP systems in supporting various strategic goals. However they do not identify specific functionality usage or solutions implemented in each stage. They indicate goals of ERP usage and organizational focus. The identification of specific functionality and solutions relevant to each phase can assist companies in developing their ERP and IT strategy. It could provide them with a roadmap while at the same time providing input into the overall business strategy. There is limited if any research in this area, and the outcomes of this type of research would greatly assist companies with decision making in relation to their ERP strategy.

These usage models tend to cover additional functionality rather than considering the penetration of functionality across the company. This becomes increasingly important when considering global and transnational companies. These companies face pressures from a number of different fronts and are becoming increasing reliant on quality information through business intelligence solutions to assist with effective decision making. However, what underpins the access to quality information is the standardization of master data definitions, business processes, and key performance indicators. Many companies struggle with this standardization in a single country operation, but the problem grows exponentially in global operations.

Many global operations are using ERP systems to support their operations in an attempt to provide this standardization. However there is the continual struggle between balancing global standardization and local customization. The concept of shared services, whereby corporate-wide activities are centralized and standardized, are becoming increasingly prevalent. The remainder of this chapter discusses how one company implemented an ERP system to support its global operations.

CASE STUDY

A case study research methodology was used for an exploratory look at how a company uses an ERP system to support its overall business strategy. The case study focused on a large company involved in the process manufacturing industry. The data collection process will include examination of existing documentation, content analysis of internal documentation, and interview of key personnel. Yin (1994) suggests that a single, in-depth case study is an appropriate research approach under a number of conditions, one being that it is a critical case whereby it meets all the necessary conditions for testing a theory.

Initial contact was made with case study company (Fonterra) after representatives of the company presented at an ERP user group conference. They agreed to participate in the research activity. Background material about the company was collected from the company's Web site. Further contact was made with the company in February 2004, and a key staff member was identified to be interviewed. The interview was conducted at the company's head office in Auckland, New Zealand, in late February. During the interview a number of documents relating to company strategy and IT strategy were supplied. A follow-up interview was conducted with another key staff member in October 2004 via telephone conference call.

Company Background

The dairy industry is New Zealand's largest industry which accounts for in excess of 20% of the country's exports and 7% of its gross domestic product (GDP) (Fonterra, 2004a). To facilitate the export market, in the 1930s the New Zealand Government established the New Zealand Dairy Board in partnership with the numerous small dairy companies. Over the years in an attempt to achieve greater efficiencies and economies of scale, there has been numerous mergers of the smaller companies. By the end of the 1990s there existed four main dairy companies, but it was realized that extra efficiencies and maintenance of competitive advantage could not be achieved unless a major reform was undertaken. In conjunction with a consulting company, the industry identified three major focuses for its future strategy. These included:

- Maintain competitive advantage as low-cost producer of diary products

- Improve performance of existing business
- Pursue aggressive growth opportunities

A number of options were considered to how best to achieve these strategic goals, and it was concluded that "a single, integrated company that collects, manufactures and sells commodities and ingredients would create [the] most value" for the stakeholders (Fonterra, 2001, p. 5).

The proposed consolidated company, which was later to be known as Fonterra, was expected to achieve an annual savings of $310 million by the end of the third year. These savings would be achieved by a combination of: elimination of duplicated facilities and activities; an increase in productivity through the integration of manufacturing, marketing, and distribution activities; and the exploitation of new markets technology and biotechnology opportunities.

Fonterra Corporation

Fonterra is a New Zealand dairy cooperative formed in 2001 (Fonterra, 2004a). The company is responsible for the collection and processing of more than 96% of New Zealand's milk involving more than 13,000 farmers. It has an annual turnover of US$6.8 billion, which accounts for 20% of New Zealand's export receipts and 7% of its GDP; it is the largest dairy ingredients producer in the world. Its supply chain extends from New Zealand to customers in 140 countries. To support this supply chain, the company has sites in 40 countries and a workforce of more than 20,000.

The three organizations, which merged to form Fonterra, were culturally, structurally, and operationally significantly different. In an attempt to achieve its strategic goals, Fonterra developed a number of strategies to facilitate the changes that needed to occur in the company. The company identified seven strategic themes and associated metrics:

- **Lowest cost supplier of commodity dairy products:** Fonterra believed that this was its main competitive advantage and aimed to achieve an improvement across its supply chain of at least 3% per annum.
- **Leading price and inventory manager in the global commodity market:** Fonterra identified opportunities to increase its global markets through access to improved information. This will enable Fonterra to develop enhanced analytical approaches to supply chain management and product development.
- **Effective developer of dairy ingredients partnerships in selected markets:** Fonterra identified the need for improved integration and collaboration with key customers. These improved interactions will strengthen relationships with existing customers and provide opportunities to establish strong relationships with new customers.
- **Leading specialty milk components innovator and solutions provider:** Fonterra believes there are opportunities to develop new innovative products customized for particular customers and niche markets.
- **Leading consumer nutritional milks marketer:** Fonterra believes that there is an increased demand for nutritional dairy products, and accordingly strengths in branding and go-to-market capabilities need to be enhanced in existing and new markets.
- **Leading dairy marketer to food service in key markets:** Fonterra believes that opportunities exist in extending the company's presence in the food service market, and that this can occur by the development of innovative products and enhance its product and distribution coverage.
- **Develop integrated strategies for four key regional markets:** Fonterra believes that there are opportunities to be realized in the global market, but there is a need for integrated strategies across the value chain

which maximizes opportunities while at the same time manages risks (Fonterra, 2004a).

Jedi Project

Fonterra developed a number of strategic projects to facilitate change in accordance with its strategic themes. One of these projects was titled "Jedi" which commenced in November 2003. The Jedi project consisted of 40 interconnected projects with the common goal of ensuring that Fonterra would realize its strategic goals as a leader in the dairy industry. The project's underlining objectives were to provide a global business model which involved common business processes, systems, and classification of customers with a focus on simplicity. Specific goals of the project were (Fonterra, 2004b, p. 20):

- "Operations work well with all other parts of the ingredients business."
- "Managers have a better understanding of costs so they can make the right decisions."
- "All the people working in Operations have the skills and equipments they need to do their jobs to the best of their ability."
- "We have one way of doing things across the manufacturing sites."
- "People want to actively share best practice and good ideas with other sites."
- "Existing projects are completed and all projects work towards common goals."

The Jedi project consisted of four major components: sales network structure (SNS), global customer service center (GCSC), global back office (GBO), and empower.

Sales Network Structure

Before the commencement of the Jedi project, Fonterra's customers receive the same level of service independent of the revenue they generate. The sales network structure was designed to segment Fonterra's customers in an attempt to customize the level of interaction and service relevant to the customer's revenue stream. This would enable Fonterra to strengthen the collaboration and integration with key customers and thus deepen the relationship. The customers were segmented into four different categories:

- **Segment 1:** Large customers who account for more than 40% of Fonterra's revenue
- **Segment 2:** Customers who provide good business and have good growth potential
- **Segment 3:** Customers who provide a steady stream of income but have limited growth
- **Segment 4:** Intermittent customers

The customers in segments 1 and 2 would receive a highly personalized sales channel through account managers, while segment 3 and 4 customers would use self-service facilities available in the global customer service center. The sales network structure proposes how offices around the world can best service each customer segment. As part of this service, the global customer service center will be established.

Global Customer Service Center

This component is designed to be a link between sales activities and order fulfillment, and will directly service both account managers acting on behalf of customers and customers dealing with the center directly. The functions will be centralized and located in Auckland, New Zealand. Due to the organization's sales network, the GCSC needs to provide worldwide support, operate 24x7, and will have multilingual facilities with approximately 120 staff members. One of the perceived advantages of this service will be a common price list, which did not exist previously and caused the company quite a lot of embarrassment when large customers could quote different prices for the same product from different sources.

Global Back Office

This component is responsible for the handling of the majority of Fonterra's accounting and human resource transactions. It will provide a mechanism to standardize business processes in these areas while at the same time deliver efficiencies through centralization and economies of scale. The company realized finance, human resources, and the associated information systems are key areas which underpin operations across the supply chain. This realization reinforces Porter's view of the value chain (Porter, 1985). Fonterra believes that once "best practice" is adopted in these areas throughout the company, then greater attention can be paid to customer-focused operations.

Empower

This supply chain management component encompasses order management, logistics, and planning. It is envisaged to change the traditional business focus from one that was reactive to a more proactive approach whereby people would work to a plan. In other words it would allow customer orders to be matched to planned customer demand. This component is expected to drive efficiencies across the supply chain by implementing standard end-to-end processes and business rules, and integrating planning and execution.

Information Systems Strategy and Jedi

Fonterra believed that the effective selection and use of information system solutions would be essential to the project's success and thus success of the overall strategy. As the company was the result of a merger of a number of existing companies, there was already a plethora of IS solutions implemented. These included various ERP systems such as J.D. Edwards, Oracle, and PeopleSoft, which indicated a considerable investment by each corporate entity.

The first phase of the Jedi project was the implementation of Empower which had an aggressive implantation with a go-live date at the end of March 2004. It was decided to implement SAP's supply chain management solution to support these functions at an expected cost of $NZ120 million (Gifford, 2004). SAP was selected as it was considered to have incorporated "best business practice" and would ensure standardized end-to-end processes in accordance with the project's goals. One of the issues with the existing SCM solutions was that they were extensively customized, which resulted in considerable maintenance problems, and therefore it was decided that to facilitate future upgrades and the global rollout of the SCM solution, minimal customization would occur in the Empower project. To facilitate integration between its various components and across the global supply chain, Fonterra implemented the WebMethods integration solution.

The second phase of the Jedi project involves the rollout of GCSC and GBO. The sales network structure was implemented in the United States with an expected go-live date in August 2004. The rollout around the rest of the world occurred in 2005. SAP solutions were implemented to underpin this phase of the Jedi project. The financial and human resource modules were implemented to support the global back office component. This will replace in-house systems and an existing Oracle ERP system. The financial module will incorporate general ledger, accounts payable and receivable, and assets management. While the HR component will involve the implementation, the "manager's desktop," and the "employee self service" (ESS). The manager's desktop enables managers quick access to information and transactions related to employee who they are responsible for, while the ESS solutions use a Web-based interface which enables employees to view and maintain personal details, as well as quick access to transactions relating to their working environment such as applications for leave, overtime, training, and so forth. A quick win for this solution will be the savings gained by the implementation of electronic pay slips.

Although the company has implemented SAP solutions, a number of existing ERP systems will remain in some areas of distribution and financial activities in factories. This will require a number of interfaces to be developed to Jedi solutions. The non-ERP systems will remain until ROI is achieved, but eventually will be phased out for SAP solutions. Fonterra intends to adopt a "vanilla" approach to its implementation whereby minimal customization of the system occurs. This is expected to facilitate the global rollout and future upgrades, and minimize the impact of future acquisitions. There will be a single implementation of the SAP system (instance) in New Zealand, and this will be based on a global template which will have restricted localization in each of the 40 countries where it will be rolled out. This ensures standardized definitions and business processes throughout the company. This will facilitate the information flow, and thus improved reporting and decision making.

Fonterra has a number of other proposed implementations to support their strategic directions which include data warehousing, advanced planner and optimization, and customer relationship management. Eventually the company will have replaced 15 core systems with SAP solutions.

The implementation of the ERP system is considered by Fonterra as fundamental to its business transformation in a global environment. The company believes that in its global operations, it has moved from autonomous independent localized operations to standardized business processes, rules, and configurations. Fonterra has centralized its business processing and customer service center as well as centralized planning and supply chain management. It now believes that the company is in a position to quickly adjust its corporate strategy to market demands.

CONCLUSION

When companies expand their operations globally, they struggle with their information systems infrastructure to support the extended business processes. ERP systems are seen as a tool to assist in this process. However the ERP systems global model varies from company to company. This is dependent on the level of standardization of processes, master data, reporting, and user interfaces required. The greater level of standardization usually occurs at the expense of localization needs. The case study company has opted for a global template to ensure an increased level of standardization.

FUTURE TRENDS

Globalization of ERP systems is becoming a major issue for many companies. There is an increased tendency to implement a global template to ensure greater standardization and compliance. As companies' global ERP systems implementations become more mature, there may be modifications made to the global template to address localization issues. The adoption of service-oriented architecture technology will assist in this variation to the global template.

ABSTRACT

The enterprise architecture provides benefits to the organization that embraces it. However, in many organizations, the enterprise architecture effort is not tightly coupled and integrated with other enterprise level programs such as investment management and system development processes. This chapter will identify the process integration and enterprise architecture touchpoints from the perspective of the investment management process and it outlines an overall integrated enterprise life cycle process flow. Specifically, this chapter explores Why it is important for an organization to follow an architecture-driven integrated enterprise life cycle? What are the processes of an enterprise life cycle and how do they fit together, specifically the enterprise architecture, investment management, and system development processes? What is an organizational structure for managing and executing the integrated enterprise life cycle? What is an approach for implementing an integrated enterprise life cycle?

INTRODUCTION TO ENTERPRISE ARCHITECTURE AND THE INTEGRATED ENTERPRISE LIFE CYCLE

An enterprise architecture provides significant benefits to an organization that embraces it. However, in many organizations the enterprise architecture effort is not tightly coupled and integrated with other enterprise level programs such as investment management and system development processes. (Bernard, 2005; Rechtin, 1991)

The target enterprise architecture and the IT initiatives needed to achieve the target should be managed in an IT portfolio within an overall investment management process. Additionally, as these IT initiatives are being implemented and deployed, there is a need for oversight and good project management. To ensure comprehensive IT governance and business/IT alignment, the enterprise architecture must be integrated into an overall "integrated enterprise life cycle" that includes not only the enterprise architecture, but also an investment management process as well as the individual system development life cycles. The challenge for most organizations is that the guidance, responsibility, and skill sets for these various processes can be spread out across the organization and are often implemented in a silo, nonintegrated fashion. Only by viewing these processes as a whole can an organization achieve the maximum benefits that an enterprise architecture can provide. This chapter will identify the process integration and enterprise architecture touchpoints from the perspective of the investment management process and it outlines an overall integrated enterprise life cycle process flow. Specifically, we will discuss:

- Why it is important for an organization to follow an architecture-driven integrated enterprise life cycle?
- What are the processes of an enterprise life cycle and how do they fit together, specifically the enterprise architecture, investment management, and system development processes?
- What is an organizational structure for managing and executing the integrated enterprise life cycle?
- What is an approach for implementing an integrated enterprise life cycle?

BACKGROUND AND MAJOR PROCESSES OF THE ENTERPRISE LIFE CYCLE

We start by defining the major processes of the integrated enterprise life cycle (IELC) which include the following:

- **Enterprise architecture:** The enterprise architecture establishes a comprehensive understanding of an organization's core business processes and defines the technology that supports and optimizes them. (Armour, Kaisler, & Liu, 1999a)
- **Investment management planning and oversight:** The investment management process (IMP) is a fluid, dynamic process by which an organization selects and monitors both proposed and ongoing IT investments (initiatives) throughout their life cycle. An organization evaluates IT investments to assess the impact on future initiatives and to benefit from any lessons learned. The IMP can contain three phases (GAO, 2004):
  - The *select phase* discovers and selects the IT investments that best support the organization's mission needs and identifies and analyzes each project's risks and returns before committing significant funds to a project.
  - The *control phase* ensures that, as the investment is implemented, the project continues to meet mission needs at the expected levels of cost and risk.

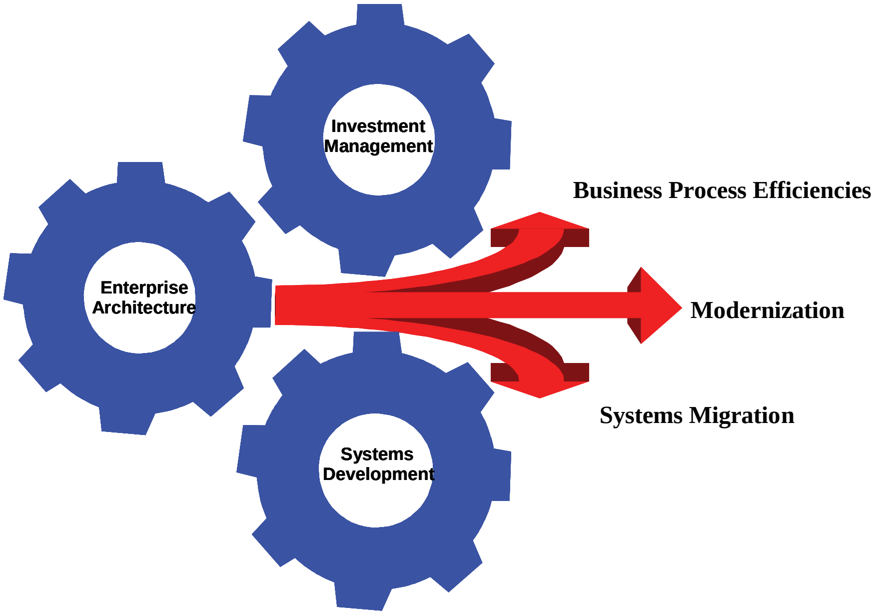
  - The *evaluate phase* compares actual vs. expected results for the implemented project.
- **System development life cycle:** A system development life cycle (SDLC) program provides guidelines and procedures for system acquisition, development, implementation and deployment, and project management. The SDLC guidelines address such areas as configuration management, risk management, requirements management, design, acquisition management, test management, and quality assurance throughout the life cycle of a project from its inception to its completion. The SDLC supports the organization's enterprise architecture and investment review processes by providing guidance for selecting appropriate methods, techniques, and tools based on specific organizational and project factors.

Figure 1 expresses an IELC that encompasses investment management, enterprise architecture and systems development (SDLC). Key components of the enterprise life cycle are discussed in the next sections.

Integrated enterprise architecture, investment management, and systems development processes are similar to a set of gears whose output is greater then the sum of the parts. The enterprise architecture provides the structure and vision as to where the organization is and where it needs to go. The investment provides the IT governance, discovery, selection, and control for the portfolio of initiatives that are needed to acknowledge the enterprise architecture target vision. For each of the individual initiatives, a system development life cycle methodology provides standard detailed guidelines for project managers. The investment management process, enterprise architecture, and systems development life cycle (SDLC) should be highly integrated to ensure projects have the needed process support.

To be most effective, these enterprise processes need to be highly integrated with multiple touchpoints. For example, to maintain alignment

Figure 1. Integrated enterprise architecture, investment management, and system development



with the organization's goals and objectives, the investment management processes should perform portfolio management to select, prioritize, and control its key IT initiatives, as this highly influences and is in turn influenced by the target enterprise architecture including its business, application, data, and technical dimensions. As new initiatives are proposed, they need to be mapped against and comply with the enterprise architecture. (Armour et al., 1999a; Armour, Kaisler, & Liu, 1999b). New initiatives are guided by the organization's defined architectural principles. (Lindstrom, 2006; Open Group, 1999) As these initiatives are developed and implemented, they need to follow an organizationally defined system development life cycle (SDLC) that specifies the project management and technical activities. The SDLC has touchpoints with the enterprise architecture to ensure that an initiative's evolving requirements, designs, and technology continue to adhere to the target enterprise architecture. In addition, the SDLC specifics integration points to the investment management process in such areas as project status reports to a project review board and risk management. This chapter identifies the process integration and touchpoints from the perspective of the enterprise architecture and outlines an overall IELC process flow. The outcome of the IELC is improved business efficiencies and more efficient system mitigation and modernization. Without an IELC:

- Organizations will have a difficult time aligning IT initiatives to strategic business goals and objectives.
- These initiatives will tend to be selected and developed in isolation of each other.
- Ongoing initiatives will not have the needed project and program oversight to ensure that they adhere to their functional cost and resource metrics.

The organization's mission and business objectives provide the key input into the IELC. They can include the organization's mission, vision, business drivers, strategic goals, strategic business objectives, information needs, IT vision, IT objectives, and guiding architectural principles. This business direction is used as a guidance tool and remains relatively stable over time. It is critical that alignment among IT applications and technology and the organization's mission and objectives be defined and maintained throughout the entire IELC. In this chapter, we use the investment management process as the framework to demonstrate the integrated of the investment, enterprise architecture, and SDLC activities.

Throughout this chapter, we will use an example to combine the concepts in this chapter with an example of a technology implementation. The example we will use is the implementation of an asset inventory system that will support the business on managing their assets.

INTEGRATED ENTERPRISE LIFE CYCLE ORGANIZATION

For an organization to fully implement and institutionalize the IELC there needs to be:

- Leadership and strategic direction, whether the organization is a sole proprietorship or a Fortune 500 company, are required to ensure the services, products, and processes are completed. Leadership and strategic direction are demonstrated by having a viable Investment Review Board (IRB), a Modernization Board, and the enterprise architecture.
- Process controls are needed that include information security, project management, SDLC, change/configuration management, and data management. These are among the normal components that should be in place to manage repeatable and ever improving processes for business efficiencies. Many individual companies use the CMMi as a

way of providing a guide to creating and maintaining those processes.

- The final key element is financial control through investment management and quality assurance processes. These two elements ensure appropriate use of funding and ensure that the processes being used by the organization are followed and efficient.

With these three elements, your organization starts to have the components needed to establish an IELC. From financial management to strategic direction to controlling the quality and security of the product, the IELC ensures that the support mechanisms are in place.

To implement the IELC, an integrated organization needs to be created. The components of the organization that will be discussed in this chapter include the following in Table 1.

Table 1 lists the organizational components of the IELC. The Investment Review Board is made up of key leadership positions representing the head of the organization, the business units, the chief financial officer (CFO), and the chief information officer (CIO). This board ensures that the strategic direction, transition plan (sequencing), and the prioritization of scarce resources are allocated to the correct portfolio.

For example a proposed asset control system that is presented to the IRB will have an executive sponsor, a project management team, and an implementation team that combines technical staff from the CIO and business subject matter experts from the business unit(s).

IELC INVESTMENT MANAGEMENT PROCESS

The Investment Management Process (IMP) is a fluid, dynamic process by which an organization monitors proposed and ongoing IT investments throughout their life cycle. The process evaluates IT investments to assess the impact on future initiatives and to benefit from any lessons learned. The IMP contains three phases—select, control,

Table 1. IELC organizational components

Organization component	**Role/Responsibility**
Investment Review Board (IRB)	Directs the strategic direction of the transition plan; approves the portfolio; assigns executive sponsorship; and sets priorities for the organization.
Office of Information Technology (OIT) (or similar organization)	Responsible for leading the planning, acquisition, implementation, operation, and management of the automated information systems.
Modernization board	Responsible for establishing and maintaining the organization's enterprise architecture reviews project proposals to ensure alignment with the enterprise architecture as part of the funding process researches new technology.
EA program office	Provides architectural oversight of all EA and SDLC projects.
Enterprise Architecture (EA) executive steering committee	Provides IT technical and managerial oversight of the EA.
Project Review Board (PRB)	Project oversight; oversees all projects assigned to OIT; monitors schedules, costs, and risks.
Information technology outreach	Coordinates with stakeholders; receives feedback on issues and progress.
Change Control Board	Addresses SDLC change issues/requests.
System Development Life Cycle methodology	Quality assurance and system development guidance

and evaluate as defined earlier in this chapter.

The IMP has been designed to scale to the unique characteristics of the information technology projects. The steps are grouped into the three phases—select, control, and evaluate to align with the investment management framework. The process described in this section is intended as a starting framework for an organization. An organization, based on such factors as size, culture, and the external environment that it operates in, should be prepared to adjust and modify this process to meet its specific needs.

THE SELECT PHASE

The first phase of the IMP includes procedures for ranking and selecting new investments and related projects based on several factors including costs, value, risk, alignment with the enterprise architecture, and the portfolio.

The activities in the select phase help to ensure that there is a solid alignment with mission and business needs and that the investments will fit within current portfolio of IT investments. This phase also provides an initial determination of the oversight level and validates whether an IT investment meets all technical and project requirements. Figures 2 and 3 highlight the key activities within the select phase; the activities are discussed in more detail next.

Yearly/Annual Budget Formulation-Select Phase Process

Before the start of every fiscal year, a budget formulation process determines the approved, baselined IT portfolio for the coming year. The yearly/annual budget call begins with a call for new projects or a renewal of projects for the next fiscal year. The OIT, working closely with the business stakeholders, compiles the projects into a proposed IT portfolio. The proposed IT portfolio is then submitted to the investment review board (IRB). The IRB reviews and analyzes the IT portfolio, making any needed adjustments to the portfolio (based on such factors as cost, benefit, risk, and priority) and approves the IT portfolio for the upcoming year. The portfolio is then baselined to include costs, alignment, as well as conformance with the enterprise architecture transition plan to that demonstrates the transition from the current state of business to the to-be state of the business.

For example, if an asset management system had been proposed, it could be selected as an item for development during this process and be weighed against other processes. If the IRB approves the development of a new asset management system, then a formal project would be started. In order for the IRB to make that determination, a concept of operations, a costing proposal, and a cost benefit analysis would be included in a business case for the initiative. The

Figure 2. Annual investment review select phase

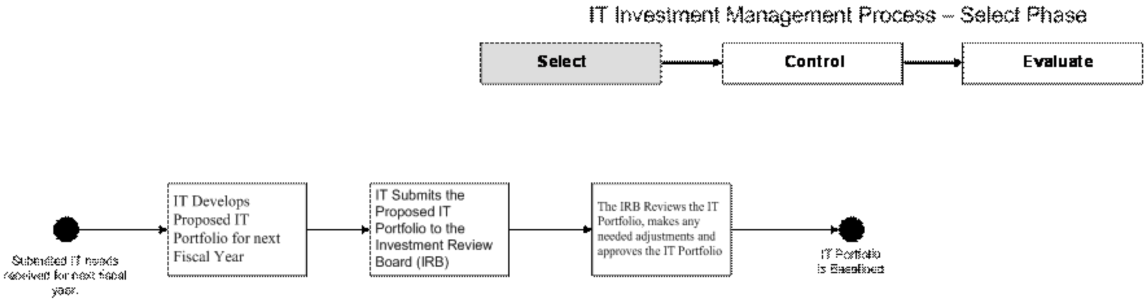


Figure 3. Ongoing investment review select phase

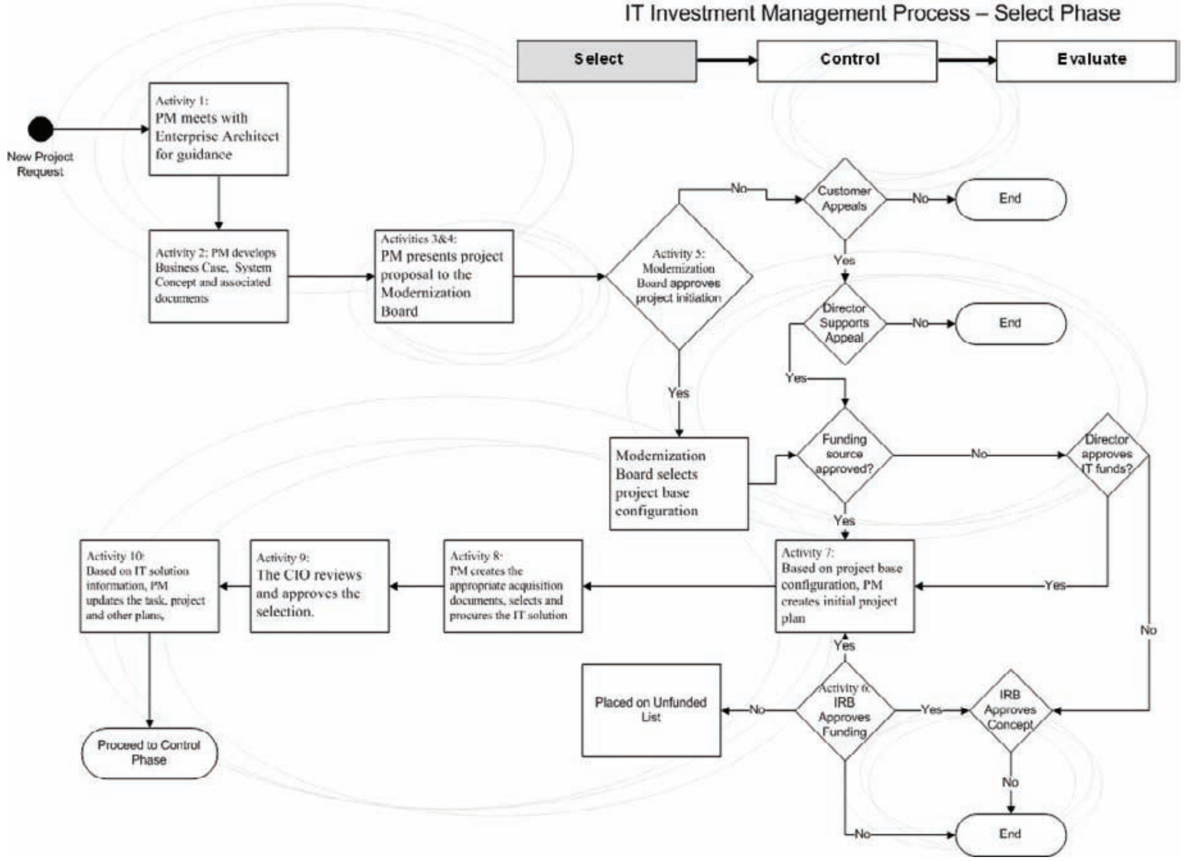


business case would also address how the initiative is aligned with the enterprise architecture's target vision, architectural principles, and the appropriate EA technical standards. Ranking of the project should be from the IRB only after the CIO has had an opportunity to review and pre-rank the projects.

Ongoing Select Review Process

During the fiscal year, when a new IT project request is received, the following ongoing select review process occurs as depicted in Figure 3. This includes reviewing the EA transition plan (Armour & Kaisler 2001) to ensure that integration points are not out of sequence as timetables, costs, and deliverables change. We will assume that an asset management system has been proposed as a new IT project in the following discussion.

Activity 1: Initial Project Setup Meeting

The project manager meets with the Enterprise Architect and Modernization Board representatives for guidance on the project approval process[1]. The EA and Modernization Board representatives, based on the initial understanding of the project's scope and characteristics, provide the project manager with guidance and advice that includes, but is not limited to:

- Initial advice on ensuring conformance with EA target vision and alignment with goals, objectives, and business processes.
- The needed documents for the Modernization Board review such as new project request form, system concept, cost benefit analysis, and feasibility studies.
- Advice on engaging additional stakeholders.
- Initial review to determine if the proposed effort is already part of the IT portfolio.

The system development life cycle (SDLC) methodology is used throughout the IMP to provide guidance and documentation support to the project manager. The SDLC also ensure cost controls during the project by creating natural milestones for financial review. At this time, the asset management system would be an outlined proposal.

Activity 2: Develop a Business Case

The project manager develops a business case for the Modernization Board for review and inclusion into the proposed IT portfolio. Other documents that may be submitted but are not necessary include a detailed costing proposal, concept of operations, detailed cost/benefit analysis, and resource plan. The business case is a means for the business community to engage and ensure that the asset management system they are proposing has the buy in of its stakeholders and the IT community. Some key questions that should be answered by the business case include:

- Will the asset management system supporting the goals and objectives of the organization?
- Does it make fiscal sense to build an automated system?

Activity 3: Submit Business Case to the Modernization Board

The project manager submits the request for a new project to the Modernization Board. The request must be submitted with all associated documents prior to the review meeting in order to allow sufficient time for the Modernization Board review.

The requestor will also work with a Modernization Board representative, the sponsoring office, enterprise architect, a senior CIO representative, and the designated project manager to score the project against a pre-defined set of value and risk criteria and to determine the base project configuration. The project manager and sponsoring office representative present the business case to the Modernization Board.

Activity 4: Presentation to the Modernization Board

Requests for new or upgraded IT projects are initially presented to the Modernization Board, which either approves the item as being in alignment with the enterprise architecture (EA), agrees to grant a waiver for the item or denies the request, possibly with a request for modifications before resubmittal. The Modernization Board will bring in stakeholder subject matter experts as appropriate to provide input on proposals.

When the Modernization Board reviews the business case, it is specifically reviewing it with the following in mind:

- Determines if the project adheres to all elements of the enterprise architecture such as architectural principles, business roles, technology standards, application data, and security principles.

- Determines key risks on the project and recommends how to address them.
- Determines if the project fits within the IT portfolio (for cost, risk, benefit, and priority).
- Determines if the project aligns with the organization's goals, objectives, and business processes.
- Recommends a base SDLC project configuration template to use. Example templates include small project, medium project, and infrastructure project.
- Determines a project's mission criticality.
- Determines if IRB approval is needed.
- Provides other guidance as needed.

Activity 5: Modernization Board Approval

The Modernization Board approves/disapproves the project. If the project is approved, it is added to the IT portfolio. The Modernization Board can also ask that it be resubmitted with modifications or additional information.

If the project is denied, the project requestor has the right to appeal to the IRB or executive agent of the organization along with the signature of the CFO and the CIO, for a final and binding decision. A waiver will be granted only by consensus (consensus in the context of this document means the majority opinion of the Modernization Board). Generally, waivers are decided on a case-by-case basis, but a few possible reasons are:

- Replacement of existing proprietary technology where it would be too expensive to convert to an entirely new set of platforms (hardware, software, telecom).
- Only one vendor provides the necessary functionality (with a proprietary system) and this can be justified based on cost, schedule, or satisfying certain unique requirements. Or if it would be too costly to customize a commercially available package to meet the requirements.
- The system is required to interface with an externally provided system that uses proprietary technology which is mission critical to the.

If the project under consideration has an impact on the EA technical reference model (TRM), the Modernization Board will determine, based on project characteristics such as risk, cost, and benefit, whether to accept or reject the proposal and what updates, if needed, will be made to the TRM. The Modernization Board will then make the final determination of proposal acceptance or rejection.

In our example, the asset management system will need to develop a proposal for purchase or development of the system. During that time, the approval of the Modernization Board would help mold that proposal based on the current technology investment, standards, and costing for the project. The asset management system may have constraints because it has to integrate with the financial system. If so, during the impact analysis with respect to the EA, the asset management system may have additional requirements added to the scope of the project including business functions as well as technical integration requirements.

Activity 6: Investment Review Board Approval

Once a project has been approved by the Modernization Board, and if it is a project that requires funding beyond what the organization can accommodate in its current budget, it will go to the IRB. The project manager will present the business case along with a concept of operations, cost benefit analysis, and feasibility study to the IRB. Projects that need funding are addressed under two scenarios: During the annual budget cycle (new project requests) and previously unplanned projects that come up during the year (e.g., new legislation, technology no longer supported by vendor, etc.) for which funding is not available.

The IRB will vote to approve or deny funding. If denied, the business unit may appeal to the CEO or head of organization based on the merits of the project. However, the CIO and the CFO as official stewards of information technology and financial management must be included. It is important that these appeals be reflected in the EA transition plan as well as the target enterprise architecture to reflect the decisions by senior management. The CEO or head of the agency that approves this may ask for an impact analysis by the enterprise architect to have an independent view of the impact to the organization as a whole.

For example, the EA transition plan may show that a delay of the acquisition of an asset management system is required if the business functions are not completely defined or the development of other systems have not been done that have more strategic importance. The enterprise architect would discuss with the CIO with IRB the relationship between systems and develop a transition plan that would help ensure the successful completion of the portfolio. The asset management system may be delayed if a major shift in the financial system was going to be done the same year because of risk or cost.

Activity 7: Initial Project Plan Development

Based on project characteristics (size, risk, etc.), the project manager develops the initial project plan, initial task plan (WBS), and other associated documentation. The focus on initial project plan is detailed planning for the upfront procurement and analysis activities. The project task plan is entered into a project management tool. (*Note: Regular PRB status reporting starts at this point*). The asset management system project plan would be input here.

Activity 8: Acquisition and Source Selection

Working with procurement, the project manager creates the appropriate acquisition documents and selects and procures the IT solution. This a strong touchpoint to enterprise architecture. Part of the acquisition and source selection of a tool or product to automate a process should be reviewed by the enterprise architect to ensure coherence with the future alignment of the business and the technology.

This is an iterative process because the business subject matter experts should ensure the system works for them. The OIT should ensure that the systems are interoperable and the CFO before the signature of the selection should ensure that it is fiscally responsible. The asset management system acquisition cycle should include those reviews to ensure business function, financial feasibility, and system integration are included.

Activity 9: CIO Approval

The CIO (senior IT manager) and executive sponsor (business unit representative) review and approve the selection to ensure that the IT solution continues to align with the goals, objectives, and business objectives.

Activity 10: Updated Project Plan

Based on IT solution information, the project manager updates the task, project, and other plans and updates them in the project management tool. As the project plan changes, deviations greater than 5% require that the enterprise architect check to see if the EA transition plan is being impacted.

THE CONTROL PHASE

The control phase of the IT investment management process provides the consistent monitoring of ongoing IT projects, reprioritizing them as conditions change, and re-selecting them for continued funding. This phase ensures that the project remains aligned and compliant with the EA.

The control phase focuses on oversight and review of a project from requirements validation through implementation. The purpose of this phase is to ensure that the project manager manages and implements the approved project in a structured manner, using sound management practices and ensuring involvement of all key parties. Each approved investment must ensure:

- Continued compliance of the proposed solution with the enterprise architecture.
- Ensure that the project adheres to the SDLC.
- Ensures scope is maintained during the project design and implementation.
- Continued alignment with goals, objectives, and business processes.
- Compliance with the systems development life cycle processes (project planning and management, requirement management, configuration management, quality assurance, testing, contractor management, etc.).
- Compliance with systems security standards and requirements.
- Continued viability assessed by compliance with project costs, schedule, and performance measures.

The project review board (PRB) has primary responsibility for ensuring that the project manager properly manages investments on an ongoing basis. Projects will continue to draw on and utilize the SDLC for direction in these areas. The IRB ensures that the investment continues to meet business and mission objectives and address any critical issues related to these. Figure 4 highlights the key activities within the control phase; the activities are discussed in more detail next.

For example, the asset management system that was purchased may have financial functions for deprecation and for investment cycles. This is where the IELC is of great value. The enterprise architect, the business subject matter experts, executive sponsor, and the project manager would work with the vender and the business units involved to resolve where the functions of the financial management of assets belongs. If the original concept of operations didn't include this business function, then the Modernization Board would review the scope change and recommend to the IRB a change. If the business function is automated in another system then it is hoped that the concept of operations included an integration point, if not then a change of scope would happen again. The enterprise life cycle should be flexible enough to include these changes.

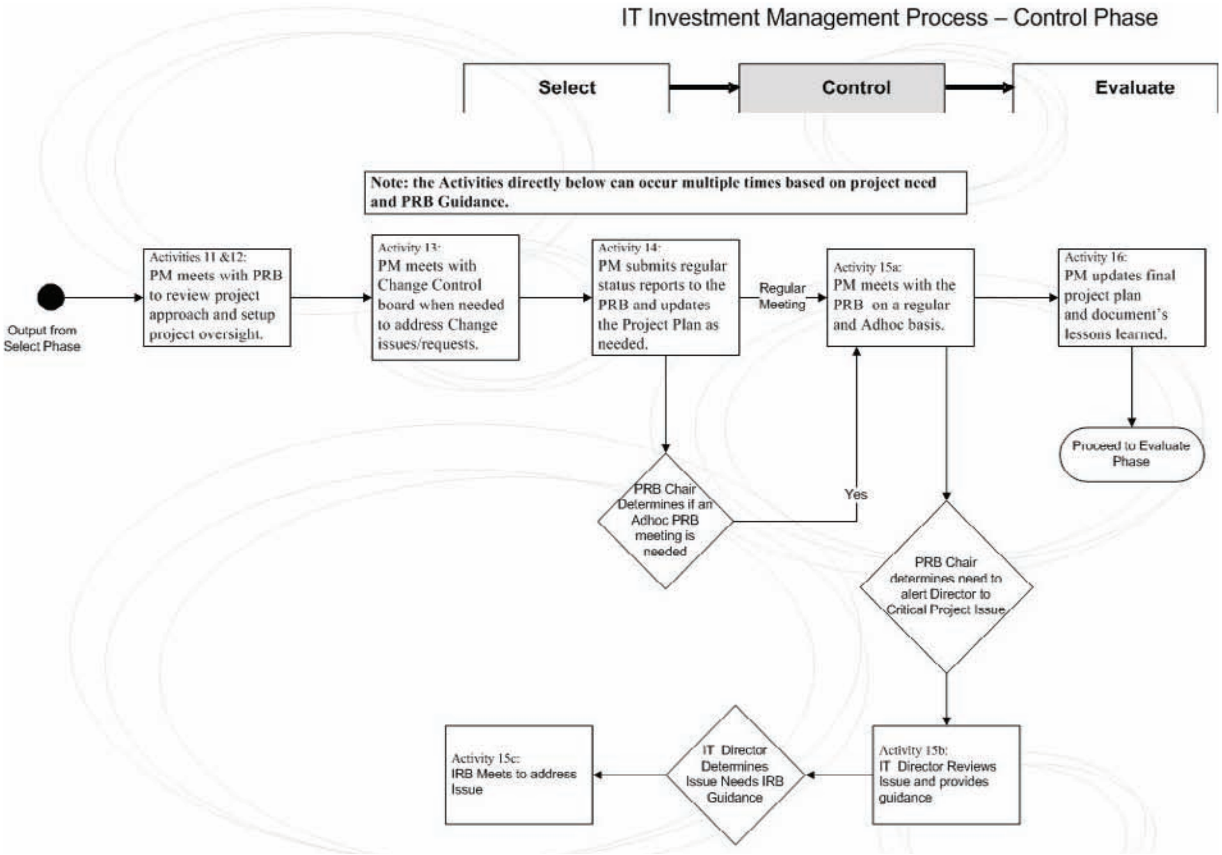
Activity 11: Initial Project Review Board Review

The project plan and any associated information is submitted to the PRB. The project manager meets with the PRB to review project approach and setup project oversight including project review schedules, as well as SDLC artifacts and activities. The PRB provides input, guidance, addresses risks, determines review gates, and approves the project. In the case of the asset management system, the PRB may identify a scoping issue that would be sent to the modernization office.

Activity 12: Baseline Project Plan

The updated initial project plan is baselined. At this point again, any changes to the associated milestones or resource allocation changes should be reported to the enterprise architect to ensure that the sequencing plan is updated and dependencies are reviewed. If there are financial impacts those should be submitted to the financial management office to ensure funding is available.

Figure 4. Investment review control phase



Activity 13: Change Control Review

The project manager meets with Change Control Board (CCB) when needed to address change issues/requests. (*Repeated throughout the project as needed*). The role of the change control board are to maintain the integrity of the system life cycle during the life of the project. This includes the documentation, code, and requirements during the design and implementation of the system.

Activity 14: Project Status Reporting

The project manager submits regular project status to the PRB chair. The PRB chair may, based on the status reports, initiate a meeting with the project manager and/or call a PRB review. Project status reports and any actions taken are captured for program management reporting. (*Repeated throughout the project*). A copy of the project status report should be given to the enterprise architect and a full project status review should be conducted if the deviation from the baseline is greater than 5%.

Activity 15: Project Status Review

The project manager meets/informs with the PRB based on a regular and adhoc review schedule. The PRB will review the project deliverables and provide guidance. The enterprise architect will continue to monitor the project during these reviews to ensure continuing EA alignment. During this activity, the appropriate SDLC artifacts are reviewed (e.g., project plan, requirements documents, design documents, test plan, etc.) to determine their quality and provide feedback and guidance to the project team. (*This activity is repeated throughout the project as needed*).

If the PRB chair determines that the project has incurred such risks or issues that a higher-level review is required, the CIO is alerted. The CIO will review the project status and provide direction and guidance. If however, there are critical risks and issues that will significantly affect the project's outcome and alignment with business objectives and performance measures the IRB will be alerted.

The IRB may review the project, its progress, and issues and make a determination as to corrective action, including cancellation of the project. This review can be requested at any time.

Project statuses and any actions taken are captured for program management reporting.

Activity 16: Update Final Project Plan

At the conclusion of the project, the project manager will update the final project plan and document the lessons learned.

THE EVALUATE PHASE

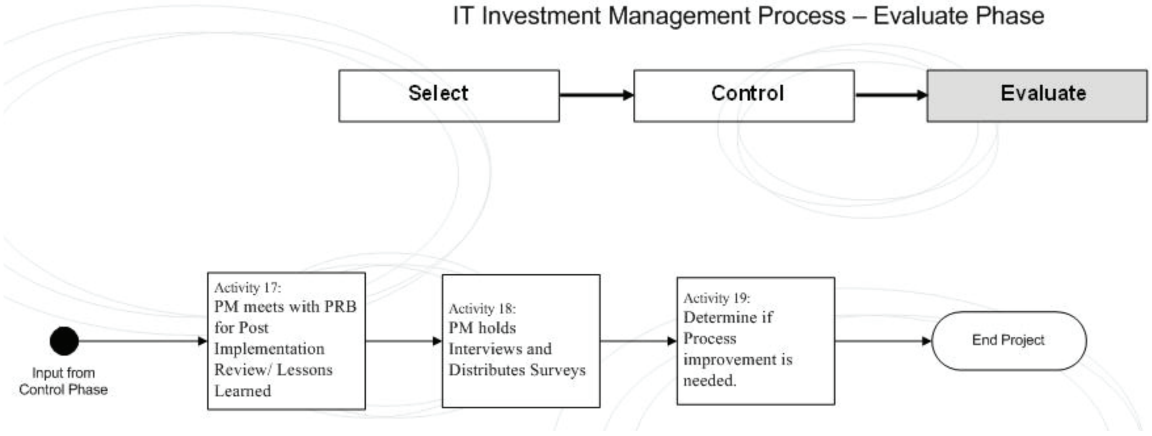
The final phase of the investment management process is the evaluate phase. A "lessons learned" (post implementation review (PIR)) meeting will be held to evaluate completed projects, a set of user satisfaction interviews/surveys will be performed, and any needed process improvements will be recorded.

Information captured will:

- Include best practices used in completing tasks in an effective and efficient manner, as well as suggestions on activities to be modified.
- Feedback on the application of the SDLC, its artifacts, and activities.
- A final assessment of a project's impact on commission the completed project.
- Capturing measurements of actual vs. projected performance.
- An updated EA based on the deployed project's impact to the organization's business, technical, and information characteristics.

The lessons learned will be feedback into the selection and control phases. The main goals of

Figure 5. Investment review evaluate phase



the evaluate phase will be to answer the questions "Were the business objectives accomplished by completing this project?" and "Were the means the most effective and efficient way to get to the end result?" Adjustments to the investment review and project monitoring process will be made. In addition, baseline project plans and costs will be compared to the actual project timeline and cost in order to improve future estimation efforts. Figure 5 highlights the key activities within the evaluate phase; the activities are discussed in more detail next.

This step is not just a review of the project but also the associated processes to ensure that they are efficient. The evaluation process should include answering the question of whether the IELC was cost effective and reduced business risk. This question is both objective as well as subjective so the evaluation should be a quantitative as possible.

In our example, the asset management system was have been deployed at this point. Like most projects, the implementation of the system had surprises along the way at this point the IELC processes could be improved. For an example, a change in scope may demonstrate that a more detailed concept of operations should have been done before the start of the project. The requirements may not have been fully vetted and that caused a change in scope or missed requirements, which had an impact on costs.

At this point, it is important to also review any gaps in business processes or in integration to ensure that the next review of the portfolio reviews these business functions. Finally, an evaluation of the cost benefit analysis should be performed to see if the automation improved the business function.

Activity 17: Post Implementation Review/ Lessons Learned (PIR)

The project manager will meet/submit with the OIT Deputy Director/PRB for the project closeout meeting. The project manager will submit the final project plan, lessons learned, and completed system user and technical documents for review and closeout approval.

Activity 18: Surveys and Interviews

Perspectives and insights of project participants, executive sponsor, and sponsoring business and end users, is also collected through:

- Surveys and interviews of end users, customers, project management, project staff, contractors, and developers.
- Project management and staff interviews.
- Interviews with senior decision makers involved in investment oversight.

Activity 19: Process Improvement

Information from the quantitative data, the post implementation review, and the surveys are used to make adjustments to the investment management process. In addition, baseline project plans and costs will be compared to the actual project timeline and cost in order to improve future estimation efforts. These reviews and post process analysis are often over looked so organizations become habitual in these inefficiencies. It is strongly recommended that just like a financial audit of an organization, the organization ensures that post implementation reviews are done to look at the health of the internal controls and systems.

CONCLUSION

Throughout this chapter, we have discussed the integration of the enterprise architecture, investment management process, and the system development life cycle. While we did this via an investment management framework of select, control, and evaluate, the critical aspect is the actual integration itself. Whatever approach an organization takes, it should be aware of the importance of the overall IELC and the multiple integration and touchpoints between the activities that make it up.

Going forward, the U.S. Office of Budget and Management (OMB) has issued and continues to evolve a set of enterprise architecture reference models (FEA) (OMB, 2005) that address the business, application, data, service component reference model, and performance dimensions of an organization. Organizations are expected to develop and specify these views (both baseline and target) and formally document how a proposed application will adhere to them in its business case. An organization is then expected to track the performance of initiative as it progresses to ensure that it remains in alignment with the views. At the same time, the U.S Government's General Accountability Office continues to evolve its investment management maturity framework (GAO, 2004) that addresses how IT projects are determined, tracked, and controlled.

Section II

Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of strategic information systems. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful management information systems, data warehouses, and decision support systems are discussed.

Chapter 2.1

Strategic Technology Engineering Planning

Tony C. Shan
IBM, USA

Winnie W. Hua
CTS Inc., USA

ABSTRACT

This chapter presents a methodical strategic technology engineering planning (STEP) approach, to effectively cope with the design complexity in service-oriented architecture and manage the strategic planning of solution development of information systems. This holistic model comprises four modules: Want-Is-Target (WIT) model, Transition and Alignment Grid (TAG), Comprehensive Architecting Process (CAP), and Joint Analysis & Roadmapping (JAR). The characteristics and features of the constituent elements in the STEP model are articulated in great detail. The WIT model defines three stages of architecture states – current, target, and end state. TAG specifies two dimensions for architecture planning, namely current-to-future state transformation and IT-to-Business alignment. CAP presents an overarching method for step-by-step engineering and design in system architecture and portfolio optimization. JAR comprises the best-of-breed strategic analysis techniques, accompanied by a hybrid method with strategy-driven and initiative-driven planning streams. Applying the framework in planning and future trends are also discussed in the context. This overarching framework provides a comprehensive multi-disciplinary approach to conducting strategic and tactical technology planning for both near-term needs and long-term goals.

INTRODUCTION

The e-business models in today's dynamic business world demand increasing flexibility and responsiveness of information systems applications. It becomes mandatory for the information technology (IT) group in an organization to provide a higher level of services and better quality products at a lower cost for the business to compete and succeed in a globalized economy. The reality is that IT must build more complex, interoperable, scalable, reusable, innovative, forward-thinking, and sustainable technical solutions, to satisfy the ever-growing business needs.

Most large companies like worldwide financial institutions have built, acquired, or purchased virtually hundreds, if not thousands, of IT systems through the years to provide electronic services for external customers and internal staff, resulting in heterogeneous technologies and architectural platforms to satisfy diverse functional requirements from different lines of business. In the banking industry, the business process generally contains different business sectors that address retail, small business, commercial, corporate investment, wealth management, and capital management markets. In particular, services are delivered through a variety of channels. In order to effectively manage the architectural assets and design high-quality IT solutions in such a diverse environment, a highly structured methodology is crucial to achieve an array of goals – separate concerns, divide responsibilities, encapsulate complexity, utilize patterns, leverage best practices, control quality, ensure compliance, and establish operationalization processes.

A majority of today's information system development planning is still ad hoc, manual, subjective, incomprehensive, and error-prone, which inevitably leads to chaotic outcomes and failures in the execution. According to recent surveys, a vast majority of information systems projects are behind schedule, over budget, or canceled. A lack of a systematic framework describing the key design practices and disciplines in the planning of service-oriented information systems is a major cause of this situation.

A new model is proposed in the next section, with more detailed descriptions of the key characteristics and features of the components presented in the section that follows. The subsequent section discusses how to apply the framework in planning, followed by sections on future trends and related work. The chapter is concluded in the last section.

BACKGROUND

Most of the previous architecture planning methods reveal the architectural aspects of a software application to some extent at a fairly high level or from a restricted perspective. A comprehensive approach to architecting the end-to-end information system solutions has become a necessity, calling for a systematic disciplined mechanism. To meet this growing need, a highly structured method is designed in this article to present a comprehensive and holistic view of the core architectural elements, components, knowledge, platforms, planning, and their interrelationships. Design procedures are established accordingly in this methodical approach to facilitate the creation, organization, and management of the architectural assets and solutions at different levels in a large organization.

Design Philosophy

Developing the disciplined mechanism followed a set of key design principles, partly derived from TOGAF (The Open Group, 2008), but significantly modified/expanded to be tailored to the services-oriented development process of information systems.

Business Principles

- ***Primacy of principles***: All stakeholders and relevant groups in an organization must follow these principles of technology planning.
- ***Maximize benefits***: Maximum benefits will be achieved for the entire organization, rather than individual divisions.
- ***Business continuity***: Business operations are not interrupted despite system and process changes.
- ***Active engagement***: All stakeholders are actively involved in the process to accomplish business objectives.

- ***Compliance with regulations***: The architecting processes comply with all relevant regulations, policies, and applicable laws.
- ***IT accountability***: The IT group owns and implements the IT processes and infrastructure that build solutions to satisfy business requirements for functionality, service levels, cost, quality, delivery timelines, and operations supports.
- ***Innovations***: The stimulation and protection of the corporate innovations is enforced in the IT architecture, design, management, and governance processes.

Technical Principles

- ***Flexibility***: The technical model is agile and adaptive to be nimble in quick response to future business needs.
- ***Incremental change management***: Changes to the corporate architecture/infrastructure environment are planned and implemented in a phased approach.
- ***Requirement scope control***: The scope creep and waterfall approach are avoided.
- ***Technology standardization***: Technological diversity is controlled to minimize immature and proprietary products, platforms, and solutions.
- ***Interoperability***: Software, hardware, network and infrastructure should conform to established standards and policies that promote compatibility for data, applications, services, communications, integration, security and technology.

Solution Principles

- ***Ease of use***: Solutions are straightforward to implement and use. The complexity of the underlying technology is abstracted from users, so they are able to focus on business functionalities and processes.
- ***Technology independence***: Technical solutions are immune from specific technology choices and hence can run on different technology platforms.
- ***Common services and processes***: Minimize the redundant development of similar functionalities to promote common services and processes across the organization.

Data Principles

- ***Data asset***: Data is an asset that has a business value to the enterprise and is managed in a federated fashion.
- ***Data ownership***: Each data element is owned by an entity accountable for the data quality.
- ***Common vocabulary and metadata***: The data definition is consistent throughout the organization, and the metadata are standardized and available to all authorized users.
- ***Shared data***: Data is shared across business lines for individual applications and systems to perform their duties.
- ***Data access***: Data is accessible for users to perform the business transactions.
- ***Data security***: Data is protected from unauthorized access and disclosure. This includes the protection of pre-decisional, sensitive, and proprietary information, besides the traditional aspects of national security classification.

General Model

The Strategic Technology Engineering Planning (STEP) approach is developed in this article as a multi-disciplinary framework. It defines a comprehensive analysis and planning method to control the application design and development practices for the quality delivery of information systems. The *STEP* model is a holistic structure to facilitate analyzing and optimizing the strategies, thought processes, methods, tradeoffs, and patterns in the IT design.

STEP forms a foundational knowledgebase to plan service-oriented architecture, integration, process and management in information systems. Its primary focuses are on architecture, execution environment, application frameworks, domain modeling, business process, information, integration, methodology, system management, security, quality of services, and governance. *STEP* is a cohesive set made of four modules, as illustrated in Figure 1:

- ***Want-Is-Target (WIT) Model***: a triangle model intended to denote the staged approach of technology evolution and interrelationships of the constructs and artifacts in the strategic technology engineering planning, and further build consensus with regard to the roles and responsibilities in the planning process.
- ***Transition and Alignment Grid (TAG)***: a quadrant model with two dimensions for technology migrations from current state to future state, and seamless IT-to-business alliance.
- ***Comprehensive Architecting Process (CAP)***: an overarching method for the step-by-step engineering and design in system architecture and portfolio optimization.
- ***Joint Analysis and Roadmapping (JAR)***: a pragmatic analysis technique for all stakeholders and parties, and subsequent future planning to construct a roadmap and action plans.

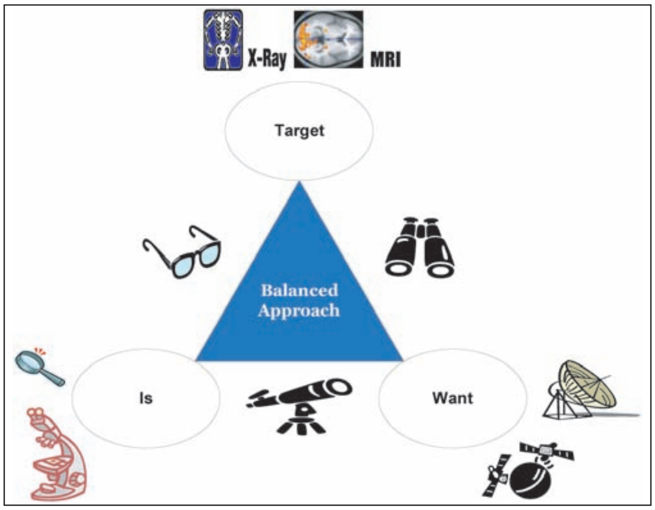
STEP FRAMEWORK CONSTITUENTS

Want-Is-Target Model

The Want-Is-Target (WIT) model for IT planning is shown in Figure 2. In spite of its apparent simplicity, the value of the model is actually its strength of abstraction at a high level. The “Is” component represents the current-state architecture we have built or acquired via mergers. The “Want” component describes the end-state architecture we wish to have in the long run. The “Target” component prescribes the target-state architecture that is feasible and reachable in the near future. The target state phase is typically a tactical approach to migrate the exiting portfolio to a strategic position through a multi-generation plan in an incremental fashion.

Figure 1. Strategic technology engineering planning

Figure 2. Want-is-Target model



To fully understand the existing situation, investigate the near-term possibilities, and explore the long-term potentials, it is not only important but also necessary to leverage tools to help analyze and investigate the details in depth. As an analogy, various tools are illustrated in the diagram. For example, when evaluating the "Want" component, a telescope is needed to see things from a distance, whereas a pair of eyeglasses may be sufficient to observe the near-term state. On the other hand, in order to inspect greater details of the "Is" component, a microscope is necessary as a magnifying glass would not reveal the fine points at the level of granularity desired. Nevertheless, these tools still can not disclose the internal structure. To overcome this limitation, more advanced tools must be used, such as X-ray or Magnetic Resonance Imaging (MRI) instruments. Likewise, more sophisticated tools (radar and satellite) augment what a telescope is capable of providing.

In reality, it is not uncommon that, due to time constraints and lack of acquaintance with tools, different parties misuse tools inadvertently from time to time when investigating various aspects in different domains. It is, however, critically important to utilize appropriate tools to look into the details of the components for analysis and synthesis. The metaphor indicates that we need not only "do things right", but also "rely on right tools to help do things right". Some tools, methods, and techniques for strategic planning will be articulated further in the sections that follow.

The Balanced Approach, represented as a triangle in the middle of the diagram, is the architecture planning process that balances the pros and cons, and resolves the conflicts with tradeoffs and compromises to lay out a reasonable path to the needed changes. Usually the balanced approach takes a hybrid approach to meet the immediate needs in the near term, but still aligning the architecture efforts with the strategic goals and vision.

Arguably, the most important factor in the strategic planning efforts are the "Stakeholders", which are all of the relevant people who have impacts on or are significantly affected by the architecture decisions and changes. The key stakeholders comprise the client users, business partners, business analysts, architects, developers, testers, system administrators, DBAs, network engineers, system managers, security specialists, risk officers, vendors, standards organizations, legal entities, consultants, and other subject matter experts. They may be for a change, be against it, be neutral, or not even know about it yet. Due to the different interests, relevant expertise, and roles played from various parties, the decision-making process must inevitably deal with conflicting forces and factors.

The process to establish the inventory of the "Is" component and define the models of the "Want" and "Target" components in a large organization is typically iterative. The current, end and target states can be represented in various formats from different viewpoints, such as business, technology, infrastructure, risk, finance, compliance, and standards.

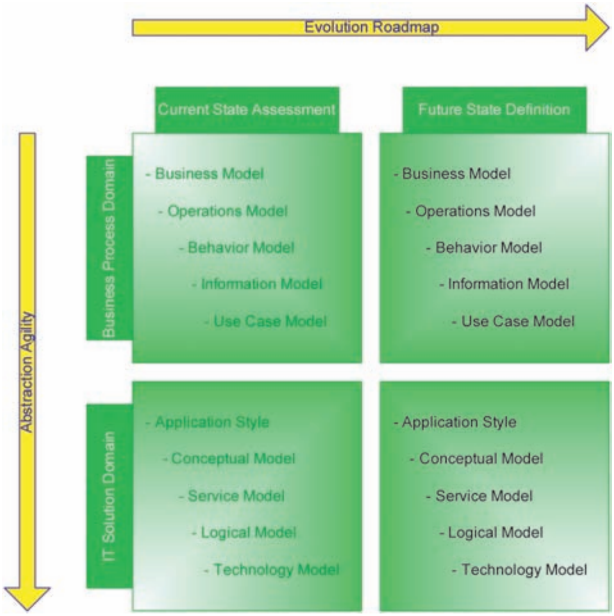
Transition and Alignment Grid

Based on this triangle model, a Transition and Alignment Grid (TAG) is constructed to identify the key artifacts and design concerns in technology planning, as depicted in Figure 3. There are two dimensions defined – current-to-future state transition, and business-to-IT alignment.

In the transition dimension, the "Is" component is mapped to the current state assessment, which collects the input data and analyzes the existing environment. Similarly, the "Target" and "Want" components are mapped to the future state definition, which combines the vision of the near-term state and the end state. The future state specification serves as a blueprint of the desired form. The gap analysis is subsequently conducted to bridge the three states. A roadmap is thus defined to transit the current state to the future state in a controlled manner. Usually the transitions are staged in multiple phases in an incremental fashion. Depending on the timeframe desired, the end state vision is typically strategic and targeted to the long term. However, tactical solutions are often needed to deliver required business functionalities in a short period of time. This creates a dilemma between the strategic and tactical needs. It is of vital importance to have the end-state vision well defined, so that the strategic goals are not deserted when pragmatic approaches are crafted for the short-term demands in the target state.

This approach serves as a use-case driven pattern-based procedure for iterative architecture planning. Round-trip architecture engineering is enforced to articulate the multi-perspective views,

Figure 3. Transition and Alignment Grid



using the industry standards on visual modeling and semantic ontology, such as UML, SysML/DSL, BPMN, XPDL, BPEL, and OWL. Loosely-coupled interface and integration are imposed in the principle of design by contract. The 80-20 rule is leveraged in the use case drill-down for objective sizing and empirical estimation in the service-centered paradigm.

To provide better abstraction and individual agility, the spectrum in the alignment dimension is divided into two areas: Business Process Domain and IT Solution Domain. The goal is to make IT responsive and adaptive, so it will be nimble and flexible to support the business operations for quicker changes. The Business Process Domain captures the information pertinent to the static and dynamic structure on which the business runs – the business process, the operations method, the behavioral process, the information requirements, and the usage scenarios. The IT Solution Domain describes the IT systems supporting and realizing the business operations. The key artifacts in the IT Solution Domain are application domain styles, conceptual model, service model, logical model, and technology model. The gap between the business model and IT model is daunting in almost every large organization. There have been constant conflicts in the alignment of IT models with business models due to delivery schedules, resources, skillset, risks, and budgets. The strategy to alleviate this pain is to seamlessly integrate the models in these two areas. The engaging of end-to-end round-trip engineering principles with traceability and auditability is a necessity to make IT models adaptive, and eventually proactive in the long run.

The key drivers in the alignment dimension are value proposition, expectations, goals, end-to-end process, degree of complexity, lean models, situational context, purpose-driven adaptation, quality, and consistency.

Comprehensive Architecting Process

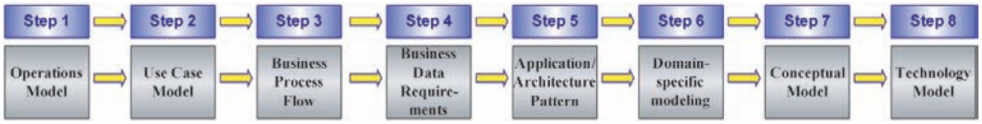
A pragmatic Comprehensive Architecting Process (CAP) is further defined in Figure 4 to facilitate the current state evaluation and future state specification. The key activities are grouped in 8 steps in the procedure:

- Step 1 – Operations Model.
- Step 2 – Use Case Model.
- Step 3 – Business Process Flow.
- Step 4 – Business Data Requirements.
- Step 5 – Application/Architecture Patterns.
- Step 6 – Domain-specific Modeling.
- Step 7 – Conceptual Model.
- Step 8 – Technology Model.

Operations Model

The operations model copes with the alignment and facilitation between the business operations and information systems. It is the business driver to all other technical models in the stack, forming the foundation of the strategic alignment of technical models with the business process mission. The in-depth analysis of the business processes often leads to the reengineering effort to improve the business operations in such a way that different divisions in a large organization can share common solutions for the business needs. The commonalities of the technology components and business logic modules are identified and reusable assets are constructed, resulting in reduced portfolio total cost of owner-

Figure 4. Comprehensive architecting process



ship (TCO) and increased operational efficiency. Business patterns are generally identified to group processes into different categories in the business domain. Common business languages are usually used.

Use Case Model

A use case model is a specification describing the functional requirements of an information system. Use cases convey the usage scenarios that characterize how the system interacts with the actors, what the system boundaries are, and how the use cases are related to each other, thereby describing the total functional behavior and specific business goals of the system.

No standard template exists for documenting use cases in detail. Different schemes and formats have been proposed, and individual teams tend to adapt from what is available or create a customized template that works for their specific situations. Standardization may be enforced at appropriate level, depending on the maturity and applicability, e.g., project, portfolio, domain, division, enterprise, industry sector, etc.

Although terminologies, section structure, and orderings may differ significantly, most use cases share an underlying similarity, so that the core sections in a use case specification look alike. Typical sections in a use case specification include: use case name, ID, version, description, actors, iteration, dependency, preconditions, postconditions, triggers, happy-path flow, alternative paths, business rules, errors, notes, author and date. Different templates may have supplementary sections, such as assumptions, exception handling, recommendations, technical constraints, and non-functional requirements. Other industry or project specific sections may be included as well. Figure 5 depicts a use case diagram for a supply chain management application.

Business Process Flow

The use cases are further decomposed to capture the details in the business process flows. Flow charts are traditionally used to illustrate the logic flow in an informal but intuitive manner. The UML activity diagram provides a standard way to specify the workflows in the Use Case Model. As an example, Figure 6 shows an activity diagram for Use Case 2 defined in Figure 5.

Other notations and standards are maturing and available for business process design and execution, such as BPMN, XPDL, and BPEL. The Business Process Modeling Notation (BPMN) is a standard graphical notation for visualizing business processes in a workflow.

Figure 5. Use case diagram example

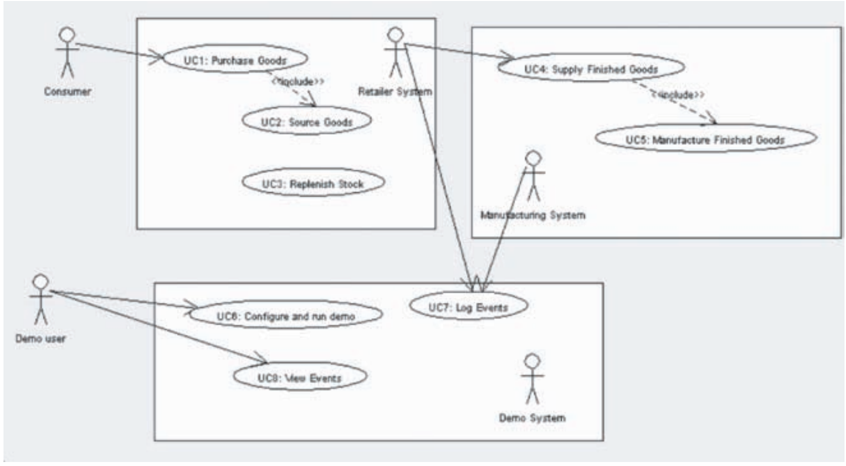


Figure 6. Source Goods Activity Diagram Example

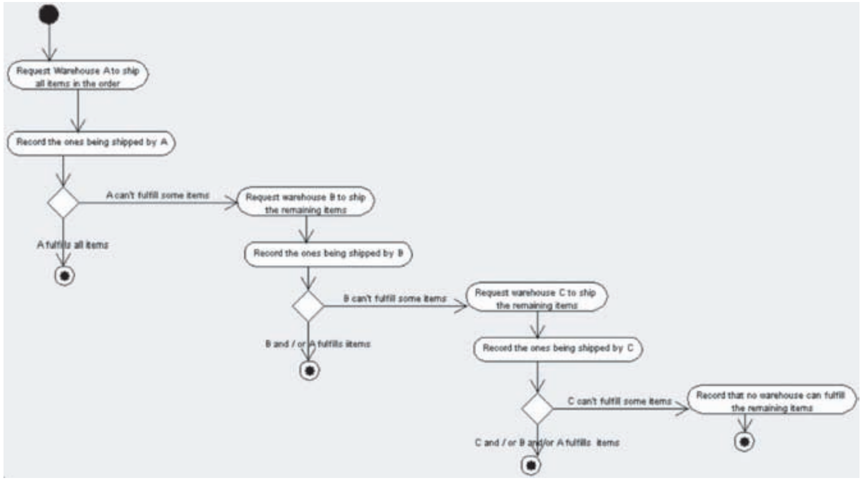
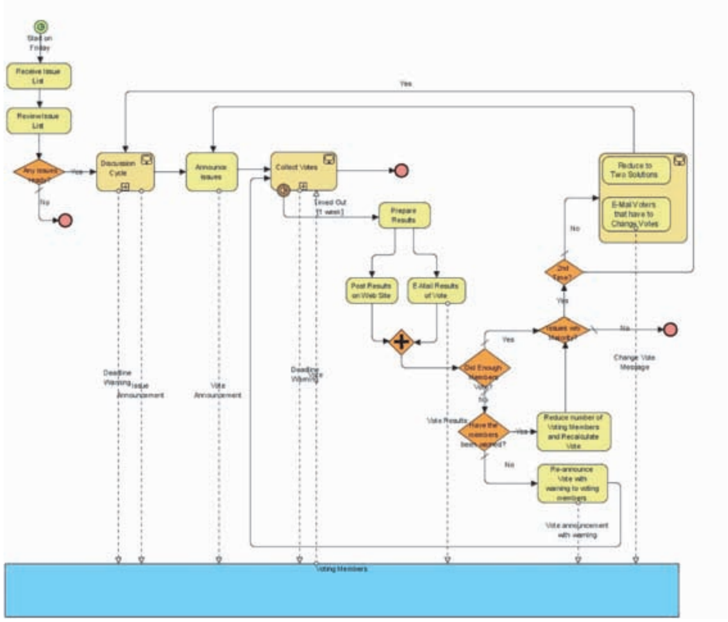


The standardization of BPMN for the description of business processes bridges the gap in communications, which often arises between the business process design and implementation, thereby facilitating the interactions between all business stakeholders, including the business analysts who identify and specify the operations, the technical designers who defines the process orchestration or choreography using a process engine, the solution developers who are responsible for implementing the process scripts, and the business managers who monitor and manage the processes in execution. Therefore BPMN is designed to serve as a common language that is understandable by all stakeholders involved. Figure 7 displays a BPMN diagram for an email voting process.

Figure 7. BPMN diagram example



The XML Process Definition Language (XPDL) is a standard format designed by the Workflow Management Coalition to exchange the definitions of business processes between different workflow products such as the workflow engines and modeling tools. A XML schema is defined in XPDL to specify the declarative part of workflow. XPDL is created to interchange the process design, both the graphical representations and the semantics of a business process workflow. The elements contained in XPDL hold the X and Y position of the activity nodes, together with the coordinates of points along the lines that link these activity nodes. By contrast, although BPEL is a process definition format as well, it is solely for the executable parts of the process. The elements to represent the graphical aspects of a process diagram do not exist in BPEL.

In the open source space, tools are available for BMPN, XPDL and BPEL, such as Intalio BPMN Modeler, JaWE, and ActiveBPEL, respectively.

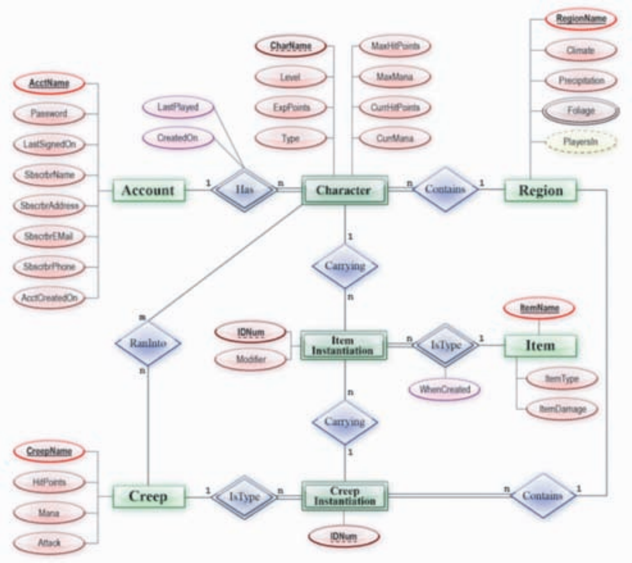
Business Data Requirements

The business data requirements are captured to specify the information requirements for the system. A logical data model is constructed with all the necessary definitions of data elements. A detailed data flow diagram specifies the data exchange and processing in the business operations. A schema is designed to map the business data to a persistence repository, predominantly a relational database system. The data structure and relationship can be defined using a variety of techniques. A graphical notation to represent data models is required in data modeling. One of the most widely used approaches is the entity-relationship modeling process, the end-product of which is an entity-relationship (ER) diagram. An ER diagram represents the schema as a logical data model for the system, which is a type of conceptual data model or semantic data model, as displayed in Figure 8 as an example.

Application/Architecture Patterns

Application/Architecture patterns are high-level artifacts that are used to describe the principal business purpose and architectural style of a solution. They identify the high-level participants who interact in the solution based on the primary objectives of the solutions, and define the nature of the interactions between the participants. In the

Figure 8. Entity-relationship diagram example



banking sector for example, the primary patterns may be classified in the following list.

- Business-to-Business Enterprise: enable business partners to collaboratively provide services with seamless navigation between sites – e.g. user account aggregation, and co-marketing with external vendors.
- Business-to-Person Self-Service: enable users to access the business functionalities via the graphical user interfaces of a thin client (web browsers), thick client (typically Windows GUI applications), and rich client (like Ajax-enabled web applications) as well as other pervasive platforms like personal digital assistants (PDA) and mobile devices such as cell phones – e.g. money transfer between accounts, and bill payments.
- Person-to-Person Collaborations: enable users to communicate with other people like loan officers or brokerage account managers electronically – e.g. emails, and web-based instant messaging.
- Person-to-Data Data Aggregation: enable users to access product information, service details, directory, branch locations, and data summary – e.g. check images, and interim account statements.
- Person-to-Application Access Integration: enable the integration of front ends of servicing applications, typically at the web server tier – e.g. Single Sign-On (SSO), and portal services.
- Application-to-Application back-end Integration: enable inter-system integration – e.g. asynchronous messaging middleware, and web services.

The pattern categories serve as a baseline to classify various information systems into appropriate groups. The cataloging effort builds a common taxonomy for the technology portfolio, and facilitates the further technology planning and technical design. Commonalities among similar systems help rationalize the portfolio and optimize the asset use in the IT environment.

Domain-Specific Modeling

Domain-Specific Modeling (DSM) is a way of designing and developing systems, via the systematic use of a graphical Domain Specific Language (DSL) to represent the various facets of a system. The support of higher-level abstractions distinguishes the DSM languages from the general-purpose modeling languages, meaning that they require less effort and fewer low-level details to specify a given system.

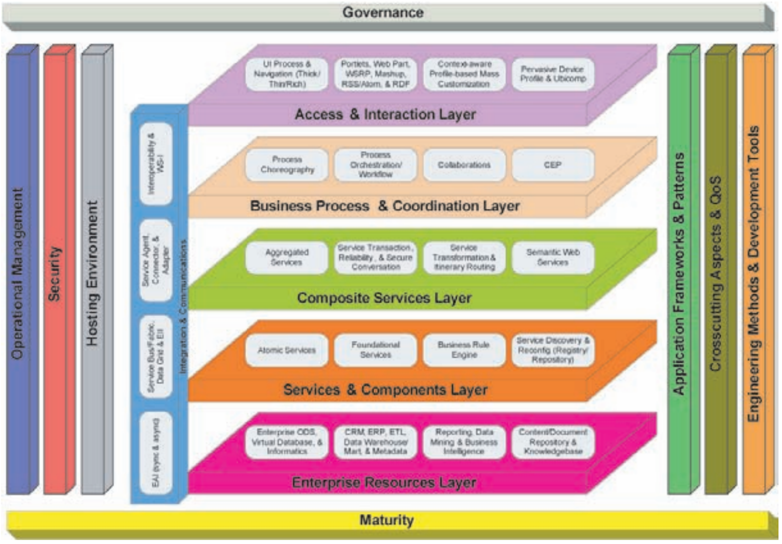
A DSM environment automates creating program components that are otherwise expensive to construct from scratch, such as domain-specific editors, browsers and components. All a domain expert needs to do is to define the domain specific rules and constructs, and the DSM environment provides a modeling tool tailored for the target portfolio. Consequently, the overall cost of obtaining tool support for a DSM language can be considerably reduced by means of a well-designed DSM environment.

Almost all existing DSM activities leverage DSM environments, via commercial tools like MetaEdit+, open source tools like GEMS, and academic tools like GME. Thanks to the increasing popularity of DSM, DSM frameworks have been bundled into existing IDEs, as seen in the Eclipse Modeling Framework Project with Graphical Modeling Framework and Graphical Editing Framework, and in Microsoft's DSL Tools for Software Factories.

Conceptual Model

A conceptual architecture model is designed in Figure 9. The layering architectural pattern is applied to organize the internal structure of an application. The structure extends the concept of the well-known Model-View-Controller (MVC) design pattern to form a generic skeleton of

Figure 9. Conceptual model



service-oriented component-based application architecture. For example, the scope of the application *View* is expanded to include the portal for easy customized navigation and content aggregation, as well as the interaction services to deal with multiple pervasive computing devices. Likewise, the application *Controller* is extended to deal with process choreography and collaborations.

The application structure is made of a stack of 5 layers and 1 vertical block. The *Access & Interaction Layer* supports various devices, handles user interface processing, and integrate single sign-on and authorization. The *Business Process & Coordination Layer* deals with process choreography, orchestration, human workflow, collaborations as well as complex events. The *Composite Services Layer* hosts the aggregated services, service transformation, itinerary routing, semantic web services, and advanced services such as transaction, reliable messaging, and secure conversation. The *Services & Component Layer* contains atomic services, foundational services, business rule engine, service registry/repository, and other servicing components. The *Enterprise Resources Layer* has enterprise ODS, federated database, CRM, ERP, data warehouse/marts, content/document repository, reporting, and analytics suites. The *Integration & Communications Block* copes with inter-application integrations, interoperability, service bus/fabric, data grid, EII, and service agent/connector/broker that encapsulates the integration logic to access internal data sources and external services.

In addition, the *Security, Hosting Environment* and *Operational Management* pillars are across the layers in the runtime environment, whereas the *Application Frameworks & Patterns*, *Crosscutting Aspects & QoS* and *Engineering Methods & Development Tools* pillars are pertinent to various aspects in the development construction. The *Governance* and *Maturity* modules are for the overall program management, policies & standards, conformance enforcement, and evolution measurements.

Technology Model

The technology model defines a detailed structure chart with complete module specifications, and system architecture of servers, nodes, and communications lines. Infrastructure network and topology of data centers is a key part of the technology model. Figure 10 illustrates an end-to-end enterprise infrastructure in a hosting environment for both Internet and Intranet as well as Extranet communications, which includes remote access, routers, switches, firewalls, Domain Name Service (DNS), print services, certificate authority, storage, database, web services, middleware, proxy, Virtual Private Network (VPN) services, high-availability failover, and backup services.

Joint Analysis and Roadmapping

All stakeholders and parties are engaged to conduct a joint analysis on the current, target, and end states. Based on this comprehensive study, the strategic planning is kicked off to construct a roadmap and action plans. A combination of best-of-breed roadmapping methods are used in this effort.

SWOT

The Strengths, Weaknesses, Opportunities, and Threats (SWOT) technique is employed to conduct a thorough inspection on each major factor and option. The analysis reveals the requirement conflicts and design constraints as well as presumptions from a particular stakeholder's point of view. Focus on a single factor is meant to minimize risks only from that attribute perspective at a fine level. This is often insufficient when a variety of conflicting attributes play an equivalently important role in the system and a balance between these interacting attributes must be established. The outcome of the SWOT exercise is the key to the unbiased justification of tradeoffs in a balanced approach. The harmonious approach resolves the conflicts in local/individual attributes to reach a global optimization.

As shown in Figure 11, SWOT is used as inputs to generate possible strategies. Based on the results, a hierarchy of objectives, strategies, and tactics (HOST) diagram can be drawn to facilitate the drill-down on each major objective. By assessing the what, when, why, who, where, which, and how (6W+1H) on these objectives and strategies, the top rank objectives can be identified and prioritized. Dependencies and interrelationships among the objectives and strategies are also elaborated in this exercise.

Porter's Models

The Porter's Five Forces Analysis is a more robust framework than a SWOT analysis for business management. The concepts designed in Industrial Organization (IO) economics are utilized to derive

Figure 10. Technology model example

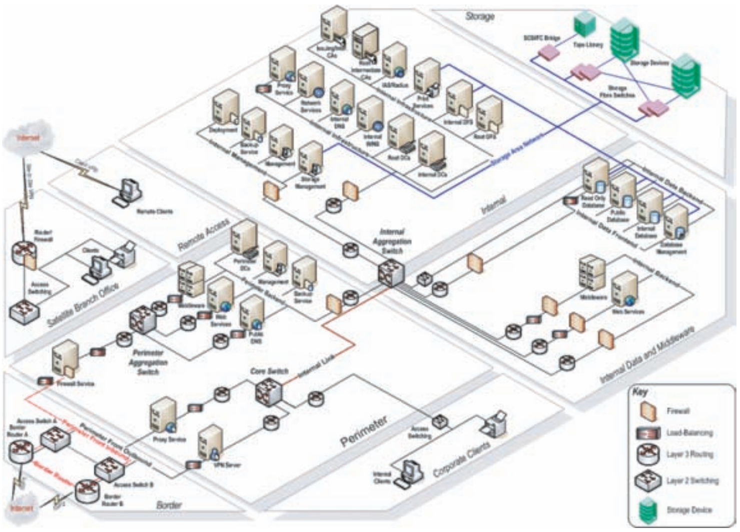


Figure 11. SWOT diagram

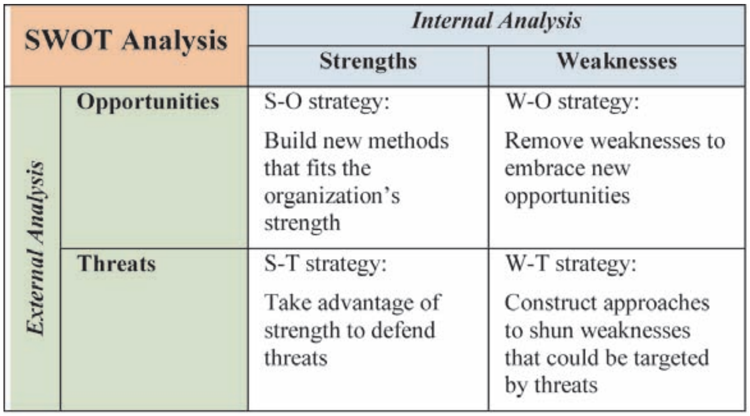


SWOT Analysis		*Internal Analysis*	
		Strengths	**Weaknesses**
External Analysis	**Opportunities**	S-O strategy: Build new methods that fits the organization's strength	W-O strategy: Remove weaknesses to embrace new opportunities
	Threats	S-T strategy: Take advantage of strength to defend threats	W-T strategy: Construct approaches to shun weaknesses that could be targeted by threats

5 forces that determine the attractiveness of a market, as demonstrated in Figure 12. A change in any of these 5 forces generally triggers a reassessment of the marketplace for an organization. The four primary forces are the bargaining power of suppliers, the bargaining power of customers, the threat of new entrants, and the threat of substitute products. The fifth force – the level of competition in an industry – is influence by the four primary forces in combination with other variables. An extension to Porter's 5 forces model is called Six Forces Model, in which the sixth force is introduced, namely the government or public.

Porter also introduced a value chain model and a generic strategies framework in his seminal work. The value chain model consists of a sequence of value-generating activities that are common to a variety of companies. The principal activities are marketing, sales, inbound logistics, operations, outbound logistics, and service. The support activities comprise infrastructure, human resources management, technology development, and procurement. The value chain model helps define a company's core competencies and the activities that a company can undertake to pursue cost advantage or differentiation. On the other hand, the generic strategies framework is composed of cost leadership, differentiation, and market segmentation. The three strategies can be further mapped to three basic value disciplines – product innovation, customer intimacy, and operational excellence. The cost leadership may be implemented as either a low cost strategy or a best cost strategy.

These two models are useful to align the technology strategies to the overall business strategies in an organization. The generic strategies help define the key drivers for the technology domain, while the value chain model helps identify the key activities in the technology area.

Figure 12. Porter's 5 forces analysis

Portfolio Planning (BCG Growth-Share Matrix)

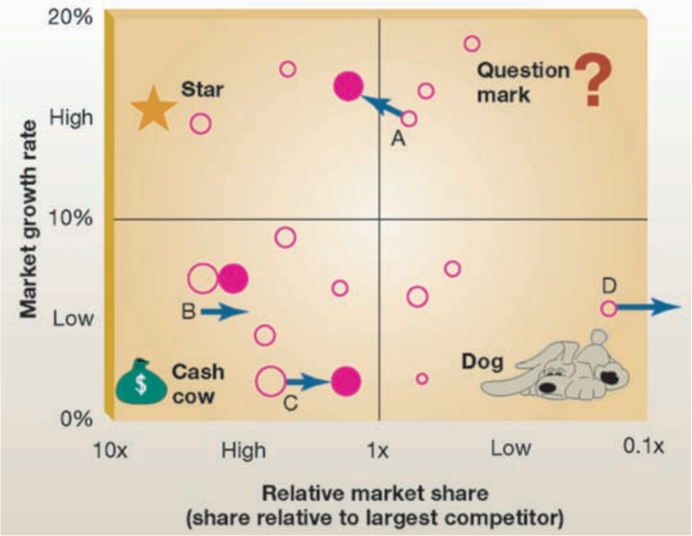
Bruce Henderson of the Boston Consulting Group designed a portfolio planning model called the BCG Growth-Share Matrix, founded on the observation that the business units in an organization can be categorized into four types – dogs, question marks, stars, and cash cows, depending on combinations of market growth and market share (growth-share) relative to the prevalent competitor in the market. The market growth is an indicator for industry attractiveness, whereas relative market share signifies the competitive advantage. Thus the Growth-Share Matrix demonstrates the positioning of a business unit along with the two most important determinants of profitability.

The original design of the Growth-Share Matrix was targeted towards allocating resources among different business lines in an organization. It can also be leveraged in the resource allocation for the products in a portfolio. The single diagram in a simple format helps visualize the relative positions of the entire business portfolio in an organization, as illustrated in Figure 13. However, the model has some limitations. Firstly, there are other important factors in the industry attractiveness and competitive advantage share that are not included in the matrix. Secondly, the business divisions on the chart are presumably independent from each other. The inter-relationship between the units is not addressed in the model. Lastly, the breadth of the market definition has a big impact on the positioning of a business group, which may dominate its small niche, but have a very low market share in the overall industry.

Scenario and Situation Planning

The Scenario Planning was originated in the military strategy studies, when Herman Kahn founded the scenario-based planning in his work related to the possible scenarios associated with thermonuclear war (Kahn, 1985). Pierre Wack transformed the scenario planning into a business tool in the development of a scenario planning system at Royal Dutch/Shell. The efforts made Shell well-prepared to cope with the oil shock in late 1973 and significantly enhanced the company's competitiveness in the industry during the oil crisis and the subsequent oil glut.

Figure 13. BCG growth-share matrix



Scenarios are efforts to detail a hypothetical succession of events that could conceivably lead to the circumstance envisioned. The Scenario Planning is essentially about making choices now with an understanding of how the selections might turn out. A common misconception about the Scenario Planning is that it is perceived as a tool of accurate future prediction or forecast. Instead, it is an approach to laying out the possible situations and combinations, leading to a set of distinct but plausible future states, which help formulate plans and tactics to cope with each of the possible circumstances.

The key benefits of scenario planning are to force the stakeholders to break their routine thinking mode, in order to identify the blind spots that might otherwise be neglected in other normal approaches. Scenarios are recognized in an early stage, enabling informed decision-making and well-preparedness for the difficult situations. The source of disagreements can be better communicated, understood, and resolved when different scenarios are analyzed and walked through.

The Scenario Planning sessions are usually conducted with the key stakeholders such as executive sponsors, technical leaders, industry specialists, program/project managers, and subject matter experts. This enables a sufficient range of perspectives to be considered without leaving out important details or situations. Inputs, participation, and contributions from those who will formulate and implement strategies derived from the scenario analysis are critical to aptly address the issues and pain points that are vital to the teams who will later execute the strategy.

Figure 14 outlines the typical steps that constitute a process of scenario planning.

A matrix of scenarios is created for the analysis of the interaction between the variables, using the two most important variables and their possible values. As displayed in Figure 15, each cell in the matrix represents a single scenario. For straightforward reference in discussions and

Figure 14. Scenario planning process

Figure 15. Scenario planning matrix

		Variable 1		
		Outcome 1A ↓	Outcome 1B ↓	Outcome 1C ↓
Variable 2	Outcome 2A →	**Scenario I**	**Scenario II**	**Scenario III**
	Outcome 2B →	**Scenario IV**	**Scenario V**	**Scenario VI**
	Outcome 2C →	**Scenario VII**	**Scenario VIII**	**Scenario IX**

communications, it is a good practice that each scenario has a descriptive name. In case there are more than two critical factors, a multidimensional matrix is developed. However it is hard to visualize beyond 2 or 3 dimensions. Instead, factors can be taken in pairs to generate several two-dimensional matrices.

PEST Analysis

The Political, Economic, Social, and Technological (PEST) analysis is a framework of macroenvironmental factors used in environmental scanning.

As a part of the external analysis in market research, it provides an overview, to a large degree, of the different macroenvironmental factors worth consideration by an organization. The political factors focus the areas of employment laws, environmental regulations, trade restrictions, tariffs, tax policy, and political stability. The economic factors include the economic growth rates, interest rates, exchange rates and inflation rates. The social factors are usually related to the cultural aspects, consisting of health consciousness, population growth rate, age distribution, career attitudes and emphasis on safety. The technological factors comprise ecological and environmental aspects that determine the barriers to entry, minimum efficient production level and outsourcing decisions. The core elements include the R&D activities, automation, technology incentives and the rate of technological changes.

From a technology engineering planning perspective, the prominent factors in technological analysis are recent technology advancements, technological impact on solution offerings, influence on cost, effect on the value chain model, and rate of technology diffusion. These PEST factors and other external micro-environmental factors can be categorized into the opportunities and threats cells in a SWOT analysis.

Hybrid Roadmapping Method

To effectively conduct strategic planning to meet the needs in both short and long terms, a hybrid method is necessary to take account of all factors and interests from different parties. Two streams are defined in this hybrid method – initiative-driven and strategy-driven.

The strategy-driven roadmapping is conducted at four levels:

- Macro-level: trend analysis
- Meso-level: competitor analysis
- Micro-level: enterprise analysis
- Nano-level: portfolio analysis

The technological trend analysis identifies the technological factors/trends that have impact on the organization. The competitor analysis determines the competition levels, analyzes competitive forces, examines competitor behavior, and identifies competitor strategies. The enterprise analysis analyzes the internal environment and identifies its competencies. The portfolio analysis investigates the conditions and maturity in a technology domain. The results of these analyses can be captured in a set of SWOT matrixes.

The initiative-driven roadmapping deals with the requests from the current initiatives, which are typically for immediate needs and near-term goals. The activities include supporting the existing business operations, replacing obsolete vendor technologies, making minor modifications to meet regulatory requirements, retiring outdated applications, and adding short-term feature enhancement in the existing information systems. A target state is defined to build out these capabilities, which serves as a transformation step towards the end state as described in the foregoing section. A value chain model can be used to assess the impact and margins in the initiative-driven efforts.

Based on the results of the strategy-driven and initiative-driven streams, a roadmap is devised, which is usually in the format of a multi-generation plan. It outlines the long-term goals, and details the specific strategies and pragmatic goals that are to be pursued. The strategic and tactical concerns and challenges are articulated and addressed in depth. Areas of risks are analyzed and specific means for mitigating those risks are adopted.

APPLYING STEP IN PLANNING

The *STEP* framework forms a coherent set of components that can be used to compose a pragmatic approach for technology planning in the real-world context. The *WIT* module serves as a basic structural model to assess the current state and define the end state as well as the intermittent target states. The *TAG* module deals with the business-to-IT alignment and roadmap transforming the current state to future state, which is the outcome of the *WIT* module. An array of models are used in the *TAG* module to describe the prominent aspects and attributes of a domain, such as business, operations, behavior, information, use case, application, conceptual, service, logical, and technology. Further, the *CAP* module provides a practical process with 8 steps grouping the activities and artifacts in this effort. Some models introduced in the *TAG* module are articulated in greater detail in this process. Templates, checklists, UML diagrams, ER diagrams, reference architecture, and patterns may be used to facilitate the standardization of the notations and practices in this procedure. Finally, a range of roadmapping methods presented in the *JAR* module can be leveraged to conduct tradeoff analysis of the roadmaps developed in the *TAG* module, and balance the constraints and conflicts to reach a compromised agreement among the stakeholders with different interests and priorities.

FUTURE TRENDS

As the advance in the technology field continues at an unprecedented pace, a practical approach is to be adaptive and build out the strategy plan in an incremental manner. An iterative process should be established to refresh the plan and re-examine the internal and external influencing factors. The strategic planning tends to become semi-automated, with a pragmatic mechanism in place to monitor the changes and trigger necessary reassessment. Various techniques and methods will converge to formulate a complete strategic framework for the digital age, from concept to execution to termination. The focal point will be on the future and people, who are involved in planning and developing the strategy and measures, so that the execution can be accelerated. It can be foreseen that a more balanced approach will be taken between the tactical actions and strategic activities, resulting in lower cost, well-managed risk, efficient alignment, higher flexibility, enhanced quality, and faster time-to-market. The matured methodology and disciplines are expected to make a real difference, create values, and build sustainable competitive advantages in an organization.

RELATED WORK

Previous studies in the last few decades have strived to tackle the issue of architecture design complexity, which has grown exponentially as the computing paradigm has evolved from a monolithic to a service-oriented architecture. The Zachman Framework (Zachman, 1987) is a logical structure for categorizing and organizing the descriptive representations of an enterprise IT environment. In the form of a two-dimensional matrix, it has achieved a level of penetration in the domain of business and information systems architecture and modeling. It is largely used as a planning or problem-solving tool. Nevertheless, it tends to implicitly align with the data-driven approach and process-decomposition methods, and it operates above and across the individual project level. Extended Enterprise Architecture Framework (E2AF) (IEAD, 2004) takes a very similar approach seen in the Zachman Framework. Its scope contains business, information, system, and infrastructure in a 2-D matrix. E2AF is more technology-oriented. Both of these approaches are heavyweight methodologies, which set a fairly steep learning curve for a team to learn and successfully adopt either method.

Rational Unified Process (RUP) (Kruchten, 2003) made an effort to prevail over these shortcomings by leveraging the Unified Modeling Language (UML) in a use-case driven, object-oriented and component-based approach. The concept of 4+1 views interprets the overall system structure from multiple perspectives. RUP is more process-oriented, and is generally a waterfall approach. RUP barely addresses software maintenance and operations, and lacks a broad coverage on physical topology and development/testing tools. It essentially operates at the individual project level. RUP has recently been expanded to Enterprise Unified Process (EUP) and part of it has become open source – OpenUP in Eclipse.

Another heavyweight approach, The Open Group Architecture Framework (TOGAF), is a detailed framework with a set of supporting tools for developing an enterprise architecture to meet the business and information technology needs in an organization. The three core parts of TOGAF are Architecture Development Method (ADM), Enterprise Architecture Continuum, and TOGAF Resource Base. The scope of TOGAF covers Business Process Architecture, Applications Architecture, Data Architecture, and Technology Architecture. The focal point of TOGAF is at the enterprise architecture level, rather than the individual application architecture level. On the other hand, Model-Driven Architecture (MDA) (Object Management Group, 2008) takes an agile approach, aiming to separate business logic or application logic from the underlying platform technology. The core of MDA is the Platform-Independent Model (PIM) and Platform-Specific Model (PSM), which provide greater portability and interoperability as well as enhanced productivity and maintenance. MDA is primarily for the software modeling part in the development lifecycle process.

Other related works on IT architecture frameworks are for the most part tailored to specific domains. They are useful references when a team intends to create their own models for their organization. The comprehensive architectural guidance for the various Commands, Services, and Agencies within the U.S. Department of Defense are documented in the C4ISR Architecture Framework (DoD, 1997), for the sake of interoperability endurance and cost-effectiveness in military systems. The Federal Enterprise Architecture (FEA) framework (Federal Office, 2007) gives direction and guidance to U.S. federal agencies for designing enterprise architecture. The Treasury Enterprise Architecture Framework (TEAF) is to guide the planning and development of enterprise architectures in all bureaus and offices of the Treasury Department. The Purdue Enterprise Reference Architecture (PERA) (Purdue University, 2008) is aligned to computer integrated manufacturing. ISO/IEC 14252 (a.k.a. IEEE Standard 1003.0) (IEEE, 1995) is an architectural framework built on POSIX open systems standards. The ISO Reference Model for Open Distributed Processing (RM-ODP) (Putnam, 2001) is a coordinating framework to standardize the Open Distributed Processing in heterogeneous environments. It creates an architecture that integrates the support of distribution, networking and portability, using five "viewpoints" and eight "transparencies". The Solution Architecture of N-Tier Applications (Shan & Hua, 2006) presents a multi-layer and multi-pillar model for web-based applications.

CONCLUSION

To effectively manage the complexity in service-oriented architecture and perform strategic technology planning in information systems, a comprehensive model is a necessity to abstract concerns, define methods, and present a holistic view of the planning aspects in a highly structured way. The Strategic Technology Engineering Planning (STEP) model introduced in this article is a holistic framework to facilitate planning information systems applications strategically and tactically. It provides comprehensive coverage of the planning artifacts from both analysis and execution perspectives. It defines a comprehensive multi-disciplinary approach to conduct strategic and tactical technology planning for both near-term needs and long-term goals.

The design principles of the framework are presented in the context. The model comprises an array of multiple modules: Want-Is-Target (WIT) model, Transition and Alignment Grid (TAG), Comprehensive Architecting Process (CAP), and Joint Analysis & Roadmapping (JAR). The characteristics and features of the constituent elements in the SETP model are articulated in great detail. The WIT model defines three stages of architecture states – current, target, and end state. TAG specifies two dimensions for architecture planning, namely current-to-future state transformation and IT-to-Business alignment. CAP presents an overarching method for step-by-step engineering and design in system architecture and portfolio optimization. JAR comprises the best-of-breed strategic analysis techniques, accompanied by a hybrid method with strategy-driven and initiative-driven planning streams. Furthermore, the elements and features of each module are detailed and the future trends are discussed.

The comprehensiveness and agility of this coherent framework has made it possible for the model to be extensively used in the service-oriented application planning in one format or another, and its usage has proved to be an enormous success. Furthermore, this structure is so scalable and flexible for dynamic extensions and expansions that the model can serve as a meta-framework to incorporate other general or specialized frameworks.

Chapter 2.2

A Technology-Focused Framework for Integrating Knowledge Management into Strategic Innovation Management

Marc Henselewski
Deloitte Consulting GmbH, Germany

Stefan Smolnik
European Business School, Germany

Gerold Riempp
European Business School, Germany

ABSTRACT

Today's business environment is characterized by highly transparent markets and global competition. Technology life cycles are decreasing due to the fast pace at which development of new technologies is progressing. To compete in this environment, it is necessary to identify upcoming innovations and trends as early as possible to decrease uncertainty, implement technology leadership, and create competitive advantage. In a parallel development, the amount of information available is already vast and increasing daily. As a result of these developments, strategic innovation management has become increasingly challenging. The goal of our chapter is to investigate to what extent knowledge management technologies support and improve strategic innovation management to face the aforementioned problems successfully. Consequently, we will develop a characterization scheme which works as a framework for the subsequent evaluation of knowledge management technologies and apply this to a real-world case.

INTRODUCTION

Competition in today's business environment is intense. The influences of the rapid pace of globalization, and of national and international markets' on-going liberalization lead to the emergence of new problem settings and, consequently, increased pressure on companies. Companies therefore face greater risks due to the higher number of players in the market. However, environmental influences created outside the market are not the only factors that have an impact on companies' complexity. The increasing speed at which innovations and new developments occur, the resultant shorter product life cycles, and decreasing production costs also add to the pressure felt by firms and their decision-makers. High technology companies that have high research and development (R&D) expenditures, have to specifically plan their research programs more carefully, because they run a higher risk of losing the competitive advantage when "going the wrong way". Consequently, decision-makers have a greater need to anticipate or forecast future developments and apply these insights in business strategies and strategic innovation management in order to keep risk levels low and the company competitive. According to Bright (1979), all "firms and governments dealing with technology have been and are doing technology forecasting. This is because each decision to explore, support, oppose or ignore a technological prospect incorporates the decision-maker's assumptions about that technology and its viability in the future" (p. 228).

Over the last few years, firms have increasingly realized that knowledge plays a key role in the development of strategies for future success and stronger market positions. The most striking examples of such firms are technology and service-oriented companies, but retailers also engage in activities to use knowledge as factors of competitive advantage. A paradigm shift can be observed in business strategies: from a focus on tangible assets to one that prioritizes intangible assets (Drucker, 1996, p. 203; Stewart, 1997, p. 23). However, information and information sources' quantity is continuously increasing, and what at first seemed to be the solution to several business problems has itself become a unique problem for today's companies—too much information. In order to gain from information and to facilitate knowledge creation within a company, new ways of filtering and selecting information have to be applied. Furthermore, the nature of knowledge is highly dynamic. The value of knowledge is difficult to measure and can change from one moment to another. Companies try to control this uncertainty to some extent and to obtain as much advantage as possible from their knowledge by integrating knowledge management paradigms into competitive strategies.

The question arises if it is possible to successfully support knowledge and strategic innovation management alignment on an operational level. With technology forecasting being an essential discipline of today's innovation and innovation management processes, it is of specific interest to know whether technology forecasting can be improved by integrating knowledge management—particularly by means of current knowledge management technologies. In the following, we understand the latter as instruments of information and communication technologies that support knowledge management processes.

In order to answer the stated question, this chapter's objective is to develop a characterization scheme that integrates aspects of both fields: knowledge management as well as innovation management process's technology forecasting. Furthermore, selected knowledge management technologies will be evaluated by applying this scheme to derive conclusions regarding the most promising solutions with which to support technology forecasting.

The section following this one introduces and defines technology forecasting and illustrates the associated standard technology forecasting process, which is tailored to comply with strategic innovation management. Thereafter, an overview of several forecasting methods is given. The section *Knowledge Management Needs Within Technology Forecasting* explains the motivation for knowledge management's integration into technology forecasting and describes the strategic and organizational reasons. The subsequent section leads to the development of a characterization scheme in order to evaluate the knowledge management technologies data mining, case-based reasoning, information retrieval, topic maps, and ontologies. The next section comprises the actual evaluation of the mentioned technologies and is followed by an integrative discussion of the findings to close the evaluation. The transfer of the developed insights to the real world through discussion of an example case is covered in the section *Towards an Exploratory Case Study*. This is taken from an innovation project at DETECON Inc., conducted for Deutsche Telekom AG. The subsequent section summarizes the main results and the concluding section suggests fields for further research.

DELIMITATION AND CONCEPTUAL DEFINITIONS

Technology Forecasting

As Granger points out, technology forecasting evolved from the argument that, in the long run, technological change is one of the most important influencing factors of economies (Granger, 1989, p. 209). Thus, technology forecasting seems to be most valuable when applied to long time horizons, which becomes even more important in strategic innovation management. For example, decisions pertaining to general strategic business planning are often based on a forecast time horizon of three to twenty years (DeLurgio, 1998, p. 8).

Besides longer time horizons, the scope of the results is another specific property of technology forecasting. Such forecasts "are generally concerned with the characteristics of a technology rather than how these are achieved" (Granger, 1989, p. 210). It was Bright (1979) who incorporated this fact into a definition of technology forecasting:

> *Technology forecasting is a quantified statement of the timing, the character or the degree of change in technical parameters and attributes in the design, production and application of devices, materials and processes, arrived at through a specified system of reasoning.* (p. 235)

Other authors (for example, DeLurgio, 1998, p. 10) stress that uncertainties about future developments can be modeled with the help of probabilities that help decision-makers plan for a variety of contingencies and scenarios. For this reason and the fact that technology forecasting mostly deals with long time horizons, we revised Bright's definition to attain a more rigorous and precise definition of technology forecasting:

> *Technology forecasting is a probabilistic, long-term estimate of the timing, the character or the degree of change in technical parameters and attributes in the design, production, and application of devices, materials, and processes, arrived at through a system of reasoning consciously applied by the forecaster and exposed to the recipient.*

In different situations, the exact technology-forecasting process can vary from a relatively simple process with just a few stages, to a process comprising a complex structure of stages and subprocesses (DeLurgio, 1998, p. 26). Armstrong (2001) divides the process into six basic steps: formulate problem, obtain information, select methods, implement methods, evaluate methods, and use forecasts (p. 8). These steps also appear in other literature, in the same or a very similar order (DeLurgio, 1998, p. 27; Reger, 2001, p.538), sometimes in combination with additional stages.

In addition to this process structure, DeLurgio (1998) mentions that on-going maintenance and verification are necessary to ensure that the results are valid and effective (p. 27). Hence, it is recommended that reality be monitored and compared to the forecasting results in order to respond to possible inaccuracies. In the context of innovation management, the suggested on-going monitoring becomes even more important, since companies have to respond to changes as quickly as possible to stay competitive. Moreover, it can be assumed that in a large company, the individuals who conduct the forecast and the decision-makers are not the same persons. Additional steps to prepare and make decisions are therefore necessary for a complete view of the process. To include these thoughts into the process, the last step of the process has to be split and a more detailed structure created. The resulting technology-forecasting process for strategic innovation management is shown in Figure 1.

Overview of Forecasting Methods

For the later discussion of technology forecasting, it is important to get a basic understanding of available classes of forecasting methods. This section is based on the "Methodology Tree" by Armstrong which illustrates the characteristics of forecasting methods and their relationships. Figure 2 depicts the Methodology Tree.

Armstrong begins with a separation of judgmental and statistical methods. He mentions, however, that judgment pervades all aspects of forecasting (Armstrong, 2001, p. 9). The further down a method is positioned in the tree, the higher the amount of judgmental and statistical integration. On the judgmental side of the tree, the methods are split into those predicting one's own behavior and those predicting the behavior of others, mostly by including experts into the forecasting process. On the side of method types predicting one's own behavior, the methods are characterized by the influence of a role. If a role influences the decision to make, *role playing* is a valuable tool for forecasting the outcome of the decision through the simulated interaction of roles affected by the decision. In case there is no influence of a role, the *intentions method* can be used in which people predict their own behavior in different situations. *Conjoint analysis* goes a step further than the *intentions method* by trying to create a connection between personal intentions and certain features of a situation through statistical analysis. For example, "a forecaster could show various designs for a computer and ask people about their intentions to purchase each version" (Armstrong, 2001, p. 9).

Forecasting methods within the *others* branch are based on *expert opinions* about how organizations or others will behave. There is a broad number of forecasting methods which belong to this type, with the Delphi method being the most famous one. In this method, questionnaires are sent out to experts in the targeted fields who answer the questions by the use of their subjective judgment. Once the questionnaires are sent back and analyzed, they are sent out again to the same experts together with the results of the first round in order to get a second estimation. The reason for this is to share the results and create a common knowledge base among all participants of the forecast. This process can be repeated for one or two more rounds after which

Figure 1. The technology-forecasting process (following Armstrong, 2001)

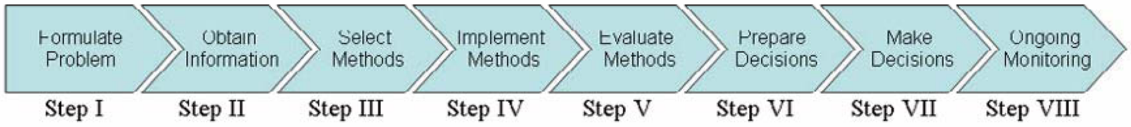

Figure 2. Methodology tree by Armstrong (2001, p. 9); dotted lines present possible relationships

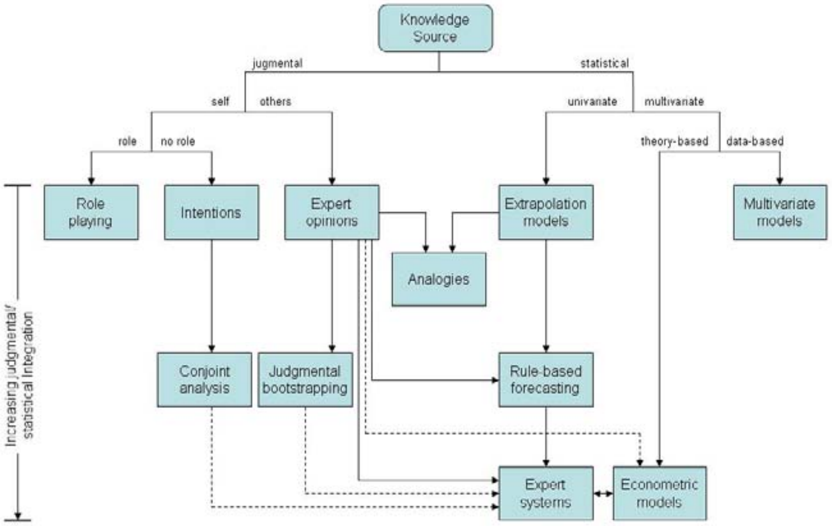


the final conclusions are drawn and the forecast is created. Further information about the Delphi method can be found in the forecasting literature (e.g., Armstrong, 2001; DeLurgio, 1998; Granger, 1989; Martino, 1983). *Judgmental bootstrapping* refers to methods which use regression analysis in order to draw conclusions and rules from expert opinions and, to a certain extent, belongs to the class of expert systems.

Judgment and statistics are merged into one method type when *analogies* are used. Based on statistical data, experts try to forecast the development of a situation. The success of such an approach depends on the degree of similarity between the situation which has to be predicted and the one the statistical data are taken from.

The statistical side of the tree is split into univariate and multivariate methods. The *univariate* part of the tree contains extrapolation methods (Armstrong, 2001, p. 10); that is, values are predicted by the use of older values within a (time-) series. The simplest method of this type is using today's number of sales to predict tomorrow's number. When domain knowledge and knowledge about forecasting procedures is combined in a type of expert system to achieve this task, one speaks of *rule-based forecasting*. Full *expert systems* utilize an even greater integration of expert rules (rules which are similar to the way experts create their judgments) in order to support forecasting.

Multivariate forecasting methods are distinguished whether they are based on statistical data or theory. The latter leads to *econometric models* which base on domain knowledge or findings from prior research. "Econometric models provide an ideal way to integrate judgmental and statistical sources" (Armstrong, 2001, p. 10).

In general, one can argue that the focus of the following sections lies within the area of quantitative or statistical forecasting methods. However, it is the goal of this chapter to identify possible knowledge management technology support throughout the entire technology forecasting process as introduced in the section before and not only for a specific type of forecasting method. Therefore, the dedicated analysis of specific statistical and nonstatistical methods with regards to knowledge management needs could lead to further improvements of the forecasting quality and is suggested as an area of future research.

KNOWLEDGE MANAGEMENT NEEDS WITHIN TECHNOLOGY FORECASTING

There are three major perspectives that have to be considered in order to determine the need for knowledge management within technology forecasting. First, knowledge management needs within technology forecasting can be considered natural implications emerging from business and knowledge strategies which companies formulate to sustain or increase their competitive advantage. Second, the topic can be approached from an inside-the-company view: which other strategic, technological, or organizational factors within a company necessitate integrating knowledge management into the technology-forecasting process? Third, a company's forecasting process is obviously influenced by the company's environment. Therefore, an analysis from an outside-the-company perspective is also crucial to achieve a complete view of the need for knowledge management within technology forecasting.

Business and Knowledge Strategy Implications

As business strategies are formulated to set the overall company goals and define a company's unique strategy to gain profits, one needs to understand that these strategies are built from different components, each delivering a fundamental part to realize a company's objectives. Various authors, for example, Geschka (1992), broadly accept that "the innovation strategy is one means to achieve overall strategic company goals" (p. 70). Therefore, innovation is becoming increasingly important within companies and is moving from an activity often conducted solely within marketing or research and development departments to a process spanning several departments steered by dedicated innovation management. Furthermore, the nature of innovation is such that it can be the sole source of a company's competitive advantage and business success. O'Hare (1988) states that "truly successful innovation does not just lead to some extra sales volume, or a temporary improvement in performance. … Rather, it is about achieving fundamental improvement in competitive position, about re-establishing the competitive equilibrium at a new, more favorable point" (pp. 39-40). However, the value of innovation and, therefore, its ability to function as a basis for competitive advantage, declines over time. This can be observed on a daily basis and examples can be found everywhere, from food to consumer technology and from health care to aviation; what seems to be a unique and exclusive product justifying a premium price today becomes a commodity product tomorrow.

It is essential to continue the development of further innovations to successfully build and sustain competitive advantage based on innovation. This undertaking is, however, influenced by many factors that determine the future of a company as well as the economy and society to which the company belongs. These factors could, for example, belong to political regulations, trends, and hypes within a society, or technological and scientific breakthroughs. Therefore, the development of innovation faces risks and uncertainty that are all future related and with which the company needs to cope through stringent innovation management. It is essential to recognize that this uncertainty with regard to future developments is the main reason for technology forecasting being a core part of current companies' efforts to plan innovation roadmaps and business strategies in keeping with future challenges. Armstrong (2001) says that:

> *We have no need to forecast whether the sun will rise tomorrow. There is also no uncertainty when events can be controlled; for example, you do not need to predict the temperature in your home. Many decisions, however, involve uncertainty, and in these cases, formal forecasting procedures … can be useful.* (p. 2)

A knowledge management strategy defines the basic direction of an organization's knowledge management structures and activities (Riempp, 2004, p. 77). The overall aim of these structures and activities is the improved utilization of knowledge that contributes to the better achievement of an organization's goals; that is, the knowledge management strategy is part of the overall business strategy. When thinking about technology forecasting and transferring it to the domain of knowledge strategies, technology forecasting can be regarded as a means to define and evaluate what Abou-Zeid (2005) calls the Knowledge-Scope (K-Scope); "K-Scope deals with the specific domains of knowledge that are critical to the firm's survival and advancement strategies" (p. 100). In other words, technology forecasting helps a company to understand which path technological innovations will follow to identify the implications for the company's own innovation roadmap and its overall competitive strategy. According to Abou-Zeid (2005), this is part of the Knowledge Strategy External Domain (p. 100). Thereby, technology forecasting is a means to support knowledge strategy creation by supporting the Knowledge-Scope definition as well as an essential part of a company's innovation management by being a driver for innovation strategy formulation.

Needs Emerging from Inside the Company

Inside a company, technology forecasting is closely linked with decision-making processes. It is part of the activities incorporated in strategic innovation management in order to support planning of innovation and R&D programs. DeLurgio (1998) argues that "it is important to recognize the role of forecasting in expanding the knowledge base of organizations and whole societies" (p. 6). Thus, technology forecasting itself can be regarded as a knowledge-creating activity; that is, knowledge in the sense of enabling managers to make strategic decisions, plan a technological innovation path for the company, and adjust business strategies. Therefore, decision-makers need an as comprehensive view of future developments as possible, which cannot be achieved with the help of technology forecasting alone. The end product of forecasting activities is, in most cases, some sort of study or report that represents all analyzed future developments. However, it can be assumed that this report does not contain enough information for a decision-maker to recreate all the knowledge that has been created by participants through the entire forecasting process. Knowledge, like perspectives and prior experiences shared by forecasters, might be valuable for a decision-maker. This facilitates interpretation of the information contained within the reports in a more efficient and comprehensive fashion, thus leading to decreased uncertainty and better-informed decisions. Moreover, reports cannot contain all the information available to the forecasters. In order to provide precise information and to reduce the document's complexity, some information has to be omitted. However, this information might become useful later in the decision process. Without efficient ways of recovering the missing information, the decision process is either slowed down, due to the additional time spent analyzing or acquiring the missing information for a second time, or it becomes less accurate.

In summary, from an inside-the-company perspective, two major reasons can be identified for the emerging need of knowledge management support for technology forecasting within strategic innovation management. Moreover, the last two major reasons have the potential to improve the quality and efficiency of the process:

- Technology forecasting is itself a knowledge-creating process.
- Knowledge that has been created during the process is not transferred to decision-makers due to, for example, the limited amount of information that can be conveyed via documentation.

Needs Emerging from Outside the Company

Making the right decisions with respect to future developments and technologies is vital for a company's competitiveness. One reason for this is the decreasing length of technological life cycles as "technological change is one of the most important forces affecting a firm's competitive position" (Burgelman, Maidique & Wheelwright, 1996, p. 6). Additional dynamics and uncertainty are created by the phenomenon of unexpected, disruptive innovations with which a company has to cope and which can never be fully excluded. Another factor that increases the pressure felt by decision-makers is cost. Vanston (1996) states that "under pressure to contain these [higher] costs, it has become increasingly important for R&D programs to focus on projects that will result in enhanced profits and sustainable competitive advantage" (p. 57). All these factors are evidence of how crucial it is for a company to make the right decisions in a constantly decreasing time frame.

On the other hand, the same reasons lead companies to face increasing uncertainty with respect to future developments. In order to deal with this uncertainty, companies have to collect and assess more information swifter and more efficiently than they used to. This is also true in the context of technology forecasting within strategic innovation management. It can be assumed that more information leads to a reduced uncertainty and thus to a better-informed decision. At the same time, however, more information also leads to greater complexity and, consequently, to a decrease in efficiency and a slower process. The amount of information required to decrease uncertainty and the time needed to collect, assess, and process information are in inverse proportion to each other. As far as possible, companies should therefore find equilibrium on the information side to keep uncertainty low, while keeping complexity on a level that the forecaster can still handle.

Hence, two main factors—related to a technology-forecasting process's efficiency and emerging from outside the company—that influence a company's competitive advantage and business strategy, and create a need for knowledge management within technology forecasting, are:

- Decisions have to be made faster to stay ahead of competition.
- More information with an increasingly complex relational structure has to be collected, assessed, and processed to decrease uncertainty.

DEVELOPMENT OF A CHARACTERIZATION SCHEME FOR KNOWLEDGE MANAGEMENT TECHNOLOGIES

In this chapter, we will develop a characterization scheme to evaluate and delineate knowledge management technologies. Since these technologies differ with respect to knowledge management as well as technology forecasting, the scheme will combine these two fields by integrating a dimension for each of them.

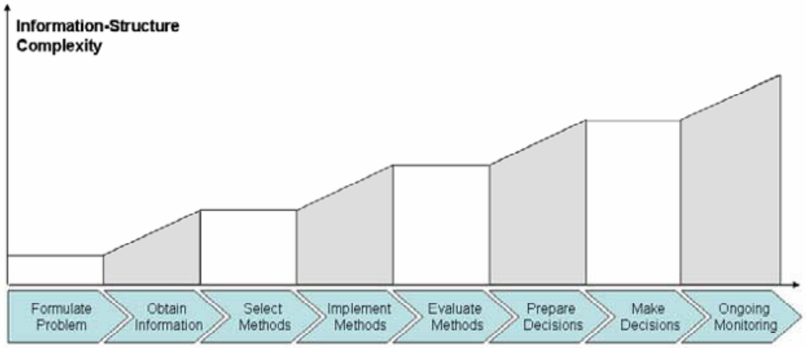
We have shown that one can argue that technology forecasting itself is a knowledge-creating process. A second look at the forecasting process reveals that each step can be regarded as a transformation process with specific inputs and outputs. Step II, for example, needs the definition of the forecasting objectives, the scope, and the time horizon as inputs. This information is utilized within the process step's activities and transformed into information of a greater complexity by combining the input with new information. New relations are identified between certain information objects, leading to the observed information structure's greater complexity. The subsequent step III also requires input from the preceding steps. It is, however, different from step II with respect to the transformation of information. While the activities of process step II increase the information structure's overall complexity, the complexity remains constant during step III, because the information is only analyzed to select suitable forecasting methods. An analysis of the other process steps reveals that the technology-forecasting process's steps can be characterized by their varying degree of complexity; in other words, either the level of complexity is increased or it remains unaltered. Figure 3 illustrates this relation on an abstract level without claiming to represent the actual degree of complexity increase.

On examining Figure 3, it is possible to identify four steps that cause the information structure's increasing complexity within the forecasting process. These steps are: obtain information, implement methods, prepare decisions, and ongoing monitoring. Reasons can be found for these four steps' contribution to the complexity when comparing each step's activities. They all have the combination of previous steps' results and newly acquired information in common, which leads to the creation of new knowledge. Such knowledge is needed to complete each process step's tasks.

Accordingly, the level of the information structure's complexity is chosen as a dimension of technology forecasting and is expressed by the four process steps identified. This dimension enables knowledge management technologies to be classified according to their capability to support these four process steps, and allows an implicit description of the level of information complexity within the technology-forecasting process that a knowledge management technology supports.

While the development of the technology forecasting dimension is based on the analysis of the forecasting process, a different approach has to be found to define the knowledge management dimension. As a starting point, the definitions of data, information, and knowledge should be considered. Since there is a defined difference between these terms, one can argue that data, information, and knowledge's definitions could be used as a structure with which to categorize knowledge management technologies; for example, the category "information" contains all those technologies that target information. Furthermore, transformation processes are required to turn data into information and information into knowledge. A categorization structure based only on the definitions of the three terms is not capable of integrating such transformation processes, and it is obvious that there are knowledge management technologies that, for example, specifically support the transformation of data into information. Aamodt and Nygård (1995) propose a model for data, information, and knowledge that takes the three terms' specific relationships into account (p. 8). The model explains the processes that are needed to transform, for example, data into information, in addition to providing data, information, and knowledge's basic structure. However, with regard to the development of a dimension for knowledge management technologies' charac-

Figure 3. Information-structure complexity



terization from a knowledge management point of view, it can be argued that this model is not applicable. Knowledge, as understood in this chapter, is closely linked with human action and the human mind, with learning being one way of creating knowledge. While there might be a number of knowledge management technologies that support learning, it is impossible for technologies to target knowledge itself.

Another disadvantage of such a model is its granularity. It can be assumed that there are several types of knowledge management technologies that target information, but each with a different focus or different application areas. Consequently, a finer granularity is needed which, in an optimal case, can be based on a single and continuous criterion to facilitate adoption and the development of a knowledge management dimension for the characterization scheme as stated previously.

Smolnik et al. (2005) suggest an approach called "the continuum of context explication", which fulfills the mentioned requirements and is based on the importance of context. Here, context explication means "discovering implicit meanings and expressing those meanings explicitly" (p. 28). The authors stress that context is an important aspect that many definitions of knowledge have in common (Smolnik et al., 2005, p. 30) and they compare several definitions of context. Dey and Abowd (2000), for example, define context as follows:

Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves. (pp. 3-4)

Besides its role in the definition of knowledge, context also plays an important role in the definition of information. Nonaka and Takeuchi (1995) argue that "knowledge, like information, is … context-specific and relational" (p. 58). Smolnik et al. (2005) found that knowledge management technologies "focus on contextual information in different ways and with varying intensity" (p. 36). Consequently, the authors present five approaches to "find and use information objects and contextual information …, each with a differing degree of context and explication ease" (Smolnik et al., 2005, p. 36). The continuum distinguishes the following five approaches:

- **The data approach:** Data are symbols or signs without a meaning or context. Thus, context cannot be explicated. Nevertheless, technologies can be applied to transform data into information or domain-specific knowledge. The data approach encompasses these methods.
- **The information approach:** Most important for the definition of information is that information includes meaning and a specific context. However, the "context is … interwoven with the content and difficult to conceptualize, which means that the methods implemented to find requested information objects have to rely on the content and cannot access contextual information" (Smolnik et al., 2005, p. 37).
- **The descriptor approach:** The addition of explicit contextual information to information objects, thereby providing context-aware methods for information search and discovery, is called a descriptor approach.
- **The metacontext approach:** This approach extends the descriptor approach, as explicit contextual information no longer resides only within information objects, but is integrated into a metalayer that lies above and spans a variety of information.
- **The knowledge approach:** The knowledge approach focuses on the human being and considers characteristics of knowledge. It is about knowledge creation through actions like communication, construction, or cognition.

The continuum's consideration of context and its explication offers a continuous criterion through which it is possible to distinguish different knowledge management technologies. This makes the continuum of context explication an ideal basis for the development of a knowledge management dimension. Each approach forms one category that can be used to classify knowledge management technologies. The only exception is the knowledge approach. Since it is closely linked to the human mind and human action, knowledge management technologies cannot explicate the person-specific context. This approach is therefore not used within the knowledge management dimension.

The combination of the developed technology-forecasting dimension with the knowledge management perspective dimension results in the context-complexity matrix. This matrix allows the characterization of knowledge management technologies with regard to the degree of context as well as to the technology-forecasting process's degree of information structure complexity. The background of each dimension implicitly provides further characteristics of the classified knowledge management technologies. A categorization of, for example, the metacontext approach within the knowledge management domain and step VIII of the technology-forecasting domain means that the knowledge management technology is capable of supporting step VIII's great information structure complexity and also comprises a high level of explicit contextual information.

EVALUATION OF KNOWLEDGE MANAGEMENT TECHNOLOGIES

The breadth of available knowledge management technologies ranges from very simple to very complex. The set of knowledge management technologies for the following evaluation has therefore been selected to represent this breadth, namely, data mining, case-based reasoning, information retrieval, topic maps, and ontologies. We evaluate these technologies in the following with respect to the presented characterization scheme.

Data Mining

Authors in the field of data mining often state that the identification of specific patterns enables the extraction of knowledge embedded within databases (e.g., Han & Kamber, 2001, p. 4; Lusti, 2002, p. 260). This view is not absolutely precise. The consideration of data-mining applications like market basket analysis, fraud detection, or risk analysis leads to the thought that data-mining functionalities enrich data through the identification of patterns or classes in a way that a person familiar with the domain is capable of deriving a meaning from the presented results. Hence, domain-specific information is generated, which can then be combined with other information and knowledge to create new knowledge. But data mining contains no functionality that specifically supports this combination of information. By considering the continuum of context explication as a dimension for a knowledge management categorization, the discussion above can be summarized by assigning data mining to the category "data approach".

With respect to technology forecasting, Armstrong (2001) argues that "an immense amount of research effort has so far produced little evidence that data-mining models can improve forecasting accuracy" (p. 10). Thus, the quality of forecasts that are solely based on data mining is debatable and, consequently, so is the support of step IV. However, it is our opinion that with the exception of the implementation of forecasting methods, data mining can be successfully utilized to facilitate specific tasks within the technology forecasting process's steps. As we explained in the previous section, step II and step VIII require the analysis of great amounts of information with respect to specified criteria. In step II, information is needed that can be associated with the forecast's objectives as defined during step I, while an on-going analysis of information based on the results of a forecast is required within step VIII. In combination with other technologies, data mining might be a suitable way to improve the efficiency of identifying interesting information objects through classification and association analysis. Data mining can therefore be assigned to the categories "step II" and "step VIII" of the technology-forecasting dimension.

Case-Based Reasoning

Compared to data mining, case-based reasoning is a concept which targets information rather than data. A case provides the solution to some problems, which can basically be viewed as providing domain-specific information (Riesbeck & Schank, 1989, p. 24). Case-based reasoning comprises certain functionalities that allow the emulation of cognitive processes in order to generate solutions (Riesbeck & Schank, 1989, p. 24). These functionalities are the capability to adapt old cases to suit the needs of new cases and the fact that a system enlarges its case base by evaluating and retaining cases that have either been solved, or provide information about faults. Systems following the structural case-based reasoning approach (Bergmann, Althoff, Breen, Göker, Manago, Traphöner & Wess, 2003, p. 21) integrate these functionalities and apply general domain knowledge to a model to improve case storage and retrieval, thereby putting the different cases into a certain context. The context is defined by a set of features that are used to index a case and to determine similarity between different cases (Aamodt & Plaza, 1994, p. 50). Thus, features are descriptors of information objects and the corresponding context.

On the other hand, there are also case-based reasoning systems that do not have an underlying domain model, like those that use the textual case-based reasoning approach (Bergmann et al., 2003, p. 21). Such systems work directly on the information and utilize certain algorithms to compare and match new cases with those contained in the case base. Consequently, with respect to the knowledge management dimension, case-based reasoning belongs equally to the category "information approach" and to the category "descriptor approach".

With regard to the dimension for technology forecasting, an appropriate characterization and the corresponding identification of the potential for supporting the technology-forecasting process is a more difficult task. Gaines and Shaw (1986) argue that as far as technology and innovations are concerned, it seems that the past is not appropriate for predicting the future (p. 3). Case-based reasoning is, however, designed around previous experiences. This leads to the conclusion that case-based reasoning cannot be applied to technology-forecasting activities. It cannot therefore be assigned to the category "step IV" of the technology-forecasting dimension. Moreover, taking the requirements of step II and step VIII into account, it is doubtful that case-based reasoning is a useful method with which to support these activities. Both steps need to handle a great amount of new information and need to put this information into context to achieve a clearer perspective of the forecast's scope as well as to collect information with which to monitor the forecast's results. Case-based reasoning is not a method that is intended for the identification of new information. It cannot therefore be assigned to the categories "step II" or "step VIII" of the technology-forecasting dimension.

Nevertheless, it is case-based reasoning's purpose to support decisions and to solve problems. Therefore, it is an appropriate technology for application during step VI. More precisely, case-based reasoning can be used to support planning activities (Lenz, Bartsch-Spörl, Burkhardt & Wess, 1998, p. 14). A company that has a long experience of pursuing and developing innovative technologies might profit from its knowledge when a new technology is about to be developed or integrated.

Information Retrieval

On considering the definitions of each single category of the knowledge management dimension, it seems obvious that information retrieval belongs to the category "information approach'. In general, such a categorization appears to be reasonable since information retrieval targets raw information. Smolnik et al. (2005) argue that although information itself comprises content and context, the context is interwoven with the content and thus difficult to explicate (p. 37). As a result, technologies that do not include additional explicit contextual information only rely on content or its representation within search functionalities. Clearly, this is true of most conceptual information retrieval models.

On the other hand, one can argue that some forms of information retrieval also integrate explicit contextual information into search and retrieval methods. While Smolnik et al. (2005) state that "authors have to provide [explicit contextual] information at the time of creation" (p. 37), the consideration of the concept of aboutness, as introduced by Ingwersen (1992, p. 50), allows an additional perspective. On considering the fact that some information retrieval systems are based on the creation of index terms through document analysis and alignment with a specific domain by individuals, we argue that such indexes represent the indexer's aboutness and therefore also the context of the individual who analyzes the documents and creates the index. Nevertheless, in the same way that indexer aboutness differs from author aboutness, the author and indexer's contexts vary. In general, the characterization of information retrieval by assigning it to the category "information approach" within the knowledge management dimension is a reasonable outcome; however, the exceptions as discussed previously should be taken into account. Information retrieval will therefore be categorized by mainly assigning it to the category "information approach" as well as partially to the category "descriptor approach".

Within technology forecasting, certain process steps include the need to identify information when a large amount of it is available, namely in step II, step IV, and step VIII. The difference between these steps' information need is that the first two steps require a broad range of new information with respect to the selected forecasting scope, while the latter step utilizes specific information that is closely linked with the developed technology forecasts in order to compare them to reality. Therefore, an efficient way to identify and assess relations and derive consequences from specific information objects is more important than the mere retrieval of interesting information from a large amount and variety of information. It is a common assumption among information retrieval researchers that searching within such systems is an iterative process (Salton & McGill, 1983, p. 3). A user starts with some sort of query and evaluates his or her own understanding of the information needed with the help of the first result set. Either the information is sufficient—it results in the retrieval of additional information through references or the like—or a user realizes that the request has to be completely revised. Reasons for this can be found when taking into account that users are only able to describe what they need, which is in turn based on what they already know. These arguments lead to the conclusion that information retrieval is not applicable to step VIII of the technology-forecasting process and, instead, can be characterized as able to support steps with a need for a wide range of new information, thus step II and step IV.

Topic Maps

Topic maps provide methods with which to navigate associatively across large amounts of information in a conscious manner, enabling a systematic identification of information and creation of new knowledge by the user. This is possible by detaching the information source from the context used to find the information, which results in topic maps being "information assets in their own right, irrespective of whether they are actually connected to any information resources or not" (Rath & Pepper, 1999, p. 9). Moreover, topic maps support "managing the meaning of the information, rather than just the information" (Garshol, 2002, p. 2). An explicit context, called metacontext, is used to organize available information in such a way that more efficient search methods can be applied. Hence, the metacontext is the most characterizing aspect when discussing topic maps; they thus clearly belong to the category "metacontext approach" when considering the knowledge management dimension of the context-complexity matrix.

Because a topic map describes certain domain knowledge, it can be very useful when created to represent the forecast's scope. Such a topic map comprises the different technologies and research areas within the focus of the company that conducts the forecast. Associations can be used to link technologies to express their influences and relations. Any information, to which the topic map is applied, can then be categorized with respect to the forecast's scope, facilitating identification of valuable information. Furthermore, once there is a comprehensive information repository, the topic map can be used to relocate information and to relate it to the forecasting activities' results. Hence, topic maps also provide additional value when used within step IV and step VI. Identifying specific information that correlates with the forecasting activities' results is especially important within step VIII. Topic maps' filtering and localization capabilities help to achieve a more precise analysis of available information and, hence, a more efficient monitoring process overall. In general, topic maps have the potential to increase the efficiency of each technology-forecasting step in the context-complexity matrix, because they can be tailored to a forecast's scope and thereby reduce the available information's complexity to a manageable level.

Ontologies

Ontologies are a means to provide a resource that unambiguously determines the meaning of terms and their relations to other terms within a certain domain (Benjamins, Fensel, & Gómez Pérez, 1998, p. 2). This structure is an autonomous construct without links to specific information resources. With respect to the knowledge management dimension of the context-complexity matrix, it is quite obvious that ontologies belong to the category "metacontext approach", as explicit context structures are created that are independent of specific information resources and can themselves be viewed as an information resource. Therefore, relations have to be created between an information resource and ontologies by means of explicit contextual information and specific references that are added to the information resource. This methodology clearly does not fit into any other category on the knowledge management dimension than the metacontext approach.

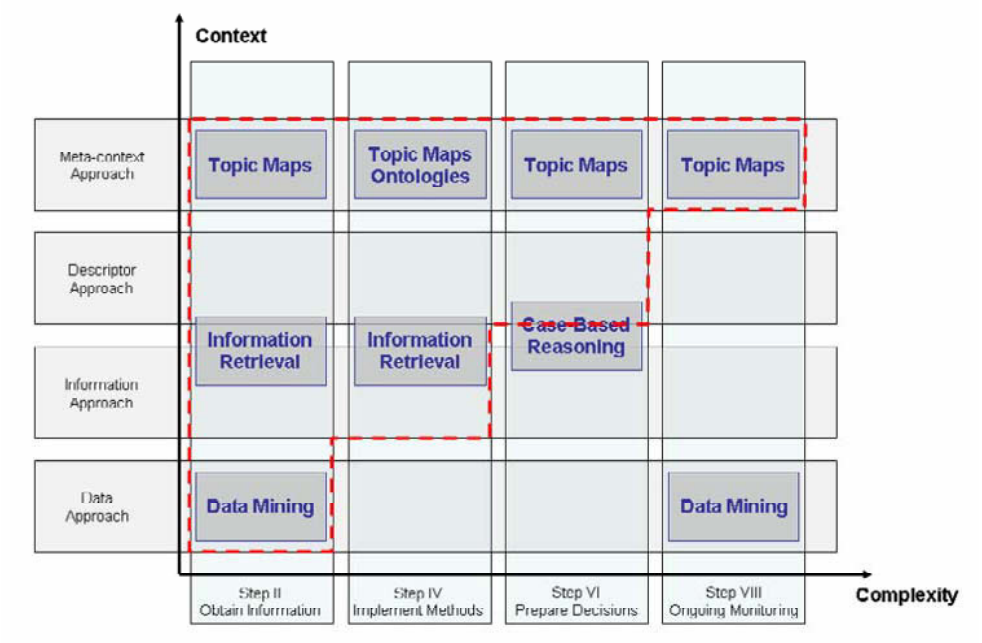
The same reasons that lead to the obvious characterization of ontologies as a metacontext approach hamper categorization with regard to technology forecasting. The question arises: which of the technology-forecasting process's steps and activities benefit from the development and application of an ontology? Following the premises regarding the benefits of ontology application as presented by Zelewski (2001, p. 4), possible applications can be derived for ontologies within technology forecasting. Zelewski (2001) argues that the knowledge intensity of the tasks to be accomplished and the degree to which the knowledge backgrounds of the parties involved in an interaction differ both influence ontologies' importance as a means to improve the considered process tasks' efficiency (p. 4). When conducted for strategic innovation management, many technology-forecasting methods such as, for example, the Delphi method (e.g., Armstrong, 2001; DeLurgio, 1998), are aimed at transforming individuals with different backgrounds' specific knowledge into statements about future technological innovations and developments. Thus, Zelewski's premises are true with regards to technology forecasting. As a result, only the category "step IV" seems to be suitable for ontology application's characterization within technology forecasting for strategic innovation management, but it is limited by the chosen technology-forecasting methods.

DISCUSSIONS

Obviously, some of the technology-forecasting process's steps can be supported by more than one knowledge management technology. Therefore, the question arises: which single technology or which combination appears to be the most promising with which to support and improve this process? To answer this question, it is helpful to consider technology forecasting for strategic innovation management with respect to the type of input each process step requires. We have shown that the complexity of the information structure within the technology-forecasting process increases in the course of the process. We argue that context too becomes more and more important. At the beginning of the process, the importance of context as well as the information structure's complexity is rather modest, but in the end, the degree of complexity and context importance reaches a maximum. As a result, the context-complexity matrix has to be refined to integrate strategic innovation management's focus in such a way that only the upper left triangle represents possible solutions, which are promising ways of supporting technology-forecasting steps through knowledge management technologies as presented in Figure 4.

A striking point of the context-complexity matrix is the fact that topic maps are capable of supporting each process step in a certain way. However, topic maps require some knowledge about the domain and its topics for their generation, while information retrieval provides functionalities that require less prior knowledge and can be used to gather a first broad variety of information. This can be especially helpful during the first phases of technology-forecasting research efforts.

Figure 4. The context-complexity matrix



Such information can then be analyzed to generate the needed topic map, which corresponds with a technology forecast's scope. Later on, the topic map can be used to classify and organize further information and, hence, allows a more systematic way of discovering additional information.

In summary, we can state that a knowledge management system that is based on topic map technologies and integrates information retrieval functionalities as extensions to those provided by the topic map, is the most promising solution with which to support technology forecasting for strategic innovation management. In order to verify the theoretical results, we test them within a real-world scenario.

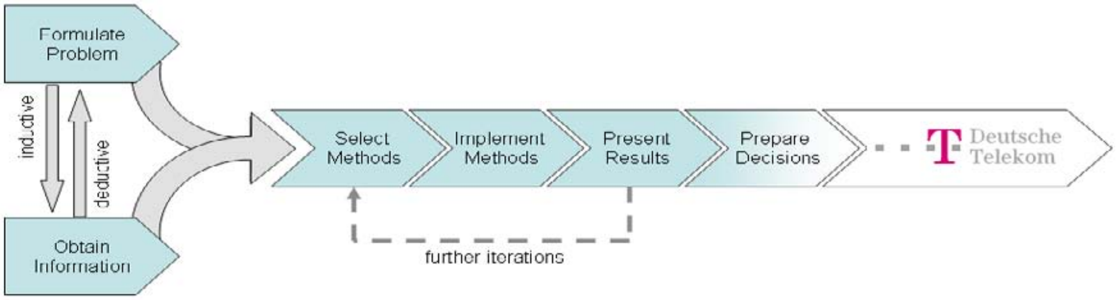
TOWARDS AN EXPLORATORY CASE STUDY

We applied our findings to a project conducted for Deutsche Telekom AG at DETECON Inc., a technology and management consulting company with a focus on innovation engineering. The main objectives of the project were the identification of technology trends and developments that are able to open new opportunities and the assessment of their innovation potential in order to define innovation strategies and achieve company goals. The technology forecasting process at DETECON Inc. differs in two main aspects from the generic process as presented in this chapter. First of all, people at DETECON Inc. distinguish between *inductive* and *deductive* approaches toward innovation and trend identification. This is comparable to what Reger (2001) calls "core technologies" and "white spaces" (p. 539). Inductive methods begin with the identification and formulation of a certain problem setting. In this case, the term *problem* refers to certain needs which emerge from inside Deutsche Telekom and are derived from, for example, internal developments or processes.

After problem formulation, specific information is obtained which is related to the problem and helps finding innovative solutions. In other cases the appearance of information about certain technology developments and innovations precedes the identification of a problem. Emerging trends and innovations are monitored by DETECON Inc. and assessed with respect to their potential influence on Deutsche Telekom AG's business or innovation strategy. An example for technological trends which lead to an innovation need from outside Deutsche Telekom is Voice-over-Internet protocol (VOIP) which, in the long run, can be considered a threat to Telekom's integrated services digital network (ISDN) landline product.

In summary, a forecasting process at DETECON Inc. can be initiated in basically two ways (Figure 5): either problem precedes information or information precedes problem. Furthermore, the technology forecasting process for Deutsche Telekom AG can be considered an iterative process. A first iteration gives a broad overview

Figure 5. Technology-forecasting process at DETECON, Inc. for Deutsche Telekom AG



of potential interesting technologies which are then communicated on a very high level towards Deutsche Telekom AG. On the base of interest, Deutsche Telekom AG requests an additional iteration with an increased analysis depth and a more precise technology scope which results in the development of *technology profile documents*. The process leaves DETECON Inc. in a phase comparable to step VI of the general process of technology forecasting for innovation management. From this point on, Deutsche Telekom AG is responsible for the remaining steps and activities and the integration of the acquired knowledge into its innovation strategy.

In the light of the previous section's results, a system based on the central utilization of topic maps seems most promising to improve technology forecasting's efficiency.

One characterizing aspect of technology forecasting at DETECON Inc. is the flexible scope required by the different steps and activities inside the process. Topic maps can be tailored to suit this flexible use. Regarding the process at DETECON Inc., the development of a single comprehensive topic map that represents the applied domain knowledge's basic structure as, for example, technologies and their relations and influences, could offer a solution. Sophisticated methods, like a topic map concept called scope, can then be used to restrict this topic map to the necessary range for single activities. This is sufficient because all DETECON Inc.'s forecasting activities deal with technology and innovation developments and their influences on Deutsche Telekom's technology and business situation. A topic map that has been built and maintained for the corresponding domain, and which can be tailored to represent only the available information's subparts through the exploitation of topic maps' scope attribute, provides an efficient solution to the flexibility requirement.

Obviously, the nature of a topic map also facilitates the organization and reuse of information, and therefore fulfills another requirement with respect to technology forecasting at DETECON Inc.: information that has been used once can be stored in a repository and can be accessed through the topic map. It is also associated with analyses, contacts, or other related information. Therefore, knowledge structures, once generated, can be represented by the topic map, facilitating the recovery of these structures. In addition, a topic map can be used to categorize new information by determining the topics that occur in the new information. This functionality can be combined with automated information retrieval methods. The information is retrieved from a source (most likely within the WWW); it is analyzed with respect to the occurring topics, and then added to the information repository. This process facilitates the identification of valuable new information without the need to analyze all new information manually. Because the information is available through the topic map, it can be accessed when needed.

Switching control of and responsibility for the process from DETECON Inc. to Deutsche Telekom AG, leads to knowledge transfer being facilitated—another requirement of a system to support technology forecasting at DETECON Inc. Once Deutsche Telekom AG considers a technology interesting and relevant, a more detailed technology profile is created, which is then sent to Deutsche Telekom AG. The integration of the mentioned profile documents into the structure of a topic map, as well as their association with the main topics and further relevant information about the corresponding technologies, facilitates this task. The technology-related knowledge can be transferred with the help of the topic map by allowing access to the profile documents and their related information. Personal meetings can then be used to discuss the technology and business consequences, creating additional knowledge that goes beyond the technology itself.

The challenge of such a system is, however, maintaining the topic map. A fully manual maintenance implies the awareness of new developments. Therefore, methods have to be found that can facilitate this task by suggesting new topics and associations. Statistical methods as applied within automatic indexing can provide a useful starting point to solve this problem.

It is obvious that the intense communication and collaboration between the two organizations cannot only rely on an underlying knowledge management system. Therefore, it can be considered valuable future research to include non-codified knowledge management processes into the analysis of knowledge management support within technology forecasting. One starting point can be to map the socialization, externalization, internalization and combination (SECI) model as presented by Nonaka and Takeuchi of organizational knowledge creation with the technology forecasting process to determine those stages which rely on non-codified knowledge creation to improve the overall forecasting process (Nonaka & Takeuchi, 1995, p. 70).

In summary, topic maps provide the needed degree of flexibility, facilitate information organization and reuse as well as knowledge transfer. Therefore, a system that is based on topic maps will be considered the solution to the increasing difficulties with technology forecasting at DETECON Inc.

CONCLUSION

As shown, knowledge management technologies play an important role in supporting the technology forecasting process as a part of strategic innovation management and overall competitive strategies. As there are several possible knowledge management technologies, the real task for technology forecasting begins with the selection of the appropriate technologies for each process step. We have therefore evaluated several knowledge management technologies, each explained according to its main characteristics, benefits, and constraints, focusing on its support of the technology forecasting process's different steps. We have furthermore aligned them all in the proposed context-complexity matrix. The successful application of our theoretical findings was revealed by the case study, realized at DETECON Inc. and Deutsche Telekom AG.

FUTURE RESEARCH DIRECTIONS

To enrich our proposed context-complexity model, we envisage the following areas of future research:

- First, within innovation management, most forecasting is done via the analysis of information as exemplified by DETECON Inc. and Deutsche Telekom AG. We have to determine whether the integration of other forecasting methods, for example, extrapolation methods, into the supporting system could lead to a higher forecasting quality and decreased uncertainty, with the aim of automating a major part of the forecasting process and achieving improved decision support.
- Second, we have to determine whether knowledge management technologies are also capable of supporting single technology forecasting methods.
- Third, we have to validate and expand our findings in further real-world cases in order to verify the theoretical results and ideas of this chapter and to identify further aspects that could potentially increase technology forecasting efficiency, improve innovation strategy formulation, and thus create and sustain competitive advantage.
- Fourth, efficient knowledge management also depends on organizational issues to a certain extent. While this chapter considers knowledge management technologies to be the focal point for knowledge management support within technology forecasting, we have to determine to what extent organiza-

tional knowledge management concepts influence technology forecasting. We assume that organizational concepts depend on the structure of a forecasting process. Processes which are conducted completely inside a single company might benefit more from organizational knowledge management concepts than processes which a scattered over one, two, or more companies. Further research in this area should discuss which combination of technological and organizational process support results into the highest value for competitive advantage and company success.

- Fifth, the main objective of this chapter is to introduce a technology focused framework for integrating knowledge management into quantitative technology forecasting. However, further research should also focus on the support of qualitative technological forecasting, for example, using methods such as scenarios, as well as on the support by noncodified knowledge management processes like those defined by Nonaka and Takeuchi's SECI model and respective technologies such as collaboration supporting tools.

The development of the context-complexity matrix and its application to selected knowledge management technologies has shown that, within technology forecasting, increasing information structure complexity leads to an increasing need for context explication. Information repositories are less useful without the application of explicit metacontexts that facilitate the discovery of needed information. While technologies like data mining or case-based reasoning provide only a marginal efficiency increase, topic maps possess a broad applicability and have the potential to increase efficiency greatly.

By returning the conclusion to the level of innovation and knowledge strategies, we can state that technology forecasting, which was originally a means of supporting an innovation strategy definition, simultaneously supports a knowledge strategy definition by presenting a basis for knowledge-scope determination. The integration of knowledge management technologies and technology forecasting by applying the proposed framework, can therefore be considered a method with which to support business and knowledge strategy alignment on an operational level.

Chapter 2.3

A Strategic Framework for City Marketing:

The SSRM Approach

Barry Mishra
University of California, USA

Erik Rolland
University of California, USA

ABSTRACT

City marketing in the broadest term can be defined as the strategic design of the city to satisfy the various stakeholders of the city who often have conflicting goals. This frequently requires an integrated approach that aligns and addresses the expectation of various stakeholders to create vibrant communities. The current trend in globalization, formation of regional trade blocks, and the shift in importance of location factors have increased the intensity of competition among regions and cities. More than ever, cities need to compete and cooperate with each other to attract companies, investments, talent, tourists, and create markets for their products and services. This entails that cities embrace strategic marketing management tools and practices, and utilize e-services such as electronic customer relationship management. The authors propose a broad approach, called strategic stakeholder relationship management (SSRM), which is enabled by information and communication technologies, including Internet, to help the decision makers succeed in designing the 21st Century city marketing initiatives.

INTRODUCTION

City marketing in broadest term can be defined as the strategic design of the city to satisfy the various stakeholders of the city who often have conflicting needs and aspirations. This frequently requires an integrated approach of thought and action that aligns and addresses the expectation of various stakeholders to create vibrant communities.

The current trend in globalization, formation of regional trade blocks and the shift in importance of location factors have increased the intensity of competition among regions and cities. More than ever cities need to compete and cooperate with each other to attract companies, institutions, investment, talent, and tourists and create markets for their products and services. Without investing in city marketing, cities will become defunct and may perish in the long run as the stakeholders will leave.

A city, in nutshell, is a microcosm of the modern political state in a socio economic sense. There are multiple stakeholders, and sometimes the boundaries between these stakeholders are blurry. Different stakeholders have different needs and aspirations while together they contribute to the overall well-being of the city. Thus, the cities must bring the various stakeholder views into a congruent strategy that benefits all its stakeholders, or at least, does not negatively affect certain stakeholders. Given the multiple stakeholders and their specific needs, it becomes imperative that any strategic approach to city marketing has to address the common as well as the competing needs in a coherent and logical manner.

The Internet, together with other technologies, has helped organizations re-orient their services as to take advantage of the available information and communications technology (ICT). Such services are often termed e-services, as they are based on ICTs (Rust & Lemon, 2001). Most industries have in the recent years seen a push towards more focus on customer relationship management (CRM)—an integral and important part of e-service. Clearly, the Internet and ICTs have helped many organizations interact better with their customers through electronic CRM (e-CRM). As a result, e-service has become a major area of study. However, it has been stated that government organizations have more trouble than the private sector in successfully applying new technology (Dawes et al., 2004). In this paper we therefore propose a framework to help city governments plan their e-service strategically: that is, align the goals of its stakeholders, as well as frame the perceived dimensions of quality inherent in their stakeholder-base. The framework, referred to as strategic stakeholder relationship management tool (SSRM) can aid cities in identifying, addressing, and managing issues that are important to their various stakeholders within the limited resources the city has.

BACKGROUND

A favorable business climate often perceived as a key factor for local economic development (Blume, 2006). Globalization has effects on regions/cities in that there have been observable shifts in intensity of competition, and shifts towards knowledge factors (Blume, 2006). Even though competitive ability of an organization depends primarily on business-related and knowledge factors (cost-efficiency, an ability to innovate, marketing and other internal factors) (Krugman, 1996), it is clear that local economic policies may enhance or inhibit such competitiveness. For example, unwanted side-effects are seen in areas such as the Inland Empire in Southern California region as well as in and China, where an overly focus on transportation and production respectively has had detrimental effects on air quality and congestion. The locational factors traditionally driving economic development in China has been the availability of cheap labor. For Inland Empire, the locational factor has been availability of cheaper land, located centrally to major distribution routes (air, ship, and road).

In the past decade, arguments have been voiced over concerns of economic growth and its potential negative impact on both local and global environments. An example of this is seen in air quality concerns over the 2008 Beijing Olympics (Der Spiegel, 2007). In addressing the air quality issues, noxious factories and power-plants have been relocated, and experiments are under way to limit car traffic (LA Times, 2007). The recent implementation of variable toll rates and congestion fees (as in Manhattan, NY), are a step in the same direction. Clearly, local economic policies related to the control of pollution drive these concerns. The immediate negative effects, in the case of the Beijing Olympics, are related to image and tourism in China as well as the poor air quality for local residents. What is clear is that there is a strong link between the marketing of Beijing as a city, and local policies for pollution control. One could clearly argue that in these areas, the local governments have not been aware of some of the issues that are important to many of its stakeholders (for example, the residents). At best, the local government has not been cognizant of one stakeholder view: the quality of life factor. Indeed, Wong (2001) found that when traditional economic factors already are in place (such as infrastructure and workforce), quality of life issues become crucial in the competitive process between cities. That is, as competition matures, the notion of being in touch with ones customers becomes even more important.

The concept of customer relationship management (CRM) is based on value maximization for the organization. The core concept of CRM is that value creation between the firm and the customer is related in such a way that an increase in customer value leads to an increase in firm value (Mithas, Krishnan & Fornell, 2005). In the words of Payne and Frow (2005):

> *CRM is a strategic approach that is concerned with creating improved shareholder value through the development of appropriate relationships with key customers and customer segments. CRM unites the potential of relationship marketing strategies and IT to create profitable, long-term relationships with customers and other key stakeholders. CRM provides enhanced opportunities to use data and information to both understand customers and co-create value with them. This requires a cross-functional integration of processes, people, operations, and marketing capabilities that is enabled through information, technology, and applications.*

The customer, in the city government setting, is a stakeholder: such as a resident, a business, a visitor, etc. It is clear from the discussion above that one should go to great efforts to clearly identify and understand the needs of the stakeholders (or the customers, as they might be). Once these issues are known, one must then align the stakeholder goals as to create a congruent plan for marketing the city. The framework proposed below provides a semi-structured way of identifying, understanding, and aligning stakeholder goals within a resource-based, e-service context.

THE FRAMEWORK

The resource-based view of the firm (RBV) argues that an above average return may be generated when the firm develops or obtains a resource that—when successfully applied in a business strategy—provides competitive advantage. The competitive advantage typically comes about after the firm discovers opportunities for change, executes on its strategy paradigms, and implements its strategy (see for ex. Barney & Hesterly, 2006). Since cities compete for customers—employers, residents, and visitors—it is clear that they must take an approach to competing similar to that of the RBV, but where the returns are to be defined by their stakeholders. In section 3.1, we will illustrate a framework for achieving this, and outline the illustration with a specific example in section 3.2.

Construction of the Framework

A city's resources are similar to most organizations' resources, yet perhaps more encompassing. Organizational theorists typically categorize the assets of the organization into logical groupings (Schermerhorn, 1999). These groupings include personnel, facilities and operational resources, and organizational knowledge as reflected in operational processes. The city's customers and specific external environmental elements should be included with the other organizational assets from the perspective of an extended resource-based view of the organization. This extended classification is often apparent in service industries where the customer has an extensive relationship with the firm—much like that of a city and its customers. The city's stakeholders should be viewed as its customers. Thus, in the discussions below, we use the term stakeholder and customer interchangeably.

Rolland, Patterson and Ward (2008) proposed a 2-dimensional framework for linking organizational resources with the customers' perception of quality (in other words, the things customers may care about). In the spirit of their suggestions, and based on the above discussion, we propose that a city possess organizational assets that can be broadly categorized into:

1. **Personnel:** this organizational asset includes all city employees with whom the stakeholders may interact.
2. **Operational Processes:** this asset includes all major organizational processes, such as city planning, issuing permits, infrastructure development, etc.
3. **Facilities and Operational Assets:** this asset includes infrastructure, land, buildings, parks, equipment, and all other non-personnel related resources.
4. **Customers:** this asset includes the stakeholder, and his/her abilities, restrictions, etc.
5. **External (or environmental) components:** this asset includes regulation, media, competition, and other external factors that may impact the customer/stakeholder.

The first three categories of organizational assets are those that are under very direct control of the city government.

In a CRM system, we are seeking opportunities to understand and improve any interaction (or potential interaction) that takes place between the organization and its customers. Burr, Patterson, Rolland and Ward (2007) as well as Rolland, Patterson and Ward (2008) proposed that such interactions be categorized into a set of "quality dimensions". These quality dimensions are related collections of factors that express (or explain) what customers care about—similar to customer satisfaction factors from studies such as ServQual (Parasuraman, Zeithaml & Berry, 1988). For city marketing, we hypothesize that a reasonable set of example stakeholders would be:

1. **Residents:** This group includes current and potential residents.
2. **Employers/Local businesses:** This group also includes current and potential businesses.
3. **Employees:** includes both people who are residents, and those work, but who do not live, in the city.
4. **Visitors:** This group primarily includes tourists and conference attendees.

Clearly, the stakeholders may have incongruent views as to their own "quality dimensions" that they care about. For example, the resident would typically value low traffic congestion and good air quality, whereas the local businesses would value lower taxes and availability of an appropriate workforce. These quality dimensions could be congruent, but typically will not be as (for example) higher taxes might be needed to reduce traffic congestion.

The dimensions of perceived quality (benefits) are typically determined through in-depth knowledge about the stakeholders, and are measured through the use of surveys (see for example Parasuraman, Zeithaml & Berry, 1988; Ward, Rolland & Patterson, 2005; or Burr et al., 2007, Rolland, Patterson & Ward, 2008). Indeed, from a quality of life and business perspective, such surveys are often found in the public domain already. For example, CNNMoney.com (Fortune, Money, and Business 2.0 magazine) publishes annual ratings for best cities for both living and business (CNNMoney, 2007; Forbes, 2007)—effectively addressing 2 of the city stakeholders: residents and businesses. Although the "quality dimensions" used in such articles sometimes are rather vague, the variables for best places to live are typically centered on variables such as job, income and cost-of-living data; housing affordability; school quality and education scores; crime rates; arts and leisure opportunities; ease of living; access to airports or teaching hospitals, and others. For best places for business, the variables often used are business costs, living costs, education, crime rates, job growth, and income growth. It should be noted that these quality dimensions differ from those often proposed in the literature. For example, ServQual (Parasuraman, Zeithaml & Berry, 1988) proposes 10 original quality dimensions for evaluating service quality: Access, Communication, Competence, Courtesy, Credibility, Reliability, Responsiveness, Security, Tangibles, and Understanding/Knowing the Customer. Sullivan and Estes (2007) implemented ServQual for local governments, and used all the 10 quality dimensions proposed in the original ServQual instrument, albeit many studies of applications of ServQual across various industries do not find support for all 10 quality dimensions. Indeed, a smaller subset of 5 ServQual dimensions is often used: Tangibles, Reliability, Responsiveness, Assurance, and Empathy. Ward, Rolland and Patterson (2005) found 4 quality dimensions to be dominant for healthcare organizations: Interaction & Communication, Access, Tangibles, and Outcome. The dimensions were found by analyzing more than 60,000 surveys of healthcare patients over a seven-year period. It would be expected that perceived service quality dimensions for cities would most likely show 3-10 dominant dimensions, where the variables listed for popular domain surveys would group into several more generic service quality variables. For the sake of the examples in this paper, we will use the following sample quality dimensions:

1. **Interaction and Communication:** This includes all interaction and communication with city resources.
2. **Access:** This could include access to city facilities and systems, schools, hospitals, airports, and others.
3. **Tangibles:** This includes cost of doing business/living, school performance scores, quality of life, quality of labor, crime rates, and other things that can be measured or observed, such as city equipment, personnel, and communication materials.
4. **Reliability:** A city's ability to perform the promised services dependably and accurately.

Once the stakeholders' perceived quality dimensions are known, we need to construct an interaction-space matrix to relate the quality dimensions to the organization resources that the city controls. Thus, for each stakeholder, we generate interaction-space matrices as shown in the examples in Figures 1 and 2. For each interaction between an organizational asset and a quality dimension, we find an interaction-space. Each interaction-space can hold zero or more interaction-points. These interaction-points constitute an opportunity for the city to interact with the stakeholder in a manner that matters positively to the stakeholder. Particularly, each interaction-point may constitute an opportunity for the city to interact with the stakeholder using electronic means (such as the internet). By definition, the interaction-points may constitute a crucial part of a CRM system, since such systems are seeking opportunities to understand and improve any interaction (or potential interaction) that takes place between the organization and its customers. Figure 3 shows the collection of interaction point matrices for 3 city stakeholders: Residents, Employers, and Visitors.

The measurement and analysis of the interaction-points can be done by surveying the customers. Survey instruments need to be developed for

each stakeholder, and data collected on a regular basis to monitor and analyze interaction-points. For example, a survey instrument should be developed that measures the customers' perceptions of the e-services. That is, the surveys are measuring the stakeholders' perceived value and their priority in relation to the organizational assets. A collection of statistically significant questions would be needed to assess each interaction-point. Such surveys typically consist of 5 point, Likert-scale questions, and must be tested and statistically validated for the survey to be deemed useful. City management can use these surveys as a basis for allocation of resources to different interaction points based on their priority and perceived value to stake holder so as to get the best return on their resources. For example, in the healthcare industry medical providers and hospitals conduct annual surveys that may be very useful in the context of healthcare; in the US these surveys are often mandated by national quality organizations such as the Agency for Healthcare Research and Quality (AHRQ). AHRQ has an online site with copies of their questions and surveys used for an annual survey where consumers assess their healthcare providers (AHRQ, 2008). J.D. Power uses similar surveys in their highly publicized annual quality measures (J.D. Power, 2008). For a brief introduction to survey use in government planning, complete with resource links, see Dawes et al. (2004)

Provided that cities regularly use and measure the performance of their interaction-points through such surveys, the organizational assets can then in turn be changed/removed/improved to promote necessary improvements in the interaction-point measures as needed. The relative importance of the interaction-points can be measured by factor analysis (Burr et al., 2007; Rolland et al., 2008), or by administrating direct questionnaires as to what the stakeholder opinions are regarding importance of interaction-points.

One major task in making the framework functional is to align stakeholder goals: that is, ensure congruency in the stakeholders' perceived quality views of the city. Rolland and Maghroori (1997) proposed that efficient organizations must be responsive to all its stakeholders. They propose a set of actions (mission realignment strategies) to correct for situations where this is not the case. The interesting thing to note about this, is that the when the stakeholder goals are aligned with the organization's mission, there is by definition congruency in the stakeholder views (Rolland & Maghroori, 1997). Thus, aligning stakeholder views may entail some tuning of the organization's mission. That is, the exercise of identifying stakeholders, perceived quality dimensions for the stakeholders, and interaction-points for the stakeholders vis-à-vis organizational assets may indeed help define or improve the goals of the city.

An Illustrative Example

In our example, we will develop the some interaction-points related to the 3 stakeholder views found in Figure 3 above. For the sake of this example, we assume that the city managers will be addressing 3 stakeholders: city residents, city businesses, and visitors. We further assume, based on surveys of the stakeholders as well as on findings from the research literature, that the 4 perceived quality dimensions dominant for servicing the 3 stakeholder groups are: Interaction & Communications, Access, Tangibles, and Reliability.

Figure 4 shows potential interaction-points for city residents. Under the *Interaction & Communication* column we see that potential interaction points between residents and city employees are through phone and online chat systems (other possibilities do of course exist). The operational processes that the city residents seeks to interact with are billing systems, appointment systems, a reminder systems (for appointments and bills due etc.) They also seek to communicate with a reservation system for use of public space/facilities.

Figure 4. Potential interaction-points for city residents

Organizational Assets	Quality Dimensions for City Residents			
	Interaction & Communication	Access	Tangibles	Reliability
Personnel	1. Phone system, including live operator 2. Live chat system	1. Live phone operator 2. Live chat with qualified employees	1. Information about employee qualification	1. Live person available 24 hours 2. Adequate police/fire staffing
Operational Processes	1. Billing system 2. Appointment system 3. Reminders - status reports	1. Appointment scheduling 2. Maps and directions 3. Status of permits/licenese/.. Applications 4. Utility services (electric, water, trash, gas) 5. Pet licensing	1. School rankings 2. Crime rates 3. Water and air quality 4. Tax rates, property taxes	1. Automated phone system available 24/7 2. Web system available 24/7 3. Provide information during non-working hours 4. IT security
Facilities & Operational Assets	1. Reservation system for use of public space	1. Available web services for all city issues 2. Emergency room services	1. Pools, parks, tennis courts, golf courses	1. Statistics of faciltities
Customer		1. Training for use of city e-Services		
External			1. Telecommunications infrastructure for the residents 2. Free wireless web access	

Under the *Access* column, we see that city residents seek to have access to the systems by which they sought to communicate (in the previous column), as well as have access to other systems, such as pet licensing and emergency room services. Access to emergency room services could for example be via live chat or telephone, or web scheduling, etc. We also note that the residents want access to training as to how to use the city's e-service systems.

The *Tangibles* dimension primarily lists factual information about issues related to the city's organizational assets. For example, information about: the city employees' qualifications, school rankings, crime rates, water and air quality, and tax issues. Additionally, the residents seek to know about the telecommunications infrastructure (for example, what broadband options are available), and if a free wireless network is available. The latter two issues are related to resources external to the city's organizational assets, but show that it may be important for cities to attract such services from the external industry.

Reliability would include adequate city staffing around the clock—particularly of police services and other emergency services. It also would include access to city e-service 24 hours per day, including holidays, and also may include statistics of city-operated facilities (police, fire, electric, water, etc.) in terms of service reliability. Of course, residents expect that all city services that are conducted electronically can be performed securely (IT security).

In Figure 5, we list some potential interaction-points for the employers/city businesses. This interaction-space matrix differs only slightly from the resident's matrix. For example, an important *tangible* related to city facilities could be the existence and size of conference centers for business conferences. Also, businesses would be interested in business growth rates, and profiles of local industry (both variables related to the employers themselves), as well as economic growth rates for the region/state (an issue external to the city). Of course, businesses would like to have access to processing times for business license issues, but they normally would not care about pet licensing as residents do. Also, businesses may care about access to a network of similar businesses for purposes of professional exchange (for a Silicon Valley-like environment), skilled labor pool, university and vocational institutes.

Figure 6 shows some potential interaction-points that visitors may deem as important. For example, potential visitors may want to have access to and interact with city personnel who are dedicated to tourist services. They also want access to maps and directions, as well as purchasing tickets for public transportation systems (all access issues). Visitors are also interested in tangibles (mostly information) related to air quality, weather, hotels, airports, beaches, mountains, and other recreational areas. On the *reliability* side, visitors would be interested in the reliability and interoperability of public transit systems, police staffing in the city, and perhaps reliable availability of city tourism experts even on holidays and nights.

Links to Organizational Strategy

Strategic planning in an organization must take into consideration an assessment of the firm, planning for the future, and implementation of the plan (see Figure 7). Bryson et al. (2007) proposed a resource-based approach to strategy formula-

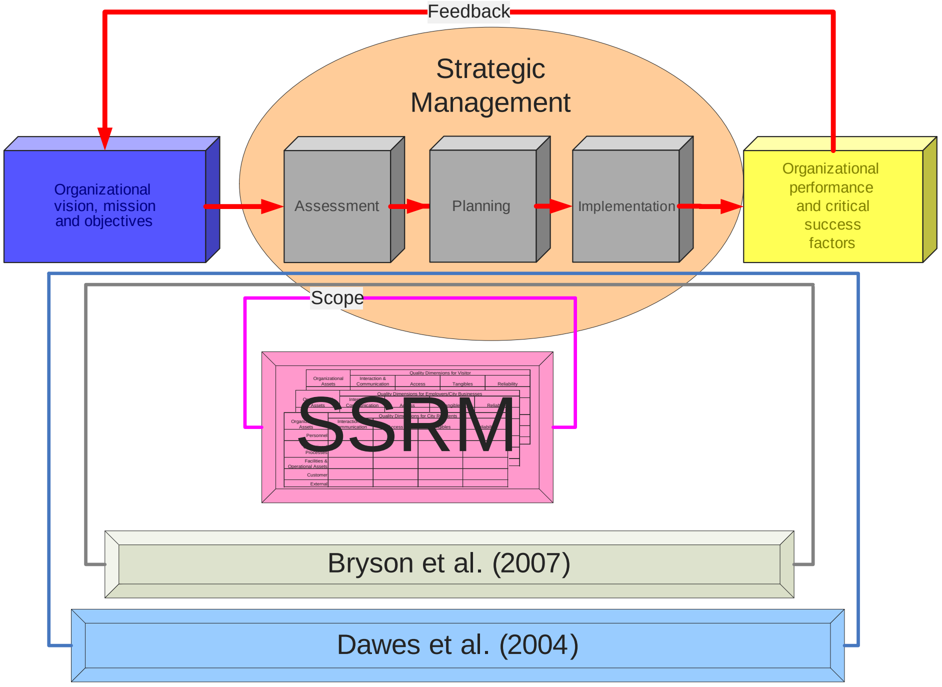
tion and implementation that is relevant to the framework proposed in this paper. In their paper, Bryson, Ackermann and Eden (2007) presented mapping methods for identifying distinctive organizational competencies, as well as a livelihood scheme that shows what the organization desires, as supported by the organizational competencies (Eden & Ackermann, 2001).

The SSRM method, as proposed in this paper, can certainly build upon (and is informed by) the approach by Bryson et al. (2007), but also is more specific in its treatment and identification of interaction-points—the latter being crucial in an e-service context. For example, Bryson, Ackermann and Eden (2007) identify distinct organizational competencies. These competencies are typically thought of as things the organization do especially well in comparison with other organizations. Such items may be thought of as subsets of the organizational resources, and would typically fall under Operational Processes in the SSRM framework. Thus, the e-service relevant capabilities found by using the method proposed by Bryson et al. (2007) can be thought of as various Operational Processes in the SSRM framework.

The SSRM framework discussed above is designed to allow for some guidance in the strategic planning process, without limiting the creativity of the city managers. That is, the goal is to generate e-service interaction-points that tie firm resources to customer-perceived issues. This planning process is clearly a creative one, and it would be counter-productive to specify in detail what must take place in such a process. However, one could clearly integrate the SSRM with existing planning methods, such as the one suggested by Bryson, Ackermann and Eden (2007). The SSRM framework by itself simply enables the managers' creative planning to take place within the context of firm resources and customer-perceived quality issues.

Figure 7. SSRM and organizational strategy



FUTURE TRENDS

It is clear that the development of e-services for cities is progressing rapidly. A large number of cities have implemented many of the services discussed in the examples above. However, it is not clear what tools have been available to city managers to conduct studies to frame proper analyses of stakeholders and interaction-points between organizational assets and perceived quality in the e-service context. Dawes et al. (2004) have presented and summarized an excellent collection of general tools and tips for improved use of ICT in government organizations, and these tools and tips are applicable across the strategic management processes. Bryson, Ackermann and Eden (2007) have proposed specific and important methods to better help government organizations to plan strategically. The SSRM method complements this prior work by specifically aiding the development of e-services in the strategic planning process. The potential strategic management scope of the research by Dawes et al. (2004), Bryson, Ackermann and Eden (2007) are shown in relationship to the SSRM in Figure 7. The rectangles emanating from each method shows the potential use of the method in strategic management. We assume that the proposed SSRM framework, along with the works of Bryson, Ackermann and Eden (2007) and Dawes et al. (2004) should be both useful and of crucial importance to city managers. This should be true whether or not one believes that cities compete with one another: at any rate, all cities are charged with providing its stakeholders with the best services in the most cost efficient manner.

Numerous future research opportunities exist in fine-tuning the organizational assets in the light of the perceived quality dimensions. That is, organizational assets can perhaps be broken into smaller chunks in order to see a finer picture of how the organization (the city) should relate its resources to the perceived quality dimensions. For example, one might want to identify the actual organizational processes, and compare those to existing or new processes that might serve the stakeholders' perceived quality better.

One limitation of this proposed method is clearly that while parts of the framework have been well tested in the healthcare setting (Burr et al., 2007; Rolland, Patterson & Ward, 2008), it is otherwise unproven in the city setting. That is, the perceived quality dimensions used herein must be proven significant for the purposes of city marketing in its e-service context. As such, another fruitful avenue for future research lies in verifying or finding the perceived quality dimensions for city marketing. Even with such a limitation, this framework constitutes the first attempt to align city stakeholders and their perceived quality dimensions to organizational assets through identifying and measuring/monitoring interaction-points in order to improve a city's e-service efforts.

CONCLUSION

In this paper we have proposed a framework to help cities plan their e-service strategically. The approach includes identifying the city stakeholders, aligning the goals of these stakeholders, as well as framing the perceived dimensions of quality inherent to each stakeholder. Each stakeholder's perceived dimension of quality can now be linked to the city organizational assets by identifying one or more interaction-point between the city's organizational asset and the stakeholder's perceived quality dimension. These interaction-points are touch-points between the city and its stakeholders.

By measuring and monitoring the interaction-points on a regular basis, using for example annual stakeholder surveys, the city can adjust the "functionality" of its organizational assets, or adjust the use of interaction points, in manners which lead to higher stakeholder-perceived service quality. For example, the city can change its assets by changing its operational processes, training its personnel, acquire or improve its facilities and operational assets, or influence the stakeholders or external entities to cooperate with the city. Also, the framework enables the city to monitor the importance of the interaction-points (by using statistical techniques - factor analysis and regression) in order to de/emphasize or delete/change interaction points. The framework also allows city managers to think about potential new interaction-points that their stakeholders may value highly—particularly such interaction points that may already be in use at "competing" cities.

The impacts of using the framework are in improved service to all of the city's stakeholders. From a management perspective, the application of the method proposed herein requires deep local knowledge along several dimensions: First, the managers must clearly understand who the stakeholders are, and what these stakeholders care about in terms of perceived quality. The strength of the proposed method is that the final interaction-points outline a broad map for the design of the city's e-services (that is, direct things to put into the web site design related to the interface for each stakeholder). Further, the framework allows city managers to think about interaction points in a semi-structured way, which does not inhibit creative thinking or discussion about the interaction-points. Use of the framework for strategic purposes (setting direction both for goals and processes) may contribute strongly to the city's dynamic capabilities, and in turn their competitiveness as a city (Rolland et al., 2008). While it has been shown that increases in the customers' perceived service quality leads to an increase in firm value (Mithas et al., 2005), we argue that this relationship should persist even if, as is normally the case, the city is a non-profit entity.

Chapter 2.4

Dynamics in IS Development: A Multi-Method Experiment to Measure the Effects of Disruptions during the Development Process

Peter Otto
Union Graduate College, USA

Salvatore Belardo
University at Albany, USA

ABSTRACT

The failure of many IS development efforts suggests that the development process, in particular the role that key antecedents play in ensuring success, is poorly understood. Information systems are based on a series of highly complex interrelated tasks that can be significantly affected by organizational (e.g., management attention), project (e.g., resources), and technical (e.g., tools) drivers. Changes or disruptions in these can have severe and, in many cases, unanticipated consequences for IS development efforts. To help understand how disruptions during the IS development initiative affect the quality of the system, we employ the system dynamics methodology to capture feedback from non-linear activities, viz., those that define a systems development effort. The results from the simulation lead to some tangible and timely recommendations to manage an IS development initiative. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION AND MOTIVATION

Developing an information system is a difficult task often plagued by cost overruns, delays and cancellations. Disruptions arise from a number of factors including technical difficulties, lack of managerial attention, lack of strategic or process alignment, or lack of user involvement. Models intended to explain factors critical to successful IS development (cf., Arnold, 1995; DeLone and McLean, 1992; Seddon, 1997) address important deployment (e.g., system quality) and usage (e.g., user satisfaction) drivers but fail to adequately explain the impact of relationships between these factors.

Research suggests that because managers have difficulty understanding the interactions among factors in complex systems, they fail to adequately account for the time delay between a control action and its effect (Simon, 1979; Sterman, 1989). They may also fail to understand the feedback between their own decisions and changes in the environment, which, as Sterman (1989) notes, can cause instability. In many cases, we assume conditions to be stable during IS development. Unfortunately, both external and internal disturbances that accompany systems development efforts can cause conditions to become unstable, and systems to become unpredictable or uncontrollable (Cambel, 1993).

The literature suggests that the most common sources of instability are changes in schedule, user requirements, staffing/leadership, and design (Rebentisch, 1996); a number of researchers have attempted to explain the impact of these factors on system development efforts (cf., Schmitt and Kozar, 1978; Necco et al., 1988; Davis et al., 1992; Pollalis et al., 1993).

IS projects fail not only because of instability but also because of management's inability to anticipate the delay that inevitably occurs before problem resolution takes full effect (Keil and Robey, 1999). Traditional IS development models (cf., DeLone and McLean, 1992; Seddon, 1997) sequentially arrange deployment and usage drivers or apply linear methods (e.g., regression) in which independent variables are used to make predictions about system behavior (Svyantek and Brown, 2000). A better understanding of the dynamic interactions that affect IS use and, subsequently, IS success can be achieved using non-linear methods.

Abdel-Hamid et al. (1989, 1990, 1992 and 1999) have applied non-linear modeling to investigate how staff turnover, resource allocation, and managerial turnover affect software development and cost. While this research stream addresses a number of important questions in regard to schedule changes and cost overruns in software development, it has focused primarily on the human resource dimension of software project management. Our study aims to extend the work of Abdel-Hamid et al. by (a) including the qualitative dimensions of the skill and knowledge of IS development teams and (b) measuring the expected outcome of IS development projects from the user's perspective. We contend, that by quantifying the different effects of instability during IS development and viewing the results from a user's perspective we are better able to measure the anticipated use of the information system and, subsequently, IS success.

The next section describes IS development characteristics with reference to DeLone and McLean's original IS success model. In the methodology section, we conceptualize the simulation model, explain our research methodology and discuss key variables and interactions between them. In the section entitled "Model Characteristics" we show how, under certain conditions, imbalances between desired and available resources and changes in project scope can have a profound impact on the development of an information system. The article concludes with a discussion of limitations and possible extensions of the model.

IS DEVELOPMENT CHARACTERISTICS

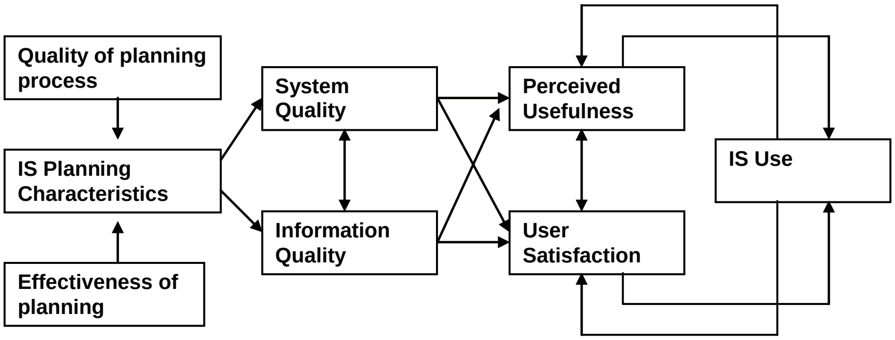
Over the last twenty-five years or so, numerous studies have been conducted to determine strategies to help improve the chances of developing successful information systems (Lucas, 1981; Bailey and Pearson, 1983; Ives et. al., 1983; Davis, 1989; Melone, 1990). The authors of one of the more widely cited models (DeLone and McLean, 1993) contend that use of the system, and user satisfaction, are highly correlated with the system's impact on the user and the organization. Rai, Land and Welker (2002) contend that there is empirical evidence to support the explanatory power of the DeLone and McLean model. In a ten year update, DeLone and McLean (2003) discuss a decade's worth of attempts to apply and validate their model.

Although DeLone and McLean (2003) suggested minor refinements to their original model and proposed an updated IS Success Model that incorporates the notion of service quality, we have chosen to focus on their original model in order to build on and extend the rich body of research that has validated this model. While DeLone and McLean suggest that system quality (e.g., consistency of the interface) and information quality (e.g., timeliness, accuracy, etc.) lead to intention to use, user satisfaction, and, ultimately, net benefits, they do not specify what determines system quality or information quality. They argue that organizational (e.g., managerial support), project (e.g., project management) and technical (e.g., standards) factors are critical to ensuring system and information quality. We contend that one of the most important of these factors is planning. A survey of senior managers confirms our contention (Luftman and McLean, 2004). This survey of CIOs and senior IS managers cited planning along with IT and business alignment as their top two concerns. Unfortunately, most of the research on planning has focused on more strategic issues such as alignment of IS planning with business strategy, the role of IS and IT in helping the firm gain and maintain competitive advantage, or understanding patterns of information use in organizations (Segars and Grover, 1998).

We agree with Premkumar and King (1994) who contend that the quality of IS planning derives from the quality of the planning process and planning effectiveness. Unfortunately, studies assessing the effectiveness of IS planning efforts generally lack consistency and have prevented researchers from making relevant conclusions about the effectiveness of information systems and practices associated with their management (Segars and Grover, 1998). Given the broader scope of our research, we have selected the characteristics "quality of planning process" and "effectiveness of planning" as the theoretical bases for conceptualizing IS planning. Collectively, these constructs represent the criteria used to assess information quality and system quality. While many aspects of effectiveness with respect to IS and IS management are complex (DeLone and McLean, 1992), with multiple interrelated success dimensions measured by multiple indicators (Segars and Grove, 1998), this study frames an aggregated theoretical and operational dimension of IS planning. Working within these parameters, the following theoretical and operational construct is developed.

The proposed study framework, as shown on Figure 1, encapsulates IS development from an aggregated perspective, integrating IS planning concepts (Premkumar and King, 1994), the technology acceptance model (Davis, 1989), and the DeLone and McLean IS Success Model (2003). DeLone and McLean suggest that their

Figure 1. Characteristics of IS development and framework for study



revised model is still constructed in a process sense, given that "the nature of these associations should be hypothesized within the context of a particular study" (DeLone and McLean, 2003). Our study framework, thus, links attitudes and beliefs (perceived usefulness and expected use of system) with the system characteristics suggested by DeLone and McLean (2003) and Premkumar and King (1994) to capture the expected use of the information system through design and implementation.

While the proposed framework shown on Figure 1 links together the major elements in IS development, it implies linear or sequential characteristics of the different measures that influence IS success. To address this deficiency, we employ a dynamic non-linear systems methodology. Even though the fundamental structure of the proposed study framework is developed by referring to a number of existing theories in the area of management information systems, our study is aimed at making policy recommendations rather than providing theory. A dynamic feedback perspective, we contend, is important because it can help policy makers better understand the impact that delay between a control action and its desired effect has on IS development (Adbel-Hamid, 1993).

In the following section we develop a basic simulation model, designed to capture the dynamic nature of an IS development initiative using the structural components shown on Figure 1. Our study is aimed at capturing key interactions in an IS development project, thus, some structural components in our model are represented in aggregated form. Nevertheless, our dynamic non-linear model provides the following advantages over traditional linear models. *First*, the simulation model captures the dynamic characteristics of disruptions that cause disequilibrium during information system development. Although the representation of the system, along with the causes of instability is highly aggregated, the model provides insight into the dynamic behavior of organizations with respect to information system development efforts. *Second*, the model can be used to simulate and test different policies that might influence the expected use of the information system and, thus, the success of the development effort.

METHODOLOGY

The main objective of this study is to conceptualize a system dynamics model to gain insight into how changes in the important deployment factor, IS planning, affects IS development efforts keeping in mind the utility function of IS users. The model is designed to test different managerial policies in order to understand interactions among various factors in a systems development effort and their impact on IS planning and ultimately on IS use and IS development success.

As Zuboff (1988) concluded, "behind every method is a belief." Our belief is that system dynamics is well suited not only to theory development but also to understanding complex behavior associated with information systems development projects. Our belief is based upon the following assumptions: (1) time is an important element in constructing a conceptual framework for capturing the social interactions and interventions between teams during IS development (Sawyer, 2002); (2) longitudinal process models employed in research often provide a limited (linear) perspective on time (Abbot, 1995); non-linear methods such as system dynamics consists of multiple measurements of both independent and dependent variables that provide graphs of the resulting data over time; (3) policy predictions are more qualitative than the predictions made using traditional approaches (Svyantek and Brown, 2000); (4) an actor's interpretation of an action and its effect is part of a larger dynamic context (Sterman, 1989); (5) system dynamics models have long been associated with the notion that complex systems are counterintuitive (Forrester, 1961).

As Figure 1 indicates, an important measure of IS development success is whether or not the system is used. It is reasonable to assume that if the system is used, it will lead to improved individual and organizational performance. While previous studies by Abdel-Hamid (1989 and 1992) focused on how resource allocation and staff turnover affect software development cost and schedule, subsequent works have applied a project management perspective. Our aim is to measure how changes in project drivers or disruptions (e.g., level of staff experience, level of organizational stress, or management attention) affect planning and ultimately IS use.

The current user satisfaction literature (cf. Bailey and Pearson, 1983; Baroudi and Orlikowski, 1988; Doll and Torkzadeh, 1988; Ives at al., 1983) provides the basis for our survey. However, instead a measuring the variables independently, we conducted conjoint analysis to measure how IT users make trade-off decisions when faced with a set of attributes. Conjoint analysis is a statistical technique normally applied to product development and positioning strategies. In our study, we employed conjoint analysis as a complementary tool in tandem with system dynamics. In this way, we were able to identify attributes and relationships among those attributes considered important by IS users.

Conjoint analysis examines the trade-offs IS users make when selecting certain IS attributes. In using the technique, we assume that an information system is a bundle of attributes, such as timeliness, ease of use, accuracy, and output--each of which consists of several hypothetical functional dimensions (discussed below). Our conjoint analysis design consists of four attributes on two levels, resulting in 32 (4x4x2) combinations. The number of relevant combinations was reduced, without invalidating the conjoint analysis technique, through the use of an orthogonal array experimental design (Green, 1974). We used SPSS conjoint analysis design, which selects the test combinations so that the independent contributions of the selected attributes are balanced and each attribute weight is retained.

Data Collection

Data was collected using a structured questionnaire and score cards representing hypothetical functional dimensions of an information system. Participants were asked to rank the score cards to indicate the combination of attributes they found most desirable. The study sample consisted of 75 executive MBA students; 68 of the 75 returned questionnaires were suitable for data analysis. The product attribute selection for conjoint analysis is based on Doll and Torkzadeh's (1988) construct for measuring end-user computing satisfaction. The following attributes were used:

Timeliness: *System is ready when needed*
System provides up-to-date information
Ease of use: *System is user-friendly*
System is easy to operate
Accuracy: *System is accurate*
System content meets my needs
Output: *System output is presented in a useful format*
System provides clear information

Using the orthogonal array experimental design technique, the original set of 32 (4x4x2) IS configurations was reduced to a parsimonious set of 8, in which the independent contributions of all 4 attributes were balanced. This reduced set of combinations representing hypothetical information system characteristics was then presented to the study participants who were asked to rank the cards, on a scale from 1 to 7, according to individual preferences. The conjoint analysis program then derived estimates of the utility function for each participating IS user, based on their evaluations of the hypothetical IS characteristics. The utility functions, which are used as input for the simulation model described below, quantify the relationship between each participant's evaluation of the hypothetical information system and the individual attributes of the information system. Thus, conjoint analysis can be used to determine the most desirable attribute configuration for a product (Green and Wind, 1975) or, in our case, the desired features and functionality of a hypothetical information system. The results of our conjoint analysis reflect the perceived usefulness of an information system as seen from the user's perspective. As will be demonstrated below, in the section entitled "Sector View: Expected Use of System", perceived usefulness is required to assess expected use of the system.

Results

The conjoint analysis output, i.e., the utility functions of the individual participants for the attributes and related levels, is used as input in the simulation model described below.

In conjoint analysis, all utility scales are expressed in a common unit of measurement. This allows for a meaningful comparison of attributes (Green and Wind, 1975). As can be seen in the importance summary (Table 1), "timeliness" had the most utility for study participants. The least important attribute was "ease of use", which may appear counter-intuitive if the implicit trade-off is not considered. In relation to "timeliness", the attributes "accuracy" and "output" are less important, though only marginally so. Given our sample size, we may not be able to project our findings onto a larger population of IS users. Yet, it was never our intention to generalize our results but, rather, to use the utility functions as input for a simulation model in order to test our theories in the context of an IS development project.

MODEL CHARACTERISTICS

As previously stated, we use system dynamics to capture the complex interrelations among factors germane to IS success. System dynamics has its roots in engineering control systems and in the theory of information feedback systems (Morecroft, 1987). In 1956, Jay Forrester reshaped a mathematical, engineering control systems approach into an analysis method for the visualization and simulation of feedback dynamics. Richardson (1996) defines modern system dynamics as "a computer-aided approach to policy analysis and design".

Figure 2 shows the major structural components, the five subsystems and feedback effects of the model. The five subsystems consists of (1)

Table 1. Relative importance of conjoint analysis factors

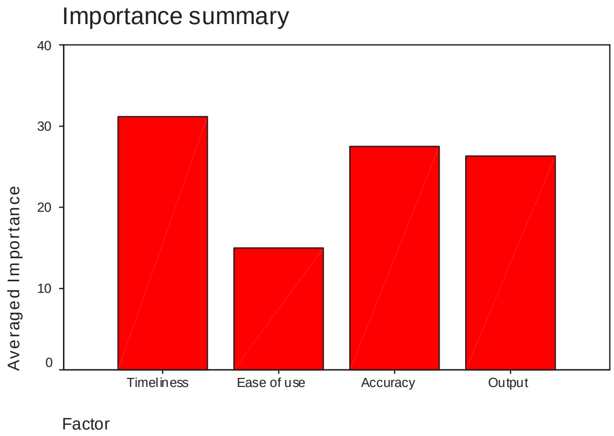


Figure 2. Aggregated overview of model structure. The polarity of the information feedbacks denotes the sign of the relationship between independent and depend variables, e.g., $X \rightarrow +Y \Rightarrow (\partial Y / \partial X) > 0$.

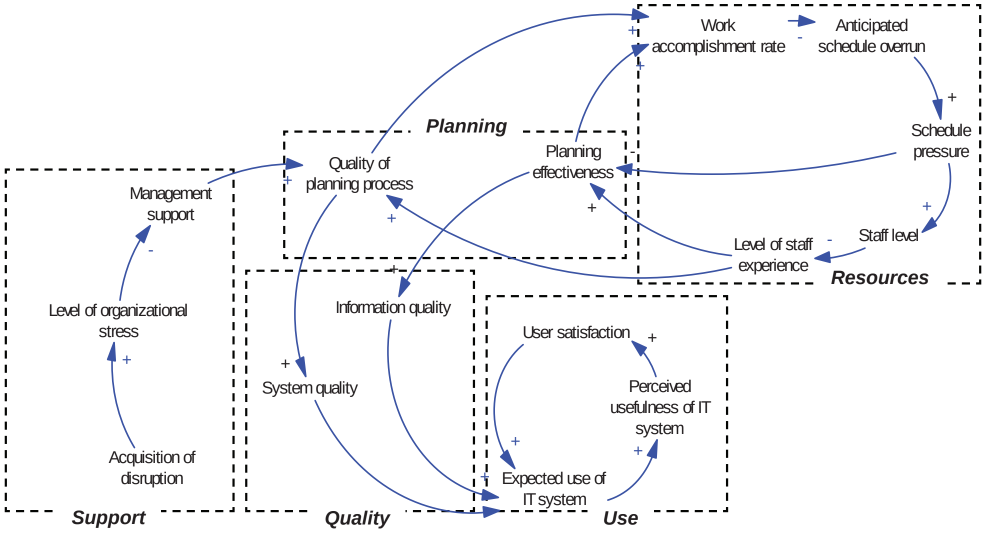

Management Support; (2) Information and System Quality; (3) Expected use of System; (4) IS Planning; and (5) the Resource Subsystem.

The actual simulation model is more detailed, containing more than 180 causal links; a detailed discussion of the model would exceed the scope of this article. Those interested in seeing the detailed model can download a free version (Vensim PLE) of the simulation software used to conceptualize the model (http://www.vensim.com) and contact one of the authors for a copy a the simulation model.

The Management Support Subsystem

A sizable body of literature attests to the fact that lack of managerial attention will either delay or undermine IS development efforts (cf., Ein-Dor and Segev, 1978; Lucas, 1975; Kaye, 1990; Keil and Robey, 1999). We assume that management has a certain capacity to respond to organizational disruptions; this influences the level of attention management can provide to IS development. The level of management attention is determined by performance ability, which is influenced by the stress level to which management is exposed. By combining the interruption theory of stress (Mandler, 1982) with the structural formulations found in Rudolph and Repenning's (2002) conceptualization of disaster dynamics, we are able to predict the level of management attention to IS development when unexpected disruptions occur. This structural formulation is based on the assumption that organizations are faced with a continual stream of incoming disturbances, which they are able to process until the influx reaches a critical threshold. At that point, management's processing capability decreases while stress levels continue to increase. The rate of disturbance is an artificial numerical value not grounded in empirical research. Nevertheless, we are able to capture stress level thresholds, i.e., the point at which management can no longer effectively respond to disruptions or provide the attention required to manage an IS development project.

To simulate the perturbation rate of incoming disruptions (acquisition of disruption) we have used Sterman's (2000) formulation of "pink noise" to capture a randomness that allows us to specify the degree of persistence or the amplitude of each frequency. We have used this formulation to simulate a certain variation in disruptions because it is assumed that instability is not a constant variable to which an organization is exposed.

The Planning Subsystem

The IS planning concept, as suggested by Premkumar and King (1994), consists of organizational and project drivers which we contend are surrogates for the quality of the planning process and planning effectiveness, respectively. The construct "quality of planning process" is operationalized in terms of the extent of detailed analysis in the three major areas of the planning process: internal, external, and technological (McLean, 1977; Boynton and Zmud, 1987; Karimi, 1988). Because our emphasis is on capturing key interactions in IS development, we aggregate the three major areas of the planning process and simplify these concepts. Improving the quality of the planning process is a function of staff experience and management attention. The level of staff experience is derived from the skill set of people assigned to the project; management attention is linked to the level of guidance provided during development. Degrading quality (of the planning process) is a function of schedule pressure and a fractional time constant, which captures a normal decay of planning quality over time. Planning effectiveness is a performance measure used to discern team effectiveness and efficiency, two important dimensions for knowledge teams (Ancona and Caldwell, 1992; Henderson and Lee, 1992; Leonard-Barton and Sinha, 1993). Because objective measures of performance are problematic in the IS field (Henderson and Lee, 1992; Kemerer, 1989) we aggregate planning effectiveness as a function of the productivity rate of experienced and new staff assigned to the team, controlled by schedule pressures, which occur when there is an anticipated schedule overrun.

The Quality Subsystem

As noted in the foregoing discussion of the DeLone-McLean model, system quality is linked to information quality, perceived usefulness and user satisfaction. We do not explicitly capture system quality and information quality in our model but, rather, the underlying measurements that influence these two constructs: "output" and "accuracy". It has been shown that output and accuracy can be employed to determine system quality, whereas ease of use and timeliness determine information quality (Doll, 1988). Since we are interested in an outcome assessment of IS development as perceived by IS users, we use this aggregated view.

The Resource Subsystem

We contend that the task of developing and implementing an information system follows a number of predefined steps. Thus, in our simulation model, development is a function of "work to do" (e.g., business process analysis or deployment of the information system) determined by a task accomplishment rate. The rate at which individual tasks are fulfilled is based on the quality of the planning process and planning effectiveness, which, in turn, are influenced by staffing decisions, team skills or management attention levels. The structural components in our model that simulate project dynamics are based on well established system dynamics concepts (e.g., Abdel-Hamid and Madnick, 1990; Richardson, 1996; Lyneis, 1999).

The IS Use Subsystem

As mentioned earlier, we conducted conjoint analysis in order to provide empirical grounding for the conceptualization of IS success and to assess its impact on IS use in the simulation model. The resulting conjoint importance summary (see Table 1) provides input variables in order to measure end-user expectations of the hypothetical information system. In order to compute the value of perceived usefulness of the information system, we apply the Multi-Attribute Utility Theory (MAUT)--an approach grounded in the utility theory of von Neumann and Morgenstern (1947) and the specific assessment techniques developed by Kenney and Raiffa (1976). MAUT allows users to: (1) determine the relative importance of attributes deemed essential to a decision or preference; (2) assess the worth (utility) of each choice regarding qualities deemed important in a decision situation; (3) aggregate individuals' preferences for the choices available, given the utility of each choice (Klersey, 1988). According to Keeney and Raiffa (1976), the utility (U) of a decision alternative with multiple attributes, x_1, x_2, …..,x_n, can be expressed as U(x_1, x_2, …..,x_n). We calculate the aggregated utility for the perceived usefulness of an information system as follows:

Perceived usefulness of system =

$$\sum_{i=1}^{4}(Wt_i \times A_i)$$

(where Wt_i is the user weight, or importance summary of conjoint analysis for an individual attribute, and A_i is the respective attribute.)

The variable "expected use of system" is directly related to the perceived usefulness of the system. Seddon (1997) argues that use precedes impact and benefit but does not cause them. We simplify the construct of user satisfaction and IS use for two reasons: first, because we cannot capture user satisfaction unless the system is already in place; second, because we contend that expected use of the system is equivalent to user satisfaction, which is traditionally conflated with IS success (Bailey, 1983). The next section discusses a number of simulation experiments designed to explore a variety of conditions that cause instability in IS development.

EXERCISING THE SIMULATION MODEL

This section describes how the system dynamics model is used to simulate different conditions and to identify potential remedies for instability in information systems development. The managerial interventions cited do not constitute all possible interventions yet they are adequate, we believe, to help develop a model robust enough to capture management's ability to successfully control an information systems development project.

Time delays influence interventions in at least two ways. First, a delay may cause managers to hire more staff in order to reduce schedule slips. Second, schedule slips can impede management's ability to initiate the required project management response, thus causing further delays. Brooks (1974) illustrates how traditional conceptions of time--linear and additive--may lead to inaccurate hypotheses within a complex social context. He argues that one might hasten to complete a project by assigning more people only to produce counterintuitive effects, i.e., slowing down the process.

Base Line: Reference Mode Behavior

The preceding sections provided the structural details of the model together with the different sectors, characterizing the problem domain for an IS development project. We contend that in applying well established and empirically grounded IS taxonomies, the structural components of the simulation model are consistent and valid. However, because most of the variables used in the model are hard to measure, the model cannot be calibrated against real data. Thus, testing the validity of the model is not an easy task.

The goal of model validation in system dynamics is to determine whether a model is appropriate for a given purpose and whether model users can have confidence in it. This is accomplished through testing and calibration. Forrester and Senge (1980) describe 17 tests for building confidence in a system dynamics model. Sterman (2000) offers 12 tests, examining models on both structural and behavioral grounds. Other tests focus on collaborative model building projects that include both modelers and model users. Richardson and Pugh (1981) divide confidence-building tests into those that test for suitability and those that test for consistency. Suitability tests determine whether the model is appropriate for the problem it addresses, while consistency tests examine whether the model is consistent with the particular aspect of reality it attempts to capture. The reality we aim to capture with the model is shown as a reference mode on Figure 3. This reference mode identifies hypothetical behavior for an information system development project over time.

The theoretical reference mode behavior depicts a successful IS development project, in which effective management of resources, appropriate team skills and the absence of disruptions lead to perfect project completion. While this reference mode is highly simplified, it captures possible behavior of an IS development initiative under perfect conditions. The assumptions upon which this reference mode is based are a desired project completion time of 100 weeks and a team consisting of experienced people. Thus, the initial value for the expected use of the system is relatively high.

The graph on Figure 4 captures the simulation model's base line, characterizing the dynamics of a hypothetical IS development initiative under perfect conditions. We contend that the model is able to replicate the reference mode behavior with regard to the expected outcome of the project. We did not attempt to calibrate the slope of the line against the reference mode. The reference mode only characterizes the expected behavior of IS development, which implies that system quality and information quality increase over time, leading to a perfect result. Richardson and Pugh (1981) contend that one can have increased confidence in the insights that derive from the model if the reference environment can be replicated.

The input conditions for the base line of the model are as follows: the project team consists of four experienced and two new staff members (with initial levels of relative quality and relative productivity of 0.5); management attention is sufficient to support the project; the initial work consists of 400 tasks. The input value for expected use of system is 0.5 at t=0 because we assume that a relatively high level of staff experience shapes the outcome of a project. The number of tasks (400) used as the initial input is arbitrarily chosen. While, in the real world, the process rate for individual tasks would vary, the model processes each task in the same unit of time.

Figure 3. Reference mode for IS success

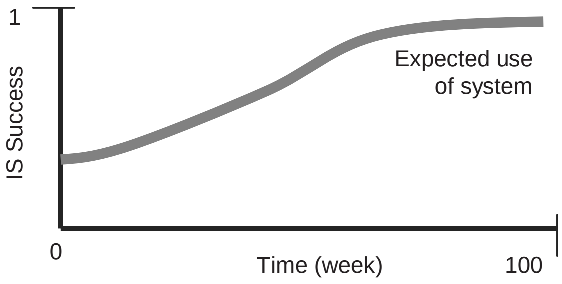

Figure 4. Base line of simulation model

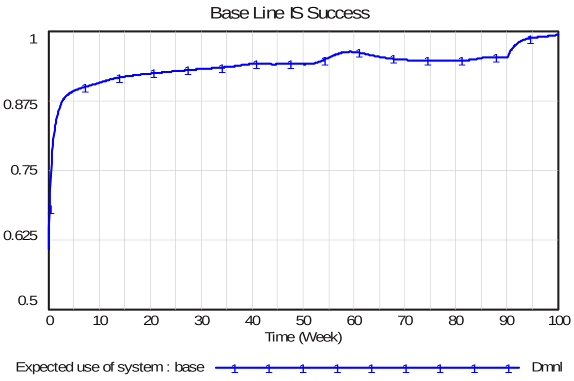

Variability of Disruptions

Aside from external organizational instability, internal disturbances can also affect IS development. Sources of internal instability leading to insufficient management attention include: lack of business process alignment; changes in corporate culture; and stakeholder involvement. We can simulate these disturbances as shocks with variable strengths, depending on the cause of the disruption. As noted earlier, the variability of perturbations captures the notion that disruptions can be quite diverse, ranging from incoming customer requests to relocation of key people to structural changes in business units. When external and internal disturbances occur, organizational resources, e.g., structure and people, can be mustered to help re-stabilize the organization. This will occur because stability is a property of non-linear systems and a complex system, even after drastic disturbances to its environment, tends to return to its original state (Bak, 1996).

Effects of Disruptions on Management Attention: Earlier in this article we discussed the role of management in IS development. In this subsection, we simulate the effect of disruptions on the management attention levels, which, in turn, affect the outcome of IS development projects. We simplify disruptions as unexpected events requiring resolution by management.

The graph on Figure 5 shows simulation runs with unexpected disruptions plotted against the base run (line 1 in the graph). In the first simulation, we increase the perturbation rate by 30 percent, beginning at t=20 and ending at t=40 (line 1); the arbitrarily chosen rate of increase is designed to capture the effect of an unexpected exogenous event on IS development. In the second simulation, the same perturbation rate begins to increase at t=60, ending at t=80 (line 2). The short increase in the slope at the beginning of the disruption corresponds to a positive stress level; management is not yet overwhelmed by the unresolved disruption or trapped by negative stress. The results of this simulation suggest that an early disruption in the form of lack of management attention has a greater negative impact on the outcome of the project than a later disruption.

This may be the result of project resource dynamics. When management attention decreases early in the process, the team needs more resources to complete the project on schedule. When inexperienced staff are added (see Figure 6a) the overall level of staff experience decreases (see Figure 6b). Once staff experience decreases, planning effectiveness also decreases.

While the literature suggests that IS development fails or is delayed because of lack of attention by management (cf. Ein-Dor and Segev, 1978; Lucas, 1975; Kaye, 1990; Keil and Robey,

Figure 5. Effects of disruptions on expected use of system

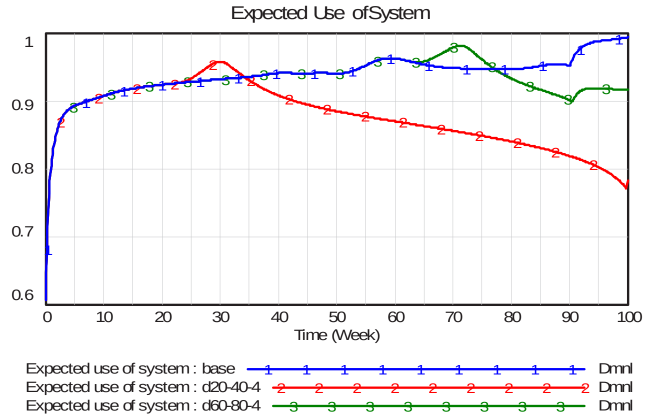

Figure 6. Resource dynamics with increased perturbation rate

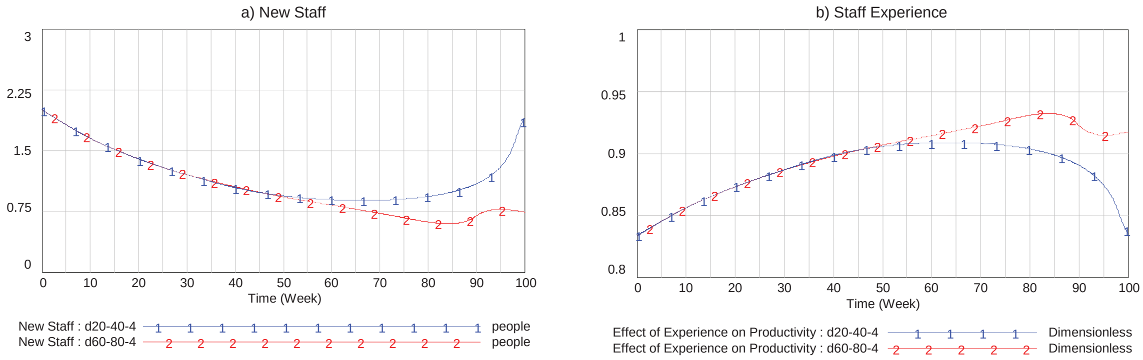


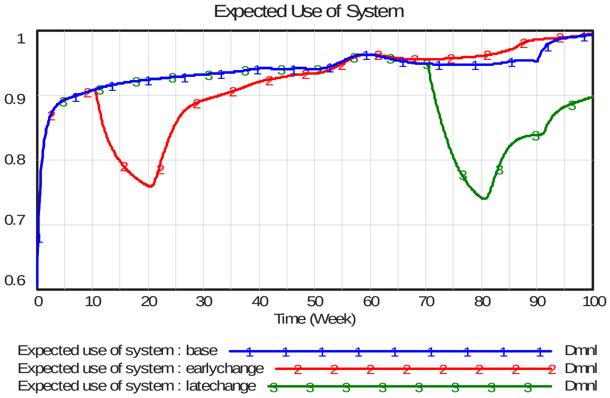
1999), the results of our simulation suggest that management's influence on the outcome of an IS development project differs greatly over time. The point at which disruption occurs directly affects patterns of resource allocation. Earlier studies designed to measure IS project dynamics (Abdel-Hamid, 1989; 1992; Abdel-Hamid and Madnick, 1990) do not include the escalating effect which occurs when management attention decreases during IS development.

Effects of Changes in User Requirement

It is well known that changes in user requirements influence the outcome of IS development. In this subsection we simulate the effect of changes in user requirements on the expected use of the system and, subsequently, IS success. For model simulation purposes, we operationalize changes in user requirements by increasing the number of tasks at to be performed at specific points.

Figure 7 indicates the results of early and late changes in user requirements. For both simulations we use a pulse (increase) of 120 tasks between t=10 and t=20 for the early change and between t=70 and t=80 for the late change. This means that over a period of 10 weeks the team has additional tasks to process because of changes in user requirements. In response to this increase, the system adds resources to complete the project on time. It is interesting to note that a late change in user requirements has a more profound impact on the outcome of an IS development project than does

Figure 7. Dynamics of changes in user requirements



an early change in user requirements. The cause of this behavior can be found in the dynamics of the resource sector shown on Figure 8a & b.

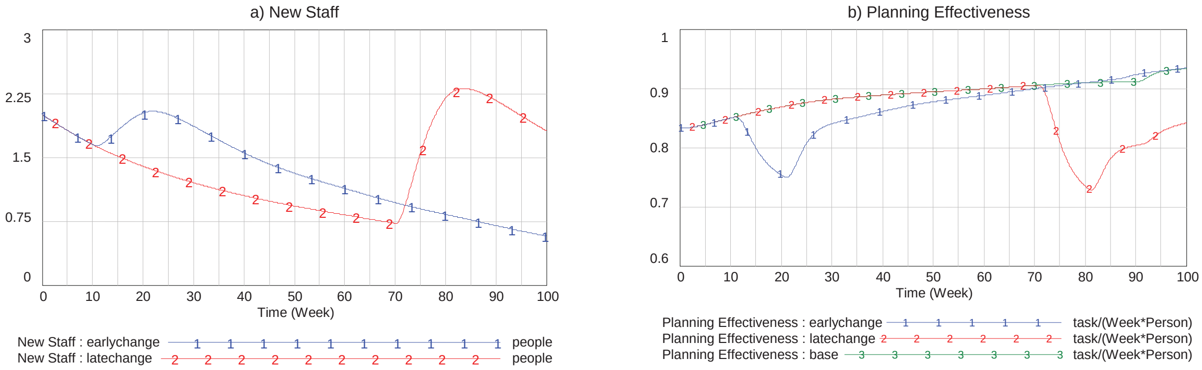
A late change in user requirements is much more disruptive than an early change; as previously noted, when new staff is added staff experience and planning effectiveness levels decline. While both early and late changes require adjustments, new staff that is added early on is able to gain experience, allowing the team to achieve the same performance measures (curve 1 on Figure 8b) for planning effectiveness as the base line. Waltz et al. (1993) conclude that team coordination breakdowns and difficulties in knowledge sharing and integration were identified as key factors hindering project outcomes. Thus, the time to train and integrate new people must be considered as important factors influencing the outcome of an IS development project. Our results support Brooks' (1974) findings that one might hasten to complete a project by assigning more people only to produce counterintuitive effects, especially during the later stages of development.

While Brooks's law – adding manpower during the later stages of a software project only delays it further – is intuitive, the use of a simulation model enables us to understand and respond to changes in user requirements in information system development projects. Abdel-Hamid and Madnik (1990) used a system dynamics model to test the applicability of Brooks's law to the DE-A project (Abdel-Hamid, 1989). The results indicated that, while adding people late in the lifecycle did increase the project cost, it did not delay the project. We do not consider costs in our simulation model; however, we measure planning effectiveness, which determines expected use of the system. Our experiment indicates that adding staff at a late project stage delays it further. While Abdel-Hamid (1990) concludes *"Obviously, the earlier in the lifecycle that people are added and the shorter the training period, the more likely the cumulative contribution will turn positive"* the results from our simulation indicate that a late change in project scope will negatively influence the expected outcome of the IS development initiative.

Effects of Varying Resources

Successfully building information systems requires not only technical skills but also effective management of staff skills and knowledge. The simulation in this subsection provides insight into team structure with regard to skills and knowledge. The initial value for new staff of 0.5 for relative quality and productivity (on a scale from 0 to 1) suggests moderate levels. In the model, the time for new staff to gain experience is 80 weeks--a value based on market observations. The following graphs summarize the results of a simulation in which the size and experience of the team structure is changed.

Figure 8. Resource dynamics under changing user requirements



The initial input for the simulation model is 4 experienced people and 2 new staff (see curve 1 on Figure 9). Curve 2 on Figure 9 shows the expected use of the system with 8 new staff and only 2 experienced people. Even though we add resources, the outcome of this change is a lower than expected use of the system. This behavior can be explained with the following graphs (Figure 10a & b).

By adding more people to the team, the feasible work rate increases, which results in an earlier completion time of the project (see curve 1 Figure 10a). However, due to the lower skill and knowledge levels of the team, planning effectiveness does not reach the desired value needed to achieve the expected outcome of the project. Research on software development teams suggests that team performance is linked to the effectiveness of team coordination (Kraut and Streeter, 1995; Nidumolu, 1995). Evaluating the effect of team coordination within a large, complex, and dynamic social system such as an IS development project can be exceedingly difficult (Wholey et al., 1996). Simulation modeling provides a viable alternative over traditional regression models (Abdel-Hamid and Madnick, 1990).

DISCUSSION

The model described in this article is aimed at extending current IS success models. We do this

Figure 9. Dynamics of changing team structure

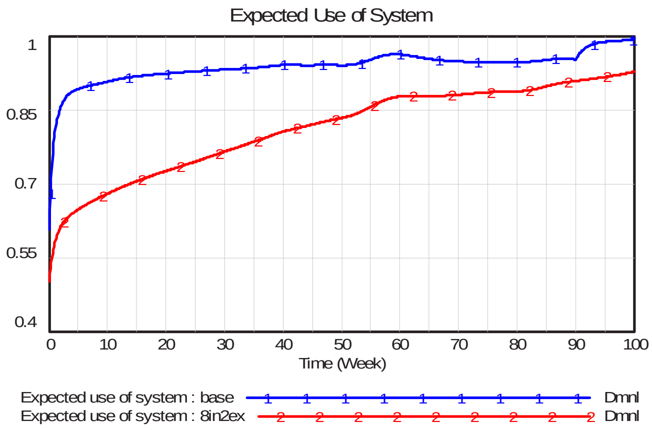


Figure 10. Work rate and effectiveness under changing team structure

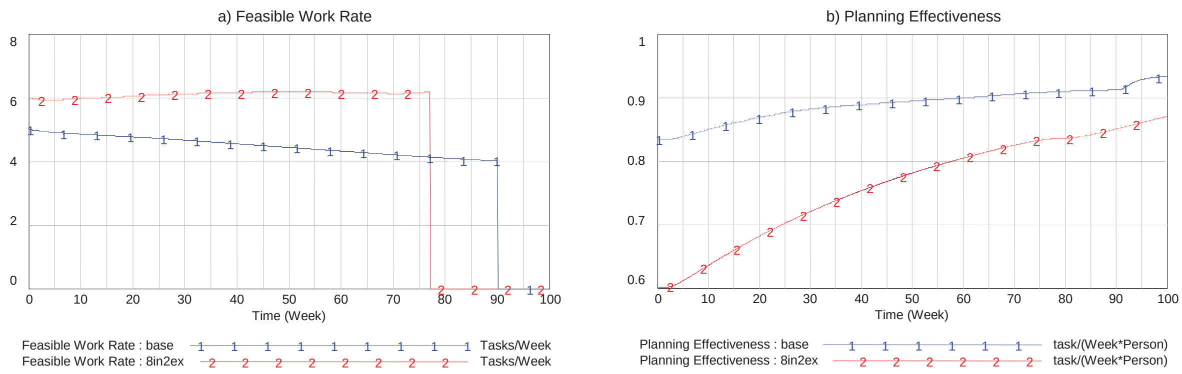

by employing a dynamic perspective involving factors that influence anticipated use of an information system as determined by utilities considered important for IS users. Using a nonlinear methodology such as system dynamics captures interactions and feedback effects and allows us to draw qualitative insights into behavior characterizing dynamics in systems development. A number of tangible and timely recommendations emerge from the simulation experiments that evaluate policy options. For example, the results of this simulation suggest that managing resources has not only a quantitative (e.g., number of people in the team) but also a qualitative (e.g., knowledge and experience) dimension. Consequently, using a simulation model provides insights for an optimal team structure that may help management reduce costs and achieve the desired outcome of an IS development project. As such, the article provides management with a tool to explore various scenarios and assess the impact that different assumptions have on the success of system development efforts.

While sufficient data was not available to quantify the parameters in our model, we contend that the validity of the model can be assumed due to the following arguments: that the causal structure is supported by logic and previous research; the resulting dynamic behavior mirrors real-world observations; the parameters used in the model match real data points to some extent.

However, the simulation model presented in this article has limitations and can be enhanced in several ways. First, the concepts “quality of planning process” and “planning effectiveness” can be decomposed and represented in more detail to capture the multifaceted activities of IS planning, e.g., linking application of IS to business goals, and determining information requirements to meet an organization’s short and long term business goals (Earl, 1989; Wiesman, 1988). Second, the linkage between IS planning characteristics and system quality and information quality can be refined to encompass a variety of context-related attributes, such as the commitment and involvement of organizational members or the influence of different stakeholders. Modeling these details introduces additional complexity and may not change the basic behavior described in the preceding sections. Moreover, interrelationships between IS planning characteristics and system quality and information quality are poorly understood. Thus, adding complexity to the model may not provide any more insight into the fundamental dynamics determining IS success.

The results of this multi-method study lead to future avenues of investigation. One area would be a longitudinal perspective on IS success with the objective of measuring changing attitudes of IS users on the perceived usefulness of an information system. It is suggested that comparing the results of a longitudinal study against the base line of expected use of the system would provide further insights into how organizational dynamics determine IS use and, subsequently, IS success.

While the simulation model presented in this article is aimed at providing an effective tool for gaining insight into the interrelated nature of key drivers affecting system development efforts, it is important to emphasize that such a model focuses on understanding the dynamics of complex systems and, thus, is a powerful methodology to complement quantitative research.

Chapter 2.5

Design Science:
A Case Study in Information Systems Re-Engineering

ABSTRACT

Recently, many organisations have become aware of the limitations of their legacy systems to adapt to new technical requirements. Trends towards e-commerce applications, platform independence, reusability of prebuilt components, capacity for reconfiguration, and higher reliability have contributed to the need to update current systems. Consequently, legacy systems need to be re-engineered into new component-based systems. This chapter shows the use of the design science approach in information systems re-engineering research. In this study, design science and the Bunge-Wand-Weber (BWW) model are used as the main research frameworks to build and evaluate conceptual models generated by the component-based and traditional approaches in re-engineering a legacy system into a component-based information system. The objective of this evaluation is to verify that the re-engineered component-based model is capable of representing the same business requirements as the legacy system.

INTRODUCTION

The objective of this chapter is to show how the design science research approach can be used for applied information systems (IS) research. Design science in information systems is defined by March and Smith (1995) as an attempt to create things that serve human purposes, as opposed to natural and social sciences, which try to understand reality.

The IS research problem chosen to demonstrate the use of design science is the re-engineering of a legacy system in a financial institution. The vast majority of legacy information systems were implemented using the traditional paradigm. The traditional paradigm consists of modeling techniques used by system analysts including system flow charts and data flow diagrams (DFD) to capture, during the analysis phase, the activities within a system. However, with recent developments, particularly trends towards e-commerce applications, platform independence, reusability of prebuilt components, capacity for reconfiguration, and higher reliability, many organizations are realizing they need to re-engineer their systems. Given the limitations of legacy systems to adapt to these new technical requirements, new component-based systems are required to meet these trends; however, there is a high degree of interest and concern in establishing whether or not a full migration to a more portable and scalable component-based architecture will be able to represent the legacy business requirements in the underlying conceptual model of re-engineered information systems.

To address this concern, the research project re-engineered a sample process to derive a component model from the legacy system and posed the question: Is the resulting component-based model equivalent to the legacy conceptual model?

In order to answer the research question, the project evaluated the conceptual models generated by the component-based and traditional approaches in the re-engineering process in order to verify that the re-engineered component-based model was capable of representing the same business requirements of the legacy system. Design science is used as the central research approach for this project.

The first section provides the background for this chapter. Then, the application of design science in information systems re-engineering is demonstrated by using a case study. Finally, directions of future research are suggested.

DESIGN SCIENCE BACKGROUND

Design Science as an Information Systems Research Approach

The design science approach has a history of providing useful results in the evaluation of constructs and models in information systems (Hevner, March, Park, & Ram, 2004). This is in line with Nunamaker and Chen (1990) who classify design science in IS as applied research that applies knowledge to solve practical problems. March and Smith (1995) define design science as an attempt to create artifacts that serve human purposes, as opposed to natural and social sciences, which try to understand reality (Au, 2001).

Fundamental Concepts of Design Science

March and Smith (1995) outline a design science framework with two axes, namely research activities and research outputs. Research outputs cover constructs, models, methods, and instantiations. Research activities comprise building, evaluating, theorizing on, and justifying artifacts.

Constructs or concepts form the vocabulary of a domain. They constitute a conceptualization used to describe problems within a domain. A *model* is a set of propositions or statements expressing relationships among constructs. In design activities, models represent situations as problem and solution statements. A *method* is a set of steps (an algorithm or guideline) used to perform a task. Methods are based on a set of underlying constructs (language) and a representation (model) of the solution space. An *instantiation* is the realization of an artifact in its environment. Instantiations operationalize constructs, models, and methods.

Concerning research activities, March and Smith (1995) identify *build* and *evaluate* as the two main issues in design science. *Build* refers to the construction of constructs, models, methods, and artifacts demonstrating that they can be constructed. *Evaluate* refers to the development of criteria and the assessment of the output's performance against those criteria. Parallel to these two research activities in design science, March and Smith (1995) add the natural and social science couple, which are *theorize* and *justify. Theorise* refers to the construction of theories that explain how or why something happens. In the case of IT and IS research this is often an explanation of how or why an artifact works within its environment. *Justify* refers to theory-proving and requires the gathering of scientific evidence that supports or refutes the theory (March & Smith, 1995).

The use of the design science research framework is justified on three grounds for the chosen research project. First, it provides a framework that can be used for Information Systems applied research. This is in line with Nunamaker and Chen (1990) who classify design science in IS as applied research that uses knowledge to solve practical problems. Second, design science provides a framework for evaluation of models. The objective of this research project is the evaluation of the capacity of component-based models to represent business requirements of legacy conceptual models. This framework seems to be aligned with this objective. Finally, the framework can be used to extend the scope of this research. Although the objective of this research is not to create new theory based on the findings, the framework provides that possibility and could be used for future research.

The objective of the project chosen to demonstrate the design science approach is to use component-based constructs to compare the representation of the same requirements in component-based models with legacy systems modeled with traditional constructs. Very few research frameworks for applied research in information systems have been developed in the past. However, design science is a scientific research method that can be used in developing an evaluation of conceptual models' frameworks (March & Smith, 1995).

For the chosen research problem, the design science approach is used to design an evaluation of conceptual models' frameworks to help IS specialists in the verification of representation of the business requirements in re-engineered component-based models originally represented in legacy conceptual models.

The *building* part of the research uses re-engineering methodologies to generate the conceptual models required for the research. There are many re-engineering methodologies that help to cope with the problem of transforming legacy systems originally developed with traditional methodologies into component-based systems.

APPLICATION OF DESIGN SCIENCE APPROACH

Research Outline

The research project chosen to demonstrate the design science framework covers the *build* and *evaluate* research activities and has a research output of *constructs* and *models. Instantiations* are not covered as the scope of this research is limited to conceptual models. Conceptual models do not include any implementation details that can be used for instantiation.

March and Smith (1995) propose a 4 by 4 framework that produces 16 cells describing viable research efforts. The different cells have different objectives with different appropriate research methods. A research project can cover multiple cells, but does not necessarily have to cover them all.

The *build* part of the framework will be used as part of this research since conceptual models need to be created for ontological evaluation. The main activity of the research project will be the *evaluation* phase, as it will allow identification of metrics to compare the performance of constructs and models.

Table 1 illustrates the cells at the intersection of research activities and research outputs of March and Smith's (1995) framework which are discussed in this chapter. Each cell/intersection contains a specific research objective of the overall research. The *build* column covers the recovery of a conceptual model for a legacy system and the generation of a re-engineered component-based model. Construct building is not required as existing constructs for both traditional and component-based are used.

The *evaluate* column in Table 1 includes evaluating the completeness of the component-based constructs (UML) in terms of ontological deficiencies that the constructs could have when modeling traditional constructs. Conceptual models need to be evaluated in order to measure the capacity of the component-based model to represent the same requirements as the legacy model.

Selection of Methodologies Applied to the Design Science Approach

In the previous section we explained the research objectives in the different cells of March and Smith's framework (1995) covered by the research study. However, as March and Smith explain, every cell and research objective may call for a different methodology. This makes it necessary to identify an adequate method for each specific research objective, resulting in an overall method mix. To achieve this, several methodologies were identified as part of the literature review. These methods are listed in Table 2.

The IS research problem chosen to demonstrate the use of design science involves three main parts: conceptual model recovery, system re-engineering, and ontological evaluation.

Methodologies Selected for Conceptual Model Recovery

The conceptual model recovery of the case study is one of the major challenges in the research since most of the legacy systems have very poor documentation in terms of models and technical design. In order to address this problem, the researcher captured the conceptual model of the legacy system by applying a reverse engineering approach as specified in the Jacobson and Lindstrom (1991) methodology. There are many re-engineering methodologies that help to cope with the problem of transforming legacy systems originally developed with traditional methodologies into component-based systems. The Jacobson and Lindstrom (1991) approach for re-engineering of legacy systems was chosen for the following reasons:

- It contemplates cases of a complete change of implementation technique and no change in the functionality, which is the case of this research;

Table 1. Research activities based on design science approach (adapted from March & Smith, 1995)

	Build	**Evaluate**
Constructs	Not required	Identifying ontological modeling deficiencies of component-based constructs in terms of traditional construct representation
Model	Recovering the legacy conceptual model of the case study Generating the re-engineered component-based model for the legacy system	Evaluating the capacity of the re-engineered component-based for representing the same business requirements embedded in the legacy model

Table 2. Methodologies selected for research project

Methodology	Definition
Case Study	Study of a single phenomenon (e.g., an application, a technology, a decision) in an organization over a logical time frame
Jacobson & Linstrom (1991)	Methodology for information systems re-engineering and legacy system conceptual model recovery
Fettke & Loos (2003)	Methodology for ontological evaluation of conceptual models
Interviews	Research in which information is obtained by asking respondents questions directly
Direct observation	This occurs when a field visit is conducted during the case study
Secondary Data	A study that utilizes existing organizational and business data, that is, document, diagrams, and so forth.
Rosemann & Green (2002)	Meta Models methodology for Normalized Reference Models generation and comparison

- It does not require the use of source code. In the case study used for this research there is no access to the source code used to develop the system;
- It also covers reverse engineering. This is useful for this research given the need to capture the original conceptual model for the legacy system;
- It is relatively simple to use.

Although Jacobson and Lindstrom's (1991) original methodology was proposed for object-oriented systems, it can be easily adapted for component-based systems since components can be viewed as a higher level of abstraction based on object-oriented methodology. The methodology for this project uses data collection methods including interviews, direct observation and secondary data.

Methodologies Selected for System Re-engineering

Once the conceptual models from the legacy system are recovered, the system is re-engineered using the Jacobson and Lindstrom (1991) approach for re-engineering of legacy systems. The output of this step is the re-engineered component-based model as detailed in Valverde and Toleman (2007).

Methodologies Selected for Ontological evaluation

The legacy system and re-engineered models generated as part of the building part of the research are then evaluated based on the ontological evaluation of grammars (Wand & Weber, 1993). As part of the evaluation research, an analysis is done using the Bunge-Wand-Weber (BWW) model. The BWW model is an ontological theory initially developed by Bunge (1977, 1979) and adapted and extended by Wand and Weber (Wand & Weber, 1989, 1995; Weber, 1997).

The BWW model is well founded on mathematical concepts. Prior research on the evaluation of grammars has shown it has been used successfully in information systems research (Evermann & Wand, 2001; Green & Rosemann, 2000; Opdahl & Henderson-Sellers, 2002; Weber & Zhang, 1996).

After developing the re-engineered model, it is necessary to compare both legacy and re-engineered models for equivalency of representation of business requirements. An ontological normalization methodology developed by Fettke and Loos (2003) is used for this activity. The Fettke and Loos (2003) methodology is considered appropriate as it provides a mechanism for the comparison of conceptual models; models can be compared based of their normalized referenced models; and it is simple to use.

In order to generate these normalized reference models in BWW terms, the Rosemann and Green (2002) BWW meta-model is used. This meta-model is based on the original entity relationship specification from Chen (1976) with extensions made by Scheer (1998). Scheer's version is called the extended ER model (eERM).

Once the legacy system and re-engineered models are generated, they can be evaluated based on an ontological evaluation of grammars (Wand & Weber, 1993). An ontological normalization for the original and re-engineered models is generated. The two models are evaluated using the Fettke and Loos (2003) methodology based on their ontologically normalized models generated by the Rosemann and Green (2002) methodology. The result of the comparison reveals that the compared models are equivalent, complementary or in conflict (Fettke & Loos, 2003). Table 3 displays the mapping of the retained methodologies to the activities.

Research Project Procedures

The case study methodology is chosen to evaluate the capacity of the re-engineered component model to represent the same requirements as the legacy traditional model (Benbasat, Goldstein, & Mead, 1987). The case-study system selected is a *Home Loan* information system developed by a consultant company in the Netherlands. The system was customized for a mid-sized home loan bank that specializes in the marketing, sales, and administration of its own home loan products. The information system was designed for use on Unisys A-Series mainframes.

In this chapter, the focus is not on reporting the outputs of the re-engineered business process but on the procedures and frameworks used by the researcher in adopting a design science research approach. Research procedures are divided into build and evaluation procedures. Build procedures are required to accomplish the build objectives of the design science approach while the evaluation procedures accomplish the evaluation objectives.

Data Collection (Build)

Data gathering is an important part of this research as it is required to commence the building part of the research. For this research, observation techniques, interviews, and review of physical artifacts and system documents were used as the sources for data gathering. The most common methods of collecting data within the case study approach are through observation and interviews (Bell, 1992).

The use of observation as a method of data collection is well documented (Bell, 1992; Benbasat

Table 3. Research methodologies selected for the design science approach

	Build	**Evaluate**
Constructs	Not required	Fettke & Loos (2003)
Model	Case Study Interviews Secondary Data Direct Observation Jacobson & Linstrom (1991)	Case Study Fettke & Loos (2003) Rosemann & Green (2002)

et al., 1987; Stake, 1995) and works well in case research (Yin, 1994).

Before observations were used in the research project, the three minimum conditions set out by Tull and Hawkins (1993) were met: the data were available for observation; the behaviour was repetitive, frequent, or otherwise predictable; and each event covered a reasonably short time span.

According to Jorgensen (1989), observation is appropriate for studies of almost every human existence. Through observation, it is possible to describe what goes on, who or what is involved, when and where things happen, how they occur, and why things happen as they do in particular situations (Jorgensen, 1989). A great deal of time is spent on paying attention, watching, and listening carefully (Neuman, 1994). The observer uses all the senses, noticing what is seen, heard, smelled, tasted, and touched (Neuman, 1994; Spradley, 1979).

In terms of research stance, Neuman (1994) identifies four possible roles for the participant observer:

- **Complete participant:** The researcher operates under conditions of secret observation and full participation;
- **Complete observer:** The researcher is behind a one-way mirror or in an invisible role that permits undetected and unnoticed observation and eavesdropping;
- **Participant as observer:** The researcher and members are aware of the research role, but the researcher is an intimate friend who is a pseudo-member;
- **Observer as participant:** The researcher is a known, overt observer from the beginning, who has more limited or formal contact with members.

In this study, the researcher visited the case study information system's site and observed its functionality as a *complete observer*. The justification for this role is to avoid intrusion in the normal operation of the information systems and learn the most by observing the users in the natural environment of the information systems.

The technique used to interview users, maintainers, and designers was open-ended interviews. The use of this technique is justified for this research by two main reasons. First, the goal is to elicit the respondent's views and experiences in his or her own terms, rather than to collect data that are simply a choice among pre-established response categories (Anderson, Aydin, & Jay, 1994). Second, the interview is not bound to a rigid interview format or set of questions that would be difficult to establish given the nature of the research and would limit the results (Anderson et al., 1994).

The final goal of the open interview is to interview system users, maintainers, and designers of the legacy systems in order to find out how the system was developed, what are the functions of the system, and the type of documentation used for the system development. The system owners consented to the participation of the developers in the interviews.

System documentation was collected in order to perform the reverse engineering analysis required to recover the conceptual models (Jacobson & Lindstrom, 1991). The legacy information system can be described by using different elements such as requirements specifications, user operating instructions, maintenance manuals, training manuals, design documentation, source code files, and database schema descriptions (Jacobson & Lindstrom, 1991). Information systems documentation is a valuable source of data. Documentation related to the system, including manuals, database schemas, and system architecture diagrams were collected.

Conceptual Model Recovery (Build)

In order to capture the conceptual model of the legacy system, the reverse engineering methodology, as specified in Jacobson and Lindstrom (1991), was applied. The following three steps were used:

- Develop a concrete graph that describes the components of the system and their interrelationship;
- Develop an abstract graph showing the behavior and the structure of the system;
- Develop a mapping between the two, that is, how something in the abstract graph relates to the concrete graph and vice versa.

The abstract graph should be free of implementation details. For example, mechanisms for persistent storage or partitioning into processes should not appear on this graph. The concrete graph must, on the other hand, show these details. The mapping between the two should explain how the abstract graph is implemented by way of the concrete graph (Jacobson & Lindstrom, 1991).

Use cases are an excellent tool for reverse engineering since they provide a sequence of user interactions with the system (Jacobson & Lindstrom, 1991). Their purpose is to define a typical way of using the system and to describe the business process, to document how the business works and what the business goals are of each interaction with the system. In the context of reverse engineering, it is possible to explore a legacy system with use cases (Jacobson & Lindstrom, 1991).

Use cases were developed to create the concrete graph for reverse engineering. These use cases show the interrelationship between manuals, documentation, interviews, source code, and researcher's observation of the system. The abstract graph described in the Jacobson and Lindstrom (1991) methodology is in fact an example of the legacy conceptual model. For this research project, the conceptual model was represented in terms of data flow diagrams (DFDs), a context diagram, and entity relationship (E-R) diagrams.

The description of the business process, business events, and responses is essential in generating a conceptual model (Whitten, Bentley, & Dittman, 2001). The use cases employed to construct the concrete graph document the business processes, events, and responses required to construct this legacy abstract graph. In order to generate the DFDs required to construct the legacy conceptual model, business events to which the system must respond and appropriate responses were identified with the help of the use cases. According to Whitten et al. (2001), there are essentially three types of events:

- **External events:** Are so named because they are initiated by external agents. When these events happen, an input data flow occurs for the system in the DFD;
- **Temporal events:** Trigger processes on the basis of time. When these events happen, an input called *control flow* occurs;
- **State events:** Trigger processes based on a system change from one state or condition to another.

Information systems usually respond to external or temporal events. State events are usually associated with real time systems (Whitten et al., 2001).

Once these events were identified, DFDs were drawn with the help of the list of mapping transformations suggested by Whitten et al. (2001). The concrete graph represented by the use case can be mapped to the abstract graph represented by the DFD. The actor in the use case that initiated the event will become the external agent; the event identified in the use case will be handled by a process in the DFD; the input or trigger in the use case will become the data or control flow in the DFD; all outputs and responses in the use case will become data flows in the DFD.

The data model of the legacy conceptual model is generated by identifying the data stores in the DFD, examining the use cases, and finally documented by using an E-R Diagram.

Component-Based Model Generation (Build)

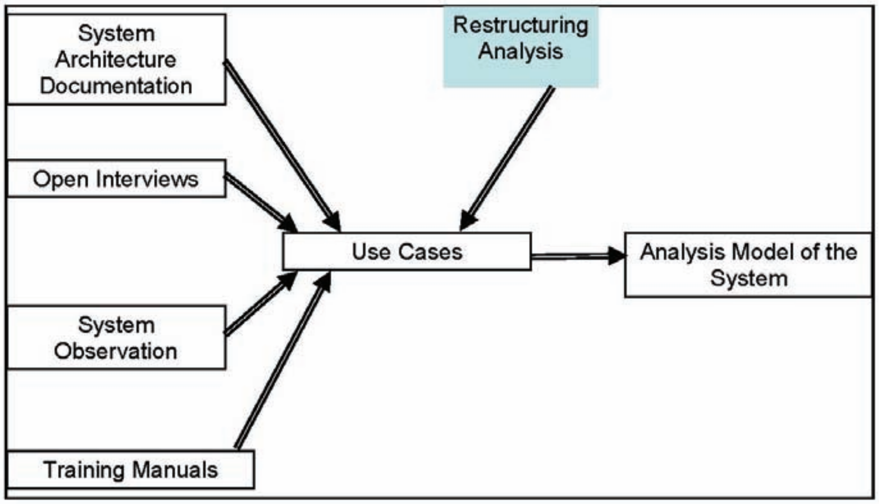
Once the model was reverse engineered from the legacy system, the legacy system was re-engineered for a complete change in implementation technique but no change in functionality by preparing an analysis model and then mapping each analysis object to the implementation of the old system (Jacobson & Lindstrom, 1991).

In the first step, an analysis model was prepared with the help of the use cases prepared in the reverse engineering process. These use cases already contain the information that was assimilated from the manuals, system architecture documentation, open interviews, and research observations described as description elements in the Jacobson and Lindstom (1991) methodology (Figure 1). Only the analysis model of the re-engineering process was required since the primary objective of the research project was the comparison of conceptual models and not the full implementation of the information systems.

An analysis model only contains the logical aspects and is free of physical implementation details. The logical representation of a component is concerned with its logical abstraction, its relationship with other logical elements, and its assigned responsibilities. The logical representation of a component-based system was modeled by using the UML diagrams: use case diagrams, class diagrams, sequence diagram, and state diagrams (Houston & Norris, 2001).

Actors were identified from the use cases and use case diagrams were constructed to identify the system scope and boundaries. The model should be free of physical implementation details. For the case of components, their logical representation was modeled using UML subsystems and identified inside the use case diagrams as proposed by Houston and Norris (2001). Class diagrams were prepared using the criteria for finding objects as described in Jacobson's (1987) object-oriented method. This step was accomplished by reviewing each use case to find nouns that correspond to business entities or events (Jacobson, 1987). Not all the nouns in the use cases represent valid business objects. A cleansing process removed nouns that represent synonyms, nouns outside

Figure 1. Preparation of the analysis model (adapted from Jacobson & Linstrom, 1991)



of the scope of the system, nouns that are roles without unique behavior or are external roles, unclear nouns that need focus, or nouns that are really actions or attributes (Whitten et al., 2001). Once objects were identified, their relationships were modeled as part of the class diagrams and interfaces were identified.

Ontological Evaluation (Evaluation)

Once the legacy conceptual model was recovered and the component business analysis model represented with the use of UML diagrams, the Fettke and Loos (2003) methodology was used to evaluate these models for equivalency of representation of business requirements.

As part of this evaluation, the ontological normalization of the legacy and re-engineered component models was generated. The ontological normalization of a reference model consisted of four steps (Fettke & Loos, 2003):

- **Step 1.** Develop a transformation mapping;
- **Step 2.** Identify ontological modeling deficiencies;
- **Step 3.** Transform the models; and
- **Step 4.** Assess the results.

In the first step of this method, a transformation mapping of the traditional and component-based (UML) diagrams used for representing the conceptual models was developed. This transformation mapping allowed converting the constructs of the traditional and component-based (UML) diagrams to the constructs of the BWW model. The first step was based on the method for the ontological evaluation of grammars proposed by Wand and Weber (1993).

The transformation mapping consisted of two mathematical mappings. First, a representation mapping described whether and how the constructs of the BWW model are mapped onto the traditional and component-based (UML) constructs. Second, the interpretation mapping described whether and how the traditional and component-based (UML) constructs are mapped onto the constructs of the BWW model (Fettke & Loos, 2003).

All ontological deficiencies of the conceptual models were identified as part of the second step of the generation of the normalized ontological models. To identify the ontological deficiencies of the recovered model and re-engineered component-based model, all constructs of the models were reviewed. Each construct of the models analyzed was examined with respect to whether the construct was used correctly regarding the interpretation mapping.

Three classifications of deficiencies were used:

- **Adequacy:** The grammatical construct is ontologically adequate. Nevertheless, an ontological deficiency can emerge by applying the grammatical construct to build the reference model. Therefore it must be examined whether the construct of the reference model is used correctly with respect to the interpretation mapping. The construct of the reference model is used adequately if it is used correctly with respect to the interpretation mapping.
- **Excess:** Construct excess is a modeling deficiency in general and needs special handling in the transformation step. Therefore, this construct should be marked as excessive in the reference model.
- **Overload:** Construct overload is a modeling deficiency in general and needs special handling in the transformation step. Therefore, this construct should be marked as overloaded in the reference model (Fettke & Loos, 2003).

Based on the representation mapping, it was decided whether the traditional and component-based grammar are incomplete or redundant.

An incomplete grammar suggests that specific facts of reality cannot be adequately represented in the model.

In the third step, the models were transformed to ontological models. The outcome of this step was two ontologically normalized models. The objective of both techniques was to represent the domain of interest in a normalized way by applying specific transformation patterns (Fettke & Loos, 2003).

The two models were compared based on their ontologically normalized models. The result of this comparison was an analysis that revealed whether the compared models are equivalent, complementary, or in conflict. In order to generate these normalized reference models in BWW terms, the Rosemann and Green (2002) BWW meta-models were used.

CONCLUSION

This chapter has discussed how design science can be used for the research of information systems re-engineering. The research activities identified by March and Smith (1995) were fundamental for this study. This framework requires two main activities: build and evaluate, which require the use of several methodologies as the first was used for construction of conceptual and BWW normalized models and the second for the evaluation of these models for equivalency of business requirements using the Fettke and Loos (2003) ontological methodology. The case study methodology was used as the main methodology to build and evaluate conceptual models. The Jacobson and Lindstrom (1991) approach for re-engineering of legacy systems was employed to build the original conceptual model of the legacy system under research and for the building of the component-based re-engineered models. Conceptual models were built with the help of data collected by using interviews, observation techniques, and review of information systems documents.

The methodology by Fettke and Loos (2003) was selected to evaluate the models generated by the reverse engineering (legacy conceptual model) and those generated by the re-engineering process (component model). Traditional and component-based constructs were also evaluated under the same methodology. The Rosemann and Green (2002) metamodels were used as the primary tool to represent the normalized models in BWW construct terms.

FUTURE RESEARCH DIRECTIONS

Future research can be concentrated in the development of automated tools for the re-engineering of information systems based on design science. A software tool could be constructed to build legacy and re-engineered conceptual models and evaluate them based on the methodology proposed. This software tool could translate the legacy and component models into ontological normalized reference models that could be used for comparison.

Chapter 2.6

Improving IT-Enabled Sense and Respond Capabilities:

An Application of Business Activity Monitoring at Southern International Airlines

Richard Welke
Georgia State University, USA

Gabriel Cavalheiro
Ernst & Young, NL

Ajantha Dahanayake
Georgia College & State University, USA

EXECUTIVE SUMMARY

Commercial airlines face an extremely challenging operating and competitive environment. To remain in business they must comply with ever-changing regulatory requirements while, at the same time, minimizing their operational costs without sacrificing customer expectations of service levels. Increasingly, airlines are realizing that a "plan-execute" mode of operation must give way to a "sense-respond" mode of operation; in other words they must become a real-time (agile) organization, capable of sensing the occurrence of unforeseen events such as the placement of a last-minute shipping order, flight delays, and cancellations, and respond effectively in real-time to such events. To enable enterprises in general, and the airline industry in particular, to improve their sense-and-respond capabilities and ensure better resource utilization, a number of software vendors are offering event stream processing and Business Activity Monitoring (BAM) solutions. This case examines a longitudinal set of real-world implementation projects using such a solution at a major US airline (referred to as Southern International Airlines) and the results and lessons gained from this deployment.

ORGANIZATIONAL BACKGROUND

This case involves the interactions between two organizations—a solutions provider (Quantive, LLC) and a client for Quantive's products and services: Southern International Airlines (not their real name).

Quantive, LLC (www.quantive.com) is a small product and services company, founded in 2000 by Dwight Jones, and based in Alpharetta, Georgia. It employs several people as well as having contractual relationships with additional personnel when needed to staff projects for clients. As its Web site indicates, it uses a combination of software tools and services to: capture critical business events in real-time without touching existing application systems, and translates these events into actionable business information (called "BAM-alerts"). It does this without the need to engage IT staff at the client organization, save to make a one-time network connection to a router on the client organization's network. To do this, it uses a stack of software to capture transactional packets of data moving over the network (Packeterm), translating these captured packets into logical transactional events (Inquisitor), and then examining these resulting events to identify exception or alert situations, and sending messages to a manager or an application to take action regarding the BAM-alert (Medusa). Finally, Quantive Factory provides additional ways to evaluate and present event alert information from Medusa. For a more complete picture of their offering, see Appendix A.

Southern International Airlines (SIA) provides both domestic and international air travel and shipping from its primary base in the Southwest as well as other hubs located throughout the world. It was founded through an incorporation of several airline companies in 1930. It operates approximately 1,000 aircraft that fly ca. 420 million seat-miles per day with 3,900 flights per day to 250+ locations. Although SIA is better known for its passenger service, its cargo division flies roughly 5 million pounds of cargo each day, with services to 250 cities in 40 countries, providing one of most extensive cargo networks in the airline industry.

SETTING THE STAGE

Initial Problem

Southern International Airlines' original motivation to adopt a (Quantive) BAM solution was to improve compliance with federal regulations issued by the US Federal Aviation Administration (FAA) and thereby reduce (or avoid) the high cost of non-compliance. In the context of this implementation project, the relevant regulation is FAA AC 43.13-1B: *Acceptable Methods, Techniques, and Practices—Aircraft Inspection and Repair*, which came into force on September 8, 1998 (FAA, 2002). More specifically, chapter 10 of this regulation sets requirements for both the calculation of take-off parameters for commercial aircrafts and the disclosure of corresponding compliance figures.

The primary reason for issuing this regulation is to improve flight safety. It is to ensure that if a significant weight variation takes place after the initial flight parameters are loaded that new parameters are re-loaded. If no action is taken to recalculate these parameters, the aircraft is likely to take-off with inadequate stabilizer settings and thus decrease flight safety. In this scenario, depending on the significance of the shift in the center of gravity resulting from the non-computed weight variations, these changes could cause the aircraft to exhibit dangerous flight characteristics (FAA, 1999). To prevent this scenario from happening, Southern International Airlines must have a proper weight and balance control system to enable the cockpit crew to know the actual values of the take-off parameters in order to set the stabilizer trim properly, prior to take-off. This involves monitoring factors influencing the weight and balance condition of an aircraft, such as total weight and position of load as well as the amount and distribution of fuel. Typically, significant weight variations can result from the loading of heavy freight, an exceptionally high fuel use during ground operations due to, say, airport congestion and/or flight cancellations causing many new last-minute passengers on the flight. Under such circumstances, the take-off configuration of the aircraft must be recalculated, taking into account the new weight and balance condition.

In addition, this particular FAA regulation emphasizes the need to improve accuracy on the disclosure of information when non-compliance occurs. Non-compliance conditions are those situations where this FAA regulation is violated and an aircraft takes off with inappropriate trim settings. To gather data about this type of non-compliance, the FAA relies on data submitted by SIA on a self-disclosure basis. On the face of it, the FAA is only able to enforce compliance by auditing the control systems of SIA in order to assess their capabilities of complying with the regulation and reporting requirements.

Beyond risks for flight safety, repeated violations of the noted FAA regulation can lead to large fines, loss of reputation, and SIA managers can be held legally liable for any resulting consequences of inappropriate weight and balance settings. Compliance with this and other FAA regulations became a primary concern and SIA must be able to demonstrate to the FAA, via audits, that their weight and balance control systems are capable of:

- Detecting significant shifts in the center of gravity of aircrafts as they occur and warning those responsible for the calculation of the take-off configurations
- Recording weight and balance non-compliance cases for FAA disclosure purposes

Assessing the Business Needs

Despite the fact that the AC 43.13-1B regulation of the FAA has been in place for some time, compliance with the mentioned requirements remained an issue for SIA. Although the information about the weight and balance condition of any given SIA aircraft could, in principle, be evaluated across several transactions generated by SIA for all its flights, detecting significant weight variations in time to take compensating action (i.e., real-time) was not feasible for several reasons. First, the application systems creating these transactions did not converse with one another. And second, the detection of an out-of-balance condition was not programmed into the current systems and the reporting of the underlying transactions could not be done in real-time.

Typically, the full content of the transactions relevant to detecting an out-of-balance condition are written directly to a “flight log”. Because SIA operates approximately 3,900 flights per day, the resulting flight log is very large. To gather data about a certain flight, the personnel of SIA must search through the time-ordered sequence of messages associated with a particular flight and print out several of its sections to analyze the situation for any particular flight. This was a labor-intensive and time-consuming process that could only be justified in the most serious cases. And, in its current, manual state, the analysis process could take from hours to days and thus could only be used for off-line, retrospective analyses where situations had to be reconstructed.

The end result was that, even though the basic information on different aspects of aircraft weight distribution and changes were available in the flight log, SIA did not have the capability for detecting significant weight variations in real-time, as required by the FAA, and SIA’s managers knew they were unable to respond to these variations and avoid penalties or worse.

Technical Constraints to Implementing a Solution

There were important technical constraints to be taken into account when implementing a solution for the preceding FAA compliance problem. These constraints stem from the dependence of Southern International Airlines on their transactional systems and the need to keep them running and available 24x7. The characteristics of the transactional systems of Southern International Airlines will be briefly explained below.

Most load and balance procedures are carried out by the flight operations system. This is a legacy system that has been used by SIA for nearly 40 years. Though this old system is stable and reliable, it is not easily modified, nor is it capable of providing real-time visibility into take-off parameters. The system was originally designed to carry out transactions rapidly and reliably, rather than to provide adequate control mechanisms to monitor specific transaction information. Despite the fact that the transactions processed by this system contain all the information involving the weight and balance condition of aircrafts, it was not possible to directly access this information during the execution interval of the relevant transactions; only well after the fact via the resulting flight log.

Modifying the flight operations system to directly satisfy regulatory requirements was viewed as infeasible because it would involve a long project with a high degree of implementation risk and, due to the dependency of SIA on this system, any potential risk of adversely affecting the existing flight operations system was deemed unacceptable. While there are plans to replace the old system with a new system that will be fully operational in a few years, SIA remains dependent on the current system for the immediate future.

To conclude, the time and accessibility gap between information available from the existing flight operations system and that needed to assure load balancing requirements in real-time, cannot be remedied by patching the existing flight operations system due to the SIA's high dependency on this system, it's age, and the risk to ongoing operations inherent in making any change to the system. Instead, SIA had to look for a different way to solve the problem that did not in any way impact the existing flight operations system. This led them to explore the use of an event capture and reporting system (Business Activity Monitoring or "BAM") and to Quantive as a prospective solution provider.

Understanding Business Activity Monitoring (BAM)

BAM is a relatively new way of conceptualizing and solving business-related problems, Chandy and McGoveran (2004) describe BAM solutions as real-time control systems that capture events in real-time from multiple, heterogeneous sources and selectively raise alerts within time-limited windows of opportunity. These quick (low latency) alerts are aimed at providing their recipients (often operational managers) with sufficient operational insights to enable effective response to critical events (DeFee & Harmon, 2004). As such, BAM solutions are particularly well suited to managers who need to respond to exceptional combinations of events, in real time. This approach can be distinguished from seemingly similar approaches such as real-time data warehousing in that the source of the information is the accumulated events themselves (event log) rather than an ETL (extract-transfer-load) from a transaction processing system's database into a specifically designed data warehouse (Golfarelli et al., 2004).

Another important aspect of a BAM approach is that it does not affect the performance of the underlying transactional systems. Rather, BAM solutions provide a transparent platform in which events are detected by separately examining individual, pre-existing transactions and defining patterns of events over an event stream that, should they occur, warrant managerial intervention. To support the development of event-driven applications, BAM solutions are likely to include event-modelling functions that define and validate event patterns (Gassman, 2004). This makes BAM solutions highly adaptable, as new event-driven applications can be rapidly developed to address new or changing business problems.

To represent BAM solutions, Gartner, Inc. proposed a BAM model in 2002 that distinguishes three basic layers: the "Event Absorption Layer," the "Event Processing and Filtering Layer," and the "Event Delivery and Display Layer." In this model, the border of a BAM solution is the "Event Delivery and Display Layer", which is the interface of the BAM solution with the recipients of BAM alerts (Govekar et al., 2002). A simple representation of the basic three-tiered BAM model can be found in Figure 1. A more sophisticated model can be found in Schiefer and McGregor (2004).

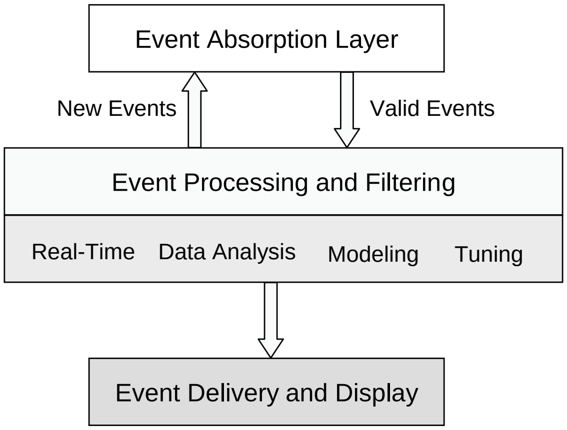
The Event Absorption Layer detects and acquires events that arrive from multiple and heterogeneous data sources (Gassman, 2004). The source of event messages will most often be business or process-related. However, technical events, such as the occurrence of technical failures during the execution of business processes might also be collected (Gassman, 2004). These sources can include both internal sources, such as (legacy) transaction processing systems, ERP systems, and RFID applications, as well as external sources such as those made available via the Internet (e.g., weather events), thus enabling a broader and richer view of business operations and its environment (McCoy et al., 2001).

These "raw" events, regardless of source, are first fed into the Event Absorption Layer. The Event Absorption Layer is most easily achieved by tapping into the stream of transaction events moving across a network via a middleware layer (i.e., data message transport layer) that carries transactional data messages across a network from transaction origination to the transaction application systems that process and store them. As these transactions move across the network, they can be defined, captured, and collected as events of potential interest and kept in an of event log, without disrupting their normal flow and usage.

At the next stage, Event Processing and Filtering software correlates this independent event stream data (McCoy, 2004). This layer sifts through and inter-relates the captured events, looking for combinations of events that occur, or should occur and does not, that in turn warrant managerial attention and intervention. More specifically, a set of event-based business rules are pre-defined and used by this layer to identify situations that are exceptions and create the conditions for an alert.

In the final layer (Event Delivery and Display) alerts created by the preceding layer are sent to those parties who are able to understand the nature of the exception and, as appropriate, take

Figure 1. Conceptual Model for BAM. Adapted from Govekar, et al. (2002)



the necessary action to circumvent or avoid an emerging problem that is identified by the event rules. The alerts can populate a display and/or trigger an action (Gassman, 2004). Alerts that are used to populate a display are often delivered via graphical displays in the form of BAM "dashboards" containing real-time values of critical business performance indicators. These corporate dashboards are normally customized for use in different parts of the enterprise and for different audiences (McCoy et al., 2001). Alternatively, or in addition to, the alerts can be sent as messages to specific recipients who are empowered to act, via existing channels such as e-mails, instant messages, pagers, and so forth (McCoy, 2003).

CASE DESCRIPTION

Initial Case: The Weight and Balance Solution

The Quantive BAM solution was first used by Southern International Airlines to design and deploy an event-driven application to improve compliance with FAA regulations. This section highlights this event-driven application by describing the event filtering conditions. In order to characterize the real-time decision support needs of the recipient for these "out-of-balance" BAM alerts, the performance-indicator monitored by the event-driven application and the tolerance for latency are taken into account. Table 1,summarizes the focus of this application.

For this case, SIA's BAM event-driven application raises alerts whenever significant weight changes occur after the initial flight parameters are set. These alerts, in turn, makes it possible for an operational manager in the weight and balance department to take corrective actions to ensure that the center of gravity is re-positioned within acceptable limits according to the aircraft flight manual before the aircraft takes off, as well as informing the cockpit crew about the actual take-off condition so that they can reset the stabilizer trim prior to take-off.

The primary event source is the Initial Weight and Balance Transaction (IWBT) used by the Flight Operations System, which contains the needed event properties that affect the weight and c.g. of an aircraft. This transaction is first captured at the absorption layer, then processed and filtered to create BAM alerts. The resulting application notifies appropriate BAM recipients (operational managers in the weight and balance department) of significant weight changes occurring that can affect the position of the aircraft's c.g.

Figure 2 provides a screenshot of all event properties captured using Quantive's event definition and absorption software, and contained in the IWBT transaction.

Table 2 shows the particular fields of the IWBT transaction that are captured in order to build the event to be logged and subsequently processed.

Event processing consists of using the resulting ZFW_CG, RMP, and TOW_WT values. Whenever one of those values comes within 2% of the forward and aft limit of the aircraft, an alert is raised and, at the third layer of BAM, a dashboard is updated to provide real-time visibility into this critical performance indicator.

Alerts raised by the weight and balance BAM application are also stored in a database. This

26	TOW_Max	Max. allowable Take-Off weight

makes it possible for SIA to disclose these alerts when reporting to the FAA about the occurrence of significant weight variations along with the corrective actions taken by SIA. In addition, the database is used to improve SIA's knowledge on patterns of balance event occurrences and, as a result, to provide this additional information to the FAA as well.

Follow-on BAM Applications

Although Southern International Airlines' decision to adopt Quantive's BAM solution was initially driven by the need to improve regulatory compliance without disturbing existing transactional systems, once managers began to see the power of re-thinking operational problems and potential solutions in terms of business events and event exceptions, other event-driven applications were identified and subsequently pursued. An additional attraction of the adopted BAM approach was that these applications could be implemented by the operations personnel directly. There was no need to have the IT unit involved in developing these solutions; operation's own people could easily master the identification of transactions moving across the organization's WAN (wide-are network) and create event definitions, filters, alerts, analysis, and display capabilities. This pattern of assimilation and adoption tended to follow the widely studied "diffusion of innovation" patterns documented in the marketing and information systems literature (Rogers, 1995).

At the time of this case (2005), ten event-driven applications, employing event 60 filters, had been implemented by Southern International Airlines. According to Quantive, these 10 applications raise an average of 30 to 40 alerts per day, each indicating a potential exception condition requiring intervention. At that level, the alert recipients are able to respond to all BAM alerts. However, it should be noted that as the number of event-driven applications increases, the risk increases of overloading the alert recipients with too many alerts (McCoy & Govekar, 2002). In such cases, BAM recipients are likely to start ignoring some of the alerts due to a lack of time to interpret and react upon the information contained in the alert (Klein & Besson, 2003). This situation is often referred to as cognitive overload (of the BAM recipient).

Three of these follow-on applications are given. Each highlights a problem identified by specific business unit managers following the installation and presentation on the original (weight-balance) application. Of these, the first two were successful. A third, while technically feasible and economically attractive, was nevertheless abandoned due to inadequate attention to social constraints.

Freight Refusal Application

Freight refusal presents an interesting problem to SIA, with significant negative financial implications. It involves scenarios in which sufficient cargo space is available on an aircraft but some of the freight booked for that flight is not loaded. This condition is referred to as freight refusal. For the sake of maximizing SIA's resources and revenues, it is obviously important to ensure that the maximum amount of freight booked for a flight is loaded onto the aircraft prior to take-off, especially for perishable goods that quickly deteriorate if they are not loaded and shipped as originally planned (e.g., flowers). In this case, SIA would have to reimburse customers for their resulting loss in addition to the loss of SIA shipping revenue. Since urgency and perishability are two of the primary reasons for using air cargo over other logistical choices, nearly all freight refusal conditions have significant economic and quality of service impacts. Table 3 summarizes the characteristics of this application.

In examining the freight refusal scenario, SIA managers determined that there are both legitimate and non-legitimate reasons for freight refusals. The list of legitimate reasons include lack of space in the aircraft, insufficient time to load all booked freight before the scheduled departure time due to

Table 3. Application characteristics of Freight Refusal

Application Characteristics	
Performance-Indicators	Shipping status
BAM recipient	Supervisors of Ramp Crew
Tolerance for Latency	Hours-Days

late arrival of the aircraft, the freight itself was not delivered to the airport in time, loading equipment damage, and so forth. In general, non-legitimate reasons result directly from failure of the ramp crew to load awaiting freight.

Southern International Airlines needed to identify the occurrence of non-legitimate freight refusal so that corrective measures could be taken with the associated ramp crew. However, the effort required investigating the reason for the occurrence of freight refusal and also required a time-consuming search of the flight log. Again, given the large volumes of data stored there, such an analysis was rarely undertaken and disciplinary measures seldom initiated, while non-legitimate freight refusal continued to occur.

The basic pattern for freight loading was then examined for the existence of signal events that could aid in identifying cases of freight refusal. For every flight of Southern International Airlines, there is a ramp controller who is in charge of registering the status of booked freight in a manifest document (transaction) provided by the flight operations system. In the case of freight refusal, the ramp controller is supposed to register the reason for not loading the booked freight.

The event-driven application designed to tackle the non-legitimate occurrences of freight refusals work was based on monitoring the execution of transactions containing cargo information. Basically, after the first IWBT is executed, a system transaction (the Cargo Transaction) containing event properties pertaining to cargo, is also executed. These two transactions, in turn, provide the basis to develop a set of event rules and BAM application that would provide real-time notification of the occurrence of non-legitimate freight refusals.

While the actual set of transaction events and associated properties used is complex, to provide a sense of this application, a few simplifications are made. First, the Cargo Transaction contains an event property that identifies each product to be shipped, which is called PIC (Product Identification Code). Second, there is an event property to indicate the status of all products that are booked for shipment on a specific flight, called SPBS (Status of Products Booked for Shipment). SPBS can assume the values:

- *Confirmed*, meaning that product is ready for shipment
- *Cancelled*, meaning that a legitimate reason exists for not shipping the product according to shipment book
- *Shipped*, meaning that product was loaded into the aircraft

The event logic then becomes that of comparing the change of SPBS values during the loading process. Specifically, alerts are generated indicating non-legitimate freight refusals by searching for *confirmed products* that do not change their status to *shipped* in the course of the loading process. By this logic, it is possible to identify a possible failure of the assigned ramp controller for this flight to load that particular product shipment.

Monitoring Flight Planners

The allocation of passenger-sensitive resources to a particular flight is the responsibility of SIA's flight planners. Such resources can range from the number of meals carried to the fuel to be loaded on the plane. SIA management sought a way to develop an event-driven application to monitor the individual performance of flight planners with respect to optimal resource allocation. It is important to mention that flight planners' work in a non-unionized department, otherwise such monitoring would likely be opposed by their representation union officials. Table 4 highlights the properties of this application.

The event-analysis approach taken here relied upon two transactional events occurring within the flight operations system: the IWBT transaction and a Passenger Destination Transaction (PDT). After the IWBT is executed, the flight operations

Table 4. Application characteristics of monitoring flight planners

Application Characteristics	
Performance-Indicators	Variation in number of passengers near flight departure
BAM recipient	Supervisor of Flight Planners
Tolerance for Latency	Minutes-Hours

system executes a PDT transaction that contains properties indicating passenger destinations. The analysis showed that the Passenger Destination Transaction is executed automatically for the first time between 150 and 92 minutes prior to departure.

By aggregating the PDT's at a particular time point, one can compare the number of passengers at a particular point in time with the passengers indicated from a preceding point in time. This, in turn, can be compared to the flight planner's resource allocation for the flight (from a different transaction). In principle, the passenger configuration of a flight should not vary significantly, especially as the time of departure approaches. Variations beyond a pre-determined, SIA-specified level, can signify that the flight planner is not keeping up with the changing status of the flight in a proper way.

Using this application it becomes possible for SIA management to analyze the performance of individual flight planners with respect to their allocating resources to their assigned flights and identify those flight planners who may need additional training and/or mentoring.

And, while this application was a post-mortem analysis, the same logic could be used to provide event alerts to the flight planner and/or his/her supervisor in real-time.

Monitoring Dispatchers

Not all event-based applications that were considered by SIA were successfully deployed. At the beginning it was acknowledged by the Quantive-provided trainers and developers that organizational resistance could be an obstacle to the deployment of some event-based applications. This proposed application is one such example.

The way of event-thinking that resulted in the preceding flight planner monitoring application led SIA management to consider extending the concept into an application to monitor the dispatchers that provide information support to the cockpit crew. The idea was to monitor whether dispatchers were paying sufficient attention to all flights by examining a combination of transactional events drawn from the flight operations system to assess the frequency and duration of message interactions between the cockpit crew and the dispatcher, as suggested in Table 5. However, this prospective application did not proceed beyond the conceptualization phase.

In contrast to flight planners, the dispatchers work in a unionized department. For this reason, the proposed development of an event-driven application to monitor individual performance of dispatchers triggered fierce resistance from their union. To avoid possible conflicts with the union, the decision was taken to cancel any further development and deployment of this application. The experience gained with this attempted application demonstrates that an application that is technically and economically feasible can be socially infeasible. As such, the organizational setting becomes a very important aspect to be taken into account when considering event-driven monitoring applications.

CURRENT CHALLENGES FACING THE ORGANIZATION

A first challenge arises from the fact that many of Southern International Airlines business processes are highly regulated. As new regulations are added, these in turn require SIA to implement new, real-time control systems to monitor for compliance. However, in order for SIA to comply, they must continue to rely on their legacy transactional systems, which were not designed to comply with such regulations. The challenge, then, is to overlay the existing systems with a new layer of processing that is transparent to the functioning of the existing systems while providing the needed regulatory compliance. While SIA was able to do this for the weight balancing regulation, there are many other regulations requiring compliance that must also be met in a cost-effective fashion. For example, the arrival of Sarbanes-Oxley (SarbOx) requires, among other things, the monitoring and control of various financial transactions and the early reporting of material events affecting financial disclosures "Section 409 is also important because material changes affecting financial disclosures must be reported on a rapid and current basis. This means systems must be able to provide timely information within days, not weeks, of an event." (Kaarst-Brown & Kelly, 2005, p. 2). Can an approach similar to the FAA compliance problem be taken to this set of regulations? If so, how does one expand the other areas of the organization, base of knowledge gained by the SIA flight operations managers in ways of event-thinking?

Another challenge (or more correctly, opportunity) faced by Southern International Airlines, once they had their initial BAM capability in place, was to re-think non-compliance-related problem-solution scenarios in event-based terms. As this case points out, there is a type of "ah-ha" moment that seems to occur when (some) managers begin to re-interpret other problems they are having in a manner that fits an event-stream, BAM-like solution. While SIA could continue to rely on random awakenings to form the strategy for their next applications, is there a better way to identify opportunities and determine which of these are most applicable for solving using a BAM approach? Conversely, how should one avoid over-use of such a capability—the all-too-familiar problem of a solution looking for problems?

A third challenge that is associated a broader application of BAM-style application, particularly into areas with higher exception frequencies, is the already mentioned "alert overload" problem. Even though the number of alerts per day has been relatively small for the applications implemented to date, an increase in the number of event-driven applications could easily overload BAM recipients with too many alerts in much the same way that e-mails have done. While the volume of alerts can obviously be throttled back by more aggressive event filtering, this gives rise to the well know statistical problem of Type I and Type II errors, for example, rejecting events that should be seen versus accepting events as alerts that are not important. Can risk analyses similar to deciding Type I vs. Type II error levels be applied here? Or, are there other, better ways to accomplish this, drawn from (say) the area of Decision Support Systems?

A fourth and final challenge is how organizations in general, and SIA in particular, should anticipate and overcome organizational issues and constraints that often accompany real-time monitoring situations. As with any system change, technical and economic feasibility are not the only pre-conditions for a successful system implementation and change. It is widely known that "social failures" (i.e., the rejection of the system by the users themselves) are a major, if not primary cause of IT implementation failures. The last case discussed illustrates that unionized departments strongly tend to oppose the implementation of applications designed to monitor individual performance of employees. But more employees in general (unionized or not) are averse to having their work monitored in real-time, particularly when the monitoring results in disciplinary action. And, while they may not be able to prevent its implementation, as the unionized employees were in this case, there are many other ways they can cause the resulting system to fail.

It should be noted, however, that BAM-style monitoring solutions are not inherently punitive; they can be used proactively as well as reactively. For example, in the case of dispatcher monitoring, the alerts could instead be sent to the dispatchers themselves as a stimulus to them to increase their engagement with the specific flight crew. Rather, from the applications presented (both implemented and withdrawn) it appears that SIA management is of the "Theory X" style and some of the BAM solutions implemented allow them to become even more so. How, then could the developers of these solutions approach their design so that the result to monitoring is more proactive/supportive rather than reactive/punitive? Should they? More generally, could/should BAM development adopt a socio-technical approach (Bostrom & Heinen, 1977; Mumford & Weir, 1979) to development so as to enhance implementation success, rather than the more mechanistic development approaches taken from real-time mechanical control system design, where the objects being monitored are machines rather than humans?

CONCLUSION

The implementation of a BAM solution at Southern International Airlines resulted in significant improvement of the event-response capabilities of the airline without having to modify or add to existing transactional systems and in time frames measured in days and weeks rather than months or years. The benefits produced by the projects described include: better regulatory compliance, reduction of operational costs, improved flight safety, greater management visibility into ongoing operations, and improved customer service. As with any new set of concepts and tools, the standard pattern of innovation diffusion can be observed as potential users of the system slowly begin to re-cast problems they may have in terms of events, real-time event monitoring and alerts. This diffusion is made particularly difficult in that the development of event-driven applications requires a combination of knowledge about business processes, regulations, transactional systems, and the BAM solution itself. A final consideration of the cases presented suggests the need for a broader framework and methodology base that addresses and integrates all the many aspects involved in an event-driven BAM implementation project and its subsequent implementation success.

APPENDIX A. TECHNICAL NOTE ON BAM SOLUTIONS

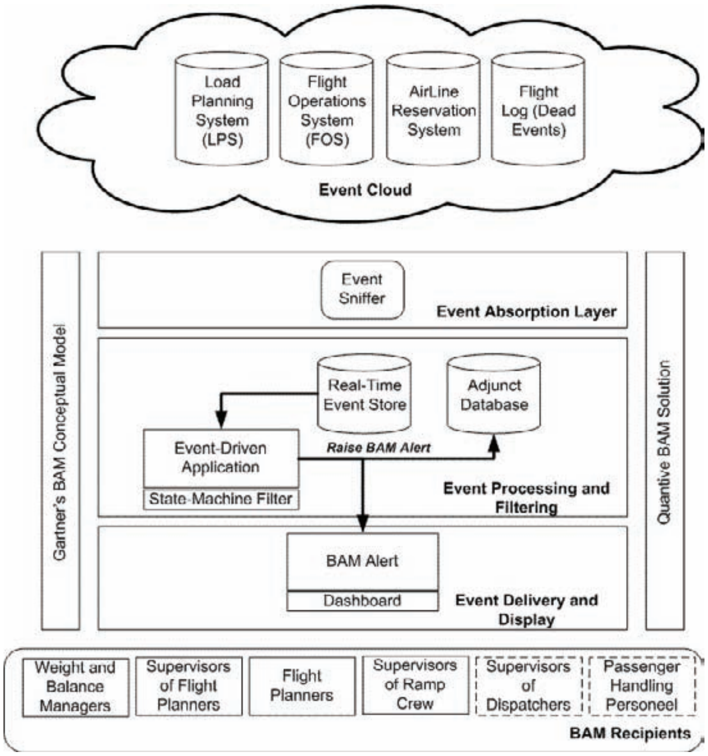
Business Activity Monitoring is a comparatively new concept, first introduced ca. 2002 in the professional literature (McCoy, 2002) and appearing in the academic literature ca. 2004; primarily in conference proceedings (cf. Golfarelli, et al, 2004). In order provide additional insight into SIA's implementation project, additional details regarding the Quantive BAM solution are provided below.

Figure A-1 places the Quantive BAM solution within the SIA flight operations "event cloud" of generated transactions and adopts the nomenclature of the previously presented Gartner conceptual model for BAM. At each level, the Quantive BAM solution provides products or built components that represent their approach to the functional need associated with the generic BAM model level.

Event Execution

For the initial SIA weight-and-balance application, the primary event of interest is considered a "complex event," for example, one that is defined as the occurrence of several basic transactional events that occur in a predefined sequence. For this application, the initial weight and balance transaction (IWBT) is the initiating transaction (triggering event) indicating the existence of a flight. The IWBT contains the basic flight information and the first execution of this transaction confirms that a flight is scheduled for departure within about 4 hours. There is a timing relationship between the IWBT and the other transactions carrying information about a certain flight. After IWBT's detection, a transaction sequence containing transactions about basic flight information regarding passengers, freight, fuel, and

Figure A-1. Functional components of the quantive BAM solution

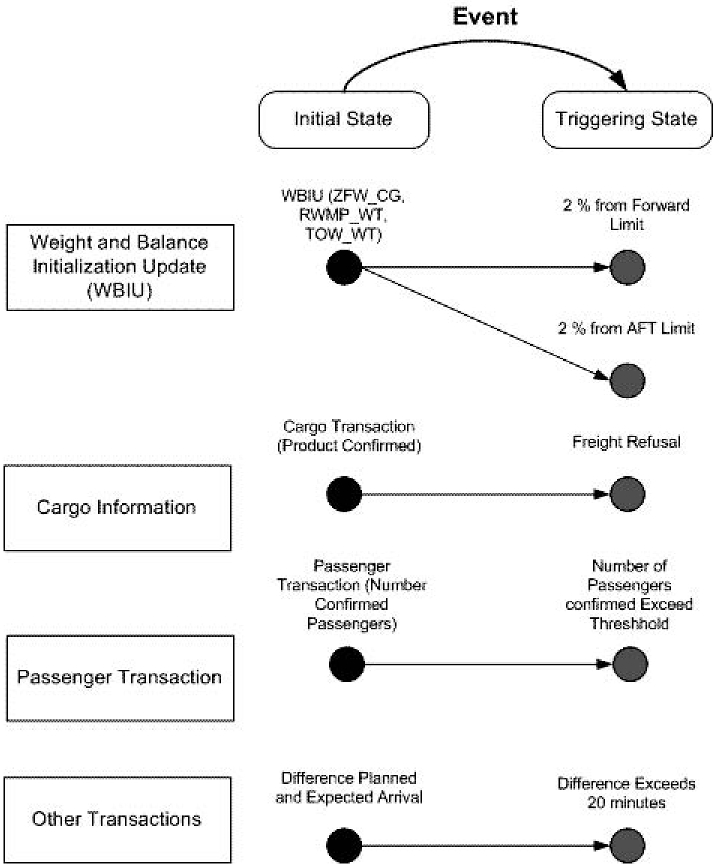


other elements of the flight occurs. Figure A-2 illustrates the associated events of interest that are then monitored by event-driven applications that were deployed by Southern International Airlines. When a pre-specified set of transactions and their associated events occur with specific values, a complex event of interest to the weight-and-balance application is then said to occur.

Event Sourcing

The primary source of events for this implementation project is the flight operations system. This is a widely distributed, message-based transactional system that is responsible for managing resources of all flights of Southern International Airlines throughout the world. The flight operations system supports transaction-based applications used by SIA's personnel to carry out business processes related to flights. Alongside the flight operations system, Quantive's BAM solution also monitors event streams output by other systems that interact with the flight operations system, such as the Loading Planning System (LPS) and Southern International Airlines' reservation system. The LPS is a subsystem of the flight operations system, which was designed to automate the load planning processes. The LPS sits on the top of the flight operations system, but executes underlying transactions that require data from both the flight operations system and the reservation system.

Figure A-2. Set of events of interest monitored by Southern International Airlines



To acquire all the raw transactional events, Quantive's solution literally taps into SIA's switched LAN and, using transaction definition filters created by SIA's operations personnel, it reconstructs the packets of data moving into complete images of the various transactions moving across SIA's corporate network. More generally, any transaction moving over the LAN can be defined, captured and logged in this manner.

Developing an Event-Driven Application with Quantive Tool Set

Quantive's BAM solution includes an application development environment called the Quantive Factory. This environment provides business event modeling tools to specify event selectors used by applications to detect both single and complex events of interest. The application development environment, which is illustrated by Figure A-3, includes modeling functions that can be used to specify the performance indicators to monitor, logic formulas to characterize a complex event pattern corresponding to an exceptional situation of interest, and the characteristics of the alert to be issued when the defined, complex event is detected. Alerts are normally delivered by graphic displays "dashboards" that are customized for different BAM recipients, although as in the SIA case, they were also sent as (real-time) messages to appropriate devices (pagers, PDA's).

The interface of the Quantive Factory was designed for use by business managers, rather than IT developers. As such, complete applications can be and were developed without the need for IT-specialist knowledge. For this reason, the development cycle of event-driven applications was much shorter then would be the case for conventional IT applications. Each of the applications discussed in this case took days or several weeks to develop and implement and in some cases, less than a day. It also provides a much higher degree of "ownership" by the business unit itself, as well as providing a tool for subsequent adaptation and experimentation.

Chapter 2.7

A Model for IT Service Strategy

Neil McBride
De Montfort University, UK

ABSTRACT

This chapter describes a suggested model for developing a service strategy within IT services. It considers the context, the organization of IT services which might be appropriate for a service strategy. It discusses the content of an IT service strategy which it suggests should be presented as a portfolio of services. It reviews the process of developing the service strategy, suggesting a set of steps which may lead to the development of appropriate content within the right management structure. The example of hospital information systems is used to illustrate the strategic process. In order to set the scene for the strategic process, the state of information systems strategy research is discussed and set in the context of the developing service management research literature. The term service-centric is used and the difference between service-centric IT management and service-oriented architecture is clarified. A case is made for a migration from an IT strategy based primarily on the development of a portfolio of IT systems to a service-strategy based on the development of a portfolio of business services.

INTRODUCTION

In the last decade there has been a significant shift in many IT departments. IT departments increasingly recognize that IT within an organization is a service which, like other services within organizations, aims to deliver value to the organization through the way that it supports the activities of the business. This has led to an increasing emphasis on the delivery of IT operations as a service which not only involves the building and delivery of the software and hardware, but also the execution of a wide range of activities around the technology.

The influences that have led to the realignment of IT as a service are complex. Economies, particularly in the West, are changing from a goods base to a service base (Rai & Sambamurthy, 2006). In terms of business models, many companies are repositioning themselves as service organizations. The technological products, which were previously the focus, become part of a larger service. The Volvo lorry is part of a logistics service and is seen in that context (Edvardsson, Gustafsson, Johnson & Sanden, 2000). A technological product is seen as a service waiting to happen. In addition to the manufactured goods being set in a service context, they are also surrounded by support services involving maintenance, replacement, and training.

In IT departments, the rise of outsourcing, the move from making software internally to buying it and the recasting of IT as a commodity has further aroused a service mindset. The service focus of these changes has particularly been around quality. In delivering services and IT products to clients, outsourcers had to work on the definition of what the service was that was being contracted by the client, how it could be measured and how it could be judged as being up to a mutually acceptable standard. Hence, outsourcing led not only to a focus on contracts, but to the development of service level agreements and to attention to the expectations and perceptions of the customer. It was not just the technology that mattered—its reliability, availability and security—but the customer-focused services around it. IT outsourcers were no longer judged by the number of bugs in their software and its usability, but by the empathy, adaptability, and competence of their staff. In IT, quality became a much more complex subject.

A third influence on IT departments has been ITIL which emerged in the 1980's as a UK government response to the need to increase the efficiency and effectiveness of IT in the public sector. ITIL was taken up by many companies during the 1990's and became the standard approach to running IT service operations. However, until the release of ITIL3 in 2007, the focus of ITIL was in service operations, and particularly in the support of information system applications. Strategy was not effectively addressed. This recent recognition in ITIL of the importance of IT as a service function and of the need for a service strategy has been recognized for some time in industry in IS management, and expressed in a central concern for alignment: alignment of strategy, alignment of operations, and alignment of culture. In ITIL3, the Service Strategy text (Iqbal & Nieves, 2007) recognizes that the purpose of IT, like any service organization, is to provide value to the customer. The service must ensure that the customer can use her assets effectively to achieve business outcomes which are produced by business processes. This suggests a massive shift away from IT as technical support to IT as a service organization delivering business value to its customers.

However, even ITIL3 is weak on the processes by which a service strategy is developed. This chapter proposes a set of steps that may be undertaken in developing a service strategy and develops an IT governance approach that complements the organizational structures suggested in ITIL3. It also draws from the management literature to suggest service strategy techniques.

BACKGROUND

The development of the field of services marketing from the late 1980s onwards provided a new set of concepts which could be used in the academic development of IT as a service discipline. An initial focus of service marketing was around the intangible nature of services (Brown, Fisk & Bitner, 1994; Bitner & Brown, 2006). A definition of the characteristics of a service remains of great significance to IT practice because of the contrast that can be drawn with a manufactured product. Although it should be recognized that the definition of a "product" in marketing is wide ranging, since a product can involve a service as part of its makeup—financial products are a good example, for the IT practitioner, the idea that IT can be portrayed as service can come as somewhat of a shock. For the IT professional, whose interest and training has focused on the technology and its construction, the idea that the IT system is subservient to the information delivery service it provides to customers, may be difficult to take on board.

While the goods vs. service paradigm has more recently been questioned (Lovelock & Gummesson, 2004), a consideration of the concepts provides a strong marker for the types of changes in management and attitude needed in IT services. Services are indeed intangible (Lovelock, Vandermerwe & Lewis, 1996). They cannot be stored. Once a service is consumed – usually at a time and place where the producer and consumer are both present – it cannot be reused, sold on or demonstrated. Unlike technical artifacts, the customer is an integral part of the service, must be present for the delivery of the services (excepting some electronic services) and takes part in service delivery.

Taking a service-centric view of IT means that the intangible and temporary characteristics of the service have wide-ranging consequences for the delivery of that service. The classification of services as service factories, service shops, mass services, and professional services according to the extent of customer involvement and the diversity of demand (Verma, 2000) has significant effects on IT delivery (Peppard, 2003; Rands, 1992). The extent of customer involvement can be managed and used as a basis for designing the service product.

The diffusion of service thought into the IT department has had significant effects on the management of quality. Service quality is itself ephemeral and difficult to measure. While the quality of the technical product, the IT hardware and software remains of importance, dimensions such as empathy, assurance and reliability come into play. Quality is much more a matter of customer expectation and perception, driven by the quality of service encounters and the perceptions of moments of truth rather than the internal quality of IT technology as defined in quality manuals. The development and use of SERVQUAL (Berry & Parasuraman, 1991; Parasuraman, Zeithaml & Berry, 1988), has had some influence on IT services and has been well explored in the information systems academic literature (Kang & Bradley, 2002; Pitt, Berthon & Lane, 1998; Pitt, Watson & Kavan, 1995; Yoon & Suh, 2004). Furthermore, DeLone and McLean (2003) in their ten-year review of their information systems success model, describe the need for service quality, as measured by SERVQUAL, as an extension to the model.

SERVICE-CENTRIC IT MANAGEMENT AND SERVICE-ORIENTED ARCHITECTURE

The recognition of the service nature of IT has not only been a concern of IT managers and information systems academics, but has also come to the attention of computer scientists. Spohrer and Riecker (2006), in their introduction to a special service sciences issue of Communications of the ACM, discuss the rise of the service sector and its influence on IT services. In that same issue, Rust and Miu (2006) suggest that it is the rise of the service sector which is driving a computer revolution. In other words they are suggesting a link between IT and Industry cemented by the spread of service concepts.

However, for many IT professionals and computer scientists, “service-oriented” refers to an approach to software architecture in which software agents are loosely coupled to fulfill an application need. Here, customers, or rather customers’ computers, request services from providers through a small set of well-defined, universally available interfaces. The service is then the unit of work offered by the service provider; and the customer can find out who can provide that service through a registry of services. The service-oriented architecture is used in the implementation of Web services (Barry, 2003). However, service-oriented architecture is about the design and management of dynamic technical architecture, not the management of people-oriented services.

Some confusion can be caused in IT circles by referring to the process of IT service management, which centres on the provision of service desks and the management of service operations, as service-oriented IT management. "Service-centric" may be a better term because it focuses on the service nature of the IT function. It is important to understand the need for a shift to a service mindset, which sets the technology – even service-oriented architecture – in the context of the people it serves.

The join between service-oriented architecture and service-centric IT management may be found in the glue of the service-level agreement which will define the nature of the service and the quality parameters of the service. Service-oriented architecture then provides a framework for delivering the technical components required as part of the service. IT service managers must then worry about the delivery of the service as a whole.

IT STRATEGY AND IT SERVICE STRATEGY

One field where the changes from techno-centric to service-centric should have a significant effect is in the field of strategic information systems planning. If we look at the academic literature, the underlying perception of strategic information systems planning has been that it is an exercise in defining a portfolio of information systems to be developed or procured which will contribute to the organization's competitive strategy (Earl, 1989; Elliot & Melhuish, 1995; Fidler & Rogerson, 1996; Hackney & Little 1999; Ward & Peppard, 2005). The focus of such academic strategic exercises has moved away from competitive advantage towards a model using the resource-based view of the firm (Gordon, Lee & Lucas, 2005; Mata, Fuerst & Barney, 1995; Ward and Peppard, 2004). However, those models that are found in the literature take a techno-centric view of IT. Their concern is to identify a set of system requirements that can then become systems development or procurement projects. Their goal is to align the outputs, the strategy, and the development of IT with the whole business.

In organizations where information system planning occurs, the concern is with identifying projects that can be implemented (Earl, 1993). However, the view taken of projects may be more service-centric in industry. The role of the Chief Information Officer, ultimately responsible for information systems planning, may be more as a deliverer of cost-effective services. But there is a paradox here. This industrial shift from a focus on a technology portfolio to a focus on a service portfolio, with the accompanying development of a service-centric mindset, may be achieved at the cost of any role for IT management in driving business strategy (Teubner, 2007).

Indeed, there is a wide gap between academic discussion of strategic information systems planning and industrial practice. Industrial practice puts IT in a much more realistic context as a service provider, supporting the information and business processes of the organization.

Its role is then more behind the business than in front. IT strategic concerns differ significantly in academic studies as compared to business practice (Teubner, 2007).

Additionally to the academic-practitioner gap, there is a gap between the service-centric focus newly found in IT departments and the competitive, business strategy focus of the organization. An IT service department, following ITIL guidelines, may end up being less strategically focused than a techno-centric IT department.

But even in the context of a service-centric IT department, the services that are supplied are support services, in support of technical artifacts. The role of IT is again too limited. It is, in a sense, hiding behind the technology. Information Technology's service role is then in servicing business processes through the delivery and maintenance of technology. This is still the prevalent philosophy of ITIL v3 where the service disciplines of ITIL version 2 are maintained. The service involves support areas such as managing the availability of technology, managing incidents when technology fails, and providing contingency plans for dealing with any disasters occurring to technical capital.

Hence, even in a service-centric IT department, which is aware of the importance of services and pursuing ITIL best practice, the services offered are still techno-centric. It is still a case of services in the support of technology, rather than technology supporting services.

THE CASE FOR A SERVICE STRATEGY

Where organizations take a service-centric view of IT, adopt ITIL, and pursue ISO20000, they run the risk of focusing on the operations and neglecting strategy. The core of ITIL is about the efficient running of service processes, not the evolving of service portfolios to meet changing business needs. The focus remains on the smooth running of the technology.

Services designed within IT services are often support services for organizational customers, e.g. a service to support desktops, or a service to procure and support ERP. They are not business services. A business process or business unit may require a service from IT services. That service will involve infrastructure (system hardware, systems software, DBMS, networks) and applications. The business functionality and requirements will be decided, teams appointed, suppliers appointed and the service delivered. The model in ITIL3 Service Design (Lloyd & Rudd, 2007), still suggests focus on the IT systems to support the system. Requirements engineering is about the functional requirements; the design outputs are essentially the classic systems development outputs—forms, user interface, object model, use cases, and process models.

IT governance may be designed around the technology or around business groups (Sambamurthy & Zmud, 1999). Departments may be grouped around technical expertise—desktops, networking, Unix, for example, or by business grouping—sales, product development, marketing, manufacture, for example. However, IT governance is implemented, and however frequently it oscillates between different organizational structures, it can remain focused on the IT artifact.

What is required is an approach to IT service strategy and IT governance which puts the IT artifact back in place as only part of a business service or process. Such an approach should consider the whole service of which the IT artifact is only a part. It should involve the design of the whole service and the whole business process. The service-centric view should permeate the whole strategic process.

The following outlines a service-centric model for IT service strategy. The context is the IT governance model which structures the IT department around business services. The content is the output of the strategic exercise which is seen as a set of services to be designed, implemented and operated. The processes are a putative set of steps and modeling tools by which that output is obtained.

THE SERVICE STRATEGY MODEL

Context: Organizing IT around the Businesses Customer Facing Services

A service-centric model seeks to divide the IT infrastructure into service teams that support the services provided by the organization. Each team provides the information and system needs of a particular service element, business process or business function. A service-focused IT infrastructure then directs the attention of IT staff outwards to the organizations' services and customers and away from a notion of the primacy of the IT.

The service team may operate within a service unit. That service unit would be driven by defined service contracts and measurables. How the service is delivered would be up to the team. For example, the team would make decisions as to whether to meet the service need by tweaking an existing computer system, buying or building. Also the team would decide when to retire an existing computer system. The delivery of the service to the organizational service area or business unit should continue without the service customers needing to get involved with implementation of a new system and without them having to organize their activities according to an IT agenda. Thus the service team retains some autonomy concerning the delivery of the service. The IT service strategy then defines the nature of the service to be delivered, its scope and quality.

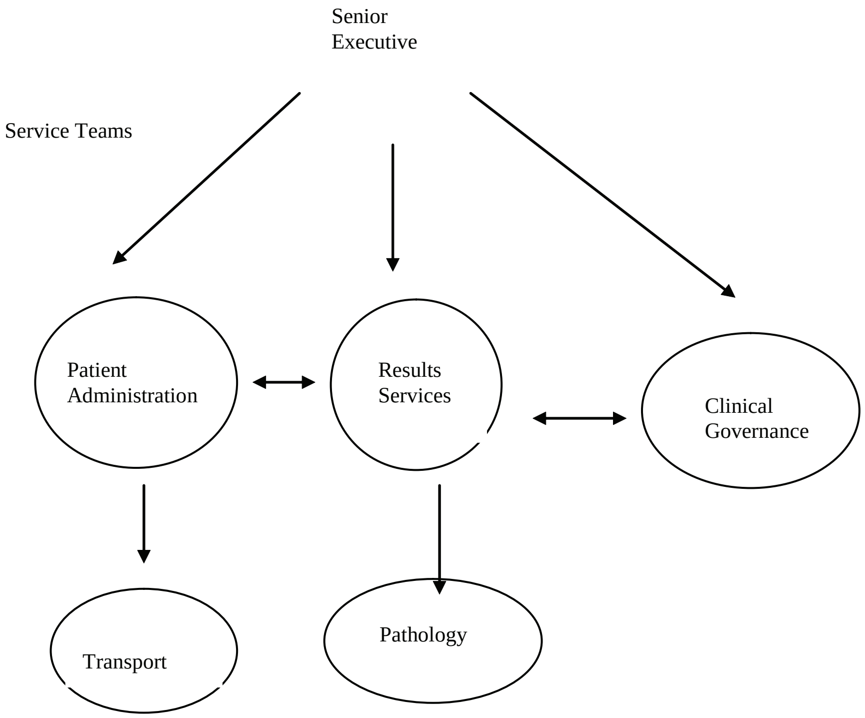
There are several key points to note in this model. Firstly, the focus of the service unit is on a business process. Whether that is loan processing, pharmaceutical sales, or patient administration, the process being supported is not an IT process. Secondly, the service unit team will need to be an integration of IT experts and business experts, all focused on the business needs. IT is subservient to, and only part of the business focus. Thirdly, it should be noted that the service is not just an infrastructure service. Services such as application maintenance, information security, and document management and disaster recovery may be part of the service unit, but they are all subservient to the business process.

Take a hospital as an example. In a hospital, a separate IT department delivers the IT requirements of the whole hospital. The department may concentrate on the large IT developments as the expense of smaller services, departmental and specialty needs. In a service oriented IT organization, there is no visible IT department. Technical expertise is grouped around business structures. An outline service-based structure for a hospital may be envisaged as illustrated in Figure 1.

Here, service teams support bounded areas of hospital services and processes. IT is an important part of each service team, and may be the primary focus of effort, but each service team has service outcome goals to meet, not technology delivery goals. At the top level, these might be:

- **Patient administration:** Provision of integrated information flows to support the entire patient experience from outpatients, through inpatients stay and operations to discharge, including connections with primary care and other organizations.
- **Results:** The results services provides information support and information systems support for the requests for diagnostic procedures including pathology, x-ray and other procedures, and the delivery of the results of those procedures inside the hospital and to requestors outside the hospital.
- **Clinical governance:** Provision of information to enable effective clinical practice, including provision of systems and services to enable evidence-based medicine, the development of integrated care pathways and the development of information databases to enable effective clinical audit. Clinical governance at a primary care group level will also be supported where it interfaces with the hospital.

Figure 1. Service-centric IT management structure for a hospital trust



These service teams may interact with more departmentally based service teams in for example, transport and pathology. Smaller service teams supporting specialist service requirements within particular specialties (for example, intensive care and Magnetic Resonance Imaging) might be formed as subteams within the patient administration or clinical governance service teams. However, note that each service unit is defined in terms of the service it delivers to meet the needs of its customer base, not in terms of the technology it supports or provides. If we replace the development of information technology strategy, with its emphasis on boxes and their technical implementation, with the development of service strategy with its emphasis on the delivery of services which make business processes work, which achieve business outcomes, we are freed up in two ways. We can consider business processes and their delivery without being constrained or slowed down by considerations of IT implementation, and we can be freer with our consideration of IT requirements for a business process because the technology requirements have not been fixed in an IT strategy, but can be changed and adapted as required.

The effect of such an IT service structure may be to:

- Generate a service culture;
- Move the IT interface right next to the appropriate hospital services;
- Enable faster support for changes in services or processes;
- Generate greater understanding of the IT within the service area and
- Generate greater responsiveness from the technologists.

It should be noted that the skills set within the service teams would need to extend beyond the IT to the organizational services. A Patient Administration Service team would need to understand the processes in outpatient clinics, medical records, ward-based services and theatre. Practitioners from these areas would be part of the team; defining services and working on the delivery of these services in concert with IT-Skilled staff who would quickly gain business and service understanding within the area. These teams may be managed by organizational service-centric staff. For example, clinical governance may be managed by a clinician.

While ideally the business and technical skills should be encapsulated within the service team, which is able to develop the service set and apply IT understanding to deliver it, we recognize that, in large organizations, economies of scale may demand that some of the IT elements are delivered by technical teams. For example, IT networking may be delivered by a networking team whose customers are the various service teams. Such technical elements may be outsourced.

However, an overall service philosophy can be used. In a service-centric IT infrastructure, business services are supported by IT services which draw on applications, training, and information resources to deliver a holistic service which meets the service needs for information and does not just focus on technology. This contrasts with a traditional model in which a computer application is built for the business and IT services support the computer application (Figure 2)

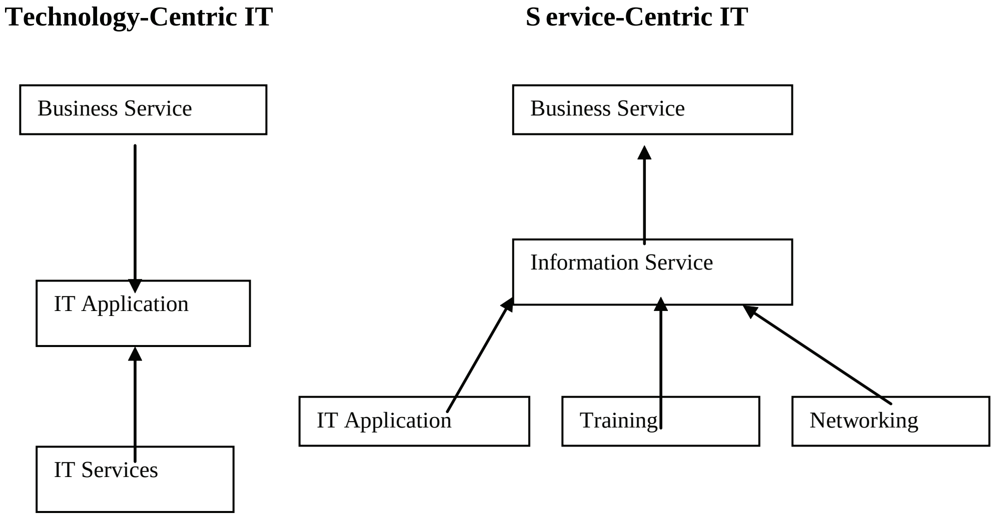
Content: IT Service Strategy as a Portfolio of Services

The content of an IT Service strategy focuses on the nature of the services to be delivered by the service teams within the IT management infrastructure and not on the computer systems and technology.

The content of the strategy will consist of a series of service definitions together with explanations of the philosophy behind each service and the strategy for service-delivery. At a greater level of detail, the IT service strategy would define the service level agreements and the level and type of service the internal customer might expect.

It may be appropriate for the strategy to define the resources required to deliver that service in terms of computer systems and applications, networking, staff training, IT staff and so on. The risk here is that the definition of the technology within what is a service strategy, moves the focus right back to the technology. However, it may be more effective to leave that level of implementation strategy to the service teams and restrict the IT

Figure 2. Changing from IT application focus to information service focus



service strategy to a definition of services, service content and SLA which the service teams will have to adhere to. Such a focus on services reduces the risk of the strategist's attention being deflected by the technology needs and hence the technology actually driving the service definitions.

The contents of an IT Service Strategy may include:

- Definition and description of business/customer services provided by the organization;
- Definition of the service teams and mapping of service teams to business services or business units;
- Description of mission and scope of each service team, including definition of strategy and philosophy behind the service;
- Definition of services provided by each team presented as a service catalogue;
- Description of service including a diagram of the service processes, delineating service team, activities, customer activities and the interaction between the two;
- Definition of one or more SLAs associated with that service;
- Constraints on service;
- Information provision associated with that service;
- Summary of resource requirements focused on enabling costing and pricing of the service;
- Definition of quality measures associated with each service and description of process by which quality will be monitored, particularly including a definition of the outcomes expected from the service and the measures associated with those outcomes;
- Management policies associated with the service;
- Definition of any generic services which may be provided on behalf of the service teams, either centrally or outsourced. Examples may include installation and maintenance of physical IT infrastructure and servicing of PCs.

The IT service strategy provides a blueprint for the development of IT services within each service group. The level of detail for the definition of each service may vary. In some cases it may be appropriate for the service team to negotiate the SLAs with the business services it supports. Also, depending on the maturity of the service area, significant service innovation and design may be required.

Process: Developing an IT Service Strategy

The process of developing the service strategy may be tackled in a number of ways. A top-down/bottom-up approach may be considered, as has been used in Method/1 (Earl, 1989; Lederer & Gardiner, 1992). Alternatively, a more evolutionary approach may be considered. Regardless of the process model, a number of tasks must be tackled. Suggested tasks in the development of an IT Service Strategy follow:

Definition of business services. An understanding of what the organization does and the structure of its services must be gained since this will be required for mapping IT services and service teams to business services. If we take a purist service view, then where a company provides products we need to consider the customer service that the product is part of. This may generate ideas for new business services which will require IT services. The definition of services that are provided by the business should be split down enough to generate service support requests (i.e., definitions of what IT services are needed to make that service work or to underpin the service.).

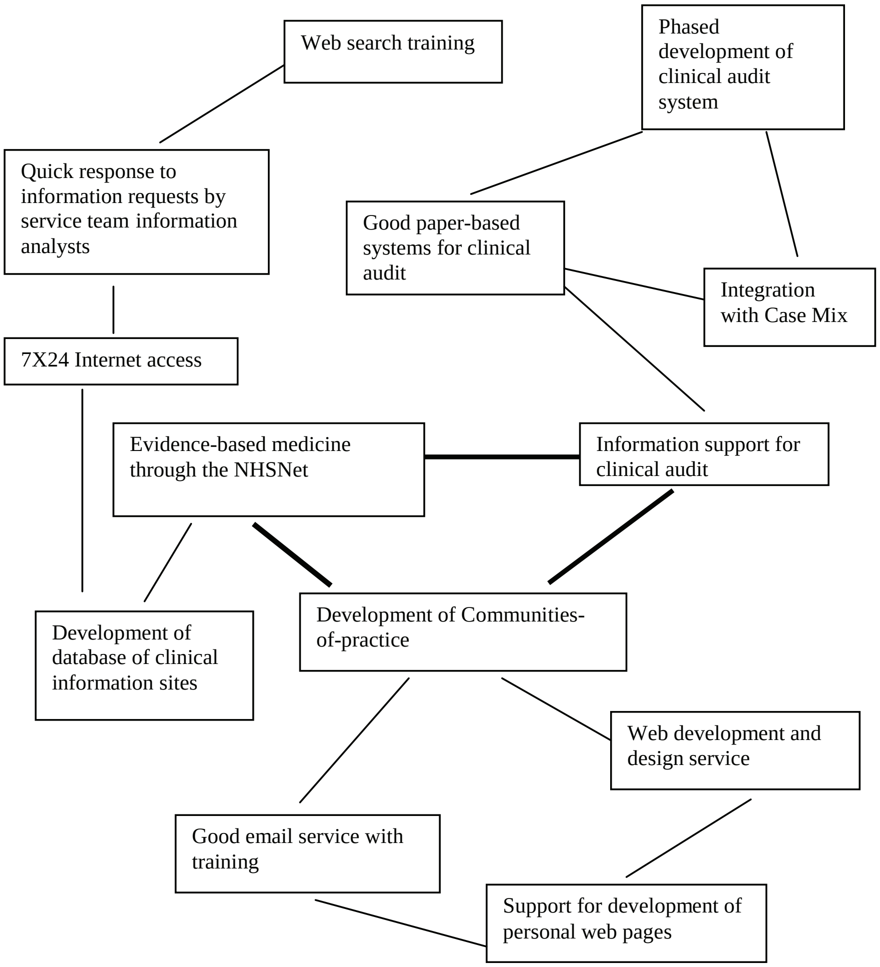
The definition of business services will require a detailed understanding of the customer and her business processes. Iqbal and Nieves (2007) see this step as driven by a marketing exercise.

Customer outcomes are analysed and a service catalogue defined to match them. Such an approach may be weighted toward type 3 services which are outsourced. Here the outsourcing company is trying to develop services – usually IT services—which will attract customers in a competitive market. In type 1, insourced IT services, an emphasis on the business processes of the host company may be more appropriate.

Definition of Service Teams. The analysis of the business's services will lead to the construction of a IT management structure consisting of a series of service teams which map to the business services.

Definition of service strategy. For each service team a service strategy should be developed. Competitive analysis and an analysis of organizational effectiveness may be carried out at this stage. While traditional management tools such as five forces and value chain can be used in determining the strategy (Botton & McManus, 1999), we would recommend the use of activity-system maps (Porter, 1996) An activity-system map enables the principle philosophy of the service and the activities which will be used to implement that philosophy to be defined (Edvardsson et al., 2000). Figure 3 illustrates an outline activity-system map for the clinical governance service team. Note that the strategy exercise is driven by

Figure 3. Outline activity-system map for clinical governance service team



the service needs of the business, taking a service view of both the organization and the information systems within it.

Definition of services. Exact service provision should be defined for each service team. Draft SLAs should be developed based on the business needs. Information needs should be explored and an initial set of services defined. Definition of services may also involve service innovation. It is in this step that technology innovation should be considered as a basis of new services. Services should be defined at a high level. Detailed service design may not take place until an understanding of current IT services is carried out and a gap analysis done.

Analysis of current IT services. Current IT in the organization may be product-oriented. The IT needs to be considered as a portfolio of services, so an understanding of how IT can currently be represented as services will be needed.

Gap analysis. Gaps between current IT services and the services required within the service teams will need to be analysed. The IT services will be mapped to the service teams. It is at this point that consideration of which IT service elements should be delegated to the service teams and which might be provided as a generic service may be considered. For example, while network administration may be offered as a centralized, generic service, all application development, application support, systems procurement, user training, and system evolution should be allocated to service teams. It should be a policy to minimize generic services since these can only be provided at a distance from the business services. We would suggest that the proliferation of generic IT services may only serve to widen the IT/ business service gap and reduce business effective and service focus.

IT business integration. Once the service gaps are understood plans can be developed for the integration of IT services and the business. How each service team is going to obtain its IT resources and take over appropriate applications should be considered.

Definition of SLAs. At this point there should be sufficient information and understanding of the services to generate detailed SLAs. These will involve negotiation between members or potential members of service teams and the business service areas.

Implementation. Detailed SLAs provide the core of the strategy. At this point a detailed IT service strategy can be written up and the focus moves to service team discussion of how the SLAs are to be fulfilled. Guidelines for implementation may form part of the written IT services strategy, but detailed implementation should, we suggest, be left to the service teams to encourage ownership and a close fit with the business services.

The IT service strategy development process needs to be conducted in a flexible manner. Since the strategy definition is a service in itself, the project team must contain a significant number of active representatives from the business service areas. Service innovation cannot be done without close involvement of internal customers. In planning the strategy development process, internal customer involvement must be defined.

CONCLUSION

It is widely recognized that there is a need for the integration of IT service elements with the business services. This process of alignment has become a major concern for IT departments. Alignment of IT services with the business it serves involves an engagement with the purpose and strategy of the business. The chief information officer cannot retreat into service support, while changing from a focus on the artifact and the technology to a focus on the service and the people. The strategic view must not become myopic. There must be continued effort to contribute strategically to the business.

Furthermore, the academic/practitioner gap must be bridged. Practitioners see strategy in terms of pursuing themes and investigating new technologies. Academics see strategy as using resources strategically to deliver competitive advantage. Both views are important and should be integrated.

While many writers have addressed the issue of IT services—for example, Applegate, Austin, and McFarlan (2003) see the managing of IT operations, the provision of reliable and secure IT services, and the management of diverse IT infrastructure as integral to corporate information strategy—the attention to service concepts is limited. There is a tendency to become techno-centric in both service strategy and service design.

At the core of this chapter is the idea that everything is a service. Even the most technical product is only of value when it is used in a service. The car is an element of a transport service. The computer is a part of an information service.

This chapter involves a call for a service first, technology second philosophy. Technology supports service. It is designed in the context of the service. Therefore at both a strategy and design level, the main concern of the IT service department should be in the developing of the service into which supporting technology is fitted.

Hence, the strategic exercise should be about the definition of services to be provided by the IT department. And those services should be business process services, centred on the services that the organization provides to its customers. Then the focus of IT is on its service catalogue, the list of what services it provides to its customers. This is of importance to its customers. For example, the service the customer gets in managing patient administration or the service the customer gets in managing materials planning is at the centre of the strategic exercise.

The information system tools used to deliver those services are of little interest to the customer, provided they support the service adequately. The technology used as platforms for those services—the relational database, the network system, the servers—and how the technology is implemented is not only of no interest to the customer but is more a positive hindrance to the customer's goals.

IT within organizations is becoming pervasive. The use of computers is a natural part of most business roles. The computer control of business environments, processes and activities is a given. But computers are not only becoming pervasive in organizations, they are disappearing. Eventually IT will become so embedded in the environment that the use of the technology will become as natural as breathing. In such an environment, technical issues are not a concern of the user who is only aware of a service, of the business processes that are being supported.

In such an environment, IT is seen by the customer as being responsible for the processes. The service is seen as business processes delivered to enable the internal customer to earn revenue for the business in some way. The technology behind those processes is invisible to the customer. It is a black box, a taken-for-granted. Issues concerning breakdowns of technology are invisible to the user: dealt with by IT without disturbing the customer. It is assumed that IT takes the best technical decisions concerning the technical support of processes and the provision of the invisible infrastructure, the invisible computers. There is no need for the customer to talk about the technology or even consider it. The customer comes to IT to talk about services, the request new services, to consider changes in existing services.

In terms of strategy, the IT department delivers those services; so the strategic exercise is about services. This chapter has provided one possible framework for developing that service strategy.

Chapter 2.8

Perspectives of IT-Service Quality Management:

A Concept for Life Cycle Based Quality Management of IT-Services

Claus-Peter Praeg
University of Stuttgart, Germany

Dieter Spath
University of Stuttgart, Germany

ABSTRACT

This chapter introduces an IT-Service management framework for the use of quality management concepts in the context of the life cycle phases of IT-Services. It argues that IT-Service management, combined with quality management and a life cycle approach for IT-Services provides a new perspective for organizations to provide high quality IT-Services. Based on the IT-industrialisation and an increased customer orientation in the IT-Service management the aspect of quality becomes increasingly important. Therefore, the authors give an overview about existing concepts of IT-Service management, life cycle management and quality management for IT-Services. The aim is to support organizations in the effective use of quality management concepts depending on IT-Service life cycles.

INTRODUCTION

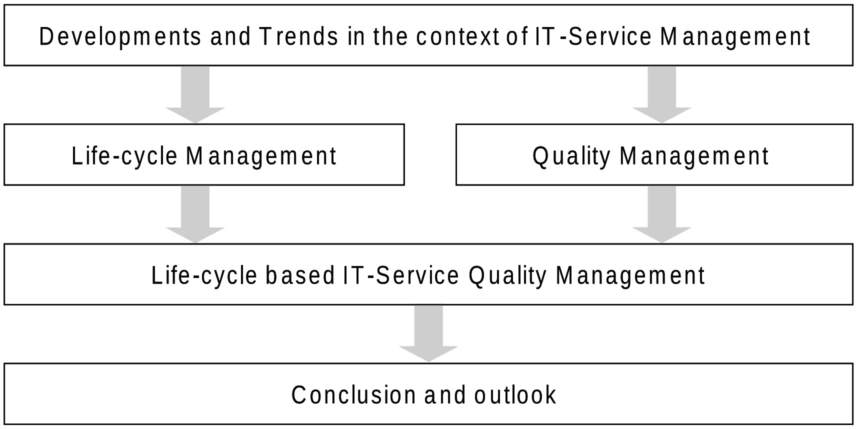
In context of IT-Governance there are numerous concepts and models that can enable organizations to be more effective and more efficient in using IT-Solutions. IT-Governance is supposed to help organizations to enhance their competitiveness by using Information Technology (IT). On the one hand a big issue in this discussion is the realization and evaluation of the business value due to the use of IT (Weill & Ross, 2004). On the other hand the constant change of business needs also demands a reliable and effective IT support for the business processes. Therefore IT-Governance and IT-Business alignment are key success factors for creating business value due to the use of IT-Services in an organization. In the wake of constantly changing business requirements the existing IT-Infrastructure and the IT-Services which support the business processes have to adapt as well. The developments in Information Technology and IT-Service management enable organizations to use IT-Solutions in a way which differs completely from earlier concepts. Therefore the management concepts for IT-Service management have to adjust to these new developments. In this situation the quality of the provided IT-Services becomes an important issue for IT-Service providers and service recipients. Hence quality management is one important aspect in the context of IT-Governance.

Experiences from the industrial sectors show that organizations are able to achieve strategic and operational targets concerning quality and customer satisfaction by using quality management approaches. In the context of IT-Quality management, IT-Governance defines the rules for the decision making process and competencies within an organization. It describes the framework for the IT-Strategy and defines the guidelines for the IT-Service management within an organization. Based on the importance of service quality, as outlined above, this chapter focuses on the quality management of IT-Services in dependence on the life cycle phase of IT-Services.

In the current discussion about IT-Services and quality management has so far not provided a concept which integrates these two dimensions in a life cycle based concept for IT-service quality management. This chapter aims to close this gap and provide a model which enables organizations to map selected quality management methods with previously defined phases of an IT-Service life cycle. The goal is to present managers a practical approach for matching quality management methods with life cycle phases of IT-Services.

From a research point of view, relevant questions concern the possibilities of transferring quality management concepts from the industrial sector to IT-Service management. In the context of the developments for IT-Service management it is important how a holistic life cycle for IT-Services can be illustrated. The final research question in this chapter focuses on mapping the different life cycle phases of IT-services and quality management concepts. To answer these questions the chapter will follow the structure outlined below (see Figure 1). It illustrates the several aspects in the context of life cycle management and IT-Service quality management which shall be merged into an integrated model of life cycle based IT-Service Quality Management.

Figure 1. Structure of the chapter life cycle based IT-service management



Following Glass Ramesh, and Vessey (2004) the described solution promoted in this chapter is a conceptual analysis and an instrumental development based on a design science approach (Glass et al., 2004; Hevner, March, Park & Ram, 2004). In IT research science the design science creates and evaluates IT artifacts intended to solve organizational problems. In this context the organizational problem is the use of adequate quality management methods for IT-Service management within an organization. IT artifacts are generally defined as constructs (vocabulary and symbols), models (abstractions and representations), methods (algorithms and practices), and instantiations (implemented and prototype systems) (Hevner et al., 2004).

This chapter focuses on illustrating a model for the transfer and use of quality management methods depending on the life cycle phase of an IT-Service. One research hypothesis is that the transfer of engineering focused quality management methods to IT-Service management can support IT-Service providers and organizations to improve the quality of their IT-Services.

The first part of this chapter provides an overview of selected developments in IT-Service management and describes and the relation between the trends and their impact for IT-Service Quality Management. The following part introduces the life cycle concept for physical products and transfers this approach to a life cycle concept for IT-Services. The third part presents the basics of quality management, the total quality management concepts as well as several concepts in context of service quality. The fourth part integrates the life cycle concepts with quality management and presents a concept for a life cycle based IT-Service quality management approach. It also offers a brief overview of the theoretical basis of the concept. This combination of life cycle concepts and IT-Service quality aspects enables organizations to match selected quality management methods with the different phases of the IT-Service life cycle and achieve increased service quality and customer satisfaction. The final part describes opportunities for further research and highlights challenges for the organizations in case of quality management for IT-Services.

DEVELOPMENTS IN IT-SERVICE MANAGEMENT

During the past years IT-Departments and IT-Service providers have been faced with new challenges. The main challenges are internal restructuring of the IT-Department, the importance of service orientation caused by increased market and customer orientation as well as the industrialisation in IT-Service management. As a result of the increasing focus on efficiency and performance, organizations recognize that the operation of IT is not their key competence. Hence the organizational structure of IT-Departments is changed from internal cost centres to market oriented service providers. Organizations have started to evaluate the added value and performance of their internal IT-Departments and benchmark them against market offers from external IT-Service providers. On the one hand, this follows in a changed position of the IT-Departments and IT-Service providers as well in a modified situation for managing IT-Services. On the other hand, this results in an increasing procurement of IT-Service via external markets for IT-Services (Kotabe & Murray, 2004).

To illustrate selected trends and developments in IT-Management this chapter shows the need for a new concept of IT-Service quality management. The goal is to emphasize important developments in IT-Service management and show their impact on the IT-Service quality management.

According to the situation mentioned before, there is an increased market and customer orientation in the IT-Management sector. The different departments in an organization become customers of the IT-Department or an external service provider. As a result, the relationship between the several departments and the IT-Provider is similar to a partnership with external customers. Both parties work together on basis of defined service levels under real market conditions.

Therefore, market and customer orientation makes new demands on IT-Departments and IT-Service providers. They are forced to define products and services which are provided for the customers. The definition of IT-Services, the "product" of the IT-Department, becomes a key challenge for the IT-Management (Zarnekow & Brenner, 2004). The development and customization of suitable service packages will be a future challenge for service providers in general (Spath, van Husen, Meyer & Elze, 2007). "IT-Products" are a combination of different IT-Services which support business processes (Uebernickel, Bravo-Sànchez, Zarnekow & Brenner, 2006). From a service providers' point of view, this product orientation implies that a portfolio of offered services has to be defined and regularly updated to the customers` demands. From a service recipient point of view, the IT-Service portfolio has to be actively managed and continuously adapted to the changing business requirements and the business processes.

The increased focus on business value and performance results puts an increasing pressure for IT-Service providers to improve their efficiency. In this context, the term "industrialisation" describes the transformation of productivity methods from the industry sector to IT-Service management.

There are four basic aspects concerning the IT-Industrialisation (Hochstein, Ebert, Uebernickel & Brenner, 2007): Firstly, automation and standardization, that is, IT-cost reduction due to standardisation of business processes and IT-Services. According to the standardisation of processes, there is also efficiency potential due to automation. The second aspect focuses on the modularisation of IT-Services. Comparable to the production industry the modularisation here enables the customizing of services to individual customer demands due to the use and combination of different standardized IT-Modules (Böhmann & Krcmar, 2003). Schnabel, Dold, Fröschle, Layer, Roll, and Skempes (2006) highlight the capability of customization of services to the stakeholder requirement as a key success factor especially for service companies. The third aspect of industrialisation focuses on the quality management and the implementation of continuous improvement processes within the providers' organization. Thanks to the use of quality management concepts, processes have to be improved, become more efficient and enable performance measurement (Hochstein et al., 2007). The fourth aspect is focussing on core competencies and fostering the outsourcing of processes and business fields which are not relevant for creating a unique selling proposition. According to this principle the depth of the value added chain in the organization will be reduced. Furthermore, this enables an organization to react faster on market developments and to provide high quality services for the market.

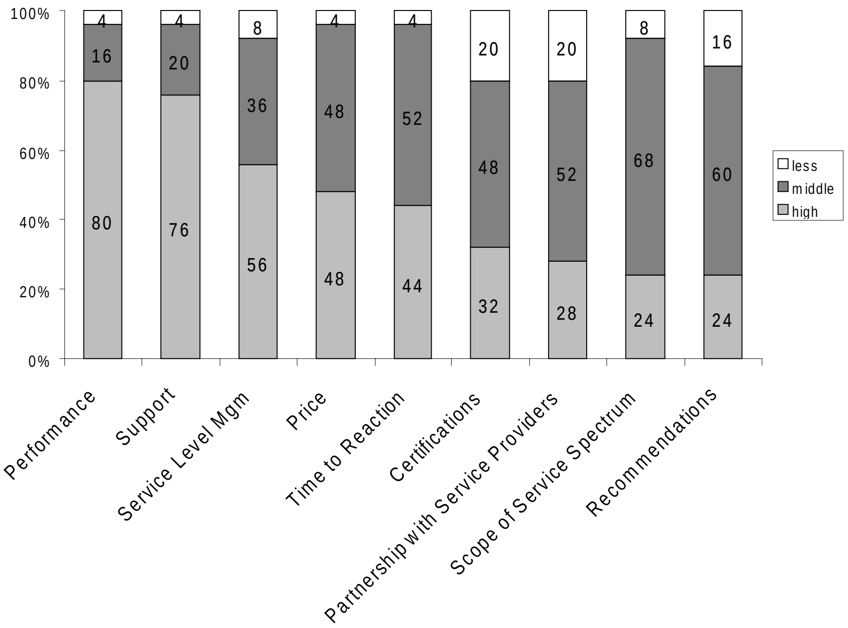
From a customers' point of view the focus on IT-Services highlights the increased meaning of the quality of IT-Services. Service quality is the output of different organizational processes and procedures which ensure a constant level of performance by systematically engineering IT-Services (Spath & Demuß, 2003). The quality parameters of IT-Services, like availability, reliability and functionality, instead of technical aspects of IT-Application and infrastructure should therefore be high priority (Zarnekow, Hochstein & Brenner, 2005). As a consequence of this increased service orientation and the supply of IT-Services through external providers, there is also a need for a systematic quality management by providers as well as service customers to ensure the availability and the quality of the IT-Services. Due to the increased meaning of IT-Services, the technical aspects became less important and. the "engineering" of IT-Services is pales in comparison to the perceived quality of the service provision. For IT-Departments and IT-Service providers this means an increased significance of quality management of offered IT-Services and customer services.

A survey form the IT-Service Management Forum (itSMF) in Germany, comprising 122 participating service providers and service recipients, highlights the importance of the offered service portfolio and the quality of the customer service (Praeg & Schnabel, 2006). This market survey proves that today, the most important criteria for customers in choosing an IT-Service Provider, is the performance of the IT-Service provider followed by the support and the performance of the service level management of an IT-Service provider (see Figure 2).

The results show that the price of the services is not the critical factor for organizations contracting a service provider. Customers focus on performance and quality of an IT-Service provider. The service quality depends strongly on the customer specific perception.

Therefore, the primary target of the IT-Service management is to align the offered service portfolio to the customer requirements and adjust the IT-Service portfolio to the customer demands regularly. To foster this management concept, the IT-Service providers must recognize that IT-Services have their own life cycle when used by the customers. The meaning of the IT-Services will change according to the change of the business processes which follow changed market situations. This concept of life cycle based management of IT-Services is not yet very common in existing IT-Management concepts. Most of the actual and instruments of IT-Management in practice are focused on separated phases (planning, development, operation) of IT-Management. But there is an important gap in the relation between the stages of the IT-Management phases. Therefore the following chapter gives an overview of different lifecycle concepts which can be adapted and used for the IT-Service management.

Figure 2. IT-Service provider selection criteria's from customers' perspective



LIFE CYCLE BASED APPROACHES FOR IT-SERVICE MANAGEMENT

The developments outlined in the previous chapter illustrate the increased product orientation of IT-Services. Within an organization, IT-Services are managed like a portfolio (Zarnekow et al., 2004). This product orientation means that the IT-Services have to be managed comparable to physical assets in an organization. Compared to the life cycles of physical goods IT-Services have shown an equal development when they are being used in organizations.

Originally, life cycle concepts have been used in the context of engineering and managing physical products. The aim here is the distribution of existing resources in dependence of the life cycle phases and also the management of costs and benefits within the life cycle. Based on these experiences the concept of life cycle management was adapted for software and application development (Mercurio *et al.*, 1990). Regarding IT-Service management there are also different concepts which directly or indirectly consider life cycle phases. The subsequent paragraphs present selected concepts of life cycle based IT-Service management.

Life Cycle Model of Physical Products

In general, a life cycle characterizes the different stages of a product during its market appearance (Bullinger, 1994). The product life cycle management is the process of managing the entire life cycle of a product. For that reason the traditional life cycle concepts are described from a market perspective. For physical products the life cycle covers several phases, from conception, design, testing to manufacturing, market introduction and the disposal of products. In the first phase of the life cycle the products' requirements are defined based on customer and markets demands. In the following phase the detailed design, development and also the testing of prototypes are center stage. This covers many engineering tasks and disciplines. These phases generate the highest costs for an organization. The subsequent life cycle phase focuses on the growth and the maturity period, before the product runs out of the market (Macharzina, 2003). The final phase of the product life cycle is the replacement of the product by other, new products. The challenge for organizations as well as IT-Service providers is the transformation of this product life cycle to the requirements of the IT-Service management. Thanks to life cycle management, organizations are able to get products faster on the market, provide improved support for their use, and manage end-of-life better. In today's highly competitive global markets, companies must meet the increasing demands of customers by rapidly and continually improving their products and services (Stark, 2004).

Concerning IT-Service management, the existing methods can be separated in public domain approaches and nonpublic domain approaches.

IT-Infrastructure Library (ITIL)

ITIL was developed at the end of the 1980's by the British Office of Government commerce (formerly Central Computer and Telecommunication Agency (CCTA)). ITIL is the de facto standard for IT-Service management and it is the most widely adopted approach for IT-Service management (Sallé, 2004). The ITIL framework is a collection of best practice processes for IT-Service management.

In the updated third version a life cycle based structure for IT-Service management was implemented. The different phases are Service Strategies, Service Design, Service Transition, Service Operation and continual Service Improvement (OGC, 2006). The Service Strategy defines the targets and the guidelines for the IT-Service management. The phases Service Design, Service Transition and Service Operation represent the implementation, operation and change of

IT-Service management within an organization. The continual service improvement supports the internal implementation of improvement programs and projects. One important issue of the ITIL version 3 is a glossary of standard terms and definitions, it emphasizes the integration between business and IT-aspects and should support the implementation of value added networks between IT-Service Providers and service recipients.

Control Objectives for Information and Related Technology (CobiT)

CobiT was developed from the Information Systems Audit and Control Association (ISACA) and is promoted by the IT-Government Institute. It is designed to be an IT-Government aid for the management in identifying and managing the risks and benefits associated with IT. CobiT creates the link between the business objectives of an entity and the specific IT and IT-Management tasks via statements about the control objectives (Sallé, 2004).

The CobiT-Framework covers a life cycle concept that is oriented on the use of IT within an organization and it is closely connected to the IT-Governance. The CobiT Framework identifies four domains which are covering 34 IT-processes. Furthermore, it defines 318 detailed control objectives and audit guidelines to assess the 34 IT-processes (Sallé, 2004).

The domains are Planning & Organization, Acquisition & Implementation, Delivery & Support and Monitoring. The domain Planning & Organization covers strategy as well as tactics and identifies ways on how IT can support the achievement of the business objectives most effectively. Acquisition & Implementation focuses on the identification, development or acquirement of suitable IT-solutions. The Delivery & Support domain is concerned with the actual delivery of required services. The Monitoring domain focuses on the assessment of quality and compliance with control requirements over time (Sallé, 2004).

Nonpublic Domain IT Service Management Methods

The HP IT Service Management Reference Model is a high level IT-process map, which provides a coherent representation of IT processes and a common language for defining IT process requirements and solutions. The model is structured around five groups: Business-IT alignment, Service design and management, Service delivery assurance, Service development and deployment and Service operations (Sallé, 2004).

The Microsoft Operations Framework provides technical guidance that supports organizations to achieve critical system reliability, availability, supportability, and manageability of IT solutions based on Microsoft products and technology. The process model is a functional model that operations teams perform to manage and maintain IT-Services. It is organized around four quadrants and twenty management functions the quadrants are changing, operating, supporting, and optimizing (Sallé, 2004).

The IBM System Management Solutions Lifecycle Framework provides a high level consulting road map. The four-phase process is similar to the former ITIL processes. The IBM approach considers the phases of process assessment, process improvement definition, analysis and design, and pilot deployment. Furthermore, there are extensions to provide an integrated and comprehensive solution (Sallé, 2004).

The Integrated Information Management Model

A life cycle concept focussing on information management is described by Zarnekow and Brenner (2003). The typical phases of the product life cycle, development, market introduction, growth, maturity and retention, can be adapted to a life cycle of IT-Systems which are defined as plan, built and run (Zarnekow & Brenner, 2004).

In their model of an integrated information management, they focus on IT-Products and describe the key processes and tasks of the life cycle from a service provider and a service recipient point of view (see Figure 3).

Traditionally, the IT-Management has a strong technology and project orientation. Conventional IT-Management focused on planning and developing IT-applications and maintaining IT-Infrastructures. Most of these tasks were organized in projects. Therefore, the management of the classical IT-life cycle is divided into three phases: Plan, Built and Run. Contrary to the traditional "plan, built and run" concept, Zarnekow and Brenner in their approach focus on the "source, make and delivery" processes (Zarnekow & Brenner, 2004). Accordingly, they regard the increased market orientation and the changed sourcing strategies of many organizations.

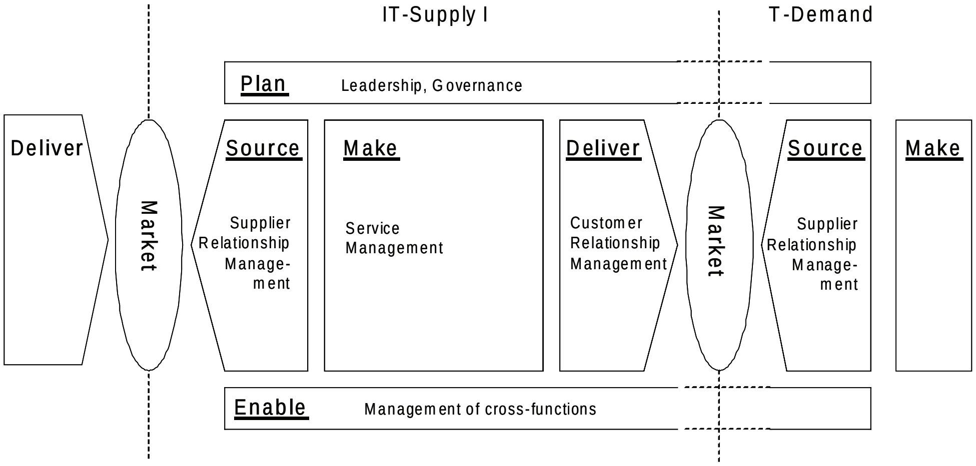
The sourcing process is the interface to the service provider and contains every task which is necessary for the procurement of IT-Products. The procured IT-Products are the basis for the "make"-process. This process describes all tasks which are necessary for the operation and maintenance of IT-solutions (Zarnekow & Brenner, 2004). The process is also responsible for managing the service portfolio, the development and the operation in the organization. The delivery process focuses on the customer relationship management. In this case, customers are all internal and/or external recipients of the IT-Services from the IT-Department. The delivery process comprises on the delivery of the IT-Services to support customers' business processes or other processes.

These concepts give a first impression that the benefits which accompany IT-Service in an organization will change during the different life cycle phases. For this reason it is necessary to have suitable and integrated management tools over the whole life cycle. Actually most of the life cycle concepts for IT issues are concentrate on the life cycle of software development projects (Zarnekow & Brenner, 2004). But the concept of Zarnekow and Brenner does not regard the entire life cycle. In this approach the life cycle ends with the operation phase and does not consider the replacement phase. The enhancement of the whole IT-Service life cycle is a real challenge for the IT-Management in organizations.

IT-Service Life Cycle Model

For the IT-Services there are different approaches which describe the life cycle of IT-Services in an

Figure 3. Integrated IT-Management model (Source: Zarnekow & Brenner, 2004)



organization. Praeg and Schnabel introduce an IT-Service life cycle model which describes five phases for the IT-Service management (Praeg & Schnabel, 2006). This model describes a complete service life cycle which considers the phases from the procurement until the replacement of the IT-Services. Other concepts do not consider this holistic view of an IT-Service life cycle. Contrary to the market perspective of a product life cycle this approach describes the IT-Service life cycle from an intraorganizational perspective.

As illustrated in Figure 4 this IT-Service life cycle model can be separated into five phases. The first phase, requirement engineering, considers all aspects which are necessary for the definition of requirements for IT-Services. In this phase it is necessary to know about the customer demands and consider the internal organizational structure, i.e. business processes as well as the existing IT-Infrastructure within the organization. As a result, during this phase the organization is able to document a description of the concrete service demands as well as a specification. With regard to the quality requirements in this phase it is necessary to ensure that the customer demands and expectations concerning the services are analyzed as detailed as possible. This is the foundation for the sourcing of IT-services from internal or external service providers.

The next step in the IT-Service life cycle covers the sourcing and procurement phase. After defining the service and customer requirements, potential service providers are identified and requested to submit an offer. Practical experience shows that the offers from different service providers differ in structure, wording, and complexity. Therefore, it is difficult to evaluate and compare the different offers with each other. Another common problem is the lack of suitable methods especially when it comes to finding and evaluating a suitable service provider. In this situation, the quality management must provide a suitable concept to evaluate the different offers as well as the service providers by providing a proofed set of quality indicators (Praeg & Schnabel, 2006).

During the design, test and orchestration phase a detailed description of the IT-service parameters is set up, the performance indicators have to be created and the measurement procedures have to be documented. The test must consider the quality in business process support, usability aspects as well as the interfaces to other IT-Services. Furthermore, the orchestration of the available IT-Services has to be tested and validated with re-

Figure 4. IT-service life cycle

Processes	• Demand identification of stakeholders • Requirement analysis • Feasibility analysis • Concept development • Service modeling • Service concept • Resource planning • ...	• Development of Sourcing strategy • Sourcing Management • Evaluation of Service Provider • Procurement Process • Service Level Management • ...	• Service customization process • Technical feasibility management • Service orchestration • Testing • Deployment plans • Risk management • ...	• Managing relationships with service providers and stakeholders • IT-Service delivery Management • IT-Service support management • IT-Service Performance management • ...	• Replacement strategy • Change management • Risk management • ...

gard to quality and performance. In this phase, the quality management has to provide test routines and configuration tests must ensure the availability and reliability of the IT-Support of the business processes. Additionally, it should start with the implementation of adequate structures, processes and methods for quality management.

The phase operation, maintenance and support cover all concepts which are relevant for a high quality service delivery. Most of the existing IT-Service management concepts focusing on this phase (Praeg & Schnabel, 2006). In this context existing IT-Service management and IT-risk management approaches can be used to support users in managing IT-services. With regard to the quality requirement for this phase, the quality management must ensure that the IT-support of the business processes is top-performing. Additionally, a continuous improvement process has to be implemented which ensures that the requirements for IT-Service quality management are met.

The final phase of the life cycle focuses on the replacement of IT-Services. Due to changed business requirements or technical developments the replacement of IT-Services could become necessary. In this phase, the demand made on quality management is to hold up the business processes and manage the possible risks caused by the replacement.

Conclusion for the Life Cycle Concepts

The benefits of a life cycle oriented management for the IT-Service management in organizations are obvious: It enables organizations to analyze new IT-Projects as well as the evaluation of the existing IT-Landscape. During the planning phase, it supports the management decision concerning the expected benefits from new IT-Services and it fosters the development of an organization-wide IT-Service portfolio management. For existing IT-Applications and services, the life cycle concept supports the economic evaluation of the possible detachment of IT-Solutions. Today, most of this decisions are made ad-hoc with neither an economical foundation nor an institutional management process (Zarnekow & Brenner, 2004).

Recapitulatory, we can see that the different phases of the IT-Service life cycle define the requirements for the quality management. The previous chapter showed that the business value of IT-Services as well as the requirements according to quality management will change during the life cycle. Hence, adequate methods for the service management as well as the quality management are necessary for an organization.

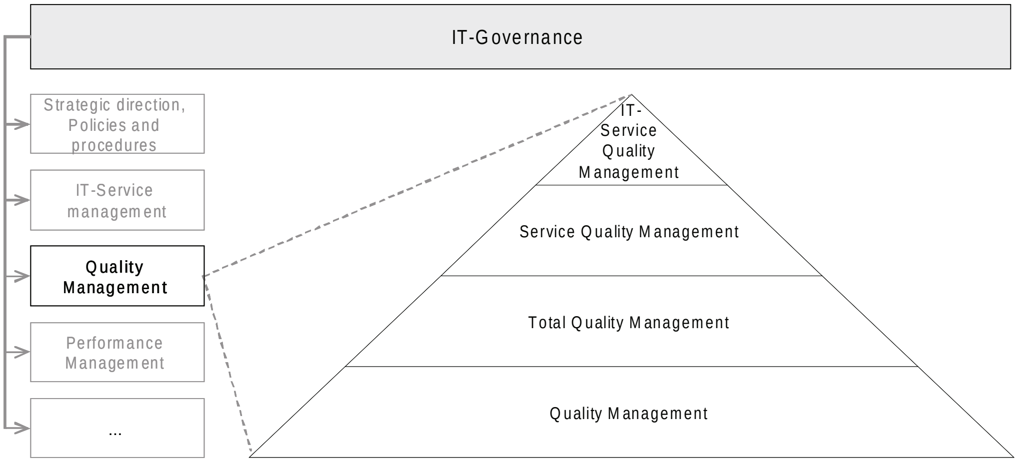
OVERVIEW OF SELECTED QUALITY MANAGEMENT CONCEPTS FOR IT-SERVICES

The quality of services is a key success factor for service providers in the market competition. Therefore it is important for the service providers to find a suitable quality management concept for managing the quality of services. Regarding the IT-Service life cycle there is no possibility for a "one-size-fits-all" quality management. An IT-Service provider has to adapt different quality management methods and match them with the different phases of the IT-Service life cycle. This chapter gives an overview about selected quality management concepts which are relevant in the context of IT-Service management. As illustrated in Figure 5, the structure of this chapter starts with a definition of quality and quality management. Based on this, quality management is introduced and selected approaches for service quality are described. The final part describes concepts and requirements for IT-Service quality management.

Quality and Quality Management

In general, the International Standard ISO 8402 defines "quality" as the total characteristic of a

Figure 5. From quality management to IT-service quality management



product or service concerning their suitability to fulfil predefined requirements (ISO 8402). Based on this definition there are two perspectives for the interpretation of the term "quality":

Firstly, quality can be described as the "degree to which a set of inherent characteristics fulfils requirements" (ISO 9000). This approach focuses on hard facts and objective criteria of products or services (product based view). Secondly, quality can be interpreted from a customers' point of view. In this case, quality is perceived by the customer conception (user-based). Contrary to the product based view, this approach focuses on the subjective perception of a service product by the customer. The customer individually evaluates the quality of a product or service with regard to his personal values. Hence, the challenge for companies is the fulfilment of a great number of heterogeneous customer demands (Bruhn, 2004).

The term "quality management" was intensively discussed in theory and in practice. Based on these discussions quality management can be described by the integration of all parts of the management which enable the internal and external analysis, planning, organization, operation and controlling of all quality relevant aspects in service offering by a service company (Bruhn, 2004). Quality management is the coordinated management task for governing an organization in terms of quality. Therefore quality management defines quality policies, quality targets, quality controlling and continuous quality improvement within an organization. To achieve these goals, quality management focuses on human resources within an organization and also considers business processes and the technological infrastructure. Based on this concept, quality of services and products is the result of a commitment from the employees to quality standards (Kamiske & Umbreit, 2001). Therefore, quality cannot only be defined and managed within an organization – first and foremost it has to be exemplified though the performance of all involved parties and employees. Besides this human aspect, quality management has to ensure that the existing processes and infrastructure enable the engineering of products and services with predefined quality levels. The management of quality also takes into account the use of different concepts and methods for achieving the quality goals in an organization. In the following paragraph selected concepts for quality management are introduced.

Total Quality Management (TQM)

The Total Quality Management approach is the foundation for an integrated quality management concept in an organization. But TQM is more than a quality management concept. Due to the high importance of quality, especially in service-oriented companies, TQM must be part of the corporate culture and strategy. It influences all management activities and leadership concepts which are used in the organization. For this reason, the conceptual basis of the TQM approach is that the management as well as the employees are responsible for the insurance and improvement of quality of products and services. Quality can not be "created" and supervised by audits. Quality must be implemented in the business processes and needs the commitment of each employee in the company (Deming, 1982). Hence, TQM focuses on all structures, processes, regulations, instructions, and measures which are relevant for ensuring and continuously improving the produced quality of products and services in all departments of an organization under participation of all employees to achieve the highest possible level of satisfaction of customer demands. The basis of this management concept is the conviction that quality is the most important key success factor for companies.

Translated into the context of service providers the TQM concept can be focused on three parts (Bruhn, 2004; Wonigeit, 1994):

- **Total:** The integration of all persons, which are involved in the service development and operation
- **Quality:** The consequent concentration on the quality demands of internal and external customers concerning all activities and processes in the service company
- **Management:** The responsibility of the management for a systematic identification with the quality culture and goals as well as continuos quality improvement.

According to the requirements of IT-Service quality management this means that customer demands, organizational structure, organizational and business processes, employee commitment as well as a quality focused corporate culture must be considered.

For the realisation of these requirements quality standards support organizations by the implementing adequate processes and structures.

The ISO 9000 Standard for Quality Management

The International Standards ISO 9000ff. define which requirements an organization have to fulfil in order to live up to a defined level of quality management. The most important standards out this collection are the ISO 9000 (describes fundamentals of quality management systems and specifies the terminology of quality management), 9001 (specifies requirements for quality management) and 9004 (provides guidelines that consider both the effectiveness and efficiency of quality management systems) (ISO 9000). The ISO 9000 standards interpret quality management as a leadership task for the continuous improvement of the organizational processes to meet customer requirements and expectation and generate customer satisfaction.

The standards promote the adoption of a process approach when developing, implementing, and improving the effectiveness of a quality management system (ISO 9001). According to the ISO 9001 "… this process orientation emphasizes the importance of:

- Understanding and meeting requirements
- The need to consider processes in terms of added value
- Obtaining results of process performance and effectiveness
- Continual improvement of process based on objective measurements."

The standard ISO 9004 suggests the implementation of quality management principles in order to lead organizations towards improved performance. According to ISO 9004 these principles are: customer focus, leadership, involvement of people, process approach, system approach to management, continual improvement, factual approach to decision making, mutually beneficial supplier relationship (ISO 9004).

Usually the ISO 9000 standards are oriented on conventional production organizations. They are focussing on distributed production processes and procedures which are typical for the production sector. Nevertheless, service organizations also recognized the advantages of a quality management system based on the ISO 9000 standards.

All the concepts and quality perspectives described above are originally developed from a traditional industrial oriented understanding of quality and quality management. Because of the focus on services in general and IT-Services in particular, it cannot focus on the customer demands but must also consider further requirements such as the competition and the general situation of the company.

Service Quality Concepts

During the last couple of years, service quality has become of great interest to researches as well as practitioners and managers. One reason is the strong impact of service quality to business performance, cost reduction, customer satisfaction, customer loyalty and profitability (Seth, Deshmukh & Vrat, 2005). Conceptual models of service quality enable organizations to identify quality problems and thus help managing a quality improvement program and support the improvement of efficiency and performance.

According to Bruhn (2004) service quality is defined “as the capability of a service provider, to provide primary intangible and customer oriented service on a predefined performance level corresponding with the customer expectations.” Based on this definition service quality represents a defined performance level of service.

For a systematic development and implementation of service quality management, certain requirements must be fulfilled. There are several criteria which help to evaluate the quality of services (Figure 7).

Figure 6. ISO 9000 process based quality management model (Source: ISO 9000)

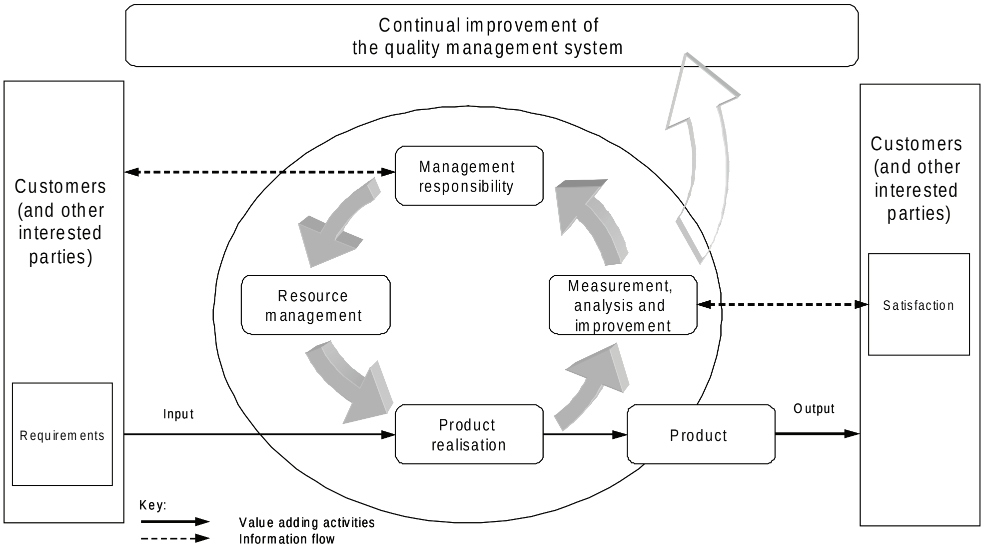


Figure 7. Service quality principles (Source: Bruhn, 2004)

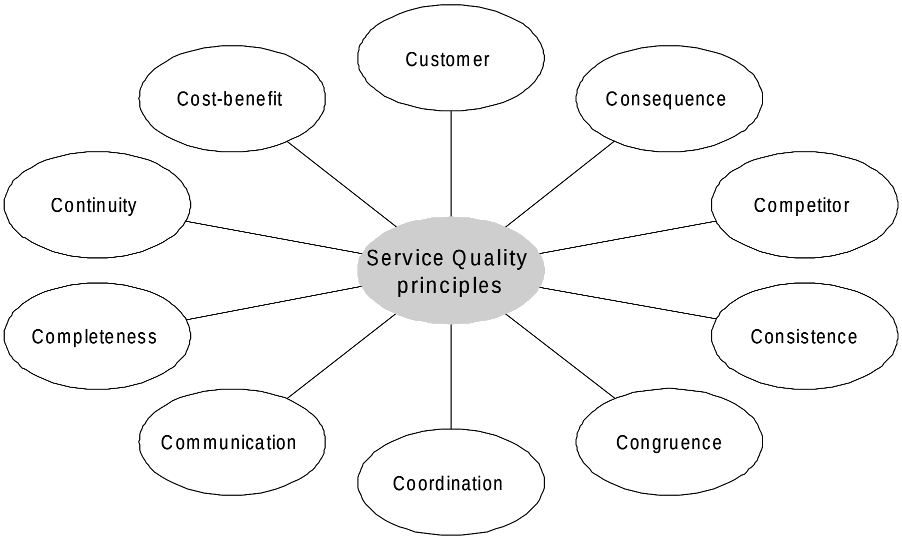


As illustrated in Figure 7, there are ten principles describing service quality management (Bruhn, 2004):

- **Customer orientation:** For successful service management the perceived quality of service by the customers is a key success factor.
- **Consequence:** Everyone within the organization has to align with the customer orientation and there is a need for awareness for quality.
- **Competitor separation:** To be successful in competition, the service provider has to separate from competitors.
- **Consistence:** It must be ensured that from a customer's point of view there are no conflicts concerning form and content during service provision.
- **Congruence:** The internal behaviour of employees has to be conform to customer communication. The congruency between internal and external service and customer orientation is an important competition factor.
- **Coordination:** Every task in the organization has to be aligned to the quality goals.
- **Communication:** The internal and external communication of the organization must be aligned with the quality requirements.
- **Completeness:** The quality management system has to take up a holistic view on quality in the organization.
- **Continuity:** The implementation of an integrated quality management needs medium and long-term experience in the use of different quality management concepts, methods and instruments.
- **Cost-benefit orientation:** The development and implementation of a quality management system must take into account the costs and benefits due to quality management. Quality management must support the performance as well as the efficiency of an organization.

These perspectives of service quality are the foundation for the development of numerous service quality concepts. There are three characteristics of services which have to be considered when managing service quality: the intangibility of services, the uno-actu principle (concurrent providing and consuming of services) and the integration of external factors (Haller, 2002).

During the last years, numerous models have been developed for managing service quality. One common goal of all these models is to operationalize service quality in order to be able to measure and manage service quality (Bruhn, 2004). An overview of selected concepts of service quality management is documented in Seth et al. (2005). Due to space restrictions, only the models of Grönroos and Parasuraman are highlighted in the following paragraphs.

The model from Grönroos defines the perceived quality as the difference between the customer expectations and their experiences according to the service (Grönroos, 1984). For an organization this means that it has to match the expected service and the perceived service to each other so that customer satisfaction will be accomplished. A high service quality is achieved if the perceived quality is higher than the expected quality level. Grönroos identified three components of service quality: technical quality, functional quality and image. The technical quality is the quality of what customers actually receives as a result of the interaction with the service provider, the importance and the evaluation of the service quality (Seth et al., 2005). Functional quality focuses on how the customer gets the technical outcome and emphasizes the subjective perception. In addition to these two dimensions the image of an organization also influences the customer perception of the service quality. The image of an organization can enforce or weaken the perception of the technical and functional quality (Bruhn, 2004).

The GAP Model of Parasuraman et al. (1985) argues that service quality is a result of the differences between expectations and performance of the service (Parasuraman, Zeithamel & Berry, 1985). In their model Parasuraman et al. describe how consumer evaluate service quality. The basis of their model is the interaction between consumers and service providers and possible gaps in this relationship. The authors identified five possible gaps (Seth et al., 2005):

- **GAP 1:** Difference between consumers' expectations and the management perceptions of those consumer expectations.
- **GAP 2:** Differences between management's perceptions of consumer's expectations and service quality specifications.
- **GAP 3:** Difference between service quality specifications and service actually delivered.
- **GAP 4:** Difference between service delivery and the communication to consumers about service delivery.
- **GAP 5:** Difference between consumer's expectation and perceived service. This gap depends on direction and size of the four gaps mentioned before, associated with the delivery of service quality on the providers' side.

The performance expectations and the performance level are defined from a customer's point of view. Service quality has a strong focus on the customer demands and the customer perception of quality. For service providers this means that they have to match requirement according to expected services and perceived services to achieve customer satisfaction (Seth et al., 2005). For the measurement of the service quality a combination between the product-based view and the user-based view is helpful.

As a result of their exploratory research Parasuraman et al. identified ten quality dimensions which are relevant for the evaluation of the perceived service quality from customers' point of view. Based on this results they refined the SERVQUAL model for measuring customers' perception of service quality (Parasuraman, Zeithamel, & Berry, 1988; Seth et al., 2005). The SERVQUAL approach covers five dimensions which are used to measure service quality: reliability, responsiveness, tangibles, assurance and empathy.

Based on the developments in the IT-Service area which are described in the previous chapters, the IT-Service management has to adapt to the demands of IT-Services. In the past there are no international agreed standards which are focusing on the quality management of IT-Services. With the implementation of the International Standard 20000 this situation has changed.

The ISO 20000 Standard for IT-Service Quality Management

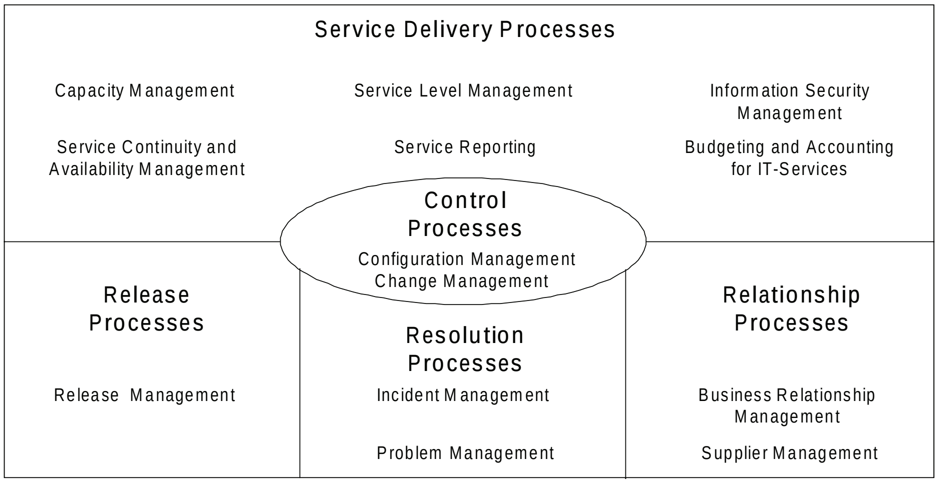
The ISO 20000 Standard suite provides a basis for a measurable quality standard for IT-Service management. It is the further development of the former British Standard (BS) 15000. Therefore the original orientation of the ISO 20000 standard was derived from the BS 15000. On the basis of the ISO 20000 standard organizations can be audited and certified to proof the compliance with this international standard. Furthermore the ISO 20000 fosters the implementation of an integrated process approach for the IT-Service management within an organization. The standard covers all aspects which are relevant to implement an optimal service management. Hereby the standard especially focuses on the service providers perspectives. ISO 20000 consists of two parts. The first part promotes the adoption of an integrated process approach to effectively deliver managed services to meet the business and customer requirements (ISO 20000). The second part is a code of practice and describes the best practices for service management within the scope of the first part.

The goal of the standard focuses on the provision of a common reference standard for all organizations which provides services to internal and/or external customers. Due to the great importance of the communication between service provider and service recipients one of the main targets of the standard is the definition of a common glossary for the service providers and their customers.

To ensure the provision of a defined quality of the IT-Services the ISO 20000 Standard specifies and describes the necessary processes which an organization has to implement to provide quality proofed IT-Services. For that reason the ISO 20000 Standard describes a set of management processes ("Objectives and Controls") which are oriented on the ITIL-processes and expand this process model (see Figure 8).

The ISO 20000 enables organizations to implement standardized processes for IT-Service management and supports the improvement of the IT-Service quality management.

Figure 8. Structure of the ISO 20000 model for IT-service management (Source: ISO 20000)



Conclusions for Quality Management Concepts

This chapter showed the basic concepts of quality management and service quality management. It was shown that the implementation of a quality management system in an organization is complex and is a strategically issue. Furthermore the overview showed that there are numerous quality management methods which can be used for organizational quality management. As a finding of the description of the different quality management methods it can be shown that from a management perspective quality management has to support the organizational goals in case of value, quality and reliability. At a high level primary management goals can be a high level of customer satisfaction, the organizational and business process performance, aligned IT-Services and –products, contracting the right IT-providers and achieve employee satisfaction. Based on these management goals, factors for quality management can be derived to manage the achievement of these goals. In this case quality management has to consider the following factors: customer demands, organizational structures and processes, IT-Services, service provider performance and employees. A challenge for organizations is to find the most relevant and suitable methods according to the life cycle phase. This mapping between quality management methods and the IT-Service life cycle phases is described in the following chapter.

MODEL FOR A LIFE CYCLE BASED IT-SERVICE QUALITY MANAGEMENT

The previous chapters illustrate basic concepts for IT-Service quality management and give an overview about life cycle concepts for IT-Service management. For the model which will be described in the following paragraphs the life cycle model from Praeg & Schnabel (2006) is the basis, because it is the only approach which describes a complete life cycle for IT-Services. With regard to the industrial sector it is common to use different quality management concepts on different parts of the organizational added value chain (Malorny & Kassebohm, 1994).

Due to the great number of quality methods and instruments and the limited space of this book we can only show the principle and make a suggestion about possible criteria for the matching between the life cycle phases and the quality management methods. The organizational implementation of this approach must regard the individual situation and competencies of the organization.

The mapping process between the IT-Service life cycle phases and the quality management methods is described in two steps. The first step covers the mapping between quality factors, derived from the methods in the previous chapter and the different life cycle phases. The reason is that each phase set different focuses for quality management. On this basis the second step in the mapping process is focussing on the association between quality management methods and the different life cycle phases. Each quality management method concentrates on the support and the fulfilment of one or more quality factors. Therefore for each life cycle phase different quality management methods can be used to support the quality factors. As illustrated in the following paragraphs there is no strict one-to-one mapping between a life cycle phase and a quality management method. Due to the different situations and competencies in organizations a regit one-to-one mapping makes no sense. The intention here is to sensitize organizations and IT-Managers to think about using suitable quality methods in dependence of the situation according to the expected goals of the IT-Service management instead of focusing on one quality management method for IT-Service management. In the following paragraphs the process of mapping is illustrated.

Mapping of Quality Factors

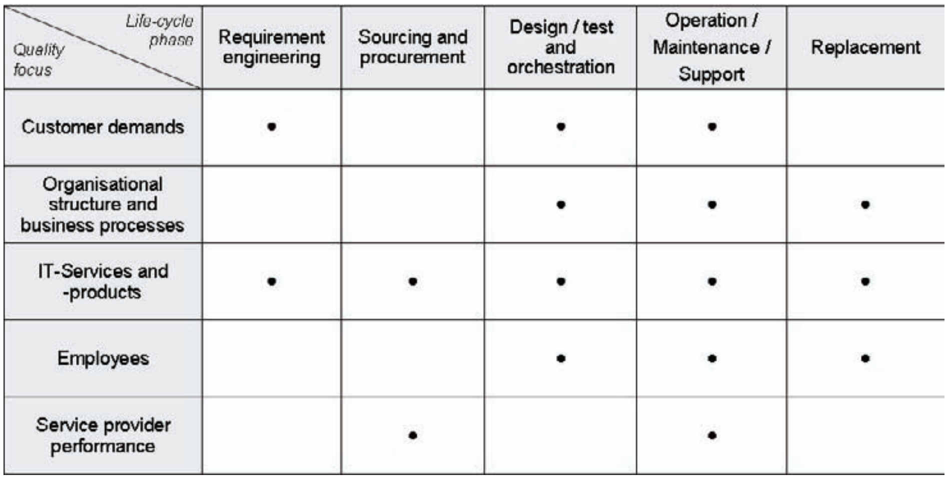
To match different quality management methods with IT-Service life cycle phases the life cycle approach described here suggests a two-step procedure. In the first step organizations have to think about the quality factors which are aligned with the strategic goals. The quality factors are the targets for organizational management. These are the outcomes from the use of quality management methods. The quality management methods are focusing on input variables which have an influence on the later outcome. Therefore it is necessary to implement an PDCA cycle (plan-do-check-act) (Deming, 1982) to measure how the different input variables influences the outcome in case of quality and in case of the achievement of the quality factors. Based on the results of Chapter 4 the following factors for managing quality within organizations and according to IT-Service are relevant for the life cycle based quality management approach:

- Customer demands,
- Organizational structure and business processes,
- Product and services,
- Employees
- Performance of service provider

As previously described the relevance of these quality factors depends on the life cycle phase and will change from one phase to another. For example in the development phase of the services, the consideration of the customer demands is more important than the focus on service providers because the goal of this phase is the documentation on the requirements for the service based on customer requirements and demands. Therefore a quality management method which focuses on considering customer requirements is better matched with the goals of this phase than a method which focuses on organizational structures or business processes. Based on this fact Table 1 show the relation and relevance of the quality factors for each life cycle phase of the IT-Services.

The markers highlight the quality factors with the highest priority in each life cycle phase. By example in the sourcing phase quality aspects regarding to the IT-Services and IT-Service providers (internal and/or) external have a higher priority in this phase than aspects according to customer demands. Due to this evaluation Table

Table 1. Life cycle phases and quality factors



Life-cycle phase Quality focus	Requirement engineering	Sourcing and procurement	Design / test and orchestration	Operation / Maintenance / Support	Replacement
Customer demands	●		●	●	
Organisational structure and business processes			●	●	●
IT-Services and -products	●	●	●	●	●
Employees			●	●	●
Service provider performance		●		●	

1 highlights the focal points according to quality issues in each life cycle phase.

Mapping of Quality Management Methods

In the second step of the life cycle based quality management procedure, selected quality management methods are mapped with the life cycle phases based on the focus of the quality criteria. Due to the scope of the quality management methods it does not make sense to restrict one quality method exactly to one life cycle phase. Based on the connections between different phases the use of the quality methods may vary.

As shown in Figure 9 the quality concepts described in the previous chapter do not depend on a life cycle phase. They are defining the framework for the quality management. The quality management methods are mapped with the life cycle phases of IT-Services.

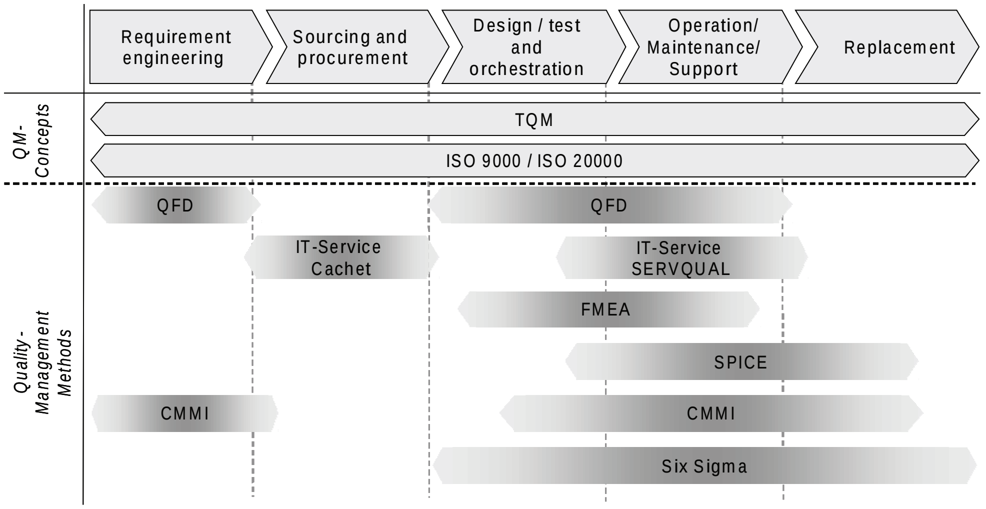
As illustrated in Figure 9 it is necessary to map one or more adequate quality management methods to the different life cycle phases. The quality factors help to select the suitable methods due to prioritize the importance of the items.

Quality Management Methods for the Life Cycle Phase 1

From a quality management point of view it is necessary to focus on the customer demands in the first phase of the IT-Service life cycle. As seen in Chapter 0 quality of service is defined by the customer requirements. Therefore it is required to find an adequate quality management method which focuses on the customer demands and requirements. But on the other hand the other quality items must also be considered in this phase but with a minor priority. As a result in this phase a quality management method is needed, which focuses on customer requirements and also consider business processes, products and services with a minor priority.

In this case the Quality Function Deployment (QFD) is a suitable method. Quality Function Deployment is a method which focuses on the planning phase of quality management. QFD supports the transformation of customer needs into engineering characteristics (and appropriate test methods) of a product or service, prioritizing each product/service characteristic while simultaneously setting development targets for product

Figure 9. Life cycle phases and quality management methods



or service development. QFD can strongly help an organization focus on the critical characteristics of a new or existing product or service from the separate viewpoints of the customer market segments, company, or technology-development needs.

The QFD method covers a six-step process. The first step focuses on the identification of relevant customer groups. In a second step the customer demands and requirements are documented and evaluated. The third step focuses on the derivation of necessary performance and quality indicators, followed by the definition of target values for each goal in the fourth step. In step five possible negative or positive correlations between the different performance and quality indicators must be analyzed. The final step focuses on internal or external customers evaluates the provided services and compares them with the services from competitors. The results of this process are documented in a so called “House of Quality” (Bruhn, 2004). The results of the technique yield transparent and visible graphs and matrices that can be reused for future product/service developments.

Quality Management Methods for the Life Cycle Phase 2

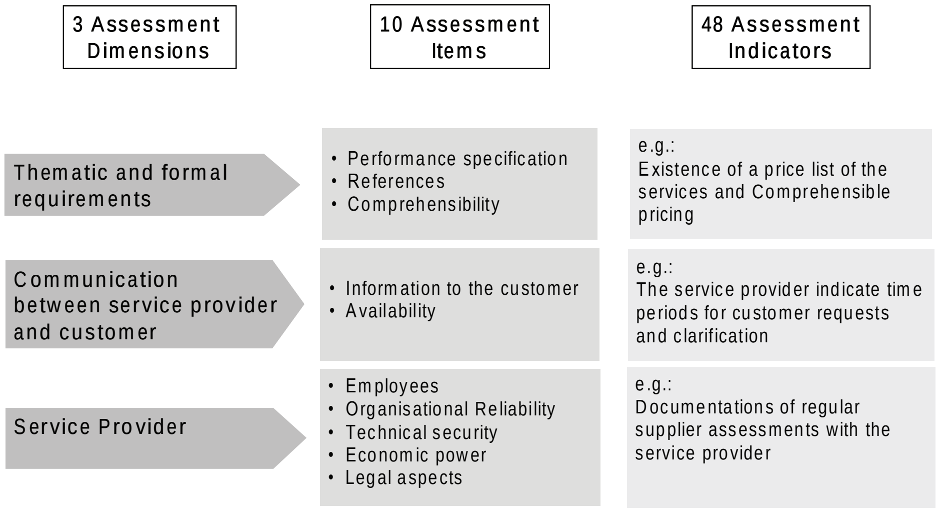
In the following phase the priority will change. After defining the requirements for the services there is a need to find a suitable IT-Service provider. Due to the developments described in Chapter 0, an internal or external IT-Service provider must be found for delivering the IT-Services. From the quality management point of view, it is required to evaluate the IT-Service provider prior signing the provider contract. In this phase a suitable quality management method must focus on the evaluation of the quality of an IT-Service provider and should also consider aspects of business processes and the delivered services. In this case organizations could use the IT-Service Cachet (Praeg & Schnabel, 2006).

The IT-Service cachet is developed by a consortium of IT Service Management Forum (itSMF, Chapter Germany) together with well-known IT-Service providers and the participation of the Fraunhofer Institute for Industrial Engineering and other research institutions. The Cachet supports organizations in evaluating IT-Service provider from a customer point of view. The cachet is developed to audit service providers concerning the quality of their offers and IT-Services from a customers’ point of view in the IT-Service procurement process (Praeg & Schnabel, 2006). To define a quality management approach for service some characteristics of service have to be considered. It must be taken into account that services are intangible and their quality is only measured with difficulties. The second aspect refers to the uncertainty in the procurement process, which exists from the customer point of view to minimize the possible consequences of an erroneous decision as far as possible. Even after completion of a contract it must be possible to evaluate the current efficiency of the service provider in a fast and simply way according to the quality management with suitable features. The decision process from the user site would be simplified and the decision maker will be supported according to the quality of his decision through a proved and guaranteed minimum level of service quality. Therefore, the customer of the IT services can easily check the price-performance payoff and is able to evaluate whether it is a good offer or it is just “cheap.”

The primary target groups of the cachet are service providers, which should be audited by means of the IT-Service cachet. However, the cachet is also helpful for the service recipients evaluating the service offers from the providers.

The evaluation catalog for the IT-Service cachet contains 48 assessment criteria to evaluate the quality of the IT-Service offers. The cachet measures the different quality dimensions with the level of fulfilment of quality indicators. These

Figure 10. Structure of the IT-Service Cachet



indicators for the service offers can be separated into ten dimensions.

The first part describes the "thematic and formal requirements of the offers," the second part focuses on the "Communication between service provider and Customer" and the third part concentrates on the characteristics of the "Service Provider." For each part several assessment items are developed which are measured due to assessment indicators. For each assessment indicator, there is a detailed description on how to measure, document and evaluate the criteria and there are defined levels of fulfilment (Praeg & Schnabel, 2006).

Quality Management Methods for the Life Cycle Phase 3

The third phase of the defined IT-Service life cycle describes the development, orchestration and testing of the IT-Services. Hence the quality items organizational structure and business processes as well as the services have a high priority in this phase. Therefore adequate quality management methods must regard these aspects. In the area of the software development there are some quality management methods which can be used for this phase. But it has to be mentioned that these methods have to customize to the requirements of IT-Service management.

In this phase suitable quality management methods are the Failure Mode and Effects Analysis (FMEA), Capability Maturity Model, software process improvement capability determination (SPICE) and the ISO 15504.

From a service provider's point of view the avoidance of failures is a central aspect for the quality management. Especially due to the concurrent providing and consumption of services an improvement of the delivered service is not possible. For this reason the Failure Mode and Effects Analysis (FMEA) is a method, which enables organization previously analyzes and evaluates potential problems and risks before they are realized. Therefore the FMEA method provides a risk assessment technique for systematically identifying potential failures in a system or a process. Failure modes mean the way, or modes, in which something might fail. Failures are any errors or defects, especially ones that affect the customer, and can be potential or actual. Effects analysis refers to studying the consequences of those failures. Comparable to the production area, there are three types of FMEA for services (Bruhn, 2004):

- System FMEA, which focuses on the organization as whole or different departments,
- Subsystem-FMEA, which focuses on service components and their interaction and
- Process FMEA, which focuses on the business and service processes.

The process of the FMEA covers the steps of failure description, risk assessment, generating suitable measures and the evaluation of the achieved results. The FMEA method supports organizations in controlling and managing the quality of IT-Services during various phases of the product life cycle.

The Capability Maturity Model Integration (CMMI) is a process improvement approach that provides organizations with the essential elements of effective processes. For the quality management CMMI can be used to improve the management maturity as well as the quality of services. According to a five level scale the processes of service providing can be systematically analyzed and the management quality improved. Originally CMMI was developed by the Software Engineering Institute from Carnegie Mellon University in 1987. This method is focused on the structured and systematically improvement of software engineering processes. During the past years CMMI was adapted to several other business areas. The CMMI model describes five levels of process maturity. On the first level (initial) there are processes defined. On the second level (repeatable) several tasks for a process management are implemented and processes can be managed with repeatable levels of performance. In the third level (defined) processes are defined and documented within the organization. The level four (managed) focuses on the quality and performance measurement of the existing processes. Level five (optimized) demands for the implementation of continuous improvement programs in the organization for optimizing quality and performance of processes.

The software process improvement capability determination (SPICE) method was originally developed for managing the software development processes. The SPICE approach is also a maturity management method which supports the quality and performance of implemented services in an organization. The SPICE method is a two dimensional approach for managing development processes. The first dimension consists of the processes that are actually assessed (the process dimension which is grouped into five categories). The second dimension consists of the capability scale that is used to evaluate the process capability (the capability dimension). The same capability scale is used across all processes (El Emam & Birk, 2000). The ISO/IEC 15504 is an international standard on software process assessment. It defines a number of software engineering processes, and a scale for measuring their capability. In ISO/IEC 15504, there are 5 levels of capability that can be rated, from Level 1 to Level 5. The rating scheme consists of a 4-point achievement scale for each attribute. The four points are designated as F, L, P, N for Fully Achieved, Largely Achieved, Partially Achieved, and Not Achieved (El Emam & Birk, 2000).

Quality Management Methods for the Life Cycle Phase 4

In the fourth phase of the life cycle the operation, maintenance and the support of the used IT-Services must be managed in the organization. Most of the established IT-Service management concepts are focussing on this phase of the life cycle (Praeg & Schnabel, 2006). From the quality management point of view it is necessary to focus on the business processes and the organizational structure which is responsible for the Service providing. Additional to this the quality of the service provider is also from high interest as well as the service itself. Therefore suitable quality management methods must consider these aspects in a proper way.

In this phase possible quality management methods are Six Sigma and IT-Service SERVQUAL.

Six Sigma is a quality management concept which focuses on the improvement of business processes in organization. It is a statistically based quality improvement program which should organization help to improve business processes by reducing costs resulting from poor quality (Hensley & Dobie, 2005). It should also support improving the levels of efficiency and effectiveness in processes (Hensley & Dobie, 2005). These processes improvement should result in an improved customer satisfaction with the firm's products and services and an increased firm's profitability (Antony & Banuelas, 2001).

The most common used tool in the six-sigma concept is the DMAIC cycle (define, measure, analyze, improve, control).

- During the definition part the processes for improvement are identified and the identified problems as well as the targeted goals are documented.
- In the measurement part the focus is on the measurement of the current process and collect relevant data for benchmarking and also determination how good the process meets the customer expectations is made.
- The analyze-part concentrates on the verification of relationships and causality of the quality factors. It determines what the relationship is and attempts to ensure that all factors have been considered.
- The improvement part optimizes and improves the process based upon the analysis using techniques like Design of Experiments.
- The part control ensures that any variances are corrected before they result in defects. Set up pilot runs to establish process capability, transition to production and thereafter continuously measure the process and institute control mechanisms.

Six Sigma was originally used in manufacturing environments but there are also transformations to the service sector. Especially financial service companies started to use Six Sigma to improve the customer satisfaction (Hensley & Dobie, 2005).

The traditional SERVQUAL is an instrument for analysing functional performance of service units. It is an instrument for assessing customer perceptions of service quality (Hochstein, 2004; Parasuraman et al., 1985). Characteristic for the SERVQUAL approach is that the different quality dimensions are measured with indicators. Quality is defined as the gap between the real value and a target-value. SERVQUAL is a multi-attributive measurement procedure, which uses five dimensions to define service performance quality. Parasuraman et al. (1985) developed this multiple-item approach consisting of five quality dimensions:

"Tangibles" describe the convenience of the material environment in which the service is rendered. Facilities, premises, technical equipment, phenotype of the staff etc., are part of it. "Reliability" is the trustworthiness of the supplier that indicates the ability to deliver the promised performance reliably and exactly. "Responsiveness" concerns the availability of the support, that the customer at the demands of the service (open-mindedness). "Assurance" refers to the safety of the performance claims on credibility of the supplier according to of competence, politeness and trustworthiness. "Empathy" concerns the ability of the service provider to cater to individual customer needs and the readiness to satisfy them (Hochstein, 2004; Parasuraman et al., 1985).

Therefore, the service performance quality arises from the difference between customer expectations and the customer perception. According to Donabedian, the five dimensions used in the SERVQUAL approach can be assigned to the dimensions of the process-, potential- and outcome- quality (Donabedian, 1980). While "Reliability" can be corresponded with the result quality and assigned to "Tangibles" and "Assurance" of the potential quality, analogies exist between "Responsiveness" and "Empathy" to the process quality (Praeg & Schnabel, 2006).

According to the special requirements Hochstein customized the SERVQUAL approach with regard to IT-Service management (Hochstein, 2004). In this approach IT-SERVQUAL is proposed due to adjusting elements for the traditional concepts and institutionalized to a service specific approach.

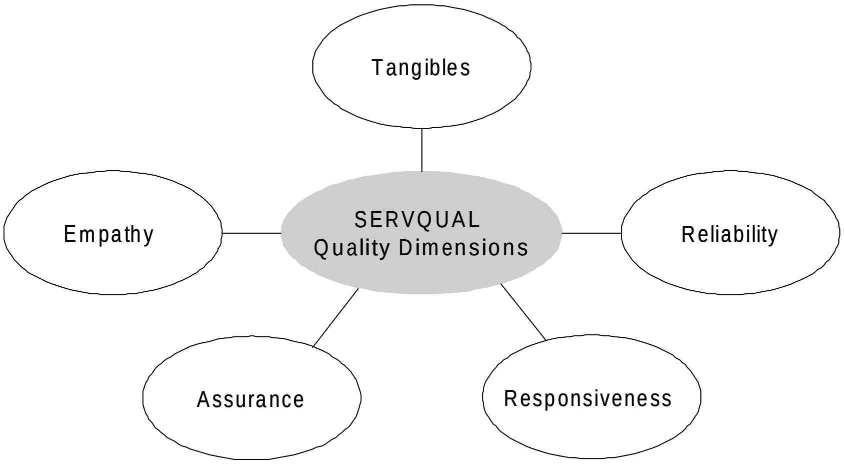
Quality Management Methods for the Life Cycle Phase 5

The final phase of the life cycle describes the detachment of the IT-Services which are no longer used in the organization. Most of the life cycle management concepts do not mention this phase but it is important to manage the detachment of IT-Services. Due to the connections and interfaces between different Services or due to a new release of an implemented serviced there is a need for the detachment of "old IT-Services" and it is also a great challenge for the organization to ensure the operation of the business processes. Therefore the suitable quality management methods have to consider aspects of change and risk management as well as the operational business process in the organization. In this phase the quality management methods previously described can also be used in this phase.

Conclusion for Life Cycle Based IT-Service Quality Management

This chapter shows the changing relevance of different quality aspects during the IT-Service life cycle phases. As a result organizations should use different quality management methods regarding to their individual situation. The described framework gives an example how organizations can map quality management methods with the changing requirements of the different life cycle phases to establish an effective and efficient IT-Service Quality Management. A great challenge from customer and providers point of view is the evaluation in which life cycle phase the different IT-Services are used. A further challenge will also be the organizational implementation of an adequate set of suitable quality management methods and instruments in the organization. Therefore the skills and capabilities for the selected quality management methods must be developed and systematically managed. It is obvious that the implementation of this model is a strategic decision

Figure 11. SERVQUAL dimensions



in the organization and it needs time to realize and establish this concept in the organizational management processes.

CONCLUSION AND OUTLOOK

This chapter showed that IT-Service quality management is an important issue for implementing and managing IT-Governance. Due to the dynamic developments in IT-Service management and the increasing focus on IT-Services, market orientation and use of external service providers as well as the quality management of services becomes more important for organizations. But not only on the customer side, there is a growing importance for this issue. The management of IT-Service quality becomes also a key success factor for internal and external service providers. In future, the satisfaction of changing customer demands will be a great challenge for them.

As a result of the industrialisation of IT in organizations, the services of IT-Providers will be more and more separated into individual IT-products which have several life cycle phases. Hence, the IT-Service quality management must consider the requirements of the different life cycle phases. The use of quality management methods have to be adapted to the demands of the life cycle phase and the business requirements.

This chapter illustrated a general life cycle concept of IT-Services and highlighted requirements according to the quality management and quality methods. Based upon this approach, a model for a life cycle based IT-Service quality management was developed. According to the traditional use case, the industry sector, the use of existing quality management methods must align with the requirements of the different life cycle phases. In the context of IT-Service quality management this perspective has not been adopted yet. In the past, there were a lot of discussions concerning the translation of approaches for service quality into the special demands of IT-Services, but the dynamics of IT-Service management were not considered.

For future developments there is a strong demand for the transformation of experiences from industrial quality management to IT-Service management. With regard to the production industry, the implementation of quality gates helps to ensure the quality from external providers. For IT-Services this concept must customized to the special demands of the organization and the services.

Due to the increased meaning of IT-Services and the importance of service quality as a key success factor, this topic has great potential and offers ample possibilities for future research. As seen in this chapter, quality management is a Top-Management issue for organizations. Consequently, there is a need for implementing suitable quality management concepts and research has to provide adequate evaluation concepts for improving quality management in dependence of the individual life cycle. Furthermore, there is a need for the organization implementation of the life cycle based IT-Service quality management. Especially the training of employees and the development of a quality focused culture within the organization represent great challenges for the management. A further challenge is the implementation and adaptation of existing infrastructures in an organization to manage the requirements which are tied to increased service orientation. An additional challenge is to establish trust between the service provider and the service recipient. Such confidence between the parties supports service perception and as a result service quality management.

Quality management is a continuous process, which will never stops and creates potential for future competitive advantages of service providers. Thus, the perspectives of IT-Managers and the focus of IT-Governance should expand to life cycle aspects of IT-Service quality management, because the quality of IT-Services is the key success factor for creating competitive advantages in the IT-Service market.

INTRODUCTION

Due to the evolution of globalization (Benavent, Ros, & Moreno-Luzon, 2005), modern companies have been striving to compete with their competitors who are operating from different parts of the world. One of the methods adopted by them for attaining this objective is the installation of quality systems by implementing ISO 9001:2000 standard (Williams, 2004). Since the introduction of this standard among the international community (Chin, Kim, & Kim, 2004), the companies implementing it enjoy reputation in the global market. It is a common practice on the part of the major companies to insist on the supplier companies to install ISO 9001:2000 compatible quality systems. Because of this trend, more than 4,00,000 numbers of modern companies of different sizes and nature have installed ISO 9000 based quality systems (Gingele, Childe, & Miles, 2002). While this is an appreciable trend, it is to be noted that mere implementation of the ISO

9001:2000 standard does not enable the companies to acquire core competence. Hence, despite their effectiveness, suitable leveraging mechanisms are yet to be incorporated with ISO 9001:2000 compatible quality systems (Gotzamani & Tsiotras, 2001; Williams, 2004). One of the additional leverages to be included is the information system component (Tan, Lin, & Hung, 2003). Hence, it is high time that information system elements were incorporated with ISO 9001:2000 based quality systems. Presumably on realizing the information requirements, ISO 9001:2000 is incorporated with more information elements (Lari, 2002) than its previous version ISO 9001:1994 (Devadasan, Kathiravan, Sakthivel, Kulandaivelu, & Sundararaj, 2003). However, careful studies revealed that those information elements are not sufficient to install and manage quality information system (QIS) compatible to ISO 9001:2000. Considering this requirement, the research project reported in this paper has been carried out. The scope of this module of work was limited to the design and development of information system pertaining to Clause 4 of ISO 9001:2000 quality system. This information system is titled as quality management information system (QMIS). Subsequently, a validation study was carried out in a high technology-oriented job shop company to assess the penetration of QMIS. After noting the existing gap, the QMIS was developed in this company. The details of this work are presented in this paper.

MANAGEMENT INFORMATION SYSTEMS AND QUALITY INFORMATION SYSTEMS

Management professionals have been using information systems for more than five decades. Particularly, managers started to use computer-based information systems which today are known as management information systems (MIS). Since then, the scope of MIS (O'Brien, 2003; Oz, 2002) has been increasing and widening (Laudon & Laudon, 2002). In coincidence to MIS development, the world has been attempting to achieve continuous quality improvement in organizations. Yet, there has been no concrete effort by management professionals toward integrating continuous quality improvement projects with information systems (Forza, 1995). In fact, no major discussions have taken place in managerial conferences and seminars about extending support to enhance the effectiveness of continuous quality improvement projects through the application of MIS concepts (Peppard, 1995). At this juncture, it should be noted that a large number of companies have been benefitted by implementing total quality management (TQM) (Pearson, McCahon, & Hightower, 1995) and enterprise resource planning (ERP) systems (Themistocleous, Irani, & O'Keefe, 2001). ERP projects are incorporated with MIS elements (Subramanian & Hoffer, 2005). Presumably, due to lack of proper guidance, not many companies have invested on developing information systems for enhancing the efficiency of TQM projects. Some experts and researchers in the TQM field have advocated the need of developing information systems to support continuous quality improvement projects. The most noticeable is the contribution of Juran and Gryna (1995) who coined the term "quality information system (QIS)" (p.548). After they advocated the use of QIS, some researchers worked in the direction of developing QIS during the 1980s (Forza, 1995). After which time, the importance of QIS was not much felt by both theoreticians and practitioners (Pearson et al., 1995). This is probably due to the reason that from the late 1980s, companies began to view ISO 9000 series as an essential ingredient for implementing TQM (Ho, 1999; Martinez-Lorente & Martinez-Costa, 2004). Hence, it is projected that the efforts directed toward bridging MIS and TQM principles would be yielding solutions for enhancing the performance quality of companies (Pearson et al., 1995).

The fundamental tenets of MIS envisage the processing of data to evolve useful information to the target users (Adeoti-Adekeye, 1997), whereas the research in QIS has addressed its development features in a different way. The difference in approaches will make it difficult or impossible to integrate MIS principles with TQM projects. Hence, QIS should be developed in accordance with the stipulations of MIS principles. Meanwhile, it is prudent to note that the TQM field has grown to a very large extent to encompass a number of new models, techniques, tools, and approaches (Tari, 2005). If the scope of QIS includes all of the earlier mentioned components of TQM, then managing it will become a cumbersome task. Hence, QIS should be coupled with only the vital elements of TQM. However, such elements of QIS should not discord the other elements. Particularly, such elements should facilitate in integrating the resources of the organizations for the purpose of attaining continuous quality improvement. In this regard, the discussion in literature (Vouzas & Gotzamani, 2005) on the contribution of ISO 9000 series quality systems standards based models in organizations is to be recognized. Moreover, during the recent times, the credibility of ISO 9001:2000 quality system standard is being appraised. Hence, it will be an effective work if QIS is developed by integrating with ISO 9001:2000 quality system based model. Hence, if a QIS compatible with an ISO 9001:2000 standard is implemented in a company, it will leverage the performance of the ISO 9001:2000 standard and offer very powerful solutions towards achieving continuous quality improvement.

DESCRIPTION OF CLAUSE 4 OF ISO 9001:2000

ISO 9001:2000 encompasses eight major clauses (BIS, 2000). Out of these, the first three are primitive and required only for referral and clarifying purposes. While installing ISO 9001:2000 based quality system, Clauses 4 to 8 are required to be adopted. Out of these, Clause 4, which is titled as "Quality management system" (BIS, 2000, p.2), is the foundation of all of the other clauses of ISO 9001:2000. This clause is considered foundational because it stipulates all of the instruments, which are required to build the quality management system (QMS). These instruments are: quality manual, procedures, quality policy, and quality objectives. Furthermore, this clause specifies the most important activity of managing ISO 9001:2000 based quality system, namely documentation.

Clause 4 of ISO 9001:2000 consists of two sub-clauses. The first sub-clause is given a code number 4.1 and titled as "General requirements" (BIS, 2000, p.2). As the title implies, this sub-clause stipulates the requirements that the organization shall adhere to manage the quality system and continually improve it. This sub-clause also specifies the processes, which shall have to be managed according to the stipulations of ISO 9001:2000 standard. This particular sub-clause is very specific in stipulating the general requirement of achieving continual improvement of QMS. The second sub-clause is given a code name 4.2 and titled as "Documentation requirements" (BIS, 2000, p.2). This sub-clause further consists of four sub-clauses. As the title implies, this sub-clause deals with documents that are required to be developed for building the QMS. Further, this sub-clause specifies the requirements for controlling the records. The filled-in documents are called records and Clause 4.2 specifies the requirements for controlling them. A distinct difference of Sub-Clause 4.2 from 4.1 is the absence of specific stipulation on continual improvement of QMS. But the stipulations of Sub-Clause 4.2 are vital for effecting continual improvement of QMS.

Organizations installing ISO 9001:2000 based quality systems without fulfilling either partially or fully the requirements of QMS specified by Clause 4 of ISO 9001:2000 are prone to fail in achieving continual quality improvement in spite of their adherence to the remaining clauses of ISO 9001:2000. This aspect is depicted in the figure given in ISO 9001:2000, which is titled as "Model of a process based quality management system" (BIS, 2000, pp. iii). The slightly modified version of this model is shown in Figure 1. This figure stipulates that the Clauses 5-8 in sequence act to achieve continual improvement of the QMS. This implies that any leveraging action that is intended to be applied through ISO 9001:2000 must have to begin from Clause 4. Accordingly, in the module of the research project being reported in this paper, the leveraging action through information system management has been applied through Clause 4 of ISO 9001:2000. In order to carry out this leveraging action, Clause 4 was searched to locate any stipulation about the information system management. Though there is no mentioning about MIS in Clause 4, the listing d) given under Sub-Clause 4.1 specifies the need of the availability of information necessary to support the operation and monitoring of the processes included in QMS. This kind of monitoring information is inadequate to develop leveraging action and hence an exclusive design of QIS by referring to Clause 4 is vitiated.

QUALITY MANAGEMENT INFORMATION SYSTEM

In order to design QMIS, the traditional MIS principles were referred. This is due to the reason that traditional MIS principles have been found to offer powerful information system management solutions in organizations of all types. The fundamental tenet of MIS is that the collected data shall be processed using appropriate models to provide information to the target users (Laudon & Laudon, 2002; O'Brien, 2003; Stair & Reynolds, 2001). This methodology is depicted in Figure 2.

The principles depicted in this figure have been used to design QMIS. For this purpose, each sub-clause of Clause 4 of ISO 9001:2000 was studied, and corresponding to four information system elements, namely Data, Database, Processing Methodology and Models and Information, have been designed. As a sample, the design of information system elements designed pertaining to Sub-Clause 4.1 of ISO 9001:2000 is described in this section.

Sub-Clause 4.1 General Requirements

The contents of Sub-Clause 4.1 of ISO 9001:2000 (BIS, 2000, p.2) are reproduced below: "The organization shall establish, document, implement

Figure 1. Continual quality improvement journey through ISO 9001:2000

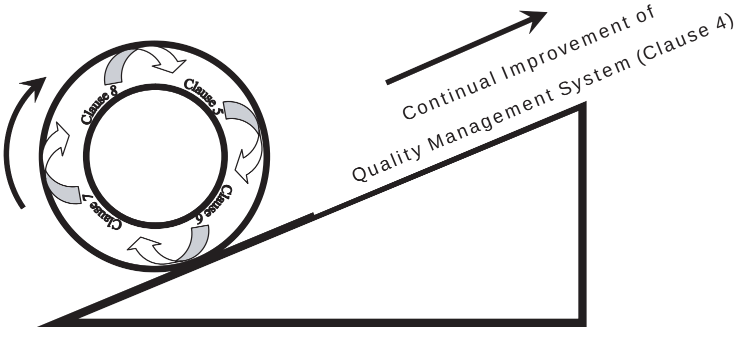

Figure 2. Traditional MIS methodology

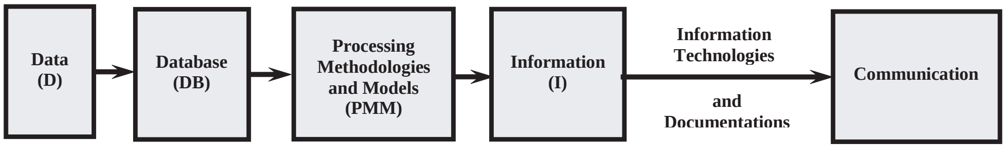

and maintain a quality management system and continually improve its effectiveness in accordance with the requirements of this International standard.

The organization shall:

1. identify the processes needed for the quality management system and their application throughout the organization
2. determine the sequence and interaction of these processes
3. determine criteria and methods needed to ensure that both the operation and control of these processes are effective
4. ensure the availability of resources and information necessary to support the operation and monitoring of these processes
5. monitor, measure and analyze these processes, and
6. implement actions necessary to achieve planned results and continual improvement of these processes."

The data pertaining to the stipulations of Sub-Clause 4.1 have been identified and listed in Table 1.

The database requirements pertaining to the "data" of Sub-Clause 4.1 have been identified and are enumerated in Table 2.

The methods and models recommended for processing the data are presented in Table 3.

The information elements designed pertaining to Clause 4.1 of ISO 9001:2000 standard are presented in Table 4.

The texts are italicized in Table 1-4 to indicate that the stipulations are pertaining to QMIS. All of the elements indicated in these tables are designed using the MIS process indicated in Figure

Table 1. Data pertaining to the stipulations of Sub-Clause 4.1

Element Number	***Data***
D-1	*ISO 9001:2000 standard.*
D-2	*List of processes needed for the QMS.*
D-3	*List of sequence and interaction required for the listed processes.*
D-4	*List of criteria and methods required for ensuring the effective operation and control of the listed processes.*
D-5	*List of locations indicating the availability of resources and information necessary to support the operation and monitoring of these processes.*
D-6	*List of methods to measure, monitor and analyze these processes and required actions for implementation.*
D-7	*List of planned results required for the QMS.*
D-8	*Data on continual improvement measures.*

Table 2. Database pertaining to the stipulations of Sub-Clause 4.1

Element Number	*Database*
DB-1	*Posting of ISO 9001:2000 standard in an electronic environment with the provision for retrieving the data based upon the clause number, product, processes, and procedures, etc. The hard copy of this standard may also be given to all employees or shall be deposited with section heads.*
DB-2	*Preparation of a handbook containing the processes needed for the QMS with proper chronological ordering and indexing procedures.*
DB-3	*Preparation of a handbook containing the sequence and interaction needed for the execution of the listed processes with proper chronological ordering and indexing procedures.*
DB-4	*Preparation of a handbook containing the criteria and methods needed for the execution of the listed processes with proper chronological ordering and indexing procedures.*
DB-5	*Preparation of a handbook containing the availability of resources and information with proper chronological ordering and indexing procedures*
DB-6	*Preparation of a handbook containing the methods to measure, monitor, and analyze these processes with proper chronological ordering and indexing procedures.*
DB-7	*Preparing a pamphlet on planned results and pasting it on strategic locations of the company. Electronic devices shall be chosen to accommodate the earlier-mentioned database elements, which should enable easy retrieval of the required data within a fraction of second.*
DB-8	*Preparing a pamphlet on data on continual improvement measures and pasting it at strategic locations of the company.*

1. As a sample, the design of the first element indicated in these tables is illustrated. As shown in Table 1, the data element denoted as D-1 (D stands for Data) pertaining to the first element is ISO 9001:2000 standard itself. As shown in Table 2, the database of this element deals with its electronic posting and deposition of its hard copy with the section head. This is denoted as DB-1 (DB stands for Database). As shown in Table 3, the indexing methodology and FAQs are stipulated as the processing methodologies and models of the Sub-Clause 4.1. This is denoted as PMM-1 (PMM stands for Processing Methodologies and Models). Finally, as indicated in Table 4, dissemination of the information is envisaged through physical disseminations and display in electronic environments. Thus, a scientific approach incorporated with the principles of MIS (as indicated in Figure 2) was adopted to design QMIS.

PENETRATION OF QMIS IN PRACTICE

Due to the economical availability of software and information technologies, modern companies have been incorporated with various elements of information systems. Hence, it is expected that even without explicit enunciation, modern companies are likely to have been incorporated with a few or many elements of QMIS. Considering this probability, it was decided to estimate the penetration of ISO 9001:2000 based QMIS in a real-time environment. For this purpose, a company involved in machining metal alloy components using high technology-based machining system namely, CNC Machining Center, was approached. This company is situated in Coimbatore City of India. Large-size companies place job orders with this company. The machined components are received by large-size companies, which in turn are exported by them to the companies lo-

Table 3. Processing methodology and models pertaining to the stipulations of Sub-Clause 4.1

Element Number	*Processing Methodology and Models*
PMM-1	*An index of the keywords may be prepared with page numbers of ISO 9001:2000 standard which should enable the user to obtain the right information. Besides, a list of frequently asked questions (FAQs) may be prepared to guide the users to get appropriate information from the standard. Display boards may be designed to paint the appropriate contents of ISO 9001: 2000 standard as required by the user.*
PMM-2	*An index of the keywords may be prepared with page numbers of the handbook containing processes needed which should enable the user to obtain the right information. Besides, a list of FAQs may be prepared to guide the users to get appropriate information from the handbook.*
PMM-3	*An index of the keywords may be prepared with page numbers of the handbook containing sequences and interaction of the listed processes, which should enable the user to obtain the right information. Besides, a list of FAQs may be prepared to guide the users to get appropriate information from the handbook.*
PMM-4	*An index of the keywords may be prepared with page numbers of the handbook containing criteria and methods needed for the execution of the listed processes, which should enable the user to obtain the right information. Besides, a list of FAQs may be prepared to guide the users to get appropriate information from the handbook.*
PMM-5	*An index of the keywords may be prepared with page numbers of the handbook containing the availability of resources and information, which should enable the user to obtain the right information. Besides, a list of FAQs may be prepared to guide the users to get appropriate information from the handbook.*
PMM-6	*An index of the keywords may be prepared with page numbers of the handbook containing the methods to measure, monitor, and analyze, which should enable the user to obtain the right information. Besides, a list of FAQs may be prepared to guide the users to get appropriate information from the handbook.*
PMM-7	*Impressive font sizes and colors of the letters should be chosen for displaying planned results, which should enable the user to obtain information.*
PMM-8	*An impressive font size and color of the letters should be chosen for displaying data on continual improvement measures, which should enable the user to obtain the right information.*

cated in various parts of the world. Two reasons prompted the company to install ISO 9001:2000 based quality system and obtain certification from TUV. The first reason is that the customers from different parts of the world insisted on the company to install ISO 9001:2000 based quality system. This is coinciding with the observation of Arauz and Suzuki (2004) who claim that the ISO 9000 certification provides opportunities for today's companies to obtain international recognition and establishment of the trade. The second reason was due to the desire of the managing partners for continuously improving the quality of performance. Due to the personal acquaintance of first and second authors with one of the managerial partners, it was possible to obtain permission to estimate the penetration of QMIS in the company. In order to carry out this estimation process, a workbook containing the design specifications of ISO 9001:2000 based QMIS was prepared. The manager who is taking care of ISO 9001:2000 quality system maintenance was approached with the workbook. This manager was interviewed by referring to the elements given in the workbook. In total, there were 24 elements included in the workbook.

The data were collected by interviewing the manager as well as by referring to the records and

Table 4. Information pertaining to the stipulations of Sub-Clause 4.1

Element Number	***Information***
I-1	*Circulation of the stipulation ISO 9001:2000 standard to the target users using circulars and display of the same through electronic media.*
I-2	*Circulation of the stipulation of processes needed for QMS to the target users using circulars and display of the same through electronic media.*
I-3	*Circulation of the stipulation of sequence and interaction of the listed processes to the target users using circulars and display of the same through electronic media.*
I-4	*Circulation of the stipulation of criteria and methods required for the execution of the listed processes to the target users using circulars and display of the same through electronic media.*
I-5	*Circulation of the stipulation of availability of resources and information to the target users using circulars and display of the same through electronic media.*
I-6	*Circulation of stipulation concerning methods to measure, monitor, and analyze the listed processes to the target users using circulars and display of the same through electronic media.*
I-7	*Pasting of the planned results in the locations where the target users are working and displaying the same through electronic media.*
I-8	*Pasting of the continual improvement measures in the locations where the target users are working and displaying the same through electronic media.*

through personal observation. After completion of data collection, the data were analyzed. The results indicated that the data pertaining to QMIS exist to the extent of 87% against the actual requirement. In the case of database, it is 50% against the requirements. However, it was understood that no activities pertaining to processing data and information have been carried out. These findings are depicted in Figures 3 and 4. These quantified results indicate that already the data and database have been created by the company while installing and managing ISO 9001:2000 based quality system implementation. This observation very much tallies with the stipulation of Clause 4.1 of ISO 9001:2000. That is, in this clause, the word information is specified only once. Accordingly, the company has developed the data and database to a good extent whereas the information is fully missed. It is understood that despite the economical availability of the Internet, intranet and extranet technologies, they have yet to be appropriately used by the company to leverage Clause 4 of ISO 9001:2000 standard to create QMIS.

DEVELOPMENT OF QMIS

As the study on penetration of QMIS revealed the existence of only the data and database, the remaining stipulations under the titles "processing methodologies and models" and "information" had to be developed in the company. As a sample, the development of first and second elements listed under the QMIS is briefly presented here. The development of QMIS was started by referring to D-1 (see Table 1). According to its stipulation, the availability of ISO 9001:2000 standard was examined. Since this was not available, a copy of it was made available in the company. While referring to DB-1 (see Table 2), it was noted that ISO 9001:2000 was not available in both electronic and hard copy forms among the company personnel. Hence, a HTML-based electronic file containing ISO 9001:2000 standard was developed. The front window of this file is shown in Figure 5. Also, hard copies of ISO 9001:2000 were made available in different sections, which are now accessible to the employees.

ISO 9001:2000 STANDARD

4. QUALITY MANAGEMENT SYSTEM

4.1 General Requirements

The organization shall establish, document, implement and maintain a quality management system and continually improve its effectiveness in accordance with the requirements of this International Standard.
The organization shall
a) identify the processes needed for the quality management system and their application throughout the organization (see 1.2);
b) determine the sequence and interaction of these processes;
c) determine criteria and methods to ensure that both the operation and control of these processes are effective;
d) ensure the availability of resources and information necessary to support the operation and monitoring of these processes;
e) monitor, measure and analyze these processes; and implement actions necessary to achieve planned and results and continual improvement of these processes.

9001:2000, a poster depicting the process-based QMS stipulated in ISO 9001:2000 was developed. In order to meet the specifications of I-1, the ISO 9001:2000 standard has been circulated among the target users, namely employees. Furthermore, the HTML file shown in Figure 6 would enable the display of the required stipulations of ISO 9001:2000 standard. For example, on pressing the link 5, the stipulations given under clause "Management Responsibility" shown in Figure 7 are displayed.

While referring to D-2 (see Table 2), it became necessary to list the processes needed for the QMS. Unlike in the case of D-1, it was possible to extract immediately and easily the list of processes shown in Table 7 from the quality manual of the company. After this, the task of preparing the QMIS handbook was started. According to the stipulations of DB-2 (see Table 2), the list of processes has been arranged according to the alphabetical ascending order of the process titles. This chronological ordering of the list of processes is shown in Table 8.

According to PMM-2, an index of titles of processes has been appended in the QMIS handbook. A portion of the page containing the index of titles is given in Table 9. According to I-2, the stipulation of processes has been circulated among the employees using circulars. Moreover, a poster facing the entry point of the company containing the list of processes was pasted. The photograph showing the pasted poster is presented in Figure 7. Furthermore, the HTML file has been developed to portray the "sequence and interaction of the process". The front page of this HTML file is shown in Figure 8. In a similar way, the QMIS has been developed according to its design specifications.

VALIDATION

In order to validate the QMIS, the managing partner was approached with a questionnaire. The questions asked and his responses in a Likert's scale of range from 0 to 10 are indicated in Table 9. As shown, the questions aimed to gather his assessment of a QMIS in achieving the requirements of the Clause 4 of ISO 9001:2000. Since his reactions ranged between 6 and 8, it is

5. MANAGEMENT RESPONSIBILITY

5.1 Management Commitment

Top management shall provide evidence of its commitment to the development and implementation of the quality management system and continually improve its effectiveness by

a) communicating to the organization the importance of meeting customer as well as statutory and regulatory requirements;
b) establishing the quality policy;
c) ensuring that quality objectives are established;
d) conducting management reviews; and
e) ensuring the availability of resources.

5.2 Customer Focus

Top management shall ensure that customer requirements are determined and are met with the aim of enhancing customer satisfaction (see 7.2.1 and 8.2.1).

5.3 Quality Policy

Top management shall ensure that the quality policy:

inferred that the QMIS is practically compatible. Furthermore, he was asked an open question to write about his opinion on QMIS developed in his company. He reacted by writing the statement, "QMIS has improved the performance of the quality management system of my company". Thus the QMIS developed was validated for checking its effectiveness in a real-time environment.

RESULTS AND DISCUSSIONS

The advantages of developing QMIS are described here by referring to its two elements 1 and 2. As mentioned earlier, it was not even possible to locate the ISO 9001:2000 standard in the company before the development of QMIS. This indicates that there existed a danger that the quality system of the company would be dragged away from the ISO 9001:2000 standard. This means that

Figure 8. Sequence and interaction of the processes

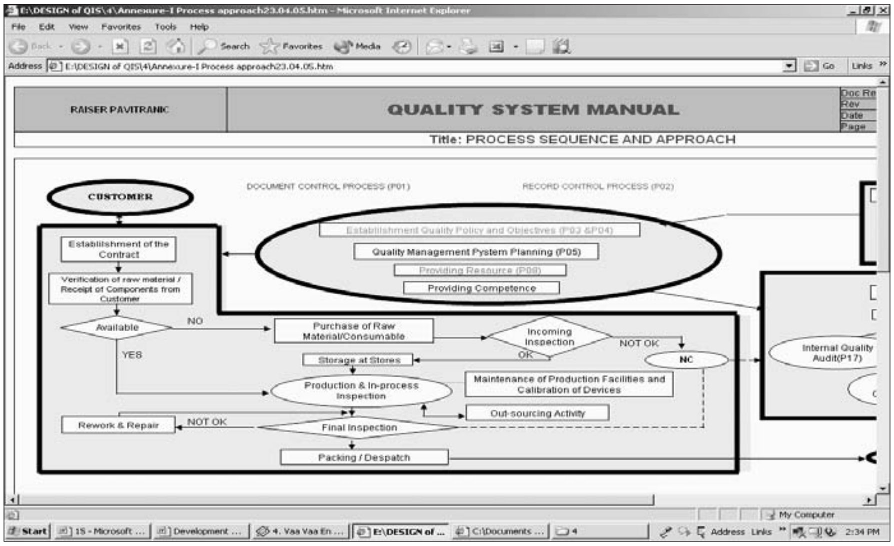

Table 9. Validation questionnaire and results

Question Number	Question	Managing partner's reactions in a Likert's scale of range 0-10. (0 - Not at all; 5 - Partially; 10 - Fully)
1	To what extent has QMIS leveraged in meeting the general requirements of QMS (as specified in Sub-Clause 4.1 of ISO 9001:2000)?	8
2	To what extent has QMIS leveraged in meeting the general documentation requirements of QMS (as specified in Sub-Clause 4.2.1 of ISO 9001:2000)?	7
3	To what extent has QMIS leveraged in meeting the objectives of developing quality manual in QMS (as specified in Sub-Clause 4.2.2 of ISO 9001:2000) ?	8
4	To what extent has QMIS leveraged in meeting the objectives of controlling documents in QMS (as specified in Sub-Clause 4.2.3 of ISO 9001:2000)?	6
5	To what extent has QMIS leveraged in meeting the objectives of controlling records in QMS (as specified in Sub-Clause 4.2.4 of ISO 9001:2000)?	7

the company was at the threshold of losing the benefits of implementing the ISO 9001:2000. As mentioned earlier, after the development of QMIS, the copies of ISO 9001:2000 standard are made available to all of the employees, and a soft copy is posted electronically using an HTML file. Likewise, before developing a QMIS pertaining to element 2, the list of processes was only available in the manual, which was not accessible to all employees. After the development of QMIS, the list of processes is made available in both document and electronic form. This activity enables the employees to be aware of the processes that take place in the company and, thereby, orients them toward attaining a higher degree of quality in totality and continually. Furthermore, the validation study conducted after developing a QMIS indicated its practical viability. As a whole, the development of a QMIS in the company led to an indication that the QIS would be a leveraging mechanism to enhance the performance of Clause 4 of ISO 9001:2000.

CONCLUSION

In order to face the ever-increasing degree of competition, companies have been striving to enhance the effectiveness of their work by adopting various approaches (Kaye & Anderson, 1999; Rho, Park, & Yu, 2001). When they are prescribed with completely new strategies, implementing them poses harder challenges. Moreover, the benefits of the heavy investment on strategies cannot be reaped back within the lifespan of the concerned projects. Hence, it is preferable that companies adopt leveraging actions by adopting the existing and proven strategies. In this direction, the leveraging action of information system management by adopting the widely installed ISO 9001:2000 based quality system draws the attention. In order to examine this proposal, a research project has been carried out in which the QMIS in accordance with Clause 4 of ISO 9001:2000 has been designed. This QMIS has been taken to an ISO 9001:2000 certified export oriented high technology machining based company. After getting the permission, the relevant data were collected. The analysis of the data indicated that this company has progressed toward data elements of QMIS to a good extent and database elements to a reasonably-satisfactory extent. However, the company has failed to incorporate the processing methodology and models and information elements of QMIS. In order to fill this gap, the QMIS elements missed in this company were developed. Finally, QMIS was validated by gathering the assessment of the company's managing partner. The experience of conducting the research project reported in this paper instigates us to postulate that QMIS can be implemented without any difficulty in companies in which ISO 9001:2000 based quality system is installed. Since this company is aspiring to move forward in the international market, this postulation may hold true for most of the modern companies situated in different parts of the world. Hence, it is a reasonable proposal that modern companies adopt the QMIS presented in this paper and gain the synergic benefits of information systems and ISO 9001:2000 standard.

ABSTRACT

Since their creation in the early 1960's, decision support systems (DSSs) have evolved over the past 4 decades and continue to do so today. Although DSSs have grown substantially since its inception, improvements still need to be made. New technology has emerged and will continue to do so and, consequently, DSSs need to keep pace with it. Also, knowledge needs to play a bigger role in the form of decision making. We first discuss design and analysis methods/techniques/issues related to DSSs. Then, the three possible ways to enhance DSSs will be explored.

INTRODUCTION

Over the 4 decades of its history, decision support systems (DSSs) have moved from a radical movement that changed the way information systems were perceived in business, to a mainstream commercial information technology movement that all organizations engage. This interactive, flexible, and adaptable computer based information system derives from two main areas of research: the theoretical studies of organizational decision making done at the Carnegie Institute in the 1950's and early 1960's, as well as the technical work on interactive computer systems which was mainly performed by the Massachusetts Institute of Technology (Keen & Morton, 1978).

DSSs began due to the importance of formalizing a record of ideas, people, systems, and technologies implicated in this sector of applied information technology. But the history of this system is not precise due to the many individuals involved in different stages of DSSs and various industries while claiming to be pioneers of the system (Power, 2003; Arnott & Pervan, 2005). According to Arnott (2006), the DSS field began in the early 1970s as a radical alternative to large-scale management information systems (MIS). Over time, major changes in information technology have enabled new decision support movements. In the late 1980s and mid-1990s, multidimensional modeling, OLAP technology, and advances in storage technology and data modeling led to the deployment of large-scale executive information systems, data warehousing, and business intelligence. Now DSSs have become very sophisticated and stylish since the early pioneering research. Many new systems have expanded the frontiers established by these pioneers, yet the core and basis of the system remains the same. Today, DSSs are used in the finance, accounting, marketing, medical, as well as many other fields.

BACKGROUND

The basic ingredients of a DSS can be stated as follows: the data management system, the model management system, the knowledge engine, the user interface, and the users (Donciulescu, Filip, & Filip, 2002). The database is a collection of current or historical data from a number of application groups. Databases can range in size from storing it in a PC that contains corporate data that has been downloaded, to a massive data warehouse that is continuously updated by major organizational transaction processing systems (TPSs). When referring to the model management system, it is primarily a stand-alone system that uses some type of model to perform "what if" and other kinds of analysis. This model must be easy to use, and therefore the design of such model is based on a strong theory or model combined with a good user interface.

A major component of a DSS is the knowledge engine. To develop an expert system requires input from one or more experts, this is where the knowledge engineers go to work, who can translate the knowledge as described by the expert into a set of rules. A knowledge engineer acts like a system analyst but has special expertise in eliciting information and expertise from other professionals (Laudon & Laudon, 2005).

The user interface is the part of the information system through which the end user interacts with the system, the type of hardware, and the series of on-screen command and responses required for a user to work with the system. An information system will be considered a failure if its design is not compatible with the structure, culture, and goals of the organization. Research must be conducted to design a close organizational fit, to create comfort and reliability between the system and user. In a DSS, the user is as much a part of the system as the hardware and software. The user can also take many roles such as decision maker, intermediary, maintainer, operator, and feeder. A DSS may be the best one in its industry but it still requires a user to make the final decision.

Power (2003) introduced a conceptual level of DSSs, which contains five different categories. These categories include model-driven DSS, communication-driven DSS, data-driven DSS, document-driven DSS, and knowledge-driven DSS. Defining DSS is not always an easy task due to the many definitions available. Much of this problem is attributed to the different ways a DSS can be classified. At the user level, a DSS can be classified as passive, active, or cooperative.

Essentially, DSS is a computer-based system that provides help in the decision making process. However, this is a broad way of defining the subject. A better way of describing DSS is to say it is a flexible and interactive computer-based system that is developed for solving non-structured management problems. Basically, the system uses information inputted from the decision maker (data and parameters) to produce an output from the model that ultimately assists the decision maker in analyzing a situation. In the following sections, we first discuss design and analysis methods/techniques/issues related to DSSs. Then, the three possible ways to enhance DSSs will be explored. At the end, future trends in DSSs will be discussed.

DESIGN AND ANALYSIS METHODS/TECHNIQUES/ISSUES RELATED TO DSSs

Design Methods

Today, DSSs hold a primary position in an organization's decision making by providing timely and relevant information to decision makers. It has become a key to the success or survival of many organizations. However, there is a high tally of failure in information systems development projects, even though they are a focal point of industrial concern (Goepp, Kiefer, & Geiskopf, 2006). Designing methods have become an important component that assures a successful information system design. This issue is in relevance to the design of a DSS.

There have been many different strategies employed for the design of a DSS, including the early decision-oriented design approach (Stabell, 1983). Current research on DDS design has witnessed the rapid expanding of object-oriented (OO) approach, which exploits object-oriented software engineering with unified modeling language (UML); knowledge management (KM) approach, which supports end-users by embedding declarative and/or procedural knowledge in software agents; structured modeling (SM) approach, which employs a hierarchically organized, partitioned, and attributed acyclic graph to represent models; and design science (DS) approach, which attempts to create artifacts that serve human purposes and solve organizational problems.

Object-oriented (OO) approach: The characteristic of OO approach is to use object-oriented software engineering with UML in the design and implementation of a DSS. OO design concepts are based on software engineering in that knowledge encapsulation present in a set of objects in an object-oriented system, where sub-classes show inheritance of the properties of the main class, is more compact and yet extensive compared to a logic-based system. Higher order logic is required to duplicate the performance of a simple object-oriented system (Pillutla & Nag, 1996). OO approach is considered a novel way of systems thinking. It provides designers and developers with easy analysis of complex systems and design of suitable software systems. It allows the developers and users to think in terms of objects and their behaviors instead of thinking about processes and process complexities. The main advantages are due to the features like data abstraction, encapsulation, inheritance, and polymorphism of OO approach (Nagarur & Kaewplan, 1999).

OO approach involves basically three major steps (Tian, Ma, Liang, Kwok, & Liu, 2005). The user's requirements are first captured by using a set of use case diagrams. These diagrams indicate all the functionalities of the system from the user's point of view. Then classes and their relationships are identified and described in class diagrams. Finally, sequence diagrams or collaboration diagrams are developed, which describe the interaction between objects (instances of classes). Tian et al. (2005) designed a DSS with the OO approach for an organization, which was implemented successfully.

Knowledge management (KM) approach: In some environments (non-preprogrammed applications), end-users, especially the less experienced end-users, need to have certain knowledge guiding them how to use the system. The KM design approach supports end-users by embedding declarative and/or procedural knowledge in software agents.

West Jr. and Hess (2002) used KM design approach to support end-users with spatially oriented decision-making by reporting on a specific spatial DSS that uses the approach. Procedural knowledge about performing spatial analysis was embedded in software agents that assist users with difficult and spatially oriented tasks. Because the system used a metadata repository, users were supported in some tasks by using the metadata repository directly and in others by using the software agents that access the metadata. According to West Jr. and Hess (2002), KM design approach provides better assistance to inexperienced users of spatial DSS, which requires a design approach that will prioritize knowledge support of the end-users' decision-making activities, and this approach, with the distribution of knowledge between metadata, agents, and end-users, has similar potential as a determinant of system success in any DSS (spatial or otherwise) where both declarative and procedural knowledge are needed to effectively accomplish the decision-making task. .

Structured modeling (SM) approach: SM (Geoffrion, 1987) approach "uses a hierarchically organized, partitioned, and attributed acyclic graph to represent models" (Srinivasan & Sundaram, 2000). It is a formal framework for describing models. SM identifies the basic components of models, the relationships among these components, and conditions under which a model may be termed structured (Lenard, 1993). It includes a language for describing a model schema and prescribes data tables for capturing the details of model instances.

SM decomposes a decision problem into genera and elements within genera in a hierarchic way, which forms a system that is sensitive to natural definitions of entities and objects in the problem (Pillutla & Nag, 1996). It consists of three levels: elemental structure, generic structure, and modular structure. The elemental structure intends to capture the definitional detail of a specific model instance. The generic structure targets at capturing the natural familial groupings of elements. The modular structure seeks to organize generic structure hierarchically according to commonality or semantic relatedness. The leveled structures allow the complexity of a model to be managed and ranked according to its hierarchies. The graph feature allows modelers and decision makers to understand the model better. A key advantage of SM is the ease with which structured models can be visualized (Srinivansan & Sundaram, 2000).

Srinivansan and Sundaram (2002) propose using SM in the design of model based DSS with the intention of solving existing design problems, such as lack of theory or design principles and domain specific issues, in other approaches. They select object relational database environment to implement SM, to be specific, they propose using SM to provide a systematic general framework for conceptual modeling and an object relational database management system (ORDBMS) to implement it. They believe an object relational platform for implementing structured models offers a development platform that is well suited to their needs. Such a platform is uniquely capable of meeting the conceptual requirements outlined by SM while satisfying many practical design concerns such as performance, persistence, and interoperability. They trust that their proposition of using SM approach for specific problem conceptualization and such a powerful environment as ORDBMS to implement it will provide design ideas that can potentially serve a very useful class of applications (Srinivansan & Sundaram, 2000).

Design science (DS) approach: Arnott (2006) defines design science as an alternative, or complement, to the natural science approach which has been a dominant research methodology in information systems field. Natural science tries to understand reality, but design science attempts to create things that serve human purposes (March

& Smith, 1995). In design science, researchers create and evaluate information technology artifacts that are intended to solve identified organizational problems (Hevner et al., 2004). Design science is especially relevant to information system research because it helps to address the role of the information technology artifact in information system research and the low professional relevance of many information system studies (Benhasat & Zmud, 1999; Orlikowski & Iacono, 2001).

The functionality of a DSS evolves over a series of development cycles where both the end-users and the systems analyst are active contributors to the shape, nature, and logic of the system (Arnott, 2004). Yet system developers have little guidance about how to proceed with evolutionary DSS development. DSS developers are facing the fact that insufficient knowledge exists for design purpose, and designers must rely on intuition, experience, and trial-and-error methods. Design science approach, on the other hand, can facilitate developers to create and evaluate information technology artifacts that are intended to solve identified organizational problems (Hevner, March, Park, & Ram, 2004). Vaishnavi and Kuechler (as in Arnott, 2006) proposed a design science methodology with the major process steps of awareness of problem, suggestion, development, evaluation, and conclusion. Arnott (2006) proposed a five steps approach, which was adapted from Vaishnavi and Kuechler, for designing evolutionary DSS: problem recognition, suggestion, artifact development, evaluation, and reflection. A research project by Arnott indicates that design science approach can tackle problems of both theoretical and practical importance.

DSS design model: DSS design model is the most recent DSS design approach developed by Klashner and Sabet and is worthy of a discussion. According to Klashner and Sabet (2007), DSS design model differs from any other models and approaches in that it is a more comprehensive design approach to address domain and nondeterministic complexities arising from real-world decision-making requirements. Incorporating morphogenetic principles, the model reflectively and concurrently informs its own evolution and directly impacts the design of the proposed DSS under development “although this new DSS design model appears simple and straightforward” (Klashner & Sabet, 2007).

The model consists of three major components: theory and analysis, simulation, and decision/design. Within the theory and analysis component, multiple data from system domain are fed into theory and analysis. A relation between the theory and domain is maintained to continuously exchange synchronous data and update the theory. The simulation component interacts with the theoretical components to integrate the data feed. As to the decision/design component, the design decision-making process will inevitably be influenced by the effect of theoretical analysis and simulation combined to the degree of not violating the decision-makers’ shared understanding of the design goals. Then the newly integrated design decisions immediately act on the relationship between the system domain and information infrastructure, thus completing the first full iteration since the general iterative flow of data.

Klashner and Sabet (2007) argue that in the early years of DSS research, design choices were intuitively understood in most cases because of the straightforward nature of the stakeholder’s requirements. But today, because stakeholder decisions have become highly subjective and complicated due to the increased problem complexity arising from various semi- to ill-structured problems (Nemati, Steiger, Iyer, & Herschel, 2002), a more comprehensive systems design approach is needed. Thus, the new DSS design model has been developed to address this issue. At present, the model application is domain specific, but it is currently being applied to another mission critical infrastructure design effort to test its generalizability to other domains where DSS plays a key role in daily operations (Klashner & Sabet, 2007).

Design Techniques

As we are advancing in information technologies, business decision makers can now have access to vast amount of information. On one hand, they may gain necessary and important information for making informed decisions, but on the other hand, they may also become overloaded by the information irrelevant to what they need. Thus, there is a pressing need for decision aiding tools that would effectively process, filter, and deliver the right information to the decision makers. Proper combination of DSSs and agent technologies could prove to be a very powerful tool for rendering decision support (Vahidov & Fazlollahi, Winter 2003-2004).

A software agent performs interactive tasks between the user and the system. The user instructs the system what he/she intends to accomplish. The software agent carries out the task. By analogy, a software agent mimics the role of an intelligent, dedicated and competent personal assistant in completing the user's tasks (Bui & Lee, 1999). In the DSS environment, software agents have been more formally described as autonomous software implementations of a task or goal that work independently, on behalf of the user or another agent (Hess, Rees, & Rakes, 2000). As the traditional, direct manipulation interface of our computing environment is much limited (Maes, 1994), software agents would seem to be a suitable and most needed solution for providing procedural assistance to end-users (West Jr. & Hess, 2002). "These 'robots of cyberspace' can be effectively utilized in automating many information processing tasks" (Vahidov & Fazlollahi, 2003-2004).

In some DSS environments, such as spatial DSS (Sikder & Gangopadhyay, 2002; West Jr. & Hess, 2002), Internet-based DSS (Bui & Lee, 1999) and Web DSS (Vahidov & Fazlollahi, 2003-2004), a multi-agent system should be designed and implemented in the DSS to facilitate the decision makers since decision making involves complex set of tasks that requires integration of supporting agents (Bui & Lee, 1999), and these agents should have behaviors to work in team (Norman & Long, 1994). Vahidov and Fazlollahi (2003-2004) developed architecture of multi-agent DSS for e-commerce (MADEC), in which intelligence team (agents), design team (agents), and choice team (agents) were composed. The multi-agent system was implemented in a prototype of MADEC, which received higher user satisfaction.

THREE POSSIBLE WAYS TO ENHANCE DSSs

Creating Knowledge Warehouses (KW)

Nemati (2002) proposed that a new generation of knowledge-enabled systems that provides the infrastructure required to capture, enhance, store, organize, leverage, analyze, and disseminate not only data and information but also knowledge (Nemati, 2002). Expanding data warehouses to encompass the knowledge needed in the decision making process is the creation of knowledge warehouses (KW). An important component of KW is a very complex process known as knowledge management. Knowledge management allows for knowledge to be converted from tacit to explicit through such processes as filtering, storing, retrieving, and so forth, thus allowing it to be utilized by decision makers.

The goal of KW is to give the decision maker an intelligent analysis standpoint that enhances all aspects of the knowledge management process. The main drawbacks of KW are the amount of time and money that need to be invested as well as some of the same problems that are found in successfully implementing DSSs. Among these factors are the users' involvement and participation, values and ethics, organization and political issues within the company, and other external issues. The development and implementation of KW still has much work to be done, however, DSSs seem to be headed toward knowledge enhancement in the future and KW looks to have a promising outlook in the upcoming years as a result.

Focusing on Decision Support

While knowledge management systems seem like a logical way to advance the shortcomings of DSSs, another view also exists. By removing the word "system" from DSSs and focusing on decision support, decision making might cause some interesting, new directions for research and practice. Decision support (DS) is the use of any plausible computerized or non-computerized means for improving sense making and/or decision making in a particular repetitive or non-repetitive business situation in a particular organization (Alter, 2004).

DS embodies a broader perspective that seems logical in environments where the user does not necessarily need the technical aspects of DSSs. This is based on the belief that most work systems of any significance include some form of computerized support for sense making and decision making (Alter, 2004). The difference between DSSs and DS is not too drastic but DS is a sensible option for many companies due to the increase in technology since the creation of DSSs; DSSs may not fit the needs of a business as it had in the past.

Integrating DSSs and KMSs

In line with Bolloju (2002), integrating decision support and knowledge management may correct some of the deficiencies of DSSs. The decision-making process itself results in improved understanding of the problem and the process, and generates new knowledge. In other words, the decision-making and knowledge creation processes are interdependent. By integrating the two processes, the potential benefits that can be reaped make the concept seem more worthwhile.

Integrating DSSs and KMSs seems to be the best choice out of the three possible ways to enhance DSS. The reasoning behind this selection is that integrating the two seems to provide a way for including both options without sacrificing one for the other. More importantly, while KW appears to have a very bright future, KW currently requires a great amount of time and money. The combination of both areas allows for a better overall utilization in the present. In time, KW may not be as time consuming and costly as it is now. However, to achieve a better balance of usefulness and efficiency, the integration of DSSs and KMSs appears to be the smartest choice.

FUTURE TRENDS

DSS in Business Analytics

The future of DSSs, Angus (2003) argued and supported by SAS (2004), is in the field of *business analytics* (BAs). BAs differ from that of the recently and previously more common business intelligence (BI). With the fast pace of business and life today it would only make sense for a shift to BA because it does focus on the many possibilities and the future outcomes for production and service.

BAs focus on the future of operations. Opposed to that of BI where it focuses on the past and what can be done to change the past if things were done wrong or repeat if things were done right. However, BAs let managers center on what future trends are developing, which allows them not to accumulate a surplus of inventory of outdated products. It also enables managers to change their prices before the market does, or introduce their new product before anyone else gets the chance to. This is known as first-to-market (Gnatovich, 2006). BAs give the companies that use it a tremendous advantage over their competitors in the market place.

Power-Hungry DSS

As everyone can see, the computing power is still accelerating. With its plan of "Itanium" processors, Intel is rushing towards its upcoming generation of 64 bit chips to support power-craving applications. Without any doubt, the power-hungry, large scale, integrated DSS application with dynamic calculation, background data mining, and high-end data visualization falls right into this end of the spectrum (Thomsen, 2003).

Web-Based DSS

The fast growing Internet and e-commerce have greatly impacted the way we conduct business. With the support of intelligent agents, DSS has been implemented for aiding decision makers in e-commerce. E-commerce combines transaction and decision support within an e-framework. Ultimately, the e-world is just another channel (Thomsen, 2003). If we can use the e-channels appropriately, integrate text engines within an overall DSS architecture, and provide for interoperability between DSS components, we may actually learn a few things about all this data we are collecting and make better decisions—without losing our humanity (Thomsen, 2003).

DSS in Retailing Business

In the retailing business sector, the competition over customers grows fierce. A customer's decision of buying from one retailer over another becomes the dividing factor in competition. Additionally, product mix between general and specialty retail is becoming homogenized. This expands the growth for more sophisticated and accurate decision support technology in the business (Rowen, 2005).

A few other trends in the retail business also call our attention. According to Rowen (2005), decision support solutions must interact with forecasting, allocation, and many other demand-chain applications from disparate vendors to increase margins. Additionally, we are being confronted with the coming onslaught of customer, events, and transactional data. Retailers are generating information at a volume that few can find significant use for today. Finally, forecasting and tracking anticipated sales has become another decision support trend within retail. Such technology enables a retailer to investigate the situation at hand, determining if a product is available.

Research in DSS

In terms of trends in DSS research, in the late 1980s and early 1990s, data warehouse and data mining was one of the focuses of research in DSS field. Since then software agents, also know as intelligent agents, emerged as an interdisciplinary area involving researchers from such fields as expert systems, DSS, cognitive science, psychology, databases, and so forth (Eom, 1999). Citations relevant to software agents in this chapter support such a proposition.

Studies of design science have shown a significant number in recent years in DSS research (Arnott & Pervan, 2005). This research stream has been rapidly expanding with a range of new topics encouraged by technological advances, methodological innovations, and increased expectations for theory development and empirical analysis of the new artifacts (Banker & Kauffman, 2004), such as the design of auction mechanisms (Bapna, Goes, & Gupta, 2003; Kelly & Steinberg, 2000) and optimal strategies for investment in knowledge by using a market mechanism (Ba, Stallaert, & Whinstone, 2001). It is likely that it will remain as a major topic in years to come.

According to Eom's (Eom, 1999) study, Web-based DSS is another emerging topic in the DSS area. Sikder and Gangopadhyay (2002) identified research issues on the design and implementation of a Web-base collaborative spatial decision support system. Vahidov and Fazlollahi (2003-2004) proposed architecture for a multi-agent DSS for e-commerce and described a prototype system for making online investment decisions with such a Web-based multi-agent DSS. In the pre-Web era, DSS was primarily used in an "island" mode. In e-commerce applications today, DSS can be an integral part of the digital environment and directly support the actions of the involved parties (Vahidov & Fazlollahi, 2003-2004).

CONCLUSION

Since their creation in the early 1960's, DSSs have evolved over the past 4 decades and continue to do so today. Although DSSs have grown substantially since its inception, improvements still need to be made. New technology has emerged and will continue to do so and, consequently, DSSs need to keep pace with it. Also, knowledge needs to play a bigger role in the form of decision making.

Shim (2002) emphasized that DSSs researchers and developers should (i) identify areas where tools are needed to transform uncertain and incomplete data, along with qualitative insights, into useful knowledge, (ii) be more prescriptive about effective decision making by using intelligent systems and methods, (iii) exploit advancing software tools to improve the productivity of working and decision making time, and (iv) assist and guide DSSs practitioners in improving their core knowledge of effective decision support.

The prior statement sums up the courses of action that need to be taken very well. The successful integration of DSSs and KMSs could revolutionize DSSs and propel it to even greater heights in the future. In closing, DSSs have a storied history that spans the course of 4 decades; however, the greatest mark may be made in the not so distant future as DSSs continue to evolve.

KEY TERMS

Business Analytics (BA): A technological system that collects and evaluates all relevant data then scrutinizes it and puts it into different simulations to find out which one is the most appropriate.

Business Intelligence (BI): A system of technologies for collecting, reviewing, and hoarding data to assist in the decision making process.

Decision Support Systems (DSSs): An interactive, flexible, and adaptable computer-based information system, especially developed for supporting the solution of a non-structured management problem for improved decision making. It utilizes data, provides an easy-to-use interface, and allows for the decision maker's own insights

Interface (or User Interface): A component designed to allow the user to access internal component of a system, also known as the dialogue component of a DSS.

Knowledge Management: The distribution, access, and retrieval of unstructured information about human experiences between interdependent individuals or among members of a workgroup.

Sensitivity Analysis: Running a decision model several times with different inputs so a modeler can analyze the alternative results.

Software Agent: A software program that intelligently performs its duties without human inter-action.

Structured Modeling: A generic design strategy for representing complex objects that are encountered in modeling applications (Srinivasan & Sundaram, 2000).

Transaction Processing System (TPS): Computerized systems that perform and record the daily routine transactions necessary to conduct the business; they serve the organization's operational level.

Use Case: A complete sequence of related actions initiated by an actor; it represents a specific way to use the system.

INTRODUCTION

The *design of manufacturing systems* is a wide open area for development and application of decision making and decision support technologies. This domain is characterized by the necessity to combine the standard decision making methods, sophisticated operational research techniques, and some specific rules based on expert knowledge to take into account principal technological constraints and criteria.

A promising trend in this area deals with the development of integrated software tools (Brown, 2004; Grieves, 2005; Stark, 2005). Their main idea consists in integrating product and manufacturing data into a common database. This enables product designers to consider the manufacturing processes constraints at the early product design stage. At the same time, all data of product design should be used directly for optimizing the corresponding manufacturing system. That is why the core of these software tools is a powerful extendable database, supported by a user friendly software environment. This database normally contains digital models of product and processes. In order to find an optimal manufacturing system configuration, a set of advanced decision making and decision support methods are used for data processing.

In this work we present the main principles and ideas of decision making by the example of decision and support soluton for machining systems used for mass production. The used approach is based on several techniques:

- Powerful database of standard solutions and
  efficient mecanisms to search the existing elements
- Expert system to choose better solutions from database;
- Line balancing model based on shortest path
  approach;
- Set of problem oriented rules; and
- User friendly software environment.

These techniques are combined in the decision support software tool for optimal process planning, line balancing, and equipment selection for optimal design of a transfer machine with rotary or mobile table.

BACKGROUND

The studing of line design problems began by considering the simple *assembly line balancing problem* (SALBP) (Baybars, 1986; Scholl & Klein, 1998). The SALBP consists in assigning a set of operations to identical consecutive stations minimizing the number of stations required, subject to *precedence constraints* between operations and *cycle time* constraints. Many exact and heuristic approaches for SALBP were suggested in literature: lagrange relaxation techniques (Aghezzaf & Artiba, 1995), branch and bound algorithms (van Assche & Herroelen, 1998; Ugurdag, Papachristou, & Rachamadugu, 1997; Scholl & Klein, 1998), and heuristics and meta-heuristics (Arcus, 1966; Helgeson & Birnie, 1961; Rekiek, De Lit, Pellichero, L'Eglise, Fouda, Falkenauer *et al*., 2001). This list is not exhaustive. A state-of-the-art can be found in (Baybars, 1986; Becker & Scholl, 2006; Erel & Sarin, 1998; Ghosh & Gagnon, 1989; Rekiek, Dolgui, Delchambre, & Bratcu, 2002).

The problem where line balancing is combined with equipment selection is often called *simple assembly line design problem* (SALDP) (Baybars, 1986; Becker & Scholl, 2006) or *single-product assembly system design problem* (SPASDP) (Gadidov & Wilhelm, 2000). SALDP considers the "high-level" logical layout design with equipment selection (one per station) from a set of alternatives. There are several equipment alternatives for each operation, and often a particular piece of equipment is efficient for some operations, but not for others (Bukchin & Tzur, 2000; Bukchin & Rubinovich, 2003). There is a given set of equipment types; each type is associated with a specific cost. The equipment cost is assumed to include the purchasing and operational cost. The duration of an operation depends on the equipment selected. An operation can be performed at any station, provided that the equipment selected for this station is appropriate and that precedence relations are satisfied. The total station time should not exceed the predetermined cycle time. The problem consists of selecting equipment and assigning operations to each station. The objective is to minimize the total equipment cost.

The *balancing of transfer lines and machines* (Dolgui, Guschinsky, & Levin, 2000) deals with grouping operations into a number of blocks (sets of operations performed by a spindle head) and assigning these blocks to stations. Each block requires a piece of equipment (a multi-spindle head), which incurs a purchase cost. Therefore, it is necessary to minimize both the number of stations and the number of blocks. To do it, all possible operations assignments to blocks and stations must be considered; otherwise the optimality of a solution cannot be guaranteed. The set of alternative blocks is not known in advance and the parameters of a block depend on the set of operations assigned to it. Therefore, the balancing of machining systems, as it was demonstrated in (Dolgui, Finel, Guschinsky, Levin, & Vernadat, 2006), is more complex than SALBP and SALDP.

MACHINE TOOL ENGINEERING

Transfer machines are dedicated to the mass production of a family of similar products and widely used in the automotive industry (Hitomi, 1996). Designing and balancing such machines is a very complex problem due to necessity to take into account the specific machining constraints. At the same time, to acquire a machine sell order, the manufacturers must provide their customers with the results of the preliminary design (general plans of the machine and an estimation of the price) as quickly as possible. Therefore, it is vitally important for manufacturers to have a decision making methodology and decision support system (Dolgui, Guschinskaya, Guschinsky, & Levin, 2005).

Thus, in order to help designers to find a high-quality (and if possible an optimal) architecture of transfer machine corresponding to the customer demand, we developed and implemented a methodology and a prototype of decision support system named "*machine tools engineering*" (MTE).

This decision support system deals with the optimization of the logical layout design of *transfer machines* and provides designers with an integrated design environment. We depicted the different design stages as well as the implemented in MTE software tool operational research and decision-aid methods.

A decision support system devoted to the design of transfer machines has to provide users with graphical tools to make the design process fast and easy. In addition, it must be capable to help designers to make decisions based on expert knowledge and technological requirements. To reach these objectives, MTE was developed in the design environment of popular commercial CAD system *AutoCad Mechanical Desktop 2006*. Its conceptual environment makes the creation, editing, and navigation of solids and surfaces simple and intuitive. The modules containing the developed optimization methods are plug-ins embedded to AutoCad Mechanical Desktop 2006. This system configuration enables designers to use the common data format at all preliminary design stages.

MTE is dedicated to the preliminary design of transfer unit head machines (machines composed from standard units) with the following configurations:

1. *Multi-positional machines with rotary table.*
   A part is sequentially machined on *m* working
   positions and is moved from one position to the next one using a rotary table. The rotary table is divided into *m*+ 1 sectors: *m* of them correspond to the working positions and one sector is served for loading the billet and unloading the part. Therefore, at each moment *m* parts are machined—one per working position. Each working position may be accessible for one or two (one vertical and one horizontal) spindle heads. The spindle heads of each working position are activated simultaneously. Thus, all spindle heads perform operations on parts in parallel.
2. *Machines with mobile table.* These machines are used for the fabrication of parts that cannot be produced on multi-positional machines with rotary table because of their dimensions (this type of machine has a lower productivity than rotary table machines since only one part can be machined within the *cycle time*). Here, a part is machined on *m* ($m \leq 3$) working positions and is moved from one position to the next one using a mobile table. Each working position has

one or two (one vertical and one horizontal, or two horizontal) spindle heads. The last working position may have three spindle heads (one vertical and two horizontal, or three horizontal). The spindle heads of each working position are activated simultaneously. At each moment only one position is active and the spindle heads of the active working position perform operations on the machined part. The first position is used also for unloading the part after machining and loading the billet.

DECISION MAKING METHODOLOGY

A design methodology for manufacturing systems can be defined as a set of procedures that analyzes and segregates a complex *manufacturing system design* task into simpler manageable sub-design tasks while still maintaining their links and interdependencies (Wilheim, Smith, & Bidanda, 1995). An illustration of *MTE decision support system* is given in Figure 1 and the corresponding decision making procedure is presented in Table 1 (Dolgui et al., 2005).

Product/Process Modeling

Part Modeling

The first step deals with the *modeling of a part* to be machined. The clients provide the machine tool manufacturer with the specifications of a part already designed, which they want to produce using a transfer machine. Usually, the manufacturing process includes milling, drilling, boring, and so forth, a set of part elements such as planes, facets, holes of different types (cylindrical, bevel, threaded, etc.). Each element concerns a certain side (or surface) of the part and is characterized by a set of technological parameters, like required tolerances and surface conditions. Figure 2 shows an example of a part that was modeled in the MTE system.

In order to use the same format for the geometric and technological data, the part is modeled with machining features. The concept of feature

Figure 1. MTE decision support system

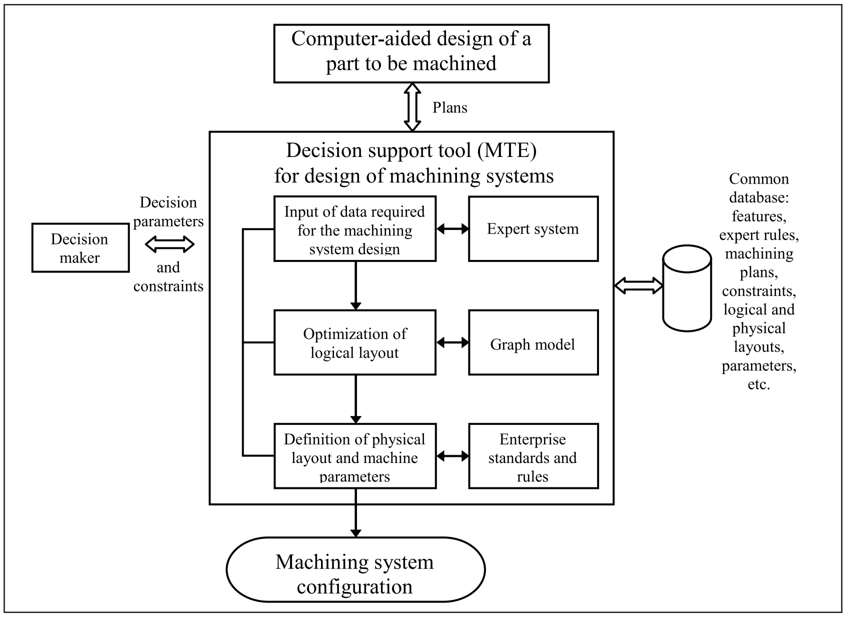

Table 1. General methodology of decision making for a machining system design

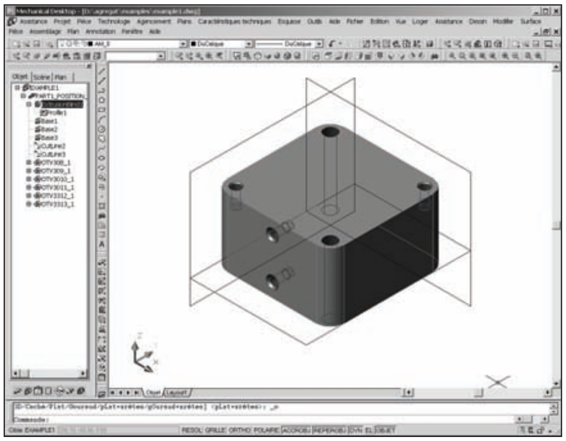
Stages and steps
Stage 1. Input of data required for the machining system design
Step 1.1. Part modeling with features
Step 1.2. Input of part and machine properties
Step 1.3. Process planning using an expert system
Step 1.4. Constraints generation based on machining data and user experience
Stage 2. Optimization of logical layout
Step 2.1. Finding all solutions minimizing the number of spindle heads and working positions while assigning operations to working positions and defining cutting modes for spindle heads
Step 2.2. Choice of a solution among the optimal ones (solution to be applied)
Stage 3. Definition of physical layout and machine parameters
Step 3.1 Working plan documentation
Step 3.2. Part positioning
Step 3.3. Equipment selection
Step 3.4. Preliminary 3D layout design
Step 3.5. Control equipment and additional devices selection
Step 3.6. Cost estimation

associates the technological characteristics of a machining element with its geometric parameters. Therefore, the part modeling step demands analyzing the part to be machined and identifying features, their geometric and topological relations.

To make the design of features easier and faster, we analyzed a certain number of standard elements. A graphic library of the most common parameterized features was developed and embedded to AutoCad Mechanical Desktop 2006. The corresponding technological characteristics are stored in the data fields associated with each feature.

When the part has been modeled, some additional characteristics of the part (for example, the material and its properties, the properties of the billet, etc.), and of the machine (for example, the desired productivity, the cooling method, the type of cooling liquid, etc.) must be defined as well as a desired type of machine (with rotary or mobile table) must be selected.

Figure 2. Part to be machined



Process Planning

At this stage, the machining operations, required tools and their parameters for each part feature are determined. The *process plan* of a part feature, that is, a set of operations to be performed in order to provide the required geometric and technological characteristics, is chosen using the following parameters: the condition of surface before machining, the diameter of machining holes, and the required precision for each machining element. These parameters are stored in the data fields associated with the features. Analyzing their values and using the expert system, all possible process plans for each feature can be chosen from the process plans database. This database contains also dependences between the feature parameters and the set of all possible operations that a machine equipped by standard spindle heads can process. Then, for each feature and each possible process plan the corresponding tolerances are calculated. The obtained values of tolerances are compared with those required and the plan providing the values nearest to the required is chosen. For this chosen plan, the parameters of operations (like cutting depth, machining length, type and material of cutting tool, working stroke, and cutting mode) are determined automatically. Cutting mode is defined by minimal, maximum, and recommended values of the following parameters: cutting speed, feed rates per minute and per revolution. Then, the user, who can replace or modify automatically chosen plans, analyzes the plans suggested by the decision support tool. New process plans can be stored in the database.

In order to establish a total process plan, the individual machining plans selected for the features must be completed by introducing the existing relations between the operations of different features. These relations are introduced using different types of constraints.

Generation of Constraints

The decision support tool MTE considers the following types of relations between machining operations:

a. *Precedence constraints* which define possible sequences of operations and are determined by a number of known technological factors (fixed sequences of operations for machining features, the presence of roughing, semi-finishing and finishing operations, etc.).
b. *Inclusion constrains* reflect the necessity to perform some operations on the same working position or even by the same spindle head. They are implied by the required precision (tolerance) of mutual disposition of machined features as well as a number of additional factors.
c. *Exclusion constrains* are used in the cases when it is impossible to assign some pairs of operations to the same working position (or to the same spindle head). It can be caused by a number of constructional and technological constraints: mutual influence of these operations, a forbidden tool location, and so forth. This type of constraint must be fulfilled also for operations executed on the different sides of the part because they cannot be performed by the same spindle head.

Some constraints are automatically generated by the decision support tool MTE. For this, all operations can be divided into four groups according to the finish state:

1. Milling operations
2. Roughing operations (boring, drilling with the
drill diameter more than 20 mm, countersinking
with the countersink diameter more than 30 mm)
3. All other operations except threading operations
4. Threading operations.

Usually, no operation of a group can be started before the end of all previous group operations, therefore the corresponding precedence constraints are generated automatically. Generally, the same equipment cannot perform operations of two different groups. Thus, they cannot be assigned to the same spindle head. Since all spindle heads of a working position are activated simultaneously, operations from different groups can not be assigned to the same working position; therefore the corresponding *exclusion constraints* are also generated automatically. In accordance with their expert knowledge or preferences users can introduce complementary constraints of any type or remove the constraints generated automatically.

The overall equipment dimensions limit the total number of working positions and the number of blocks at each working position by the values of the parameters $\overline{m}$ and $\overline{n}$ respectively. The values of $\overline{m}$ and $\overline{n}$ are obtained taking into account the available machine configuration and economical constraints.

The objective production rate is obtained, if the machine *cycle time* $T(P)$ does not exceed the maximum authorized value T_0.

Logical Layout Optimization

The manufacturing information as well as diverse constraints related to the design of spindle heads and working positions are used as input data for the second design stage, that is, *logical layout design* (Wilheim et al., 1995; Zhang, Zhang, & Xu, 2002). The quantity of equipment (spindle heads, working positions) required to produce a part with the given productivity rate defines the final cost of the *transfer machine*. Therefore, the goal of the logical layout optimization is to find a design variant that minimizes the number of working positions and the total number of spindle heads while satisfying all given technological and economical constraints (Dolgui, Guschinsky, Levin, & Proth, 2008).

Problem Statement

If the machining is organized on m working positions, then at the k-th working position $k=1, ..., m$, a subset N_k of the given set **N** of operations is performed. Each set N_k is uniquely partitioned into n_k subsets (N_{kl}, $l=1,...,n_k$), where the operations of each subset N_{kl} are performed by the same spindle head. Such a partition is unique due to the fact that each operation corresponds to one "side" of the part, and only the operations of the same side can be performed by one spindle head. Parameters of the kl-th spindle head and its execution time depend both on the set of operations N_{kl} and their cutting modes.

The logical layout optimization consist in determining simultaneously:

a. The number m of working positions;
b. The partitioning of the given set **N** of operations into subsets N_k, $k = 1,...,m$; and
c. The feed per minute X_{kl} for each N_{kl}, $l = 1,\ldots, n_k$.

Let $P=<P_1,...,P_k,...,P_m>$ is a design solution with $P_k = (P_{k1}, ..., P_{kl}, ...,P_{kn_k})$ and $P_{kl} = (N_{kl}, X_{kl})$. Let C_1 and C_2 be the relative costs for one working position and one block, respectively. Then the objective function of the considered design problem can be formulated as follows:

$$Min\ Q(P) = C_1 m + C_2 \sum_{k=1}^{m} n_k \qquad (1)$$

Cycle Time Calculation

Let $\lambda(i)$ be the given length of the working stroke for operation $i \in$ **N.** The execution time $\tau^b(N_{kl}, X_{kl})$ of the set N_{kl} of operations performing by the kl-th spindle head working with the feed per minute X_{kl} is equal to:

$$\tau^b(N_{kl}, X_{kl}) = L(N_{kl})/X_{kl}, \qquad (2)$$

where $L(N_{kl}) = max\{\lambda(i) \mid i \in N_{kl}\}$.

The execution time for all operations of the k-th working position (k=1,…,m) is equal to:

$$\tau^p(P_k) = max\ \{\ \tau^b(N_{kl}, X_{kl})\ |\ l=1,\dots,n_k\ \}. \quad (3)$$

The *cycle time* for *machines with a rotary table* is defined by the maximum value among the execution times of the working positions:

$$T(P)=\boldsymbol{\tau}'' + \max\{\tau^{\,p}(P_k)\ |\ k= 1, 2..., m\}, \quad (4)$$

where $\boldsymbol{\tau}''$ is a given constant, an additional time for loading the billet and unloading the part after machining.

The cycle time for *machines with a mobile table* is defined by the sum of the machining times of the working positions:

$$T(P)=\boldsymbol{\tau}'' + \sum_{k=1}^{m} \tau^p(P_k) \quad (5)$$

Let $\mu(i)$ be a constant that characterizes the tool life rate, $[s_1(i),s_2(i)]$ and $[v_1(i),v_2(i)]$ the ranges of the feasible values of feed per revolution $s(i)$ and spindle speed (cutting speeds) $v(i)$, respectively, for each operation $i\in\mathbf{N}$; $s_0(i)$, $v_0(i)$ are their "recommended" values:

$$\begin{aligned} x_0(i) &= s_0(i)v_0(i),\\ x_1(i) &= s_1(i)v_1(i), \qquad (6)\\ x_2(i) &= s_2(i)v_2(i). \end{aligned}$$

The interval of possible values of the feed per minute for the spindle head which executes the set N of operations $\mathbf{X}(N)= [\underline{X}(N), \overline{X}(N)]$ is calculated as follows:

$$\underline{X}(N)=\max(\max\{x_1(i)|i\in N\}, L(N)/(T_0\text{-}\tau'') \quad (7)$$
$$\overline{X}(N)=\min\{x_2(i)|i\in N\} \quad (8)$$

If the set $\mathbf{X}(N)$ is empty, then operations of the set N cannot be executed by one spindle head. Otherwise, a preliminary value $x\in\mathbf{X}(N)$ might be chosen in the following way:

$$x^*(N)=\min\{(L(N)/\lambda(i))^{\mu(i)}x_0(i)|i\in N\} \quad (9)$$
$$x^{**}(N)=\max\{\underline{X}(N), x^*\} \quad (10)$$
$$x(N)=\min\{x^{**}, \overline{X}(N)\} \quad (11)$$

In this case, the feed per revolution for operation i is equal to $s(i,x)=\min[s_2(i),x/v_1(i)]$, and the cutting speed is equal to $v(i,x)=x/s(i,x)$.

Modeling of Constraints

We assume that the given productivity is achieved, if the cycle time $T(P)$ (calculated) does not exceed the maximum value T_0.

$$T(P) \le T_0 \quad (12)$$

The *precedence constraints* can be specified by an acyclic digraph $G^{OR}=(\mathbf{N},D^{OR})$ where an arc $(i,j)\in D^{OR}$ if and only if the operation i has to be executed before the operation j. Thus, for each operation $j\in\mathbf{N}$, a set $Pred(j)$ of its immediate predecessors is determined.

The *inclusion constraints* can be given by undirected graphs $G^{SH}=(\mathbf{N},E^{SH})$ and $G^{SP}=(\mathbf{N},E^{SP})$ where the edge $(i,j)\in E^{SH}$ if and only if the operations i and j must be executed by the same spindle head, the edge $(i,j)\in E^{SP}$ if and only if the operations i and j must be executed on the same working position.

The *exclusion constraints* can also be defined by undirected graphs $G^{DH}=(\mathbf{N},E^{DH})$ and $G^{DP}=(\mathbf{N},E^{DP})$ where the edge $(i,j)\in E^{DH}$ if and only if the operations i and j cannot be executed by the same spindle head, the edge $(i,j)\in E^{DP}$ if and only if the operations i and j cannot be executed on the same working position.

Since for this type of machine the set N_k is partitioned into subsets for spindle heads uniquely, we can define a function $O(N_k)$ whose value is equal to the number of obtained spindle heads. We assume also that this function takes a sufficiently large value if the operations of the set N_k cannot be partitioned into subsets with regard to precedence, inclusion and exclusion constraints, that is, where one of the following conditions holds:

$$\{i,j\} \subseteq N_k,\ \ (i,j) \in (D^{OR} \cup E^{DP}) \qquad (13)$$

$$|\ \{i,j\} \cap N_k| = 1,\ (i,j) \in E^{SP} \qquad (14)$$

$$\{i,j\} \subseteq \mathrm{N}_{kl},\ (i,j) \in E^{DH},\ l=1,\ldots,\ n_k \qquad (15)$$

$$|\{i,j\} \cap N_{kl}| = 1,\ l = 1,\ldots,n_k,\ (i,j) \in E^{SP} \qquad (16)$$

$$\boldsymbol{X}(N_{kl}) = \emptyset,\ l = 1,\ldots,n_k$$
(17)

Optimization Model

The optimization model of the considered decision making problem for *logical layout design* can be formulated as follows:

$$Minimize\ Q(P) = C_1 m + C_2 \sum_{k=1}^{m} O(N_k), \qquad (18)$$

subject to:

$$T(P) \le T_0 \qquad (19)$$

$$\bigcup_{k=1}^{m} N_k = \mathbf{N} \qquad (20)$$

$$N_{k'} \cap N_{k''} = \emptyset,\ \forall\ k',\ k'' = 1,\ldots,m \text{ such that } k' \neq k'' \qquad (21)$$

$$O(N_k) \le \bar{n},\ \ \text{for all } k=1,\ldots,m \qquad (22)$$

$$X_{kl} \in \boldsymbol{X}(N_{kl}),\ \text{for all } k=1,\ldots,m;\ l=1,\ldots,n_k \qquad (23)$$

$$m = m(P) \le \bar{m} \qquad (24)$$

The objective function (18) is the estimation of the equipment cost; constraint (19) provides the required productivity rate; constraints (20-21) ensure the assignment of all the operations from **N**, each operation to one and only one working position; (22) provides precedence constraints for operations, inclusion and *exclusion constraints* for spindle heads and working positions; (23) chooses feasible values of the feed per minute for each spindle head; and (24) is the constraint on the number of working positions.

The values $\bar{m}$ and $\bar{n}$ are defined by the type of the machine: for machines with rotary table $\bar{m} \le 15$ and $\bar{n} = 2$, for machines with mobile table $\bar{m} \le 3$ and $\bar{n} \le 3$. For machines with mobile table the expression (22) is replaced by (22'):

$$O(N_k) \le 2,\ \ k=1,\ldots,m\text{-}1;\ O(N_m) \le 3 \qquad (22')$$

Optimization algorithms are based on the shortest path approach (Dolgui et al., 2000; Dolgui et al., 2008). They find all optimal solutions corresponding to the different machine configurations with different operations' assignment or allocation of spindle heads to working positions. In order to choose a solution to be applied, these solutions can be evaluated by user with other criteria and user's preferences. If the results of the optimization do not satisfy user, it is possible to return to previous stages and make the necessary modifications of constraints and input data.

3D-MODEL AND COST ESTIMATION

The obtained logical layout defines the general configuration of a *transfer machine* and enables designers to complete this logical architecture by selecting the corresponding modular equipment from the library of standard units of *MTE*. At first, designers specify the overall dimensions of the movable table and place the part to be machined on it. The part position defines the angles and positions of the spindle heads.

Then, designers define the dimensions and the specifications of the required equipment that will automatically be designed using the graphical library of standard units. Finally, designers can obtain a preliminary 3D-model of the machine. Figure 3 illustrates a machine with rotary table which consists of six working positions and

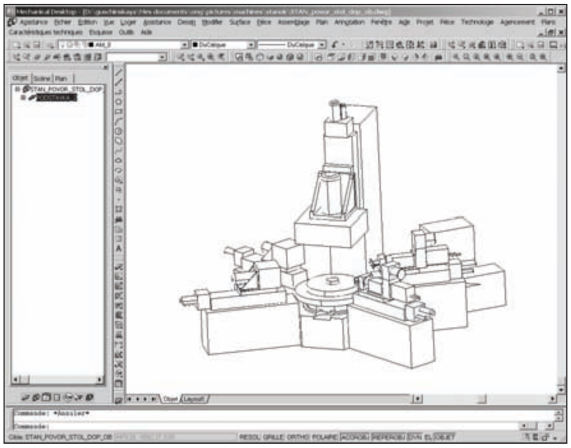


Figure 3. 3D-model of a machine with rotary table

equipped by one vertical spindle head. Figure 4 shows a machine with mobile table, which consists of two working positions.

In order to estimate the total machine cost, additional devices are to be selected, like control, tool storage, and loading-unloading systems. This choice is guided by some automatically generated suggestions and accompanied by the verification of compatibility with all previous decisions. The costs of all selected devices are obtained from the database which contains market prices of standard units (spindle heads and other machine elements). The total cost estimation enables designers to formulate a commercial offer for customers. Therefore, using the decision support system MTE, machine tools manufacturers can provide their clients with technological plans and a commercial offer in really short times. If clients accept this offer then the detailed design of the machine with the chosen configuration is to be prepared in order to establish a manufacturing plan. At this stage more detailed analysis of machine properties is needed, the manufacturability of parts can be verified using, for example, the finite elements model and simulation (Daschenko, 2003).

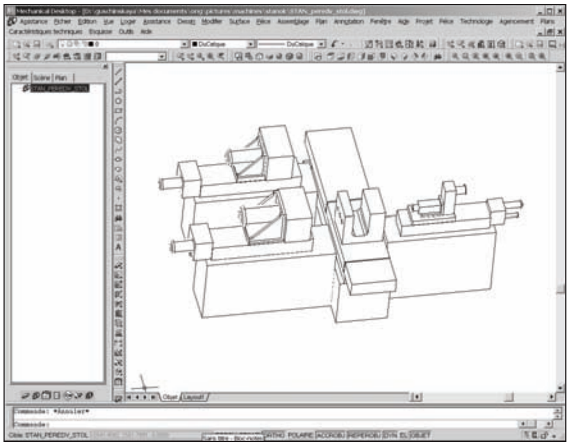

Figure 4. 3D-model of a machine with mobile table

CONCLUSION AND FURTHER RESEARCH

A novel and promising applied area for decision making methods and decision support technologies is the development of decision-aid software tools for manufacturing system design. It is necessary to use conjointly advanced operational research methods, standard decision making approaches, decision support technologies and problem oriented specific rules. We have presented an example of such a decision support system for preliminary *design of machining systems* for mass production.

The integrated *decision support system* MTE was developed to help machine tool designers to obtain a high-quality (and if possible optimal) architecture of *transfer machines*. The system supports the different stages of the logical layout design of a transfer machine: modeling of a part to be machined, process planning, optimization of the machine configuration, its preliminary 3D layout, and cost estimation. The optimization problem of the logical layout is to find the number of working positions and the number of spindle heads, to assign the manufacturing operations to positions, and to choose the cutting modes for each spindle head while minimizing the total equipment cost.

The perspectives of this research consist in the improvement and extension of the suggested approach for a larger class of manufacturing systems: linear *transfer machines*, transfer lines with buffers, multi-flow transfer lines, assembly lines, and so forth. Another promising approach is the integration of the process planning and logical layout steps in a common optimization model using heuristics and meta-heuristics.

KEY TERMS

Feature: A standard element characterized by both technological and geometrical parameters that have meaning in the definition and machining of a part.

Integrated Decision Support Tool for Design of Machining System: A software tool, which includes the functions of part modeling, process planning, logical and physical layouts optimization, and machining system cost estimation. It is used for the preliminary design of the machining systems.

Logical Layout: An assignment of all operations to be executed to pieces of equipment; usually an optimal logical layout is obtained by solving the corresponding line balancing problem.

Physical Layout: An arrangement of pieces of equipment in the production area.

Process Planning: The activity of taking the product design or specification, which is defined in terms of size, shape, tolerances, finish, material properties, and so forth, and transforming it into detailed list of manufacturing instructions such as specifications for materials, processes, sequences, and machining parameters.

Spindle Head (Spindle Box): A device where several tools are fixed to perform several operations in parallel; all tools of the same spindle head have the same parameters (working stroke, feed per minute) and are activated simultaneously.

Transfer Machine: A machine tool used in the mass production of a unique product or a family of similar products by processing the drilling, boring, milling, and other machining operations in a given order on each part machined.

Chapter 2.12

Context in Decision Support Systems Development

Alexandre Gachet
University of Hawaii at Manoa, USA

Ralph Sprague
University of Hawaii at Manoa, USA

INTRODUCTION

Finding appropriate decision support systems (DSS) development processes and methodologies is a topic that has kept researchers in the decision support community busy for the past three decades at least. Inspired by Gibson and Nolan's curve (Gibson & Nolan 1974; Nolan, 1979), it is fair to contend that the field of DSS development is reaching the end of its expansion (or contagion) stage, which is characterized by the proliferation of processes and methodologies in all areas of decision support. Studies on DSS development conducted during the last 15 years (e.g., Arinze, 1991; Saxena, 1992) have identified more than 30 different approaches to the design and construction of decision support methods and systems (Marakas, 2003). Interestingly enough, none of these approaches predominate and the various DSS development processes usually remain very distinct and project-specific. This situation can be interpreted as a sign that the field of DSS development should soon enter in its formalization (or control) stage. Therefore, we propose a unifying perspective of DSS development based on the notion of context.

In this article, we argue that the context of the target DSS (whether organizational, technological, or developmental) is not properly considered in the literature on DSS development. Researchers propose processes (e.g., Courbon, Drageof, & Tomasi, 1979; Stabell 1983), methodologies (e.g., Blanning, 1979; Martin, 1982; Saxena, 1991; Sprague & Carlson, 1982), cycles (e.g., Keen & Scott Morton, 1978; Sage, 1991), guidelines (e.g., for end-user computer), and frameworks, but often fail to explicitly describe the context in which the solution can be applied.

BACKGROUND

A DSS is broadly considered as “a computer-based system that aids the process of decision making” (Finlay, 1994). Sprague uses a definition that indicates key components of the DSS architecture. A DSS is a “computer-based system which helps decision makers confront ill-structured problems through direct interaction with data and analysis models” (Sprague, 1980). In a more detailed way, Turban (1995) defines it as “an interactive, flexible, and adaptable computer-based information system, especially developed for supporting the solution of a non-structured management problem for improved decision making. It utilizes data, provides an easy-to-use interface, and allows for the decision maker’s own insights.” This second definition gives a better idea of the underlying architecture of a DSS. Even though different authors identify different components in a DSS, academics and practitioners have come up with a generalized architecture made of six distinct parts: (a) the data management system, (b) the model management system, (c) the knowledge engine, (d) the user interface, (e) the DSS architecture and network, and (f) the user(s) (Marakas, 2003;Power, 2002).

One section this article, Key Terms, briefly defines nine DSS development methodologies popular in the DSS literature. A typical methodology is represented by the steps in Table 1.

The exact number of steps can vary depending on the aggregation level of each phase. Moreover, steps are usually sequenced in an iterative manner, which means the process can iterate to an earlier phase if the results of the current phase are not satisfactory. Even though these processes are useful from a high-level perspective, we argue that they poorly support the DSS designers and builders to cope with contextual issues. The next paragraphs provide a couple of examples to illustrate this argument. The first example is related to the user interface. The DSS community widely recognizes that the user interface is a critical component of a DSS and that it should be designed and implemented with particular care. But how critical is this component? On the one hand, if we consider a DSS that is intended to be used by a wide range of nontechnical users (for example, a medical DSS for the triage of incoming patients in an emergency room that will be used by nurses and MDs working under pressure), then the user interface is indeed the single most critical component of the DSS, at least from a usability/acceptability point of view. In this context, the human-computer interaction (HCI) literature tells us that usability must definitely be considered before prototyping takes place, because the earlier critical design flaws are detected, the more likely they can be corrected (Holzinger, 2005). There are techniques (such as usability context analysis) intended to facilitate such early focus and commitment (Thomas & Bevan, 1996). On the other hand, if we consider a highly specific DSS that will be handled by a few power-users with a high level of computer literacy (sometimes the DSS builders themselves), then the user interface is less critical and usability considerations can be postponed until a later stage of the development process without threatening the acceptability of the system. This kind of decision has an impact on the entire development process but is rarely considered explicitly in the literature.

Table 1. Phases of the DSS design and development life cycle (Sage, 1991)

1. Identify requirements specifications
2. Preliminary conceptual design
3. Logical design and architectural specifications
4. Detailed design and testing
5. Operational implementation
6. Evaluation and modification
7. Operational deployment

The second example deals with the expected lifetime of the DSS. On the one hand, some DSS are complex organizational systems connected to a dense network of transaction information systems. Their knowledge bases accumulate large quantities of models, rules, documents, and data over the years, sometimes over a few decades. They require important financial investments and are expected to have a long lifetime. For a computer-based system, a long lifetime inevitably implies maintenance and legacy issues. The legacy information systems (LIS) literature offers several approaches to deal with these issues, such as the big bang approach (Bateman & Murphy, 1994), the wrapping approach (Comella-Dorda, Wallnau, Seacord, & Roberts, 2000), the chicken little approach (Brodie & Stonebraker, 1995), the butterfly approach (Wu et al., 1997), and the iterative re-engineering approach (Bianchi, Caivano, Marengo, & Vissagio, 2003). Some authors also provide methods fostering the clear separation between the system part and the knowledge base part, in order to maximize reusability (Gachet & Haettenschwiler, 2005). On the other hand, some DSS are smaller systems used to deal with very specific—and sometimes unique—problems, that do not go past the prototyping stage, that require minimal finances, and use a time-limited knowledge base. Maintenance and legacy issues are less salient for these systems and their development follows a different process.

We describe in the coming sections of this article a unifying approach to DSS development allowing DSS designers to explicitly take these contextual aspects into considerations in order to guide the development process of a DSS. This new approach is based on the concept of value-based software engineering.

VALUE-BASED SOFTWARE ENGINEERING

Suggesting that the DSS community never considered the context of a DSS prior to its development would be unfair. Several authors acknowledge that a systems design process must be specifically related to the operational environment for which the final system is intended (Sage, 1991; Wallace et al., 1987). For example, Sprague and Carlson (1982) explicitly specified in their "DSS action plan" a phase consisting of steps to develop the DSS environment. The purpose of this phase is to "form the DSS group, articulate its mission, and define its relationships with other organizational units. Establish a minimal set of tools and data and operationalize them." (p. 68). Nevertheless, how these tasks should be carried out is not specified. In this section, we propose an approach allowing DSS designers to model contextual value propositions and perform feedback control of a DSS project. This approach is inspired by the concept of value-based software engineering (Boehm & Guo Huang, 2003).

Two frequently used techniques in value-based software engineering are the benefits realization approach and the value-realization feedback process. The benefits realization approach (Thorp, 2003) allows developers to determine and reconcile the value propositions of the project's success-critical stakeholders. The centerpiece of this approach is the results chain (Figure 1). This chain establishes a framework linking initiatives that consume resources, such as implementing a new DSS, to contributions (describing the effects of the delivered system on existing operations) and outcomes (which can lead either to further contributions or to added value, such as increased profit). A results chain links to goal assumptions, which condition the realization of outcomes. Once the stakeholders agree on the initiatives of the final results chain, "they can elaborate them into project plans, requirements, architectures, budgets, and schedules." (Boehm & Guo Huang, 2003, p. 36)

Once the benefits-realization approach is completed, stakeholders can monitor the development of the project using the value-realization feedback process (Figure 2). As explained by Boehm and Guo Huang (2003):

The results chain, business case, and program plans set the baseline in terms of expected time-

Figure 1. Benefits-realization approach results chain (adapted from Boehm & Guo Huang, 2003)

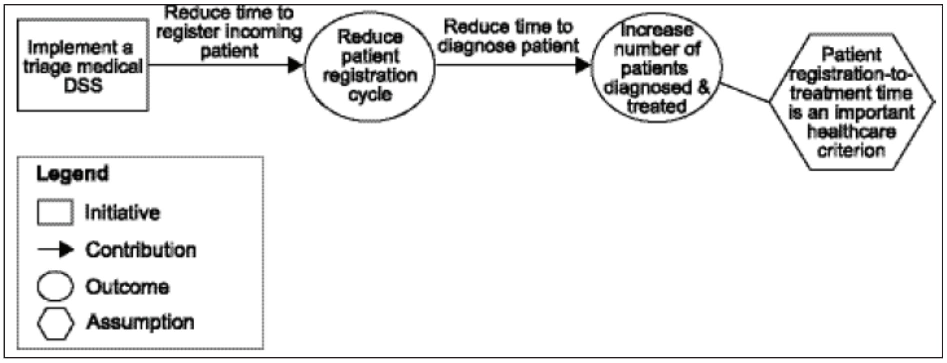

Figure 2. The realization feedback process (adapted from Boehm & Huo Huang, 2003)

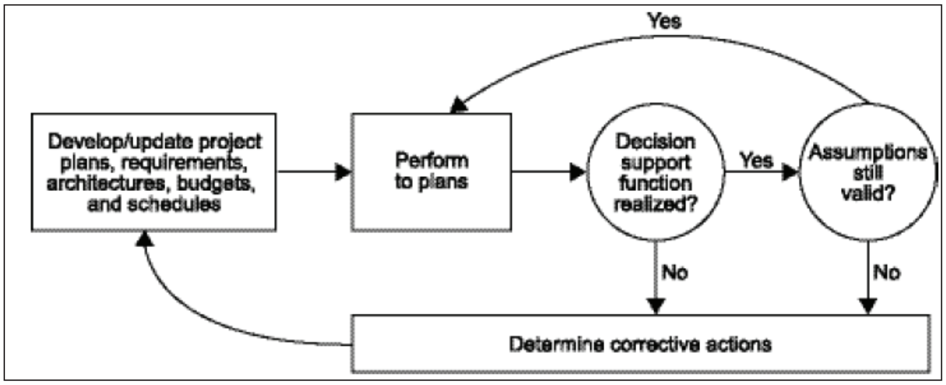
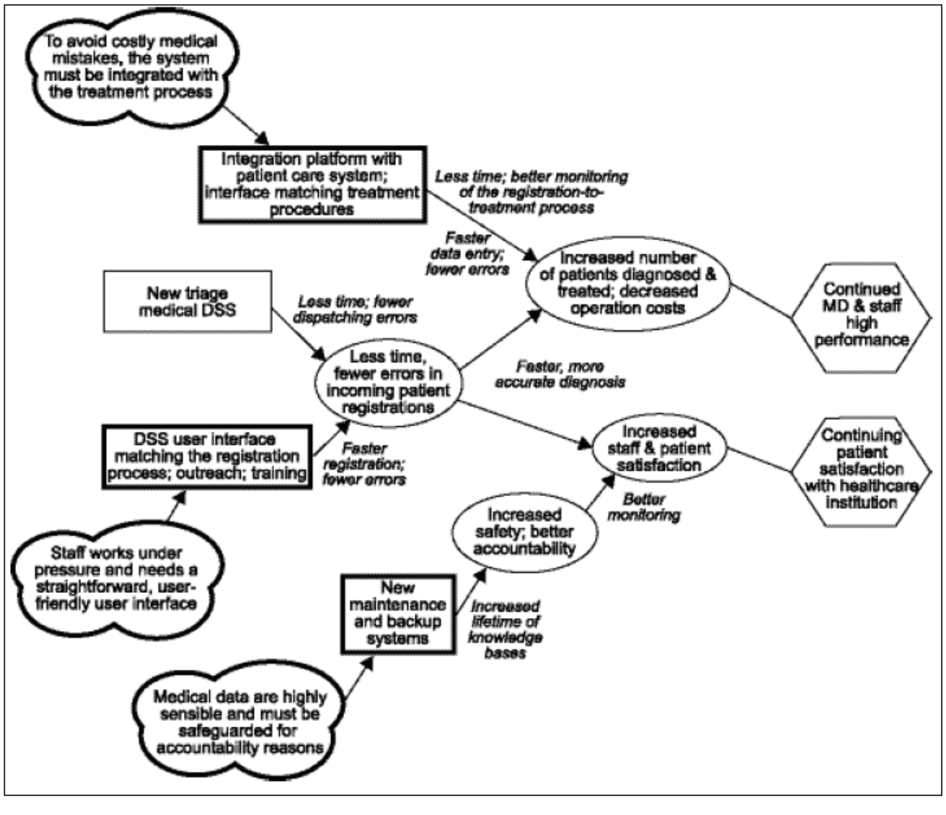


phased costs, benefit flows, returns on investment, and underlying assumptions. As the projects and program perform to plans, the actual or projected achievement of the cost and benefit flows and the assumptions' realism may become invalid, at which point the project team will need to determine and apply corrective actions by changing plans or initiatives, making associated changes in expected cost and benefit flows. (p. 37)

One obvious advantage of this feedback process is its ongoing consideration of the goal assumptions' validity. The development of an organizational DSS can take time and the project's plan can change several times during the whole process. It is therefore important to regularly monitor the process to be sure that the system still meets the local needs and helps answer the right questions (the popular "do the right thing" proposition). Otherwise, a DSS can be seen as very successful in terms of cost oriented earned value, but a complete disaster in terms of actual organizational value. The feedback process used in value-based software engineering focuses on value realization. Assessing the value of a transaction information system is a difficult task (Tillquist & Rodgers, 2005). However, assessing the value of a DSS is even more difficult, since its main function (supporting decision-makers) leads to effects that are very difficult to measure in isolation from the complementary processes and activities in which the DSS is embedded. Even worse, measuring the value of a DSS during its development is almost impossible. Therefore, the feedback process that we propose in Figure 2 focuses more of the realization of the decision support function of the DSS ("do the thing right") rather than on an objective measure of value realization. Another advantage of this process is that it clearly identifies the design and implementation feedback cycles of a DSS project. First, the upper loop where the two questions are answered positively represents the implementation cycle during which the DSS is gradually built by the DSS builder according to design plans. Second, the lower loop where either one of the two questions is answered negatively represents the design feedback cycle, during which the DSS design must be overhauled by the DSS designer to make sure that the DSS will "do the right thing right." This clear identification of both cycles is important because it overcomes a problem found in many DSS development processes that make an abundant use of feedback loops between their various phases, but fails to explain how the DSS designer and builder can go back to a previous stage in case of a goal failure at a later stage. Finally, another advantage of this feedback process is that it emphasizes the fact that context is not simply a state, but part of a process: "it is not sufficient for the system to behave correctly at a given instant: it must behave correctly during the process in which users are involved" (Coutaz, Crowley, Dobson, & Garlan, 2005, p. 50). Even though Coutaz et al. (2005) are mostly interested in the context of a system in use, we argue that the statement remains valid for the entire development process of a system.

Modeling the context-based development of a DSS consists in defining the initiatives, contributions, outcomes, and goal assumptions of a results chain. For the purpose of this article, Figure 3 uses the example scenario of a medical DSS for the triage of patients in an emergency room and extends the results chain of Figure 1 by adding new initiatives explicitly dealing with the two issues we

Figure 3. Extended results chain for a triage medical DSS. Stakeholders and contextual information are explicitly considered



mentioned in Section 2, namely the user interface and the maintenance and legacy issues. A third issue, integration with the patient care system, is also considered. These additional initiatives are shown with bold borders. Needless to say, a realistic and complete results chain for a triage medical DSS would be much more complicated than Figure 3, with many more initiatives, outcomes, and goal assumptions related to other value propositions. For the sake of simplicity, however, we decided to limit the scope of the results chain in order to improve its readability. The ultimate purpose of the figure is to show how the benefits realization approach allows DSS designers to dynamically identify the project's success-critical stakeholders and to determine their propositions in terms of decision support.

Figure 3 also introduces a new kind of symbol, graphically represented as a cloud, which identifies contextual requirements. A contextual requirement is defined as a specification of a contextual imperative. The three contextual requirements of Figure 3 describe three imperatives related to the DSS integration with the rest of the patient care system, the DSS user interface, and the DSS maintenance, respectively.

Contextual requirements adequately supplement functional requirements. Traditional techniques to capture functional requirements (for example, UML use case diagrams in the object-oriented community at large) focus on describing how to achieve business goals or tasks. As such, they help define the inner environment of the target system. Defining the inner environment of the system, however, is only one part of the design phase. The DSS designer also needs to define the conditions for goal attainment, which are determined by the outer environment of the system. This is where contextual requirements come into play. The importance of contextual requirements to model the outer environment of the DSS can not be overemphasized. As Simon (1996) indicates, "in very many cases whether a particular system will achieve a particular goal of adaptation depends on only a few characteristics of the outer environment" (p. 11). For example, our example triage DSS is most likely to fail, independently from its intrinsic qualities (the inner environment), if it does not consider the working conditions of the medical staff, the sensitivity of medical data, and the tremendous risk associated with medical mistakes (three characteristics of the outer environment).

Obviously enough, functional requirements are driven by the contextual requirements. For example, the first contextual requirement in Figure 3 (in the top left corner) considers the legal environment of the system (medical mistakes can lead to costly malpractice lawsuits) and indicates how important it becomes to tightly integrate the triage DSS with the rest of the patient care system, to ensure patients are being given the drugs corresponding to the diagnosis. This integration also leads to an increased number of patients diagnosed and treated and keeps up the performance of the medical staff. Based on this contextual requirement, the DSS builder can derive a set of functional requirements to attain this integration goal.

The second contextual requirement in the results chain (in the middle left part of Figure 3) explicitly considers the work environment of the medical staff and shows that MDs, nurses, staff, and patients are considered as important stakeholders in the initiatives. Their satisfaction and acceptance of the new system are deemed critical for the DSS success and depend on a straightforward, user-friendly user interface. Expected outcomes such as the increased staff and patient satisfaction, or initiatives focusing on user and system interfaces acknowledge this fact.

Finally, the initiative to include maintenance and backup systems because medical data are highly sensible (last contextual requirement in Figure 3) illustrates the necessity to safeguard the data and knowledge bases of the entire infrastructure, for increased safety and better accountability.

With DSS more than with any other kind of IS, working on functional requirements that are not driven by contextual requirements is like shooting in the dark. You may end up with a great functionality from a technical point of view, but still be completely off target in the context of the target system. In short, contextual requirements are used by the DSS designer to define the outer environment of the system, which determines the conditions for goal attainment. Contextual requirements drive the functional requirements used by the DSS builder to define an inner environment capable to achieve these goals.

Once the contextual requirements and the initiatives of the results chain are set, the DSS designer can turn them into plans, architectures, budgets, and schedules. At that stage, traditional DSS development processes and methodologies (see the section on Key Terms for examples) can be used with a context-based flavor. Instead of focusing on traditional performance issues, the context-aware DSS designer can focus on the most salient and relevant aspects of the target system. In our example DSS for medical triage, the requirements specification phase should focus on user interface requirements (to guarantee the system acceptability) and on data integration and workflow activities (to prepare a smooth integration with the global patient care system). Maintenance and backup considerations are traditionally postponed until the last step of the process (operational deployment). In our example, however, we clearly identified maintenance and backup as critical value propositions for the DSS. Therefore, it is wise to move the corresponding requirements to the first step of the process. Traditional methodologies defined in the Key Terms section, such as functional mapping (Blanning, 1979), decision graph (Martin, 1982), and descriptive and normative modeling (Stabell, 1983), can be used to identify functional requirements specifications.

CONCLUSION

In this article, we have described a unifying approach to formalizing the notion of context in the study of DSS development. The proposed solution relies on the concepts of value-based software engineering and contextual requirements. It provides DSS designers and builders with the appropriate techniques to explicitly consider the context of the target DSS during the entire development process.

The first technique is the benefits realization approach, which uses diagrams called results chains to determine and reconcile the value propositions of the project's success-critical stakeholders. The results chain establishes a framework linking contextual requirements to initiatives, contributions, and outcomes. The results chain also links to goal assumptions, which condition the realization of outcomes.

The second technique is the realization feedback process, which regularly monitors the realization of the expected decision support functionalities and the validity of the goal assumptions. If the decision support functionalities are not realized, or the assumptions' realism becomes invalid, the DSS designers need to determine and apply corrective actions by changing plans or initiatives.

Contextual requirements are used by the DSS designer to define the outer environment of the system, which determines the conditions for goal attainment. Contextual requirements then drive the functional requirements used by the DSS builder to define an inner environment capable of achieving these goals.

We provided an example to illustrate how a somewhat impractical, context-free DSS development life cycle can be turned into a context-based life cycle focusing on the most success-critical aspects of the target DSS, without overwhelming the DSS designers with long checklists that are not necessarily relevant in the context of the target system.

The inability of the DSS community to come up with unified and standardized methods to develop decision support systems is a recurring topic that has kept researchers and practitioners busy for the past three decades. We strongly believe that our approach finds a partial answer to the problem by explicitly acknowledging the fact that DSS can be widely different in their goals, scope, depth, lifetime, and costs. Rather than looking for an elusive context-free, one-size-fits-all solution, we propose a context-based set of tools able to formalize the DSS environment and context before choosing the appropriate development methodology. It is not our intention to define yet another solution in the existing proliferation of processes and methodologies for DSS development. Quite the opposite, we believe that our approach can help the field of DSS development enter in a formalization, or control, stage. Finally, it is our hope that the approach described in this article provides a vehicle for researchers and practitioners to develop better and more successful DSS.

KEY TERMS

Design Cycle: DSS development methodology introduced by Keen and Scott Morton in 1978 (Keen & Scott Morton, 1978) which can be considered as the ancestor of most of the other DSS development processes and as an authoritative model. The global cycle is made of several steps focusing both on the decision support functionalities and their implementation in the actual system.

Decision Graph: DSS development methodology introduced by Martin in 1982 (Martin, 1982) as a modification of the descriptive system dynamics model. The methodology emphasizes graphic rather than computer simulation results, changes terminology from an engineering to a decision oriented context, and allows the use of a standard computer template. The methodology is purely graphical and uses symbols inspired by system dynamics structures. Decision graphs are used to create the decision model, with the purpose of identifying pertinent decisions.

Decision-Oriented DSS Development Process: DSS development process introduced by Stabell in 1983 (Stabell, 1983) in reaction to the technocentric, system oriented development methodologies proposed at the beginning of the 1980s. The development process relies on interrelated activities collectively labelled decision research. Emphasis in this decision-oriented, normative methodology is placed on changing the existing decision process to increase decision-making effectiveness.

Decision Support Engineering: DSS development methodology proposed by Saxena (1991) as a comprehensive methodology based on a life cycle model of DSS development, which encompasses an engineering approach to DSS analysis and design. Prototyping is also an important part of the methodology.

DSS Development Phases: DSS development methodology proposed by Sprague and Carlson in 1982 (Sprague & Carlson, 1982). The methodology can be broken down into two broad parts: an action plan and the ROMC methodology, a processing dependent model for organizing and conducting systems analysis in DSS.

DSS Prototyping (also known as evolutive approach): DSS development methodology defined by Courbon in 1979 (Courbon et al., 1979, 1980) as a methodology based on the progressive design of a DSS, going through multiple short-as-possible cycles in which successive versions of the system under construction are utilized by the end-user.

DSS Design and Development Life Cycle: DSS design and development methodology proposed by Sage in 1991 (Sage, 1991) as a phased life-cycle approach to DSS engineering. Its basic structure is very close to the software development life cycle (SDLC) methodology. However, it tries to avoid the drawbacks of the SDLC by embedding explicit feedback loops in the sequential life cycle and by promoting prototyping during system implementation in order to meet the iterative requirements of a DSS development process.

End-User DSS Development: Refers to people developing decision support applications for themselves or for others even though they are not trained IS professionals.

Functional Mapping (sometimes referred to as functional category analysis): DSS development methodology introduced by Blanning in 1979 (Blanning, 1979) as a DSS design approach mapping the functions of a DSS with the organizational units of the company. The methodology clearly identifies the responsibilities and/or benefits of the various organizational units vis-a-vis the DSS.

Chapter 2.13

Flexible Spatial Decision-Making and Support: Processes and Systems

Shan Gao
University of Auckland, New Zealand

David Sundaram
University of Auckland, New Zealand

ABSTRACT

Spatial decision-making is a key aspect of human behaviour. Spatial decision support systems support spatial decision-making processes by integrating required information, tools, models, and technology in a user-friendly manner. While current spatial decision support systems fulfill their specific objectives, they fail to address many of the requirements for effective spatial problem solving, as they are inflexible, complex to use, and often domain-specific. This research blends together several relevant disciplines to overcome the problems identified in various areas of spatial decision support. We proposed a generic spatial decision-making process and a domain-independent spatial decision support system (SDSS) framework and architecture to support the process. We also developed a flexible SDSS to demonstrate an environment in which decision-makers can utilize various tools and explore different scenarios to derive a decision. The use of the system is demonstrated in a number of real scenarios across location, allocation, routing, layout, and spatio-temporal problems.

INTRODUCTION

Decision-making is an essential element of our lives and critical for business success, because many natural phenomena and socio-economic activities take place in a spatial context. Spatial decision-making (SDM) becomes one of the important aspects of human behaviour. SDM activities are either dependent or influenced by geographical information. They are based on spatial problems that are normally semi-structured or ill-defined. Spatial problems are also multi-dimensional as they contain both spatial and non-spatial aspects.

It is not easy to measure or model all the aspects of a spatial problem in a single step. Therefore, a sophisticated modelling process is needed for solving these spatial problems.

Spatial decision-making usually involves a large number of alternative solutions, and these alternatives need to be managed using an appropriate scenario management facility. The multi-criteria decision-making (MCDM) method helps the decision-maker to select a solution from the many competitive alternatives. It facilitates the evaluation and ranking of the alternative solutions based on the decision- maker's knowledge or preference with respect to a set of evaluation criteria.

Decision support systems (DSS) have been proposed to support decision-making. Silver (1991) broadly defines a decision support system as a computer-based information system that affects or is intended to affect the way people make decisions. A focused DSS definition given by Sprague and Carlson (1982) states that a decision support system is an interactive computer-based system that helps decision-makers to solve unstructured problems by utilising data and models. To support spatial decision-making, a variety of systems have been developed: These include geographic information systems (GIS) and spatial decision support systems (SDSS). Our focus is on SDSS in this research. Peterson (1998) defines a spatial decision support system as an interactive and computer-based system designed to support a user or a group of users in achieving higher effectiveness for solving semi-structured or non-structured spatial decision problems.

As technology progresses, there is increasing opportunity to use SDSS in a variety of domains. Flexible support of decision-making processes to solve complex, semi-structured or unstructured spatial problems can offer advantages to individuals and organisations. We synthesise ideas, frameworks, and architectures from GIS, DSS, and SDSS. In addition, concepts from spatial modelling, model life cycle management, scenario life cycle management, knowledge management, and MCDM methodology are explored and leveraged in the implementation of a flexible spatial decision support system using object-oriented methodology and technology.

BACKGROUND

Moloney, Lea, and Kowalchek (1993) observe that about ninety percent of business information are geographically related and cover diverse domains, for example, resource management, environmental modelling, transportation planning, and geo-marketing. Spatial problems are normally categorised into allocation, location, routing, and layout problems based on their geographical features. The primary goal of SDSS is to support decision-making activities using its flexible modelling capabilities and spatial data manipulation functions. SDSS encompass spatial analytical techniques and enable system output in a variety of spatial forms. The characteristics of the spatial data, models, and operations as well as the integration processes of non-spatial systems with spatial systems make SDSS more complex. Currently- available SDSS frameworks and architectures are suitable for their specific objectives. However, they fail to properly address many of the requirements of a generic, flexible, and easy-to-use SDSS. As we have noted earlier, incorporating a GIS with a DSS develops some of SDSS frameworks and architectures. However, the existing SDSS frameworks and architectures are neither comprised of all the DSS components, nor are they generic. Fedra's (1995) framework is good for analytical modelling, but the solver is tightly integrated within the model, which does not provide flexibility in using a solver with different models. It does not provide any mapping instrument for flexible integration of model and data; rather it uses a pre-customised integration system that is limited to a specific domain. The model management framework of Yeh and Qiao

(1999) supports the modelling life cycle but overlooks spatial presentation functionalities. The dynamic environmental effects model (DEEM) is a software framework that provides optimal interoperability among environmental models, supports flexible decision-making, but fails to address scenario development and run-time model generation. The SDSS framework proposed by Armstrong and Densham (1990) does not separate model and solver. The knowledge management system framework of Mennecke (1997) does not pay attention to spatial visualisations, but rather focuses on the queries and reports. Some implemented SDSS are good in modelling systems, for example, Illinois River Decision Support System (ILRDSS) and Environmental Decision Support System (EDSS). Some are good in spatial data analysis and visualisation, for example, GRASSLAND, but none of these systems is generic and domain-independent.

The scenario-based SDSS architecture of Hall, Bowerman, and Feick (1997) is the only one that supports scenario management and facilitates the multiple scenario development. The system allows the decision-makers to generate, save, and recall solutions and supports comparing different scenarios. It is well developed for solving domain specific spatial problems, but the scenario evaluation has not been fully explored in this system as a non-spatial model; for example, the evaluation model has been absent in this framework. None of these frameworks and architectures addresses multi-criteria decision-making.

ISSUES, CONTROVERSIES, PROBLEMS

Though significant progress has been made in the context of decision-making and decision support systems, there has not been sufficient emphasis on SDM nor on SDSS. Densham (1991) argues that the main objective of a SDSS is to support decision-makers to make well-informed decisions based on complex spatial tasks. The processes and the various mechanisms used for solving spatial problems are also complex. The available technologies related to spatial decision-making are neither quite sufficient nor easy-to-use for managing this complexity.

Decision-makers often perceive the decision-making process adopted to solve complex multi-dimensional spatial problems as unsatisfactory. Decision-makers have been using the decision-making frameworks and processes for many years, but the general approaches proposed by Simon (1960) and others were not particularly developed for solving spatial problems; rather they provide a guideline for development of decision-making processes. Though Malczewski (1999) has proposed a multi-criteria decision-making framework, the implementation of the process has not been fully explored in the spatial context. A generic process to guide decision-makers to solve spatial problems is lacking. Decision-makers have to rely on their own processes and experience for spatial decision-making.

On the other hand, existing GIS, DSS, and SDSS that support decision-makers have their limitations in solving spatial problems. GIS do well in managing spatial data, but lack flexible modelling capacity. DSS are typically used in the non-spatial domain. SDSS encompass analytical techniques inherited from DSS and spatial modelling and various spatial input and output mechanisms provided by GIS to support decision-makers to make well-informed decisions. Densham (1991) argues that SDSS should facilitate a number of functions such as spatial data input, model-based analyses, and powerful visual presentations. Furthermore, these systems generally do not facilitate flexible spatial data manipulation mechanisms and lack output facility for presentation of the result of the decision-making process. They do not provide knowledge storage facility and lack a process-oriented user interface, thus enlarging the complexity of using the systems. A review of SDSS frameworks and architectures led us to conclude that current approaches fulfill their specific objectives, but fail to address many of the requirements of a generic, flexible, and easy-to-use SDSS.

In addition, model and scenario management processes have not been well developed in SDSS. The modelling process is ad hoc rather than generic and does not address the need of separation and integration of spatial and non-spatial models. Research indicates that the difficulties in synthesising various decision alternatives are primary obstacles to spatial problem-solving (Ascough II et al., 2002). Some SDSS support the development of single spatial or non-spatial scenario at one time, but few systems support integration of spatial and non-spatial scenarios to develop numerous multi-attribute spatial scenarios simultaneously. And also, spatial problems often have numerous alternative solutions, and use multiple criteria upon which they are evaluated. These complex spatial problems can be solved efficiently by incorporating the analytic modelling capabilities of the application specific spatial decision support system. The multi-criteria decision-making helps in screening alternatives and identifying the best solution. At this point many strategic requirements of SDSS have not been implemented completely. Their capability to solve complex multi-dimensional spatial problems is very limited.

Based on the problem areas identified in the field of spatial decision-making, we believe that a generic process for solving complex spatial problems is needed for achieving high effectiveness in spatial decision-making. The ideas from related disciplines (i.e., spatial modelling, model and scenario life cycle management, knowledge management and MCDM) need to be addressed in this process. Current SDSS frameworks and architectures address or implement one or a combination of requirements that are needed for complex spatial problem-solving, but they are incapable of managing all the issues required in a single coherent way. Synthesising ideas, frameworks, and architectures from related disciplines helps to overcome some of the problems identified in spatial decision support systems. A generic spatial decision-making process and a domain-independent SDSS framework and architecture will improve spatial decision quality and provide more opportunities for the use of SDSS.

SOLUTIONS AND RECOMMENDATIONS

To address the issues of spatial decision-making and spatial decision support systems, we first propose a spatial decision-making process that allows the decision makers to better use SDSS to solve spatial problems in a generic way, thus resulting in a better decision. We then develop a flexible spatial decision support system (FSDSS) framework and architecture to support this spatial decision-making process. The FSDSS provides flexible spatial data manipulation facility and supports integration of spatial and non-spatial data; it also facilitates the entire model and scenario management life cycle process, as well as support for multi-criteria spatial problem solving. We further implement a prototypical FSDSS that acts as a proof-of-concept for these proposals.

Spatial Decision-Making Process

Malczewski (1997) identifies *complexity*, *alternatives*, and *multi-criteria* characteristics as key features of spatial problems. Spatial problems are complex because they are semi-structured or ill-defined in the sense that the goals and objectives are not completely defined. Spatial problems are multi-dimensional and often related to non-spatial information. Each spatial problem can have a large number of decision alternative solutions. These alternative solutions to the spatial decision problems are normally characterised by multiple criteria upon which they are judged.
