Salmeron (2002) reports that "*it is surprising that external information is so seldom included in Spain*" (p. 43) for tactical decision-making or strategic decisions. This can be possibly accounted for by the fact that most large Spanish organizations which have implemented EIS, are first-generation EIS (Salmeron, 2002). The external environment has been found to be an important predictor of EIS use (Watson et al., 1991). Executives need information from outside the organization about facts and things happening in their external environment. Research into environmental scanning highlights the outside view of an organization's boundary and recognizes that strategic thinking begins with a study of the external environment.

The business environment is seen as a source of information that continually creates signals and messages that organizations should consider important. Continuous scanning is a deliberate effort to obtain specific information that follows pre-established methods. It is characterised by a proactive, broad in scope, part of an organization's planning process. While the external dimension of the business environment has been emphasised with respect to strategic uncertainty and strategic information scanning, the question arises around the "nature" of the information included or held by EIS. This question is of critical importance for SQ since without an executive being able to focus on or interpret cues from the "right" information, the executive cannot make appropriate strategic planning decisions for addressing the future impact of these cues. It is therefore important that EIS should contain the "right" types of information and sources of this information (whether it be scattered in an organization's internal and/or external environments) should facilitate strategic decision-making for executives. In order to gauge the current situation in respect of this information in EIS and for managing future EIS development, the authors decided to undertake research, using questionnaire surveys, on EIS in organizations in two selected countries: South Africa and Spain. The findings from this research will serve to contribute to our understanding and knowledge of current EIS (as used towards SQ by executives) and for future EIS development.

In the next section, the EIS research undertaken in South Africa and Spain is described. A comparative analysis and discussion of the authors' results is then given.

EIS RESEARCH UNDERTAKEN IN SOUTH AFRICA AND SPAIN

The authors compared two studies of EIS implementations in organizations in South Africa and Spain. The rationale for the comparative EIS study in these two selected countries is to identify any similarities and differences with respect to:

- Types of information included in EIS
- How information is held by EIS in organizations
- Sources of information that support EIS in organizations

This is useful as any information shortcomings identifies which do not facilitate SQ for executives can then be meaningfully addressed in future EIS development. The research methodologies adopted in these EIS survey studies in South Africa and Spain studies are now discussed.

Research Methodology in South African EIS Survey

A survey questionnaire was developed based on previous instruments used in published research papers. The instrument was validated using expert opinion. Four academics participated in separate field tests. A similar process was undertaken by Rainer and Watson (1995b) who solicited expert opinion for "additions, modifications and/or deletions to the survey" instrument. A survey instrument was submitted to three EIS software vendors (Cognos®, JDEdwards®, and ProClarity®) in South Africa. A senior employee (e.g., managing director) from each vendor independently furnished some suggestions regarding the survey instrument. Using the "snowball" sampling method (Biernacki &Waldorf, 1981), the survey instrument was administered to an EIS representative in 31 organizations in South Africa during the period May to June 2002. The representatives were from the following three constituencies:

- EIS executives/end-users who utilize EIS
- EIS providers (i.e., persons responsible for developing and maintaining the EIS in the organization)
- EIS vendors or consultants in the EIS arena

These three constituencies were identified and used in EIS research by Rainer and Watson (1995a). The use of multiple perspectives is frequently suggested in IS research.

Organizations considered for survey were chosen over a spread of industries (e.g., banking, manufacturing, retail). Where an organization had implemented more than one EIS, the most recent EIS implementation was selected for survey purposes. All respondents were computer proficient and were able to provide a meaningful business perspective on their organization's EIS implementation.

From the previous EIS studies reflected in Table 1, it will be noted that this study of 31 organizations exceeds the previous EIS survey sample size in South Africa (during 1995 I. J. Steer surveyed 24 organizations) and the majority of EIS sample sizes in other countries.

For brevity in this chapter, this EIS study in South Africa is referred to as the Averweg (2002) study. The research methodology adopted in the EIS study in Spain is now discussed.

Research Methodology in Spanish EIS Survey

A survey instrument was used to gather data to develop the EIS study in Spain. The questionnaire used was based upon previous EIS literature—mainly the works of Watson et al. (1991), Fitzgerald

Table 1. Investigations about EIS with descriptive endings

Authors	Year	Investigation	Country	Replies (n)
Watson, H.J., Rainer, R.K., Jr., & Koh, C.E.	1991	*Executive Information Systems: A Framework for Development and a Survey of Current Practices*	United States of America	112 suitable replies of which 50 have an EIS in operation or in an advanced stage of implementation
Fitzgerald, G.	1992	*Executive Information Systems and Their Development in the U.K.*	United Kingdom	77 questionnaires received, 36 of whom are proceeding with an EIS
Watson, H.J., Rainer, R.K., Jr., & Frolick, M.N.	1992	*Executive Information Systems: An Ongoing Study of Current Practices*	United States of America	68 questionnaires received of which 51 indicated they have an EIS
Steer, I.J.	1995	*The Critical Success Factors for the Successful Implementation of Executive Information Systems in the South African Environment*	South Africa	24 questionnaires from organizations with EIS implementation
Thodenius, B.	1995	*The Use of Executive Information Systems in Sweden*	Sweden	29 replies from organizations with EIS implementation
Watson, H.J., Watson, T., Singh, S., & Holmes, D.	1995	*Development Practices for Executive Information Systems: Findings of a Field Study*	United States of America	43 suitable questionnaires from organizations with EIS implementation
Allison, I.K.	1996	*Executive Information Systems: An Evaluation of Current UK Practice*	United Kingdom	19 suitable questionnaires received from organizations with EIS
Park, H.K., Min, J.K., Lim, J.S., & Chun, K.J.	1997	*A Comparative Study of Executive Information Systems between Korea and the United States*	Korea and United States of America	27 suitable questionnaires from organizations with EIS implementation
Pervan, G.P., & Phua, R.	1997	*A Survey of the State of Executive Information Systems in Large Australian Organizations*	Australia	12 suitable questionnaires from organizations with EIS implementation
Poon, P., & Wagner, C.	2001	*Critical success factors revisited: success and failure cases of information systems for senior executives*	Hong Kong, China	6 suitable questionnaires from organizations with EIS implementation

(1992), Watson and Frolick (1993), Thodenius (1995, 1996) and Watson et al. (1995) were analyzed. Questions and items were translated and adapted to the EIS context in Spain.

The survey was carried out in Spain from January to June 1998. A pilot test of the survey was conducted in order to assess content validity. The instrument was pretested with four EIS consultants and three business and IS professors. Suggestions were incorporated into a second version that was then tested by two other management professors. No additional suggestions were made. Bias in response from misinterpretation of the survey instrument was therefore reduced.

The sample was selected following the "snowball" sampling method obtaining an initial list of 178 organizations based on the contributions of seven software development and distribution organizations and 4 consulting organizations. Between March and June 1998, the manager in charge of the EIS implementation was contacted via telephone. In this survey the existence of an operative EIS (or at least an EIS under development and implementation) was confirmed. After explaining the study's objectives to the persons responsible for EIS implementation, they were asked for their collaboration. Following this communication process, cooperation of 136 organizations was achieved.

Valid responses from 75 organizations were obtained—this represents a participation of 55.2%. After analysing the EIS situation in this group of entities, 70 questionnaires which could be analyzed were selected. These questionnaires represented organizations with EIS, operative or in a development/implementation stage sufficiently advanced as to enable the answering of the questions asked. This number of valid questionnaires is higher than any obtained in previous EIS descriptive studies—see Table 1. For brevity in this chapter, this EIS study in Spain is referred to as the Roldán (2000) and Roldán and Leal (2003a) studies.

Comparative Analysis and Discussion of Two EIS Surveys

Tables 2 to 7 presented in this chapter were extracted from the Averweg (2002), Roldán (2000), and Roldán and Leal (2003a) studies and refer to the EIS surveys conducted in organizations in South Africa and Spain respectively.

The number of permanent employees in organizations participating in the EIS study in South Africa and Spain is reflected in Table 2.

From Table 2, 64.6% of organizations surveyed in South Africa had more than 500 employees. Some 53.3% of organizations surveyed had a gross annual turnover exceeding ZAR500 million (approximately U.S. $72 million).

In the case of the EIS study in Spain, according to the European Union classification, most of the participating entities were large organizations and 71.0% had more than 500 employees (see Table 2). Some 62.0% of organizations surveyed had gross revenues exceeding U.S. $139 million.

A rank descending order of applications for which EIS is used in organizations in the Averweg (2002) study is given in Table 3. Research has found that the accessibility of information is more important than its quality in predicting use (O'Reilly, 1982). It has been shown that accessibility of information has a significant influence on perceived usefulness and perceived easy of use of EIS (Pijpers, Bemelmans, Heemstra, & van Montfort, 2001). Furthermore, Roldán and

Table 2. Number of permanent employees in organizations: Frequency and percentage

	South Africa (N=31)	**Spain (N=69)**
More than 5,001 employees	6 (19.5%)	12 (17.4%)
Between 2,001 and 5,000 employees	5 (16.1%)	9 (13.0%)
Between 501 and 2,000 employees	9 (29.0%)	28 (40,6%)
Between 251 and 500 employees	5 (16.1%)	12 (17.4%)
Between 51 and 250 employees	5 (16.1%)	6 (8.7%)
Less than 51 employees	1 (3.2%)	2 (2.9%)

Table 3. Rank descending applications for which EIS is used: Frequency and percentage (multiple answer question)

	South Africa (N=31)
Access to projected trends of the organization	23 (74.2%)
Access to current status information	22 (71.0%)
Performing personal analysis	16 (51.6%)
Querying corporate and external data bases	16 (51.6%)
Office automation activities	5 (16,1%)
Measuring Key Performance Indicators (KPIs)	1 (3.2%)

Leal (2003b) report that EIS service quality has a greater effect on EIS user satisfaction than EIS information quality. Therefore, access to updated online information is a basic characteristic of EIS (Houdeshel & Watson, 1987; Martin, Brown, DeHayes, Hoffer, & Perkins, 1999).

The different types of information included in an EIS in an organization is given in Table 4. From Table 4, for organizations surveyed in South Africa, financial information (90.3%) appears as the most important item followed by business/commercial sales (74.2%) and then strategic planning (35.5%). In the Roldán and Leal (2003a) study, the three highest ranking types of information held by an EIS in an organization are business/commercial sales information (82.9%), financial information (65.7%) and production information (55.7%). While previous research studies agree in presenting these three types of information (sales, financial, and production) as the most relevant ones (Allison, 1996; Kirlidog, 1997; Thodenius, 1995), the Averweg (2002) study partially support these findings with business/commercial Sales (74.2%) and finance (90.3%) types of information. Executives taking cues from trends of the organization is an integral component of SQ.

Holding strategic planning information in EIS in organizations in South Africa appears to have a higher importance than holding production information (Averweg, Erwin, & Petkov, 2005). In this respect, the low percentage in EIS in Spain that include strategic planning information (14.3%) seems to indicate the systematical failure of many EIS to support scanning, processing and providing of meaningful information to managers engaged in strategic decision-making (Xu & Kaye, 2002). Environmental scanning is a basic process of any organization since it acquires data from the external environment to be used in problem definition and decision-making. The low percentage in the Spanish EIS situation can be a potentially dangerous weakness, since it was found that the EIS success is linked to the support provided by the system to organizational strategic management processes (Singh, Watson, & Watson, 2002).

Watson et al. (1996) recognise that executives require information (often provided informally) for decision-making. Soft information is “fuzzy, unofficial, intuitive, subjective, nebulous, implied, and vague” (Watson et al., 1996, p. 304). Watson et al. (1996) found that soft information was used in most EIS but the Averweg (2002)

Table 4. Types of information included in EIS: Frequency and percentage (multiple answer question)

	South Africa (N=31)	Spain (N=70)
Finance	28 (90.3%)	46 (65.7%)
Business/commercial sales	23 (74.2%)	58 (82.9%)
Strategic planning	11 (35.5%)	10 (14.3%)
Inventory management/suppliers	10 (32.3%)	14 (20.0%)
Human resources	9 (29.0%)	31 (44.3%)
Production	8 (25.8%)	39 (55.7%)
Quality	7 (22.6%)	22 (31.4%)
Soft information	4 (12.9%)	25 (35.7%)
Trade/industry	4 (12.9%)	14 (20.0%)
Competitors	3 (9.7%)	16 (22.9%)
External news services	1 (3.2%)	9 (12.9%)
Stock exchange prices	1 (3.2%)	5 (7.1%)

study (12,9%) does not support this (Table 3). One possible explanation is that it is often policy not to allow unsubstantiated rumours into IS without a reference to a source and tagged by the individual entering the information (Turban & Aronson, 1998).

Nowadays, databases exist for just about any kind of information desired—from competitor sales and financial matters to overall statistics. These can be used for a wide range of strategic management purposes to augment SQ for executive decision-making. From Table 4 it can be observed that the information that appears predominantly in EIS has an internal characteristic (Preedy, 1990). Some authors have defended the inclusion in the EIS of further reaching information with multiple perspectives and including a set of financial and nonfinancial, external and internal indicators (Taylor, Gray, & Graham, 1992). However, it can be observed that the information that appears predominantly in these systems has an internal characteristic.

External information obtains low response levels: Trade/industry (12.9%), external news services (3.2%), competitors (9.7%) and stock exchange prices (3.2%). Roldán and Leal (2003a) report similar low response levels. Other studies agree in presenting this scenario (Allison, 1996; Kirlidog, 1997; Salmeron, 2002). According to Xu et al. (2003), this internal orientation with low response level for external information is the main reason for dissatisfaction with EIS. An organization's environmental scanning process must be able to identify and differentiate among a variety of external issues if the organization's strategic responses are to predict the direction in which environmental elements may be moving that is for identifying trends. In SQ, executives need to develop strategies for addressing the future impact of these trend cues.

Some reasons that may shed light on this significant predominance of internal information are:

- It is much easier to provide internal data since it usually already exists in some form in the organization (Fitzgerald, 1992).
- Some executives will not really know how to use external EIS data, particularly data which is relatively soft and difficult to validate (Fitzgerald, 1992).
- The expense of electronically supporting and maintaining infrequently updated external information may not be justifiable in most situations (McAuliffe & Shamlin, 1992).
- The automated collection process of external data may tend to deliver too much unfiltered data to be useable by general management (McAuliffe & Shamlin, 1992).
- Research suggests that senior executives choose to do much of their own environmental scanning because they feel that

Table 5. Types of soft information included in EIS: Frequency and percentage (multiple answer question)

	Spain (N=25)
Predictions, speculations, forecasts, estimates	13 (52.0%)
Explanations, justifications, assessments, interpretations	12 (48.0%)
News reports, industry trends, external survey data	6 (24.0%)
Schedules, formal plans	5 (20.0%)
Opinions, feelings, ideas	1 (4.0%)
Rumours, gossip, hearsay	0 (0.0%)
Other	3 (12.0%)

subtleties exist that only they will see (El Sawy, 1985).

Executives often prefer doing this task personally instead of delegating it to staff since senior managers find great value in filtering external data through their own mental models (Rockart & DeLong, 1988). Therefore they try to develop and maintain its own external information sources, which are frequently rich and personal media of communication.

The literature suggests that periodical and newspaper reviews are a frequently used source of competitive intelligence. Considering the hard/soft information continuum proposed by Watson et al. (1996), in organizations surveyed in Spain, Roldán, and Leal (2003a) observe those types of qualitative information more quoted are included in a halfway house between hard and soft information: predictions (52.0%) and explanations (48.0%) (Table 5). Roldán and Leal (2003a) emphasise the absence of cases for the soft information extreme of the continuum (i.e., rumours, gossip, and hearsay) and suggest some explanations for this situation:

- This kind of information can be considered too sensitive
- It can jeopardize competitive plans
- It could expose the organization to legal risks (Watson, Harp, Kelly, & O'Hara, 1992)

How information is held by EIS in an organization is given in Table 6. From Table 6, information is generally presented by products (71.0%), operational/functional areas (64.5%) and geographical areas (58.1%). Roldán and Leal (2003a) report similar findings for operational/functional areas (62.9%), products (61.4%) and geographic areas (52.9%). Roldán and Leal (2003a) note that "*information according to processes ranks quite low, existing in only 20% of participating entities*" (p. 295). From Table 6 there is a striking commonality with the Averweg (2002) study of 19.4%. This situation was highlighted by Wetherbe (1991) as one of the traditional IS problems for top managers that is these systems are considered as functional systems rather than being considered as systems crossing functions. Nevertheless, this result is understandable since the most important EIS user groups are top functional managers and middle managers.

The different types of sources of information that support an EIS in an organization are given in Table 6. One of the capabilities or characteristics of EIS is the filtering, organization, and consolidation of multiple data sources (Nord & Nord, 1996). This quantitative data stems from

Table 6. How information is held by EIS in organizations: Frequency and percentage (multiple answer question)

	South Africa (N=31)	**Spain (N=70)**
By products	22 (71.0%)	43 (61.4%)
By operational/functional areas	20 (64.5%)	44 (62.9%)
By geographic areas	18 (58.1%)	37 (52.9%)
By key performance areas	14 (45.2%)	33 (47.1%)
By company	11 (35.5%)	not available
By strategic business units	10 (32.3%)	37 (52.9%)
By processes	6 (19.4%)	14 (20.0%)
By projects	5 (16.1%)	11 (15.7%)
By customers	1 (3.2%)	0 (0.0%)

corporate data bases (80.6%) and operational data bases (64.5%).

Table 4 reflects that the information that appears predominantly in EIS has an internal characteristic. Table 7 shows that a significant majority of the information came from internal sources. External sources have a low presence: external databases (25.8%) and Internet, Intranet or Extranet (16.1%). This trend towards internal sources supports the results obtained in previous research studies (Basu, Poindexter, Drosen, & Addo, 2000; Kirlidog, 1997; Roldán & Leal, 2003a; Watson et al., 1991; Watson, Rainer, & Frolick, 1992; Xu et al., 2003). Salmeron, Luna, and Martinez (2001) suggest "the extent to which information coming from the environment is included in the EIS of Spanish big businesses should reach higher figures, due to the fact that all elements that currently form economy are interrelated" (p. 197).

Given the presence of Web-based technologies and from Table 6 it is therefore somewhat surprising that the Internet, Intranet and Extranet rank as the lowest source of information which support an EIS in organizations in the Averweg (2002) and Roldán and Leal (2003a) studies. This tends to suggest that future EIS development and implementation should focus on developing an organization's external sources for strategically important accommodation and assimilation information. This will serve to promote a systematic scanning of the external environment. Xu (1999) suggests that an organization should differentiate and selectively identify the most influential environmental factors for scanning. Scanning does not imply only collecting competitor's information. Environmental factors such as changes in economic conditions, cultural and social patterns, political climate and legal representations, and technology should be selectively monitored since they may significantly affect developing an executive's SQ.

Making important strategic decisions must be based on accurate data. The data held by EIS must facilitate SQ for executives. While new Web-based architectures may replace old architectures or they may integrate legacy systems into their structure in organizations, from this study it is evident that EIS in South Africa and Spain are in a state of flux and future EIS development will require new emerging features for SQ.

From the above EIS survey results in South Africa and Spain, the findings that emerged between these two countries are now summarized. Two parallelisms were identified:

- External information (e.g., trade/industry, external news services, competitors, and stock exchange prices) in EIS have low internal presence.
- There are similar trends in how information (e.g., by products, operational areas, and geographical areas) is held by EIS in an organization.

Table 7. Sources of information that support EIS in organizations: Frequency and percentage (multiple answer question)

	South Africa (N=31)	**Spain (N=70)**
Corporate databases	25 (80.6%)	61 (87.1%)
Operational databases	20 (64.5%)	29 (41.4%)
Individuals	12 (38.7%)	23 (32.9%)
External databases	8 (25.8%)	19 (27.1%)
Documents or reports	7 (22.6%)	24 (34.3%)
Internet, Intranet or Extranet	5 (16.1%)	2 (2.9%) (only Internet)

With the low internal presence of external information, it appears that environmental scanning is not being actively pursued by executives and the advantages of Web-based technologies are not being utilized. These apparent "shortcomings" need to be incorporated in future EIS development.

Two significant differences between the EIS survey in organizations in South Africa and Spain were identified:

- Holding strategic planning information in organizations in South Africa appears to have higher importance than holding production information.
- There is a higher presence of holding soft information in organizations in Spain but this is less than when compared to organizations surveyed in North America.

The implications of the above parallelisms and differences are that:

- It may provide a research agenda for an in-depth study of these parallelisms and differences.
- This information is useful for IT practitioners when considering future EIS development in these countries.

Some practical implications for future EIS development will now be given.

SOME PRACTICAL IMPLICATIONS FOR FUTURE EIS DEVELOPMENT

Executives place substantial requirements on EIS. Firstly they often ask questions which require complex, real-time analysis for their answers. Hence many EIS are being linked to data warehouses and are built using real time OLAP in separate multidimensional databases along with organizational DSS. There are also efforts to use data warehouse and OLAP engines to perform data mining.

Secondly, executives require systems that are easy to use, easy to learn and easy to navigate. Turban and Aronson (1998) report that current EIS generally possess these qualities.

Thirdly, executives tend to have highly individual work styles. While the functionality of the current generation of EIS can be moulded to the needs of an executive, it is more difficult to alter the general look and feel or method of interaction with a system.

Fourthly, any IS is essentially a social system. Turban and Aronson (1998) note that one of the key elements of EIS is the electronic mail capabilities it provides for members of the executive team. Nowadays, the electronic mailing of multimedia documents is becoming critical. Given this scenario, EIS of the future will look significantly different from today's systems.

Nord and Nord (1995) report that developers of decision support technology for executives must be alert to the needs of top executives and EIS evolution. Like most other IS, EIS have migrated to the networked world of the technical workstation and Intranets. The advent of Web services now allows interaction between software and systems that would previously only have been possible with extensive systems development.

Turban and Aronson (1998) describe some of the features that have been emerging or likely to appear in the next generation of EIS:

- **A toolbox for building customized systems:** To quickly configure a system for an executive, the builder of the system requires a toolbox of graphic and analytical objects that can be easily linked to produce the system. Commander EIS LAN®, Forest and Trees® and Pilot Decision Support Suite® are examples of such tools.
- **Multimedia support:** The requirement that an EIS can be configurable also requires support of multiple modes of output and

input. The current generation provides text and graphic output with keyboard, mouse, or touch screen input. The rapid proliferation of databases supporting image data, voice, and video will no doubt mean that future EIS will be multimedia in nature. Audio and video news feeds (soft information) via the Internet through local area networks are currently a reality.

- **Virtual reality and 3-D image displays:** The development of virtual reality standards, the ability to examine megabytes of data on a landscape or in a map form via 3-D visualization, and higher resolution monitors are beginning to affect EIS. As these tools are deployed for general use executives will adopt them to assist in their data visualization for information evaluation and decision-making. By scanning the IT environment and interpreting such visual cues, this process may serve to enhance SQ for executive decision-making.
- **Merging of analytical systems with desktop publishing:** Many reports prepared for executives contain text, graphs, and tables. To support the preparation of these reports, some software companies have merged desktop publishing capabilities with various analytical capabilities. In keeping with multimedia features, EIS have the capability to cut and paste data and graphs from various windows and to ship that document (via e-Mail) to other executives or post it to a Web site.
- **Client/server architecture:** This approach is extremely important for EIS as the server provides data to client software running on the executives' workstation. The original architecture of EIS was the client/server environment and it has now been adopted for many IS applications including data warehousing and Web technology. For a technical discussion of Web client/server communication, see, for example, Schneider and Perry (2000).
- **Web-enabled architecture:** Web browser software is the cheapest and simplest client software for an EIS. This is leading toward Web-enabled EIS. The current generation of software supports information delivery via the corporate Intranet and is evolving into the norm rather than the exception. Some examples are: Comshare provides Commander DecisionWeb®, Pilot Decision Support Suite® contains an Internet publishing module and the SAS Institute provides Internet support for its flagship enterprise software suite.
- **Automated support and intelligence assistance:** Expert systems and other artificial intelligence systems are currently embedded or integrated with existing database management system or DSS. Clearly this adds more automated support and assistance to the analytical engines underlying EIS. The researchers indicate that one is also likely to see other forms of intelligent or automated assistance. One such form is the intelligent software agent. An agent can learn how the executive uses an EIS and adopts the appropriate screens in the executive's preferred order. Other agents are actively used in Web search engines and can be deployed in Web-enabled EIS.
- **Integration of EIS and group support systems:** Much of the technology developed for group support systems (i.e., groupware) can be used effectively by executives for a number of managerial tasks. For example, Haley and Watson (1996) document ten cases where Lotus Notes® was specifically chosen for EIS development.
- **Global EIS:** As organizations become more global in nature, providing information about international locations around the world is becoming critical to organizations' success. The accuracy and timeliness of information for decision-making become critical. The challenge has become to find ways to

> integrate information across the enterprise. The transparency of the integration of the information process is what makes Web technology so effective. Palvia, Kumar, Kumar, and Hendon (1996) investigated the types of data that executives require in two scenarios: (1) introducing a new service or product into other countries; and (2) distribution channel expansion into other countries.

Most of the executive information requirements include demographic and marketing data from public sources and soft information from personal contacts. Palvia et al. (1996) indicate that EIS can be used to provide the soft information. Soft information that is provided in EIS can be classified in groups according to their softness (Watson et al., 1996). This classification helps the executive user judge them.

In the next section, future EIS trends are presented. Thereafter the conclusion for this chapter is given.

FUTURE EIS TRENDS

Strategically important information for executives may be scattered in an organization's internal and external environments. The main issue facing the successful development and implementation of EIS in an organization is the importance of clean, organized source data. This is applicable to both structured data and unstructured data.

One future trend is that the processes of acquisition, cleanup, and integration will have to be applied for both structured and unstructured data. Furthermore, structured and unstructured data types are further segmented by looking at the internal and external data sources of the organization. These two dimensions are data type and data source. However, the transition between structured and unstructured data types and between internal and external data sources is not currently defined in absolute terms. This will require further investigation. Problem-pertinent data will be available from external as well as internal sources (Forgionne, 2003).

Another future trend is the challenge of EIS to deal with soft information. While the authors report that 12.9% and 35.7% soft information is held in EIS in organizations in South Africa and Spain respectively (see Table 4), it is envisaged that the future trend will be to pay militant attention to this (soft) information so that users will ultimately get to a single version of the truth. Rigorous data standards may need to be deployed. There also needs to be a secure delivery of accommodation and assimilation information to the EIS.

Another trend will be a greater focus on learning phases that users have to go through to ensure they receive the information they thought they will be receiving. Mental modes are important not only for decision-making but also for human-computer interaction (Turban et al., 2004). Organizations will need to ensure that users understand how to use EIS so that they do not draw the wrong conclusions (or insights) from data because they submitted incorrect queries or misused the results. This will lead to poor strategic decision-making by executive users and SQ will thereby not be facilitated.

With more and more information becoming available in electronic form, organizations have increasingly carried out environmental scanning using EIS linked to online databases (Vandenbosch & Huff, 1997). This trend is likely to grow as the borderless nature of the Internet suggests that organizations may be able to scan a greater variety of information sources that cover a wider range of environmental sectors (Tan, Teo, Tan, & Wei, 1998). In a business environment characterised by complexity and turbulence, scanning by executives will become more important for their SQ. Environmental scanning often initiates a chain of actions that lead to organizational adaptation to environmental changes (Hambrick, 1981).

The viability of an organization depends on its ability to stay ahead of environmental challenges and thus environmental scanning can be considered a vital organizational task (Boyd & Fulk, 1996) and this soft information is needed for successful competition and survival (Turban & Aronson, 1998). Some scanning of news stories, internal reports, and Web information is performed by intelligent agents. The ease of access to information on the Internet and as a borderless information resource which transcends traditional boundaries and notions for information acquisition and use, may change the way executives conduct environmental scanning (using EIS) in the future (Tan et al., 1998). Nonetheless, executives will still need to interpret the cues so that they can develop appropriate strategies for addressing the future impact of these cues.

CONCLUSION

The accessibility, navigation, and management of strategic data and information for improved executive decision-making is becoming *critical* in the new global business environment. As decision-making is being facilitated from anywhere at any time, future EIS development will be significantly impacted. This is an important consideration as there is an need for EIS to effectively facilitate SQ for executive decision-making.

Chapter Summary

In this chapter the concepts of strategic information, EIS and SQ were discussed. A survey of EIS in organizations in South Africa and Spain was undertaken to identify the nature and sources of information included in the surveyed organization's EIS. The implications of this information for SQ for executive decision-making was then discussed. Some practical implications for future EIS development were given. Future EIS trends were then noted.

Key Findings

Four key findings from this EIS research can be summarized as follows:

- In both the South African and Spanish studies, external information (e.g., trade/industry, external news services, competitors, and stock exchange prices) in EIS have low internal presence.
- In the South African and Spanish studies, there are similar trends in how information (e.g., by products, operational areas, and geographical areas) is held by EIS in an organization.
- Holding strategic planning information in EIS in organizations in South Africa appears to have higher importance than holding production information. In organizations in Spain, the converse holds true.
- When compared to organizations in South Africa, there is a higher presence of holding soft information in EIS in organizations in Spain but this is less than when compared to organizations surveyed in North America.

Management Implications

Web-based systems which began to emerge in the mid-1990s, deliver business applications via the Internet. Many of the innovative and strategic systems found nowadays in medium and large organizations are Web-based. Using their browsers, employees in organizations collaborate, communicate and access vast amounts of information by means of Web-based systems. There is therefore both scope and need for research in the particular area of EIS being impacted by Web-based technologies. Executives need systems that provide access to accommodation and assimilation information so that they can interpret the cues from this information and formulate strategies for addressing the future impact of these cues.

EIS are becoming more enterprise-wide with greater decision support capabilities and also gaining in intelligence through the use of intelligent software agents. EIS are going through a major change to take advantage of Web-based technologies in order to satisfy sense-making information needs of an increasing group of executive users. As these users need IS that provide access to diverse types of strategic information which may be scattered in both internal and external environments, there is also a need for research in the area of managing future EIS development so that SQ for executive decision-making is in manifested in these SIS.

Chapter 4.7

Using Information Technology for Strategic Growth from Single-Mission Transportation Company to Multi-Faceted Global Logistics Corporation

Shirley Hanshaw
Mississippi State University, USA

Lemuria Carter
North Carolina Agricultural and Technical State University, USA

ORGANIZATION BACKGROUND

The brainchild of Chairman and CEO John A. James, **O-J Transport** acquired its name from the first initials of James' surname and that of Calvin Outlaw, his paternal uncle and co-founder. They started the company during a time when very few, if any, minorities were involved in the transportation industry in the United States because of widespread discriminatory practices. From humble beginnings, they migrated north from rural Mississippi to find jobs in the automotive industry—James in labor relations at Chrysler Corporation and Outlaw as a mechanic at Hertz Truck Rentals. Serving as president and vice-president, respectively, of the embryonic business, James and Outlaw possessed complementary business styles that contributed greatly to the success of the company.

Significantly, O-J Transport grew out of another minority business, Skypak, a malt liquor distributorship that needed a common carrier to transport its products from Milwaukee, WI, to Detroit, a niche that James used to his advantage while employed in Labor Relations at Chrysler. This need provided the opportunity for him to fulfill a lifelong ambition, that is, to go into business for himself, according to James (interview, March 14, 2006). Little did he know, however, that the trucking industry was "a closed entity" that was heavily regulated; consequently, the greatest challenge was to obtain licensing authority to enter the business before being able to compete with the "insiders" on an uneven playing field.

Shortly after incorporation of the company, the owners of O-J Transport discovered that they needed to file an application for an operator's license with the Interstate Commerce Commission (ICC), a government agency formed during the latter part of the 19th century to regulate railroads. Later, in 1935, it began regulating the trucking industry. To James' dismay, O-J Transport received only temporary authority—180-day permits—while the application was pending approval. These permits allowed transportation of malt liquor from Milwaukee to Detroit but prevented a backhaul of goods on the return trip. This process, that is, hauling one way and returning with an empty truck, was called "deadheading" (interview, January 5, 2007) according to James; and it limited his ability to do "serious borrowing" (Booth, 1983, p. 60) to expand the business.

Determined to increase his profit margin, and thereby grow the company, James surmised that he needed either to haul beer in a westward direction or to transport a totally different commodity. Realizing the potential for profitability in Detroit—the automotive capital—James made a strategic move in 1972 when he contacted several of the large auto manufacturers soliciting their business to backhaul automotive parts in addition to seeking their support for common carrier certification from the ICC. American Motors, the smallest of the Big Four car manufacturers at the time, was the first company that he approached; but they were reluctant to enter uncharted territory, that is, allowing an African American into the all-white trucking industry, unless General Motors, Ford or Chrysler were willing to support the application as well. After literally knocking on doors at General Motors for several months with no success, and being told that they were satisfied with using the existing carriers, James went the World Headquarters of Ford Motor Company where he met Harvey Warburton, supervisor of transportation analysis.

Impressed with James' integrity and honesty, Warburton (interview, July 23, 2007) not only pledged Ford's support but also suggested that he retain a transportation law attorney if he intended to challenge the ICC's ruling. Providing assistance in this effort, he offered three names, from which James chose Robert McFarland, a young attorney at the beginning of his career in 1972, who has continued to represent James in legal battles related to his businesses over the ensuing 34 years. Armed with support from American Motors and Ford Motor Company, along with General Motors who later signed on, O-J Transport filed application for permanent authority with the ICC in 1972 with Atty. McFarland as counsel. This was the beginning of a protracted legal battle of denials, partial orders, reversals, reconsiderations and appeals that were costly and time-consuming and that spanned several years.

Following denial of more than seven applications, the ICC finally granted partial authority in 1973. But the battle was not over. Essentially the decision was overturned, prompted by protests from over twenty-five of the largest trucking companies in the United States claiming that O-J Transport must show the need for its service by proving "public convenience and necessity," a legal maneuver designed by the ICC to favor those protected by a "grandfather clause" in the trucking industry. Essentially the ICC "grandfathered" in anyone already in the business back in 1935 and issued certificates; however, anyone desiring entrance afterward had to apply for permission, with the burden of proof being on the applicant to prove a public need for their service (interview with Attorney McFarland, March 15, 2006). Regardless of letters of support from prospective customers, such as Ford and General Motors, O-J Transport had to fight against protests from those in the trucking industry determined to keep African Americans out. Such hostility was displayed most graphically when one of O-J Transport's trucks was torched about one-and one-half block from James' home. According to Attorney McFarland, this act of vandalism was a "message from someone about what we were trying to do."

The years during the early 1970s proved to be trying times for the company financially. Seemingly outnumbered by giants in the trucking industry, James could have given up the struggle. Undeterred, however, he tenaciously used what could have been a stumbling block as a stepping-stone not only to survive but to thrive. Through sheer determination, hard work, and sacrifice, James sought to further his business interests when he set out to prove not only the need for the services of O-J Transport but also to open the doors of the transportation industry for other minority carriers throughout the United States. Therefore, in 1976, he appealed his case all the way to the U.S. Supreme Court. However, in its decision the Court remanded the case to the Sixth Circuit Court of Appeals, stating that authority should be granted by the legislature (Spink, 1977).

Concurrent with the ICC challenge, for several years O-J Transport was also pursuing operating authority from the Michigan Public Service Commission (MPSC) to transport auto parts within the state. Though this intrastate application was also protested by large trucking companies, the MPSC ruled in favor of O-J Transport with the issuance of the MPSC Common Carrier Motor Certificate in 1978. This decision received nationwide publicity, earning O-J Transport the distinction of being the first African American trucking company to be granted intrastate authority by the MPSC for transporting automobile parts, a feat that ICC Administrator Bernard Gaillard heralded as "a giant step" for the trucking industry. He stated further, "I applaud your persistence and fortitude … which will benefit minority truckers throughout the State of Michigan" (letter to James, January 26, 1978). Later that year, James quit his job at Chrysler and took the first step to expand his company when he purchased the Hertz Trucking Company site where his uncle, Calvin, previously worked as a mechanic, establishing O-J Transport's first terminal. The company's new home was equipped with modern office facilities, complete maintenance service, and a fully fenced yard for its equipment. James also bought 23 used trucks from Ford Motor Company. In 1979, Ford assisted in his entrepreneurial venture by providing him with twelve diesel tractors and the services of a consultant (letter of thanks from James to Ford Motor Company president, October 29, 1979).

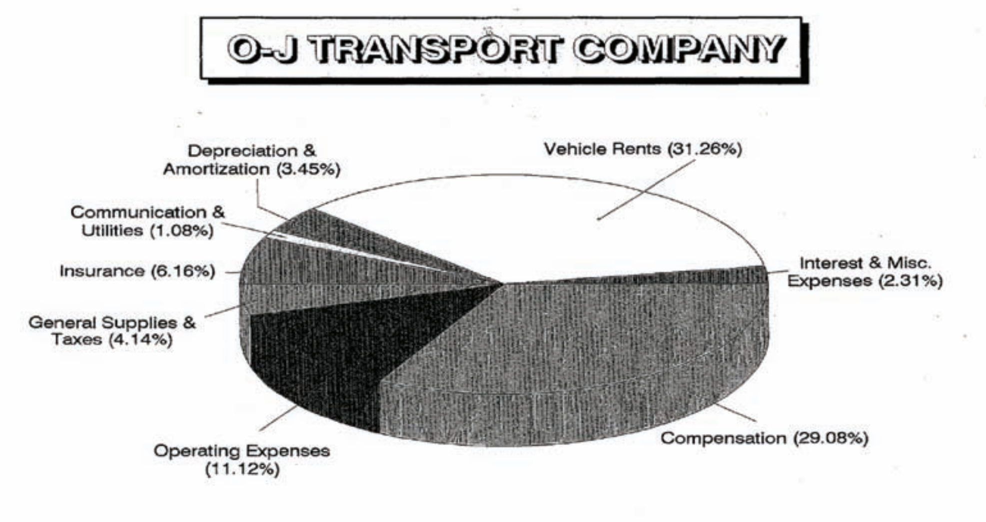
In the ensuing years, after more than 16 additional applications to the ICC were denied, O-J Transport was finally granted permanent carrier authority, but only after the Interstate Commerce Act was amended and greatly liberalized to include within its National Transportation Policy the participation of minorities in the transportation industry. This landmark legislation, S. 2245, the Motor Carrier Act, was signed by President Jimmy Carter in 1980, essentially disbanding the ICC. This was not only a benchmark date for O-J Transport but also an historic moment for the United States. In the summer of that year, President Carter's Assistant, Anne Wexler, wrote on behalf of the President a letter of appreciation to James for his "contribution to this landmark legislation" (letter dated July 1, 1980). Despite what to some would have been considered setbacks along the way, James used these potholes in the road to success to propel him toward his destiny in the automotive supplier industry.

Consequently, rising from its humble beginnings with one Ford heavy-duty truck and annual sales of less than $50,000, O-J Transport by the late 1980s had developed into a multi-million-dollar corporation. As a full-time, Tier I auto parts carrier, it continued to thrive, with Ford Motor Company as the major customer. By 1986 O-J Transport owned a dispatching facility conveniently located in the I-75 and I-94 interchange area. This 10.5-acre-facility also featured a rail spur and a 30-ton gantry crane with piggyback rail shipping capabilities and a warehouse with 90,000 square feet of capacity. Possessing a vast fleet of over 300 multi-axle tractors and trailers with a wide variety of features such as drop-frame jumbo vans and side-unloading trailers, O-J Transport was poised to meet its customers' needs. As a U.S. Customs bonded carrier, the company was able to handle shipments from Canada and other foreign shipping ports. This success resulted, largely, from the leadership, managerial expertise and exceptional entrepreneurial skills of James, whose former administrative assistant, Gerri Carter, describes as a "genius" and a "visionary" who envisioned where the company could go and "just made it happen" (interview, April 25, 2005).

But this success was punctuated by loss. Following a lengthy illness, Calvin Outlaw, James' uncle, passed away in 1998. Earlier in the 1990s, the Big Three automakers—General Motors, Chrysler and Ford—adopted "lean production" systems, that, according to Charles Hill (2005), were based upon "innovations that reduced setup times for machinery and made shorter production runs economical (p. C51)." Lean systems, therefore, yielded increased "gains in productivity" and quality of products. Within this same timeframe, auto manufacturers also encouraged their suppliers to locate their facilities in proximity to assembly plants. This practice allowed delivery of inventory to the assembly line on a "just in time" basis. As a supplier, James had to "step up to the plate" to remain competitive; therefore, he implemented both the lean systems and "just in time" inventory with remarkable success. As a result, business increased. According to Stephen Larson, manager of the supply diversity program at Ford, O-J Transport at one time during the early 90s "hauled more loads for Ford than any other carrier in the country" (Interview, January 12, 2007). From 1979 to 1993 the company's business with the Big Three automakers steadily increased, with Ford Motor Company having the lion's share of O-J Transport's business. Revenues increased phenomenally from approximately $1 million in 1980 to over $12 million by 1988. By 1992, the company reported revenues exceeding $29 million (James Group International Archives, January 2007). Because of the lack of information technology (IT) capability, that is, only a little more than one per cent of the budget being allocated to communications in 1993 (see Figure 1), James mainly outsourced IT services to its customers. This situation would change dramatically when the company later expanded.

Following a downturn in the trucking business by the mid-1990s, James strategically changed the direction of the company from its original designation as a single-mission trucking company and expanded its capabilities into a full-service firm. His diversification included the formation of several companies, and during the latter 1990s the firm evolved to become The O-J Group, a multi-service transportation and logistics enterprise encompassing six units with divisions in ocean, land, logistics, assembly, import and export, and supply chain management. James sold the trucking portion of the business because of lack of profitability. By 1997, reported revenues for the O-J Group were $52.3 million, and, as Ron Butler, executive director of administration reports (interview, November 2007), the company has been listed every year since in *Black Enterprise Magazine* among the Black Enterprise Top 100 "Service/Industrial" Businesses. Through several strategic moves James continued to expand the company; consequently, by 2002 the O-J Group had expanded and evolved to become James Group International (JGI), a global logistics corporation with domestic operations in Michigan (Detroit and Warren) and Park City, KY. Currently, it also ships out parts to over twelve countries, including Japan, Venezuela, Australia, Brazil, China and South Africa. Listed below are the companies that comprise JGI and the dates they originated:

Figure 1. O-J Transport budget with IT allocations, 1993 (Source: O-J Transport Archives, 1993)



- 1991 — **Motor City Intermodal Distribution (MCID)**, a marine terminal and Foreign Trade Zone company involved in truck, rail and sea operations.
- 1993 — **Motor City Logistics (MCL)**, a warehousing and parts sequencing operation in Romulus, MI, that receives auto parts from Asia. These parts are then deconsolidated and shipped to customers across the United States. Bowling Green, Kentucky, is the site of a more recently built MCL facility involved in receiving, warehousing, and sequencing Corvette headlamps for General Motors. Accommodating GM's just-in-time requirements, MCL is located near the Corvette plant.
- 1998 — **Renaissance Global Logistics (RGL)**, a global consolidation operation that packs and exports automotive components, as CKD (complete knock-down), to South Africa, South America, Australia, Asia Europe, and other foreign countries.
- 2000 — **JASCO International**, a joint venture with Sumitomo Corporation of America and Sumitrans which currently has three operations—two deconsolidation centers for inventory arriving from Japan, Malaysia, Spain, the United Kingdom and Korea; and a sub-assembly operation in Park City, KY.
- 2001 — **Motor City Express (MCX)**, an operation providing truckload transportation services.

The flagship company of JGI is Renaissance Global Logistics (RGL), a 400,000-square-foot warehouse facility located in Detroit's Empowerment Zone, a designation by the government to "empower" desolate, blighted areas of the city (called "brown fields") that had been abandoned by industry. Desiring to stimulate business in the empowerment zone, Ford Motor Company selected JGI to undertake the operation. When JGI acquired the contaminated property, it was a trash dump surrounded by desolation and neglect. Through his acquisition and development of the land as well as the establishment of RGL with over 400 employees, however, James initiated an economic revival in the area. Being the first to locate in and rebuild this previously neglected area, JGI began a "renaissance" in business revitalization with RGL that prompted other companies, such as Federal Express, Vitech, Hispanic Manufacturing, and Johnson Controls, to establish facilities there.

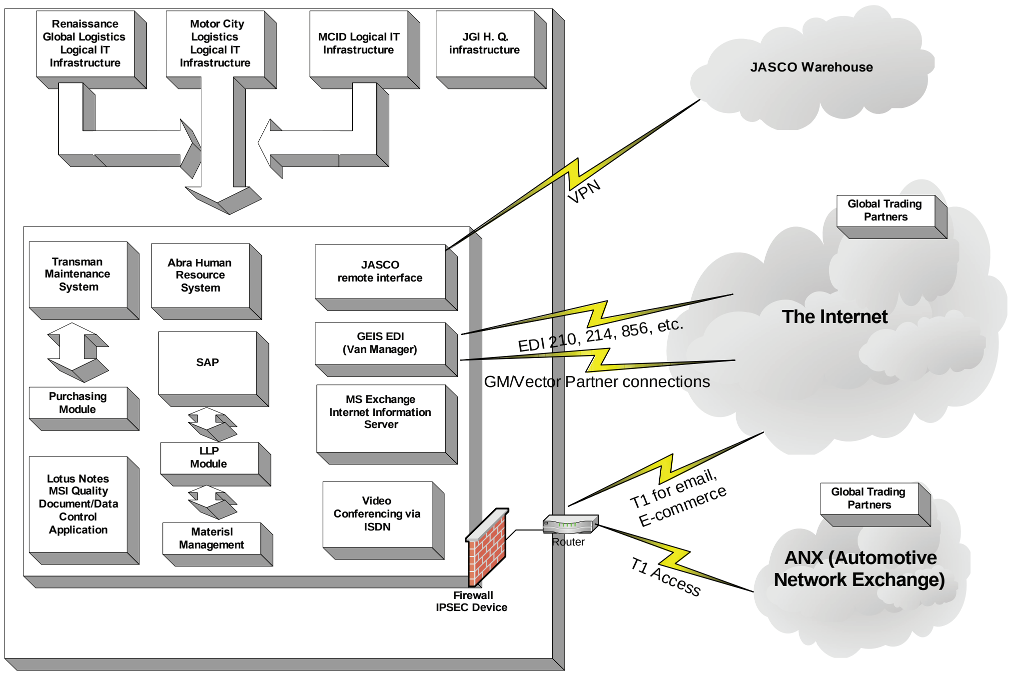
SETTING THE STAGE

When the company began in 1971, it had only one employee and two pieces of equipment, a tractor and a trailer. However, as the company grew management recognized the importance of IT. By 1986, the office support team was equipped with electronic scheduling, tracking and billing systems. And the trucks were stocked with cellular phones to support "just-in-time" product delivery. In 2000, the company adopted OmniTRACS, a mobile communications system that uses mobile, two-way satellite technology to support text messages between drivers and dispatchers. In 2002, JGI purchased a major information system: an enterprise resource planning (ERP) system. The IT director selected SAP R3 with the hopes that it would enable JGI to become a leader in supply chain management (SCM).

In addition to using technological advancements to improve employee and company performance, the company also uses technology to improve customer satisfaction. For example, in 2004 JGI implemented an automated real-time vehicle information system (ARVIS), which is an electronic inventory and shipment management program designed to improve accuracy and accountability between warehouses. Accurately capturing shipping information to ensure that customers are not over-billed, the ARVIS system receives customer information through electronic data interchange (EDI). The system uses this information to create advanced shipping notices (ASNs) which it then e-mails to customer destinations before delivery. Providing accurate, timely information, ARVIS enables the customer to develop better strategies to manage its distribution network.

Currently, JGI has two full-time IT personnel. The company maintains its centralized IT infrastructure in-house; only 10 percent of the IT work load is outsourced. Figure 2 illustrates JGI's IT infrastructure. The first four boxes represent the IT infrastructure of the companies that comprise JGI. The middle section illustrates the interaction

Figure 2. James Group International logical IT infrastructure (Source: James Group International Information Technology Department, December 2006)



of JGI's major information systems, including its ERP system (SAP), human resource system and data control application.

Additionally, it depicts the company's use of computer-aided tools such as video conference and EDI, and JGI's use of security measures such as firewalls and virtual private networks (VPNs) to protect transactions between its global trading partners.

CASE DESCRIPTION

The purpose of this study is to assess the level of e-government adoption in JGI, a global, multi-million dollar firm. Although the company has adopted several mainstream systems that support SCM, ERP and EDI, this international powerhouse has yet to take advantage of e-government initiatives. Government-to-business (G2B) services can help companies manage corporation tax, new company registration, contractor registration, government auctions, wage reporting and patent/trademark development. Yet, despite the benefits of G2B, such as faster data transmission, greater data accuracy, and improved clerical efficiency, companies have been slow to adopt this innovation. The literature suggests that G2B adoption is still in its infancy (Devadoss et al., 2002; Mahmood, 2007; Tung & Rieck, 2005). In the European Union (EU), the majority of transactions between government and business are paper-based (ICT 2007). Reddick (2004) states "there is much room for improvement" in the area of G2B adoption (p.74).

The Ministry for Investment, Industry and Information Technology (MIT&I, 2006) suggests that agencies should set a goal of making all interactions between businesses and government possible electronically within the next two years. In an effort to assess the progress of e-government initiatives, several studies have proposed models of e-government development. Hiller and Belanger (2001) explain growth in terms of the major types of e-government relationships, such as government delivering services to individuals (G2IS), government to business as a Citizen (G2BC), and government to business in the Marketplace (G2B-MKT). Layne and Lee (2001) present a four-stage model of e-government growth that includes the following phases: cataloging, transaction, vertical integration and horizontal integration. The first stage involves the agency establishing a Web presence and presenting information online. In the second stage, the agency supports electronic transactions. Vertical Integration enables municipalities to interact electronically with higher levels of government in similar areas, while horizontal interaction refers to integration across various government functions. Windley (2002) proposes an e-government maturity model that includes four levels: (1) simple website, (2) online government, (3) integrated government, and (4) transformed government. The first level is similar to Layne and Lee's cataloging phase; it includes static web pages and downloadable forms. The second level includes e-mails, online payments, online surveys, FAQs, account inquiry, and so forth. The third level includes automated procurement, cross-departmental information sharing, automated advice/problem solving, and Web-based training. The final level, transformed government, supports business process integration and community-centric intergovernmental processes (Windley, 2002).

As aforementioned, the purpose of this study is to assess the level of e-government adoption in JGI. Based on previous research (Alvai & Carlson, 1992; Denzin & Lincoln, 2005; Myers & Newman, 2007), we used employee interviews and company archives to collect data. To obtain general information about the company and the role of technology, the CEO contacted several key employees and set up times for us to meet with them. These interviews were audiotape recorded and then transcribed. To obtain more specific information about the IT infrastructure we interviewed the IT director, James Herrmann. These sessions were conducted over the phone and via e-mail. In addition to interviews, the CEO allowed us to review the company's archives that contain information (files, letters, charts, graphs, etc.) dating back to 1971 when O-J Transport was incorporated.

After applying Windley's (2002) maturity model to the data, it is clear that JGI, like many companies, is at level one. James Herrmann, the current IT director, states "I am not aware of any systems or processes set up for e-government services" (Response to interview questions, November 9, 2007). Herrmann's statement is consistent with the literature. Reddick (2004) identifies the lack of information about e-government applications as a major barrier to adoption. The literature also suggests that a lack of expertise and a limited IT staff minimize e-government adoption (Reddick 2004). Currently, JGI has only two employees dedicated to IT. Considering the complex systems that these two employees maintain, it is understandable that they may not have the time to explore a relatively new initiative such as e-government.

Although JGI does not use transactional e-government services, it does use e-commerce systems. As depicted in Figure 2, the company uses electronic data interchange with its global trading partners. As a result of its e-commerce transactions, JGI has the IT infrastructure necessary to support e-government transactions. The company also has software and hardware that support a large-scale ERP system, and it uses security measures such as firewalls and virtual private networks (VPNs) to secure electronic transactions. Technologically, the company is well equipped to capitalize on the benefits of electronic transactions with the public sector.

According to Mr. Herrmann, JGI does correspond with the government via e-mail. This correspondence suggests the company is beginning to enter the second level of e-government maturity: online government. Makolm (2002) posits that frequently e-government initiatives begin as information applications; however, that is only a starting point since the availability of ample information creates the demand for interaction. Currently, JGI uses the Internet to interact with the government sparingly. However, as public awareness about G2B services and their benefits increases, it is conceivable that JGI will utilize its IT infrastructure to implement e-government initiatives.

CURRENT CHALLENGES / PROBLEMS FACING THE ORGANIZATION

Supply Chain Management

Supply chain management can be described as a path of value creation from basic producer through customer, including all transportation and logistics services that connect them. Several stages are involved in the chain, the first being the basic producer who extracts raw materials from natural resources. The converter is the second stage of product value creation. The third stage consists of the fabricator, or manufacturer, who converts the input into components used by the assembler. Products are then transferred to the retailer and the consumer. Along these stages in the chain, transportation, storage, distribution and warehousing are important—all of which constitute logistics (Finch, 2006). Some companies have their own transportation and warehouse services. However, today, as corporations initiate lean systems, they are outsourcing the services to companies known as "third party logistic[s] firms," or 3PLs. It was estimated two years ago that at least 73 percent of high-volume shippers were outsourcing transportation and logistics services (Hoffman, 2006). Some companies provide a single service, such as warehousing or transportation. James Group International, however, provides all these services along the supply chain.

Transportation Logistics

Common wisdom in the industry is that the transportation infrastructure is aging and needs an overhaul. Logistics costs have risen significantly over the past few years, from approximately $500 billion in 1985 to $1.18 trillion in 2005. Inventory carrying costs rose 17 percent, the largest jump since the 1980s, an increase resulting from higher interest rates and increases in the amount of inventory that companies carry (*Industrial Engineer,* 2006). Also, within the transportation logistics industry there is more integration than ever before. New and better software and communications links on the internet have greatly reduced problems involved with integrating supply chain systems. Today, transportation management systems aggregate data and report it to enterprise resource planning and other applications to provide more complete visibility and control of all information available for logistics decision making (Hoffman, 2007).

Additionally, more 3PLs are offering integrated services as part of their package of services. Consequently, the need for supply chain technology integration has grown, as manufacturers, vendors and retailers seek to use technology to reduce cost and increase response time. The logistics industry has to deal with surging fuel costs, a severe shortage of drivers, escalating security costs, and chronic rail and port capacity shortfalls. According to industry consultants, "everything is going up." As a result several trucking and transportation specialists recommend that transportation companies and shippers work together to improve the efficiency of logistics. Transportation costs are rising faster than rates. Traffic congestion has worsened, adding extra time and higher fuel expenditures. Another factor affecting trucking costs has been the shortage of drivers, a problem that continues to worsen.

E-Government

The General Services Administration (GSA) (2001) states there are several challenges that may hinder the progress of G2B adoption. The first major challenge entails determining who can and should do what. Should initiatives be spear-headed by government agencies or by the private sector? Hence, should government regulations and policies guide e-initiatives or should the needs and resources of the private sector guide the growth and development of electronic interactions? Perhaps the public and private sectors could work together to promote G2B adoption.

Secondly, there are numerous institutional and cultural factors that may hinder the massive systemic change needed to adopt new business practices and business models (GSA, 2001). If necessary, is JGI ready to re-engineer its business process to take advantage of e-government services? Simply automating existing processes may not be the most efficient and effective way to employ this innovation. JGI should be willing to re-evaluate its procedures and implement strategic changes to capitalize on e-government technology.

In addition to institutional and cultural challenges for the private sector, there are also several issues that the public sector must consider. For instance, are government agencies willing and able to provide intuitive, seamless e-services that are easy to adopt? E-government Web sites should be designed so that even novice computer users can find information and complete transactions. These sites should be accessible to people with disabilities. Indeed, those with special needs should be able to access e-government services as readily as the non-disabled. The sites should also be interoperable (Fang, 2002) and provide links to other relevant, up-to-date e-government websites. Government agencies should work together to present a unified and accurate system to its constituents. Moreover, businesses should be able to easily navigate government websites without encountering broken (out-dated) links.

Finally, once government agencies make e-services available, they still must establish initiatives that promote awareness and adoption. Previous studies have focused on e-service adoption by small and medium-sized firms (Reddick, 2004). However, few studies have explored the adoption of G2B in large firms. As indicated by this study, although large firms may have an IT infrastructure that's capable of supporting e-government, many IT directors are not aware of these services and their benefits. Government agencies may want to provide face-to-face and web-based training on their electronic options for business.

CONCLUSION

In their ongoing quest to deliver supply chain and logistics services to the transportation industry, the James Group International group of companies must face these challenges that plague the industry and meet the ever-changing needs of its customers in America and abroad to compete in these dynamic times. The company must be flexible, adjusting to the needs of customers as well as changes within the transportation industry. Based on past performance JGI is poised to fulfill its obligations to its customers as well as turn a profit. Featured recently as one of the “champions” among *Black Enterprise Magazine*’s “Top 100 Businesses” (Hughes, 2006), James attributes a substantial growth in revenues to business with foreign as well as domestic automakers. In 2006 JGI was listed as No. 52 on the BE 100’s list with revenues of $78.3 million; while in 2007 the logistics and supply chain giant has moved up to No. 47 with reported revenues of over $88 million (Jefferson & Hughes, 2007). Three of the companies that comprise JGI—RGL, MCX and MCID—are all ISO 9001:2000 MMBDC certified, attesting to the highest quality performance in the industry. Additionally, in 2006 MCX received the “General Motors Global Supplier of the Year Award,” and in 2007 James Group International received what has been touted as the “Academy Award of the Auto Industry”—The Urban Wheel “Supplier of the Year” Award at the North American International Auto Show in Detroit. This track record, along with continuing expansion of and new initiatives in information technology, will enable JGI to remain competitive into the future.

Chapter 4.8

Adoption and Implementation of IT Governance:

Cases from Australian Higher Education

Jyotirmoyee Bhattacharjya
The University of Sydney, Australia

Vanessa Chang
Curtin University of Technology, Australia

ABSTRACT

This chapter introduces key IT governance concepts and industry standards and explores their adoption and implementation in the higher education environment. It shows that IT governance processes, structures and relational mechanisms adopted by these institutions generate value through improvements in a number of key focus areas for IT management. It is hoped that the study will inform both practitioners and researchers and lead to a better understanding of the relationship between IT governance structures, processes and relational mechanisms and business benefits.

INTRODUCTION

Over the past decade, IS/IT governance has become a key issue of concern for senior IT decision makers around the world. The underlying goals for adopting formal IT governance practices are improvement of business performance and conformance with regulations. This exploratory study examines how IT governance is implemented in two Australian institutions through a number of structures, processes, and relational mechanisms and how industry best practice frameworks such as CobiT, ITIL, ISO17799 and ISO/IEC20000 have been utilized in the implementation. The study reveals a number of important findings in the context of the implementation of IT governance in the higher education environment. The relationship between IT governance adoption and implementation and business benefit issues will also be discussed in the chapter. The next few sections of this chapter contains a detailed literature review regarding IT governance, and the important IT related issues in the Australian higher education sector. This is followed by a discussion of the research questions and methodology and then the case study institutions are described. Finally, the findings from the study are presented and the conclusions and directions for future work are discussed.

BACKGROUND

Corporate and IT Governance

Corporate governance has become increasingly important worldwide, especially in the wake of the Enron and MCI WorldCom incidents in the US. The Australian Stock Exchange Corporate Governance Council defines corporate governance as *"... the system by which companies are directed and managed. It influences how the objectives of the company are set and achieved, how risk is monitored and assessed, and how performance is optimised"* (ASX, 2003). IT governance has increasingly become a key area of concern under the umbrella of corporate governance because of the pervasive influence of information systems and the associated technology infrastructure in every area of an organization's activities. The IT Governance Institute describes IT governance as being an integral part of the corporate governance which consists of "the leadership and organizational structures and processes that ensure an organization's IT sustains and extends the organization's strategy and objectives" (ITGI, 2003).

Previous Research in IT Governance Implementation

The term IT governance, started to appear in the research literature towards the late 1990's, with its main proponent being the IT Governance Research Institute (De Haes & Van Grembergen, 2005). Recent surveys suggest that the need to implement and improve IT governance has been receiving growing recognition amongst senior IT management across the world. A survey of top 10 priorities for senior IT management by Gartner Inc. in 2003, found the need for improving IT governance to be included in the list for the first time (De Haes & Van Grembergen, 2004). Surveys of members of the Society of Information Management (SIM) in 2003, 2004 and 2005 also revealed that IT governance was amongst the top ten concerns of IT executives (Luftman, 2005; Luftman, Kempaiah & Nash, 2006). However, implementing IT governance can be an extremely complex undertaking (Brown, 1997; De Haes & Van Grembergen, 2004; Duffy, 2002; Marshall & McKay, 2003; Sambamurthy & Zmud, 1999; Weill & Ross, 2005). In 2003, a survey conducted by the IT Governance Institute through PricewaterhouseCoopers of 335 CEO/CIO level executives around the world showed a lag in practice (ITGI, 2004). The survey found that while 75% executives recognized the requirement for implementing IT governance only 40% were taking any action in this direction. This may be explained by the complexities of implementing IT governance.

While previous research on IT governance implementation focussed on IT governance structures and associated contingency factors (e.g., Brown, 1997; Sambamurthy & Zmud, 1999), later work has identified a number of different mechanisms for implementing IT governance (De Haes & Van Grembergen, 2004; Weill & Ross, 2005). This chapter adapts the framework presented by De Haes & Van Grembergen (2004) to explore IT governance implementations in the higher education sector. Based on the work of Peterson (2004), De Haes and Van Grembergen (2004) propose that IT governance can be implemented through a framework of structures, processes, and relational mechanisms. Structures include the existence of well defined roles and responsibilities and IT steering committees. Processes involve strategic decision making and the use of various IT governance frameworks and standards (e.g., CobiT and ITIL) which can provide the IS organisation with the means of examining its activities and its value to business. Relational mechanisms include shared learning and strategic dialogue between business and IT, and ensuring proper communications at all times.

The structures, processes and relational mechanisms are also divided into tactics or roles and mechanisms or means to implement IT governance (De Haes & Van Grembergen, 2004). For example, the tactics for structures are to form IT executives, committees and councils. The mechanisms are to ensure that there is an IT organisation structure; roles and responsibilities are assigned, a CIO appointed, and the formation of an IT strategy or steering committee. As for processes, the tactics are to ensure that strategic IT decision making and monitoring are formed. This may be accomplished by setting mechanisms such as strategic information systems planning, balanced IT scorecards, service level agreement, COBIT, ITIL and IT alignment of governance maturity models, that would enhanced the processes of implementing IT governance. Finally, relational mechanisms are required to ensure participation from stakeholders, businesses and IT. This is required to ensure an on-going dialogue with the main players. The mechanisms to ensure a smooth running of this include a shared understanding of business/IT objectives, nonavoidance conflict resolution, crossfunctional business/IT training, and crossfunctional business/IT job rotation.

International Standards and Commercially Available Frameworks for IT Governance and Management

A number of IT best practice frameworks and standards such as Control Objectives for Information and Related Technology (CobiT), ISO/IEC 17799, IT Infrastructure Library (ITIL) and Capability Maturity Model (CMM) are available to IT organizations to help them improve their accountability, governance, and management. CobiT is designed by the IT Governance Institute as a high-level "umbrella" framework for IT governance and it works very well with other frameworks like ITIL and ISO/IEC 17799 which focus on specific aspects of IT management. The framework identifies 34 IT processes over 300 control objectives across four IT domains: (1) planning and organization, (2) acquisition and implementation, (3) delivery and support, and (4) monitoring (ITGI, 2000; 2005). The planning and organization domain addresses strategic and tactical issues and how IT can optimally contribute to achieving business goals. The acquisition and implementation domain deals with the development or acquisition of IT solutions, as well as their implementation and integration with business processes. This domain also covers the maintenance of existing systems. The delivery and support domain covers the actual delivery of services ranging from security and continuity related operations to training. Support processes are required to ensure the delivery of services. The monitoring domain addresses the issue of management oversight of the organization's control processes and the need for independent audits. The IT Governance Institute has recently published the fourth edition of CobiT, the first update since 2000. It is described as an incremental improvement on CobiT 3.0 and provides a number of useful additions to the older version (Bodner, 2006; Symons, 2006).

The IT Infrastructure Library (ITIL) is a comprehensive documentation providing guidance regarding best practices for IT service management (ITIL, 2007a; 2007b). The Central Computer and Telecommunication Agency (CCTA) in the UK established the Information Technology Infrastructure Library (ITIL) in 1989 (Sallé, 2004) in order to improve its IT organization. At present the UK's Office of Government Commerce (OGC) is responsible for managing ITIL. ITIL is also supported by the IT Service Management Forum (itSMF). In 2000 the OGC, in collaboration with the British Standards Institution (BSI) and itSMF, revised ITIL in order to integrate it with the BSI Management Overview, the BSI specification for service management (BS 15000-1) and the BSI code of practice for service management (BS150000-1) (ITIL, 2007a). The BSI Management Overview provides a high level introduction to ITIL, while the ITIL books expand on the information and provide guidance regarding the subjects addressed within BS150000. BS15000 has now been replaced by ISO/IEC 20000:2005. Like its predecessor, ISO/IEC 20000 is a two part standard (1SO, 2005a). The first part specifies requirements for IT service management while the second part provides a code of practice. The ITIL documentation, now available in version three, takes a lifecycle approach to guidance (ITIL, 2007b). It is organized around five core titles: (1) Service Strategy which provides a view of ITIL that ensures that all elements of the Service Lifecycle is focused on customer outcomes, (2) Service Design which provides guidance for producing and maintaining IT architectures and policies and documents for designing appropriate IT infrastructure service processes and solutions (3) Service Transition which provides guidance for the transition of services in the business environment, (4) Service Operation which details control and delivery activities for achieving excellence in daily operations, and (5) Continual Service Improvement which focuses on the process of identifying and introducing improvements to service managements.

Another standard that can be implemented alongside CobiT and ITIL is ISO/IEC 17799:2005 (expected to be renamed ISO/IEC 27002 in 2007/08). The standard was originally developed from BS 7799 which provides a code of practice for developing information security standards in an organization (ISO, 2000). However, unlike CobiT and ITIL, it was not designed to be a certification standard. It has recently released a companion standard, ISO/IEC 27001 that can be used for the purpose of certification instead of the older and superseded BS 7799-2 on which it is based (ISO, 2005b). A new risk management standard BS 7799-3:2006 is also presently available from the British Standards Institute. This standard provides support and guidance for the risk management aspect of ISO/IEC 27001:2005.

In addition to these frameworks and international standards, Australian organizations have three local standards available to guide their IT governance and management practices. These are AS 8015-2005 (ICT governance standard), AS ISO/IEC 20000.1-2007 (specification for ICT service management) and AS ISO/IEC 20000.2-2007 (code of practice for ICT service management).

The ICT governance standard, AS 8015-2005, provides a set of guiding principles for senior business decision makers regarding the effective and efficient use of information and communication technology (ICT) within their organizations, irrespective of the industry sector. The standard addresses the governance of ICT resources for the provision of information and communication services within the enterprise (Standards Australia, 2005). The standard is currently in the process of being developed into an international standard. It has been accepted as a Draft International Standard (ISO/IEC DIS 29382) by the ISO in early 2007 (ISO, 2007).

Standards Australia (2007a; 2007b) provides a two part service management standard AS ISO/IEC 20000-2007. The first part (AS 20000.1-2007) outlines the requirements that a service provider needs to fulfil in order to deliver an acceptable quality of managed service to customers, while the second part (AS 20000.2-2007) recommends a common terminology for IT service providers, so that effective processes may be established. AS 20000.1-2007 is identical to ISO/IEC 20000.1-2005 and AS 20000.2-2007 is identical to ISO/IEC 20000.2-2005. They supersede AS 8018.1-2004 and AS 8018.2-2004.

Implementation of these frameworks may vary from one region to another. A recent Forrester Research survey of 135 IT managers in North America revealed that about 20% rely on CobiT while another 20% use ITIL (Dubie, 2005). A survey of 110 respondents by Cater-Steel and Tan (2005) at a recent Australian itSMF conference showed that while all respondents were at different stages of implementing ITIL, less than a third are also implementing CobiT. These frameworks are not necessarily mutually exclusive and increasing the value of IT from a business perspective requires an understanding of their strengths, weaknesses and focus (Symons, 2005). IT governance frameworks are being increasingly adopted around the world because they not only assure conformance with regulations but also help in ensuring performance (Liew, 2006). Organizations may benefit from adopting what they find useful from each framework rather than just adopting a single one (Chickowski, 2004).

There are, however, very few academic publications examining the issues and problems with the adoption and implementation of these frameworks and standards. Ridley, Young, and Carroll (2004) found that this to be particularly true in the case of publications related the CobiT framework, a majority of which tend to be practitioner publications. Cater-Steel and Tan (2005) make a similar observation regarding the available publications on ITIL.

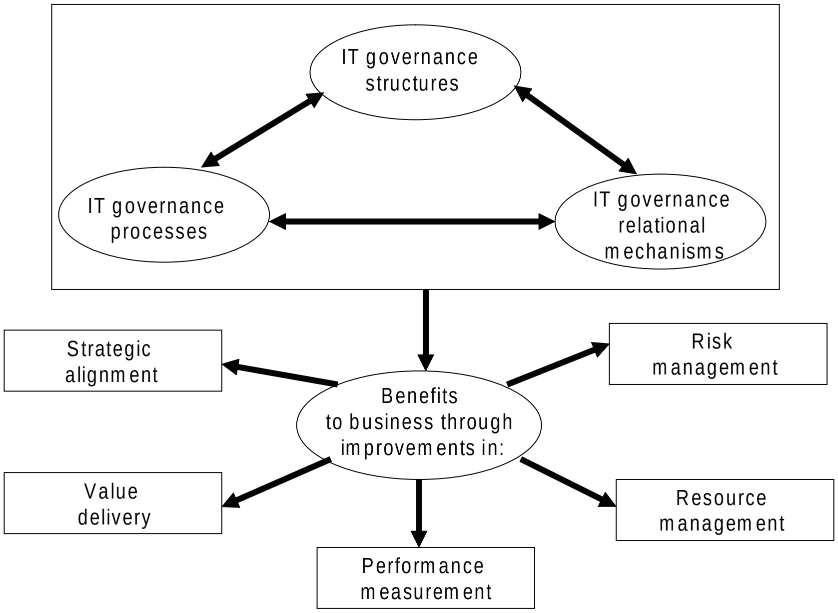
Emergent Framework of IT Governance Mechanisms and Focus Areas

The IT Governance Institute has identified five focus areas of IT governance (ITGI, 2005): (1) strategic alignment, (2) value delivery, (3) resource management, (4) risk management, and (5) performance measurement.

According to ITGI (2005, p. 6): Strategic alignment is about ensuring the linkage of business and IT plans; on defining, maintaining and validating the IT value proposition; and on aligning IT operations with enterprise operations. Value delivery is about executing the value proposition throughout the delivery cycle, ensuring that IT delivers the promised benefits against the strategy, concentrating on optimising costs and proving the intrinsic value of IT. Resource management is described as the optimal investment in, and the proper management of, critical IT resources in applications, information, infrastructure and people. Key issues of resource management relate to the optimisation of knowledge and infrastructure. Risk management is concerned with risk awareness by senior corporate officers, understanding of compliance requirements, transparency about the significant risks to the enterprise, and embedding of risk management responsibilities into the organisation. Performance measurement is about tracking and monitoring strategy implementation, project completion, resource usage, process performance and service delivery, using, for example, balanced scorecards that translate strategy into action to achieve goals measurable beyond conventional accounting.

The two primary concerns of IT governance, value delivery and risk management, are driven by strategic alignment and accountability concerns respectively. Both require adequate resources and need to be measured against the objectives of the business.

Figure 1. The emerging IT governance and business benefits framework



The emergent framework as illustrated in Figure 1 combines the framework of De Haes and Van Grembergen and the IT governance focus areas. In order for a business to be effective, the framework indicates that an organization's IT governance structures, processes and relational mechanisms must be set in place.

As mentioned previously, IT governance structures identify various roles and responsibilities in the context of IT governance in an organization (De Haes & Van Grembergen, 2004). Processes describe how those with appropriate responsibilities are involved in the governance rather than the day-to-day operational management of IT. Relational mechanisms ensure the success of structures and processes by addressing ways of improving the relationship between business and IT (De Haes & Van Grembergen, 2005). This suggests a dynamic relationship between these three components of IT governance as shown in Figure 1. Optimizing the balance between structures, processes and relational mechanisms could lead to substantial benefits for business through improvements in the five focus areas of IT governance identified by the IT Governance Institute (ITGI, 2005).

This study uses the framework presented in Figure 1 to explore the IT governance implementations in two institutions of higher education.

IT Governance in Australian Institutions of Higher Education

Higher education is a multibillion dollar industry in Australia, and as such, it is of vital importance to the country's economy (Higher Education IT Consultative Forum, 2000; Nelson, 2002). It is both a major consumer of IT products and services as well as a major provider of services using ICT. IT has helped the improvement of a range of activities including research, teaching, learning and administration in the higher education environment. Significant developments have been made by these institutions in the area of online teaching and learning. The demand for IT based products and services, has also increased as a result of the rapid increase in student population in the last 15 years.

There is much work that needs to be done by university governing bodies and policy makers in order for these universities to continue tapping emerging information technologies in order to maintain their competitive positions internationally (Higher Education IT Consultative Forum, 2000). The issues range from infrastructure, applications, delivery and services to staffing and appropriate regulatory frameworks. IT applications have also not yet penetrated all aspects of university teaching and more effort is required to bring about improvements in this area. However, despite the wide range of concerns facing IT governing bodies in Australian universities in the information economy, there has been very little research regarding how IT governance may be suitably implemented in these institutions in order for them to provide optimal benefits to higher education.

RESEARCH QUESTION AND METHODOLOGY

The chapter investigates the adoption and implementation of IT governance in two Australian institutions for higher education. The research question is:

How is formal IT governance adopted and implemented within the higher education environment in Australia?

As suggested by Benbasat, Goldstein, and Mead (1987), the case research method is useful for addressing the "*how*" questions, that is, in the exploratory stage of knowledge building. This is particularly useful for a study on IT governance in the context of institutions of higher education in Australia, where the knowledge of researchers regarding new methods, techniques, problems and prospects lags that of practitioners. A case research strategy is expected to provide rich insight in this context.

Two leading institutions of higher education in Australia in different stages of adopting and implementing formal IT governance practices were selected for the study based on the availability of senior IT and business decision makers in these institutions for participating in this research. The study was undertaken in 2006. In keeping with participants' requests for anonymity, the institutions will be referred to as Institution A and Institution B in this chapter. The data collected was primarily qualitative in nature. The data was gathered from semi-structured interviews with senior IT and business decision makers in both institutions as well as from relevant documents obtained from interviewees and the websites of the institutions. The interviews were recorded and later transcribed and analysed. The data sources from the institutions are summarized in Table 1.

Table 1. Data sources from the two case study institutions

Institution	Interviewees	Documents
Institution A	- 2 senior IT decision makers - 2 senior business decision makers	- Overall strategic plan and strategic IS plan - Disaster recovery plan - Organizational chart and committee structures - Security policies and procedures - Personnel statistics - Student satisfaction surveys
Institution B	- 2 senior IT decision makers - 1 senior business decision maker	- Overall strategic plan and strategic IS plan - Proposed IT governance model - Organizational chart and committee structures - Security policies and procedures - Personnel statistics

THE CASE STUDY INSTITUTIONS

Institution A was established in the 1960's. The institution has over 3,000 academic and administrative staff members and over 30,000 students. Its primary goals are to achieve excellence in teaching, learning, research and development. Its present priorities include providing flexible learning opportunities, developing facilities and technological infrastructure to support research priorities, forming partnerships with industry and government and improving its revenue generation. The institution has an overall strategic plan as well as a number of divisional plans and maintains a balanced scorecard. It has six academic divisions which are subdivided into several schools, centres and departments, as well as a number of support areas including central IT services, finance, and student and staff services. The institution is publicly funded, with annual revenue of around A$400 million, 10% of which is spent on IT. The institution's IT history began in the 1960's, with the acquisition of a computer for the mathematics department. In the early 1970's, a computer system was installed primarily for teaching purposes. This was followed by the in-house development of an accounting package, signalling the first move towards corporate applications. The institution decided on continued development of both teaching and administrative applications, although these were to be handled separately. Since the various teaching and administrative divisions had specific application needs, the decisions regarding the procurement or development of applications lie with the divisions. In the late 1980s the institution received its first Australian Academic and Research Network (AARNET) connection and the use of email followed soon after.

Institution B was established in the early 1900's. It has over 2000 academic and administrative staff members and over 16,000 students. Like Institution A, it aims to advance teaching, learning and research. It has nine academic divisions and a number of support areas. The institution has an overall strategic plan and a number of divisional plans. The publicly funded institution's annual revenue is around A$500 million about 1.5% of which is spent on central IT and about 4.5% across the divisions. Divisional IT services and the library have separate IT budgets. Historically IT has been devolved to central administration, the academic divisions and the library.

In 1999 Institution A had an ICT review conducted by an external consulting firm. The review identified a devolved IT structure. A number of key issues including the negative impact of divergent IT directions in the divisions on overall corporate effectiveness, inadequate strategic planning and coordination related to ICT across the institution, inadequate ICT resources and lack of leadership at the senior level of senior management were reported in the review. As a direct result of the 1999 review, they adopted CobiT in the year 2000 to evaluate the current IT processes within the institution.

Institution B has recently adopted a formal IT governance model. In early 2006 they commissioned a new Strategy Manager and Director of IT to set up their IT governance model with an aim to centralize their IT governance structure. The next three sections explore the adoption and implementation of IT governance through a mixture of structures, processes and relational mechanisms in these two institutions.

As proposed in Figure 1, the institutions implement IT governance through a combination of structures, processes and relational mechanisms in different focus areas.

IT GOVERNANCE STRUCTURES

IT governance structures include clearly defined roles and responsibility of IT executives to manage the IT structure within the organization (De Haes & Van Grembergen, 2004). This may include setting up of IT committees to oversee various IT strategies and functions of IT within the organization.

Institution A

Currently, Institution A has about 200 staff members employed in the IT area. Of the 200 staff members, 100 are located in the central IT services and the other 100 within the divisions. Despite the observations made in the 1999 review it has not been possible to integrate the ICT across the institution into a single unit due to lack of an institution wide support for such a change. However, some enterprise wide standards for ICT have been developed and the need for compliance by the divisions has been recognized. Duplication of some services across the divisions remains a cause of significant concern and it is believed that considerable cost savings could result from avoiding such duplication.

Institution A has a formal reporting channel whereby the Director of central IT services reports to the Pro-Vice Chancellor. The role of the Director is primarily that of a technology professional though there is a growing realization of the need for the role to be more business oriented. The Director of central IT oversees three Associate Directors who are responsible in the infrastructure, applications and services areas respectively. A recent development has been the formation of the IT strategy committee, which reports to and advises the institution's planning and management committee. The IT strategy committee in its present form was established in mid 2005. It currently includes the Director of central IT services, representatives of all divisional IT groups, the Director of Finance, representatives from R&D, the Pro-Vice Chancellor and key stakeholders. The committee makes recommendations regarding the alignment of ICT with the goals of the institution, monitors the activities of the central and divisional IT service providers and fosters effective communication amongst them.

The formation of the IT strategy committee in mid 2005 and the development of the enterprise wide standards reflect the recognition by senior business and IT decision makers of the need for a formal IT Governance model to support a centralized decision making structure. The shift from a devolved or decentralized IT structure to a centralized structure in Institution A is consistent with the results of a survey by Mendez (2005) of IT executives in Europe which showed a significant shift in the IT organization structure from decentralized or federated models to centralized ones.

Telecommunication and network related decision making in the institution has been centralized since the beginning. However, this has not been the case with desktop computers and servers because of the IT revolution in the 1980's. This has continued to this day, resulting in the institution's federated IT organization structure. There are six divisional IT groups which manage their own servers and desktop PCs independently of central IT. The divisional IT groups have independent funding and decision-making structures from central IT. Although they provide the same kind of services as the central IT group, their standards and practices may vary from those of central IT. Over the past year central IT has moved towards developing good relationships with divisional IT managers. This has helped in the achievement of some alignment between the central and divisional IT groups.

Institution B

In Institution B, there are about 70 IT staff in central IT and a similar number spread over the nine divisions and the library. As in the case of Institution A, this structure has led to considerable duplication of IT staff efforts. IT has five major areas – administration including budget and staffing, strategy and governance, client services including desktop and student Internet support, systems services including database support and systems development, and technical services looking after network and servers. The managers of these areas report to the Director of IT who reports to the Director of Finance.

Unlike Institution A, the role of the Director of IT in Institution B is that of a general business manager rather than a technology professional. This shift in the role for the Director of IT was decided in 2005 by the new Director of Finance based on his experience in the resources sector. It was believed that the position of the Director of IT required someone who clearly understood the business needs of the institution and has an overall technology focus.

A formal IT governance model specifying the various roles and responsibilities based on CobiT 4.0 was adopted at the beginning of 2006 when the new Strategy Manager was appointed. This model is now in the process of being implemented. The adoption of the model has led to a significant improvement in the involvement of business in IT decision making. The IT steering committee is expected to meet on a quarterly basis and provide an opportunity for communication on key IT issues amongst IT and business decision makers. The IT steering committee is advised by a technical advisory group which is comprised of all the central and divisional IT managers. Smaller working groups are also constituted from the divisional stakeholders and central IT staff as and when required for specific projects. The IT Director and Strategy Manager are responsible for decisions regarding standardization of IT infrastructure strategies and architecture. Decisions regarding business application needs are made by business decision makers with input from IT.

A summary of IT governance structures in Institution A and Institution B, based on the De Haes and Van Grembergen framework is shown in Table 2.

IT GOVERNANCE PROCESSES

IT governance processes involve strategic decision making and the use of various performance monitoring frameworks and tools such as Strategic Information Systems Planning, CobiT, ITIL, Balanced Scorecard, Information Economics and others (De Haes & Van Grembergen, 2004).

Institution A

The institution has an overall strategic plan and follows a balanced scorecard. ICT has an ICT enabling plan, which is regularly updated. An important issue in this regard is that this ICT enabling plan is not directly associated with a budget for strategic expenditures. The present budget allocation for ICT is for staff, software licenses, site licenses, and refreshing the IT infrastructure. Although the need for a new document management system has been recognized by both IT and business decision makers, in order for the institution to improve its record keeping, appropriate funds for such procurement are yet to be acquired.

IT management decision making within the institution is influenced by the guiding principles of the Australian ICT governance standard AS 8015-2005 and the service management standards AS 8018.1-2004 and AS 8018.2-2004. CobiT 3.0

Table 2. A summary of IT governance structures in the case study institutions

	Structures	Institution A	Institution B
Tactics	– IT executives and accounts – Committees and councils	– Yes – Yes	– Yes – Yes
Mechanisms	– Roles and responsibilities – IT organization structure – CIO on board – IT strategy committee – IT steering committee(s)	– Yes (evolving) – Yes (evolving) – No – Yes (recent) – No	– Yes (evolving) – Yes (evolving) – No – No – Yes (recent)

has been adopted since the year 2000 for assessing and improving the institution's IT governance processes. A direct effect of this has been the realization by senior IT decision makers that the effective utilization of CobiT across the institution requires a more centralized IT governance environment. However, given the size of the CobiT 3.0 framework, only a small number of processes and objectives are identified for review each year. The objectives were initially based on a large number of interviews conducted across the campus in 2000 by IT staff. In subsequent years, objectives have been identified based on the original interviews and results of an annual survey of student and staff satisfaction on IT issues.

ITIL is used as the standard for service management. A number of operational level staff members have ITIL Foundation level training. The current focus is on getting better at incident management, change management, problem management, IT strategic planning and managing the IT architecture. The progress made has also been assessed against CobiT and ITIL. Consultative, Objective and Bi-functional Risk Analysis (COBRA), a software package, based on ISO17799 is being used for facilitating risk management.

Since CobiT requires the use of a standard project management methodology, Project Management Body of Knowledge (PMBOK) has been selected as the guide in this regard. Based on the perceptions of business decision makers, in the last two years IT has shown considerable maturity in project management and delivery. This is the result of adopting a strong project management methodology.

People Capability Maturity Model (P-CMM) is used as the standard of IT staff management and development. However, a lot of work is required in the area of staff development.

The value to business from the implementation of best practice frameworks has been in terms of reducing the number of ad-hoc processes, bringing a lot of discipline to IT support activities and improving accountability. Whilst IT has made significant strides since the year 2000, the IT management recognizes that there is a long journey ahead.

One problem that has been faced in implementing the best practice frameworks like CobiT, which have high resource requirements, has been the shortage of adequate staff. The demand for staff time and services are also increasing. Most of the central IT teams find it difficult and at times challenging to achieve their operational objectives. Staffing in the server support area, for example, consists of about 10 people supporting 300 servers of various kinds, implementing changes to the infrastructure as well as managing large applications being used by thousands of people. Despite the staffing issue, however, process improvements continue to take place because of the continued commitment of senior IT management.

Another key area of difficulty has been that of finding appropriate performance metrics measurement. Currently, technical measures being used include percentage downtime, percentage access failure, the number of students accessing their email on a regular basis on the official communications channel and so on. One particular measure, the number of available desktops in the computer laboratories per student was found to be not particularly useful. It was found that when the number of desktops was doubled based on survey responses; the satisfaction level was actually lower than in the previous year. Management decision makers in the institution attribute this to the increasing expectations from ICT facilities with the rapid advances technology. The institution continues to work on developing balanced business-IT metrics.

Institution B

While Institution A has been using CobiT 3.0 to evaluate and improve key IT processes, Institution B has utilized CobiT 4.0 to develop its overall IT governance model and outline the various roles and responsibilities. The development of the IT governance model has resulted in substantial involvement of business decision makers in making decisions regarding IT investment, risk and priorities. This has made it easier for business decision makers to appreciate the value of key decisions regarding IT. The initial problem faced in the implementation of the model was the lack of IT governance concepts amongst business decision makers and the resistance to change. This is gradually being overcome and the need for accountability for IT related decision making across the institution is better accepted. This is achieved by communicating to business decision makers their roles and responsibilities in IT related decision making for the benefit of the business, without making it necessary for them to know any technical details regarding CobiT.

CobiT is also being used for risk assessment and management. While ISO17799 provides guidance on what needs to be done in the context of security, CobiT guides management on how these goals should be achieved. The IT security manager has been trained in ISO17799 and will additionally undertake the security management training program provided by the developers of CobiT.

The institution has an overall strategic plan and central IT undertakes strategic information systems planning under the supervision of the IT steering committee. Service level agreements are in place for hosting and managing application systems including the student system, the facilities management system, the HR and finance system.

At present there is a lack of enterprise-wide standards for infrastructure and applications. The key issues that IT intends to tackle over the next year include the lack of standards and controls and the existence of multiple help desks. As part of the central IT service desk project, it is planned to implement ITIL to handle change and incident management over the next few months. As part of the ITIL implementation service desk staff will be required to undertake ITIL Foundation level training. Capability is also being built up in the project management and business process analysis domain to reduce the current dependence on external consultants.

As in the case of Institution A there is difficulty in deciding on which metrics to measure. Current metrics being used include the number of service calls being answered to completion, the number of network and database administrators and the ratio of total IT cost to organizational cost. However, there is a realization that these metrics are not adequate for representing the value of IT to business.

A summary of IT governance processes in Institution A and Institution B, based on the De Haes and Van Grembergen framework is shown in Table 3.

Table 3. A summary of IT governance processes in the case study institutions

	Processes	Institution A	Institution B
Tactics	–Strategic IT decision making –Strategic IT monitoring	–Yes –Yes	–Yes –Yes
Mechanisms	–Strategic IS planning –Balanced IT scorecards –Information economics –Service level agreements –CobiT and ITIL –IT alignment/ governance maturity models	–Yes (improving) –No (some technical measures) –No –No –Yes along with other standards since 2000 –No (considered early days for maturity models)	–Yes (improving) –No (some technical measures) –No –Yes –CobiT with ISO17799 since early 2006 –No (considered early days for maturity models)

IT GOVERNANCE RELATIONAL MECHANISM

Relational mechanisms according to De Haes and Van Grembergen (2004) include shared learning and strategic dialogue between business and IT, and ensuring proper communications at all times.

Institution A

The key stakeholder groups for central IT include teaching staff, students, business process owners, research and development, and divisional IT management whilst those for divisional IT include teaching staff and students. There are efforts being made by central IT to improve the quality and frequency of communications with these groups.

Communications often take place at the tactical level. For instance, if a significant outage of services is being considered, divisional IT contacts and business process owners are informed and their responses are used to guide appropriate decision-making. In case of policy changes, e-mails are sent out by the particular group within IT that is responsible for that policy. The senior IT decision maker responsible for infrastructure also meets with the divisional IT management on a monthly basis. Over the last couple of years there has been emphasis on strategic level dialog. The monthly meetings of the newly formed ICT committee are also helping to improve communications between business and IT. This increased effort made by IT decision makers to liaise with business, has led to a growing perception of IT as a valued service provider rather than just a cost of doing business.

An area requiring further attention is staff development. Currently there is no staff retention program for IT staff and no opportunity for cross-training. There is also a need for increasing staff numbers in central IT. While an integration of IT services centrally might help solve the problem of staff shortage, opposition at the divisional level has yet to be overcome.

Institution B

Communication with key stakeholders is being considered to be of vital importance over the coming months in order to successfully implement the new IT governance model. The principal stakeholder groups for IT include the teaching staff, students, research and development, university administration, and the library. Communication with these groups is carried out through informal discussions, working groups and committee meetings. Unlike in previous years, conflicts between central IT and divisional IT are now actively resolved through discussions at the steering committee meetings.

The understanding of IT by business and vice versa is improving gradually and IT is emerging as an asset and a valued service provider. There has been a recent policy shift geared towards more balanced business and technical hiring within central IT.

A summary of IT governance relational mechanisms in Institution A and Institution B, based on the De Haes and Van Grembergen framework is shown in Table 4.

FINDINGS

A Comparison Between Institutions A and B

The chapter addresses the question of how formal IT governance practices can be adopted within the higher education environment. The increased dependence of IT in the higher education environment has also led to the awareness of the need for adopting formal IT governance practices. As seen in the previous sections both institutions have been implementing IT governance through a mixture of structures, processes and relational mechanisms.

Table 4. A summary of IT governance relational mechanisms in the case study institutions

	Relational Mechanisms	Institution A	Institution B
Tactics	– Stakeholder participation – Business/IT partnerships – Strategic dialog – Shared learning	Improving on all counts	Improving on all counts
Mechanisms	– Active participation by principal stakeholders – Collaboration between principal stakeholders – Partnership rewards and incentives – Business/IT co-location – Shared understanding of business/IT objectives – Active conflict resolution (non-avoidance) – Cross-functional business/IT training – Cross-functional business/IT job rotation	– Improving – Improving – No – Improving – Improving – Recent attempts – No – No	– Improving – Improving – No – Improving – Improving – Recent attempts – No – No

Based on the experiences of Institutions A and B, the following findings emerge with regard to the implementation of IT governance:

1. Professionals in both institutions agree that while an institution of higher education has to deal with low staffing levels, this should not be a deterrent in adopting industry best practices. They also agree that instead of adopting any one best practice framework, it is important to evaluate the strengths and weaknesses of the business and selectively adopt a combination of the relevant elements of best practice frameworks and standards such as CobiT, ITIL, ISO17799, AS 8015-2005, AS 8018.1-2004 or AS 8018.2-2004 that are necessary to support the business.
2. The two institutions vary in their approach in implementing CobiT and in the version of CobiT being implemented. The application of CobiT 3.0 for improving individual processes was an important eye-opener for management in Institution A because it focused attention on the need for centralization of decision making, having well defined IT governance roles and responsibilities, and developing enterprise-wide standards. In Institution B the overall IT governance structure is being implemented based on the CobiT 4.0 framework. It is believed that this approach would help in the utilization of CobiT 4.0 for improving processes across the university rather than just at central IT.
3. Institutions of higher education may benefit from experiences gained in IT governance implementation in other industries. In the case of Institution B, the background of the Director of Finance in the resources sector helped in identifying the need for the role of the Director of IT to be more business oriented (a need also being gradually recognized in Institution A). The Strategy Manager's background in the finance sector helped in developing the governance model for the institution fairly quickly based on the CobiT 4.0 framework.
4. CobiT requires the use of a good project management methodology. Institution A's adoption of CobiT has led to its adoption of PMBOK. This was particularly important as the institution's IT staff does a considerable amount of the project implementation and delivery work in-house.
5. A key difference between CobiT and ITIL noted by professionals in both organizations is in the availability and cost of documentation. There is a considerable amount of CobiT related documentation and research papers available free of cost from the Information Systems Audit and Control Association (ISACA) Website and additional information is available through mailing lists. ITIL

documentation, on the other hand, is considerably more expensive.

6. Both institutions have realized that although the use of multiple learning management systems and multiple email systems may be the existing norm in the divisions, this leads to duplication of ICT staff efforts without increasing the satisfaction of staff and students across the institution. A consolidation of systems could potentially help in the reduction of staff numbers (leading to reduced costs) while providing a better direction for staff efforts.
7. In both institutions, the disparity in ICT services across the institutions lead to difficulties in managing the perceptions of students and staff. In Institution A, student dissatisfaction with ICT services at the divisional level is reflected on their perception of ICT in general in the annual surveys. A consolidation of services (e.g. helpdesks, printing) could help in maintaining the same standards of services across the institution (in both cases) and make it easier to manage perceptions.
8. In both institutions improving communication between central IT and divisional IT groups are helping in the general acceptance of central IT standards.
9. In both institutions improving communication between IT and business has led to the gradual acceptance of IT as a valued service provider rather than just a cost of doing business, in an institution whose core business is not IT.

The Relationship Between Structures, Processes and Relational Mechanisms

As discussed previously, De Haes and Van Grembergen (2004) provide a broad framework for implementing IT governance through a mixture of structures, processes and relational mechanisms. However they do not explicitly discuss the relations between these three and how they relate to business benefits. The findings of the study support the emerging framework presented in Figure 1.

The study suggests that the development of IT governance structures (eg. IT strategy committee) leads to improved relational mechanisms and the adoption of IT governance processes (eg. the implementation of best practice frameworks such as ITIL) across the enterprise. The findings associated with Institution A suggests that there is a need to have a formal IT Governance structure with clearly defined roles and responsibilities in order to facilitate the adopted IT governance processes. As discussed in the findings, Institution A is shifting to a centralized IT governance structure. By adopting a formal IT Governance structure, Institution A strives to strengthen relational mechanisms. Improving relational mechanisms through formal and informal communications ensures broader support for improving IT governance structures and processes. The findings associated with Institution B affirms the framework as shown in Figure 1 in that they used COBIT to guide, develop and establish a formal IT Governance model including various structures, processes and relational mechanisms. Whilst Institution B presently lacks enterprise-wide standards (e.g., architectural, service management), they plan to implement ITIL as the service management standard with their IT staff requiring to undertake ITIL Foundation level training. Institution B has also considered key stakeholders to be vital and this has resulted in a policy geared towards a more balanced between business and IT hiring within central IT. While the institutions are in the early stages of experiencing business benefits from their evolving structures, processes and relational mechanisms, a longitudinal study would shed further light on the benefits of their IT governance practices.

The study also suggests that the range of structures, processes and relational mechanisms implemented by each organisation may differ from those presented in the De Haes and Van Grembergen (2004) framework.

The Five Focus Areas of IT Governance

The focus of IT governance implementation in the two institutions seems to be on five key areas as shown in Figure 1.

IT governance in the two institutions is implemented through a number of processes, structures and relational mechanisms in the context of these five areas. The focus area of strategic alignment in the four institutions appears to be addressed through processes such as strategic IS planning and the adoption and implementation of industry frameworks such as ITIL and CobiT that help in the attainment of business objectives. Structures like steering committees are used to involve business decision makers in strategic level IT decision-making. This growing interaction between business and IT is helping to build a shared understanding between business and IT on key issues. This is an important relational mechanism in the De Haes and Van Grembergen framework (2004).

With respect to value delivery (Figure 1), the adoption of standards such as PMBOK and ITIL for improving project management and service delivery was found to be an important process. While ITIL has been adopted by both institutions, PMBOK appears to have been adopted by institutions A only. Attention given by management to ensure staff training was found to be an important relational mechanism.

CobiT and ISO17799 were found to have been adopted by institutions A and B for risk management purposes. The adoption of P-CMM is guiding the management of human resources in institution A. It must be noted that although both institutions had reasonably well understood roles and responsibilities for the management of key resources such as business applications and supporting infrastructure, the institutions are all yet to have a formal documented governance model in place clearly outlining these structures.

As in other industries measuring the performance of IT remains a big challenge for IT decision makers in institutions of higher education and suitable measures are gradually being developed. CobiT has been used for evaluating IT process maturity in Institution A.

While there has been progress in all five focus areas, the development of formal governance models with input from key business decision makers could help in continuing to generate value for business in the two institutions.

LIMITATIONS AND FUTURE WORK

The study focuses on the implementation of structures, processes and relational mechanisms in two institutions of higher education and the focus areas for these implementations. It does not seek to address specific educational market drivers influencing IT governance implementations or the operational management issues that a well designed IT governance model helps to facilitate. Future research in these directions as well as on the integration of IT and corporate governance in the higher education sector would help in strengthening the findings. Further longitudinal investigations of IT governance practices in the higher education sector would help in testing the IT governance-business benefits framework presented in Figure 1 and addressing the present limitations of the study.

CONCLUSION

The chapter highlights some key issues regarding the adoption of formal IT governance practices in the higher education sector for the benefit of practitioners, academics, and researchers. As discussed in the previous section, the findings of study provide support for the framework presented in Figure 1. Institutions A and B were found to have implemented IT governance through a combination of various structures, processes and relational mechanisms. Benefits to business in the two institutions were found to arise from improvements in strategic alignment, value delivery, performance measurement, resource and risk management as the various mechanisms of IT governance evolve in these institutions. However, it must be noted that as both institutions are in the process of developing their formal governance models and the extent of benefits from IT governance may become more clearly understood in the future. One of the institutions has already received feedback from the authors regarding the findings of the study and is in the process of implementing some of the recommendations.

Chapter 4.9

Enterprise Resource Planning (ERP) Implementations:

Theory and Practice

Joseph R. Muscatello
Kent State University, USA

Injazz J. Chen
Cleveland State University, USA

ABSTRACT

Enterprise resource planning (ERP) systems have been widely implemented by numerous firms throughout the industrial world. While success stories of ERP implementation abound due to its potential in resolving the problem of fragmented information, a substantial number of these implementations fail to meet the goals of the organization. Some are abandoned altogether and others contribute to the failure of an organization. This article seeks to identify the critical factors of ERP implementation and uses statistical analysis to further delineate the patterns of adoption of the various concepts. A cross-sectional mail survey was mailed to business executives who have experience in the implementation of ERP systems. The results of this study provide empirical evidence that the theoretical constructs of ERP implementation are followed at varying levels. It offers some fresh insights into the current practice of ERP implementation. In addition, this study fills the need for ERP implementation constructs that can be utilized for further study of this important topic.

INTRODUCTION

Enterprise resource planning (ERP) systems are widely implemented as the backbone of many manufacturing and service firms. They are designed to address the problem of information fragmentation or "islands of information" in business organizations (Muscatello, Small, & Chen, 2003). A typical ERP system integrates all of a company's functions by allowing the modules to share and transfer information freely (Hicks & Stecke, 1995; Chen, 2001). In addition, all information is centralized in a single relational database accessible by all modules, eliminating the need for multiple entries of the same data. Customers and suppliers with network security clearance are allowed to access certain types of information by way of an external communication interface.

ERP systems offer tremendous opportunities to more consistently provide information to organizations in a standardized, centralized, and cost efficient manner (Olson, Chae, & Sheu, 2005). Many industry reports extol the virtues of ERP and its multiple benefits for those firms that can successfully implement these systems. One of the primary objectives for installing ERP is the ability to integrate business processes (Brakely, 1999; Davenport, 1998, 2000). ERP has also been found to be effective in reducing inventory costs, improving efficiency, and increasing profitability (Appleton, 1997; Brakely, 1999). In addition, ERP has been credited with reducing manufacturing lead times (Goodpasture, 1995; Davenport & Brooks, 2004). Other potential benefits of ERP include drastic declines in inventory, breakthrough reductions in working capital, abundant information about customer wants and needs, and the ability to view and manage the extended enterprise of suppliers, alliances, and customers as an integrated whole (Muscatello, Small, & Chen, 2003). Clearly, the integrated information technology of ERP software has the potential to provide manufacturing firms with extensive new competitive capabilities, especially since the real-time information can improve the speed and precision of enterprise response. Given the widespread popularity of ERP software, and the spectacular successes achieved by a few firms, an open question remains: Why has the effective deployment of ERP systems proven to be elusive for the majority of firms (Stratman & Roth, 2002)?

Implementation of an ERP does not come without significant technical and managerial challenges, huge financial investments, and a great deal of organizational change. Operational problems at Hershey Foods, Whirlpool, FoxMeyer Drugs, and more recently Hewlett Packard, have been blamed on poor implementations of ERP solutions (Becerra-Ferandez et al., 2005). ERP also has the reputation of being notoriously over-sold and under-delivered (Millman, 2004). Cliffe (1999) even reported that 65% of executives believed that ERP could be harmful to their organizations.

Researchers have attempted to identify the set of factors that are critical for ensuring success with ERP implementations. Most of these authors, however, have developed their list of critical success factors from a small number of case studies. For example, Holland and Light (1999) and Motwani, Mirchandani, Madan, and Gunasekaran (2002) offered a list of critical factors using two case studies. More recently, Kumar, Maheshwari and Kumar (2003) identified several success factors based on data collected from 20 Canadian firms. Employing a large scale survey, this article seeks to ascertain how businesses receive these concepts and, more specifically, which concepts are practiced widely and which are not. With this goal in mind, pertinent constructs of ERP implementations based on a critical review of business and managerial literature are first identified and developed in the second section. The research design, including data collection is then explained in the third section. The fourth section presents the results along with implications of the study findings. In the concluding section, the limitations of the study are highlighted along with guidelines for future research.

THEORETICAL CONSTRUCTS

This section identifies key factors of ERP implementations based on a critical review of both scholarly and managerial literature. These constructs include strategic initiatives, executive commitment, human resources, project management, information technology, business process, training, project support and communications, and software selection and support. The constructs developed by the authors are very similar to the ones developed by Stratman and Roth (2002), further validating the research effort undertaken here.

Strategic Initiatives

Successful integration of the internal functions of the business does not necessarily guarantee business success. End-to-end processes that transfer information from module to module will not in themselves improve cost effectiveness and efficiency. The ability to use the information to drive the business is the key to successful integration. Performance measurements must be developed to measure the impact of the ERP system on the business. It has been suggested that an ERP system that is not strategically tied into the supply chain will lack the ability to provide the type of business intelligence that is needed to grow the business (Hickes & Stecke, 1995; Koch, 1999; Carr, 1999; Melnyk & Stewart, 2002; Davenport & Brooks, 2004). Therefore, it is essential that firms must have strategic goals in place before undertaking an ERP implementation (Motwani et al., 2002).

Executive Commitment

Top management is often advised to look beyond the technical aspects of the project to the organizational requirements for a successful implementation. It is consistently identified as the most important success factor in ERP system implementations (Bancroft, Seip, & Sprengel, 1998; Davenport 1998; Sumner, 1999; Bingi, Sharma, & Godla, 1999; Welti, 1999; Gupta, 2000; Rao, 2000). It can be inferred from the literature that executives and managers believe that ERP systems help their company achieve greater business benefits. However, they are mystified as to how to design, implement, and manage an ERP project. When it comes to ERP projects, Fortune 500 companies are beginning to sound like children in the back seat of a car on a long drive—"Are we there yet? Are we done yet? No! We're not there and we are not done. And we may never be done" (Koch, 1999).

Any executive planning the implementation of an ERP system needs to make some savvy decisions, from identifying what business needs the ERP system must meet to preparing for post-implementation maintenance and user support (Musson, 1998). Many executives are having a hard time understanding that ERP implementation is not simply a package installation. It is a long journey of fine-tuning, upgrading, and continual learning, not a sprint. Therefore, it may lead to a sense of frustration and anger at the system and in some cases total abandonment. Unlike any other software project, an ERP system does not merely change employees' computer screens the way previous generations of software did; it changes the way they do their jobs and how the company does business. Top management, therefore, must fully understand the degree of the changes and supports needed for the new project and be comfortable with the fact that the decisions their planners make will have a profound impact on the entire supply chain (Chen, 2001).

Human Resources

The most recurring theme in management literature concerning the failure of ERP systems is the inability of firms to take into account the new organizational, interdepartmental, and personnel aspects of work organizations. Unintended consequences include the emotional fallout when employees are suddenly given much greater responsibilities. Managers sometimes neglect to assess not only the skill development needed by employees but also the organizational changes required of them (Appleton, 1997). Small firms often lack financial resources and may be forced to adopt, at best, a piecemeal approach to integrating the typically expensive ERP systems into their facilities (Ferman, 1999). This can be very difficult for employees as the project seems to be 'never ending.' It is also felt that the low information technology (IT) staff levels in smaller enterprises are inadequate for the rigorous and extensive IT training and development requirements of an ERP project (Hill, 1997). In many cases of ERP implementations, consultants are required to help meet the projects' needs (Muscatello et al., 2003).

Project Management

A project team must be flexible and deal with the problems as they arise in the implementation process. Anyone who revisits the charter documents of a large-scale ERP project will see that the ultimate product is almost always shaped by unanticipated and late breaking circumstances. It is a fact of business life that important things come up later rather than earlier in complex new projects (Cliffe, 1999). However, these interruptions should not encourage "scope creep," when processes or functions are added after the project has begun. As mentioned, unanticipated circumstances are the norm; however, wholesale changes such as adding an additional process, module, or department after the project has been scoped and started may lead to a "never ending" project. To prevent scope problems, firms need to make sure a project charter or mission statement exists. It is paramount to nail down the project requirements and have them documented and signed by the senior management and users. Furthermore, it is essential for firms to clearly define change control procedures and hold everyone to them. Tight change control procedures may end up causing tension between the project team and those who do not get the changes they want. Ultimately, though, the project will not be successful if the project team is trying to hit a constantly moving target (Trepper, 1999).

A survey by the Meta Group found that it takes an average of 31 months before an ERP system will show benefits (Muscatello, 1999). There is no magic in implementing ERP systems, but, when they are carefully conceived and executed, ERP systems can radically changed the way companies do business. In many companies, it would now be unthinkable to manage financials, customer relationships, and supply chains without ERP (Oliver, 1999).

Information Technology

Deloitte Consulting (2000) reports that the second largest ERP implementation challenge related to people issues is internal staff adequacy. If a firm's existing technology will run the new ERP system, then the technology training may be an upgrade of the skill set. If a wholesale change is required, such as moving from an IBM mainframe to a Sun Microsystem, then an in-depth hardware and software training program must be implemented. In fact, some firms have selected their ERP systems based on their current technology and business process, and research has showed this approach to be a mistake since it is very limiting (Anderson, 2000). Because some firms may not be willing to change current technology, they may consequently report a lower significance on technology training for ERP implementation. Firms who account for business processes first and technology fit second reflect IT training positively (Davenport, 2000).

Managers cannot minimize the importance of technology training regardless if it is an upgrade of current software and hardware or a complete technology change. An upgrade of current software usually includes new file structures, report writers, functional modules, and other changes. An upgrade of current hardware usually involves a re-installation of the operating system or at least installing the operating system changes, new functionality, and new modules. If a complete technology change (hardware and/or software) is required, then a much larger commitment must be undertaken to insure that the proper employees can manage the technology after going live. In either case, managers must be proactive in securing the technology training to insure that their technical employees can run the ERP system effectively. The consequences of not having enough technical training can be catastrophic and lead to outright failure of the ERP system (Evangelista, 1998; Hill, 1997).

Business Process

As suggested by Hammer and Champy (1993), reengineering of business process activities focuses the firm on identifying and improving the efficiency of critical operations, on restructuring important non-value-adding operations, and on eliminating inefficient processes. Reengineering should be undertaken to insure that the strategic objectives mentioned earlier are feasible. The reengineering effort should create a uniform response from all aspects of the business. When goals are common, improvement becomes a shared task (Hill, 2000). Using reengineering techniques to develop a homogeneous vision depicting the company's processes after the ERP implementation, a firm is more likely to minimize uncertainty and achieve success. Researchers have found a strong correlation between the attention paid to business process improvement and the likelihood of ERP success (Muscatello et al., 2003; Motwani et al., 2002; Carton & Adams 2003; Millman, 2004; Olson et al., 2005).

Training

ERP skills have been in acute shortage because of the high demand for people with good understanding of business and ERP systems. This and the radical process changes brought about by ERP implementation have made providing sufficient and timely training to project persons and users a critical requirement in ERP implementation (Davenport, 2000). Assessing the needs for training usually uncovers several training and skills deficiencies. Rectification of training deficiencies can be accomplished in three ways: reassignment, outsourcing or replacement of staff, hiring of new personnel with substantial knowledge in ERP systems, or training of managers and key employees. In most cases, a firm implementing ERP engages in two types of training: fundamental ERP systems education and technical training in the usage of the ERP software (Evangelista, 1998; Muscatello, 2002; Yusuf, 2004; Sarkis & Sundarraj, 2003). In international cases, language and cultural barriers can be a technical hindrance that requires additional training (Al-Mashari, 2000).

Project Support and Communications

ERP applications lock the operating principles and processes of the adopting organization into software systems. If organizations fail to reconcile the technological imperatives of the enterprise systems with their business needs, the logic of the system may conflict with the logic of business processes (Davenport, 1998). Needless to say, managers have found ERP implementation projects the most difficult systems development projects (Kumar et al., 2003). Thus, upfront and ongoing communication to all employees affected by the new ERP system is a must. Olsen et al. (2005) found that it is necessary to inform organizational employees of how the system can help them do their jobs better. They also found that all retained employees are going to find their jobs changed. People are naturally resistant to change and it is very difficult to implement a system within an organization without some cooperation. Effective communication and ongoing support has also been noted by several researchers (e.g., Motwani et al., 2002; Muscatello et al., 2003; Sarkis & Sundarraj, 2003).

Software Selection and Support

ERP systems are software packages generically designed, keeping the industry-wide needs and best practices in mind (Kumar et al., 2003). One of the major challenges an adopting organization faces is that software does not fit all their requirements (Davenport, 1998). A systematic "needs assessment" therefore must be commissioned to determine the specific ERP modules, subsystems, and hardware that are required to achieve the desired level of systems integration. Where there is a lack of internal knowledge of ERP systems and their operating requirements (either at the corporate or division level), management should solicit the help of knowledgeable outside consultants for the assessment (Chen, 2001; Davenport, 2000; Booker, 1999). Firms that analyze their software "fit" and individual module needs can enhance the likelihood of a successful ERP implementation (Yusuf, Gunasekaran, & Althorpe, 2004).

RESEARCH DESIGN

Data Collection

Based on a thorough review of the literature, the theoretical constructs identified by this study are well grounded in existing theory (Muscatello et al., 2003). The theoretical constructs are made up of four or more items using a 7 point Likert scale with a score of 1 labeled "not important" and a score of 7 labeled "very important."

A cross sectional mail survey was conducted in the United States, during 2006, drawing from members of the American Production and Inventory Control Society (APICS), The National Association of Accountants (NAA), the American Productivity and Quality Center (APQC), and the Institute for Supply Management (ISM) because of their potential involvement in an ERP implementation. The survey was very clear that only those with ERP implementation experience should respond.

A modified version of Dillman's total design method was followed in order to increase the response rate (Dillman, 1978). All mailings were first class mail including a cover letter, survey, and postage paid return envelope. Three weeks after the initial mailing, reminder cards were sent to all potential respondents. Of the 973 surveys mailed, 28 came back due to address discrepancies. From the new sample size of 945, 203 were received resulting in a response rate of 21.5%. A total of six were discarded for incompleteness/damage for an effective response rate of 197/945 or 20.8%. Considering that this is a lengthy survey, this response rate is acceptable and correlates well with recent empirical studies in operations management (OM) and supply chain management (SCM) (e.g., Paulraj & Chen, 2005, 23.2%; Krause et al., 2001, 19.6%).

Respondent and Firm Profiles

The profile of the final sample of 197 included top executives (17%), middle managers (73%), and others (10%). Almost half of the firms had been in business for over 30 years (48%) and

Table 1. Respondent profile

Title	Count	Percent
Manufacturing/Business Executives	34	17%
CEO, CFO, COO, CIO		
President, Vice-President, Director		
Manufacturing/Business Middle Manager	143	73%
Purchasing Manager		
Operations/production Manager		
Other	20	10%
Buyers, Planners		
Supervisors		

most were engaged in end product manufacturing (49%), followed by subassembly (30%), components (19%), and others (2%). Firm size was fairly evenly distributed between large and small firms with respondents with sales of over $20B (6%), $1B~$20B (31%), $500M~$1B (30%), $100M~$500M (19%), $10M~$100M (6%), and under $10M (8%). Most firms employed 500 or more employees (81%). The vast majority of the respondents were working on their first ERP system (78%) with some (22%) on their second or third system. Furthermore, most had not worked on multiple ERP systems (87%), but some had multiple systems in the same facility (13%). The distribution of the sample regarding respondent and firm profiles is presented in Tables 1 and 2, respectively.

RESULTS AND DISCUSSIONS

Exploratory factor analysis (EFA) was performed to empirically test the nine strategic ERP constructs included in this study using the principle component method. Items with a factor loading of 0.3 or greater were retained for further analysis (Flynn, Schroeder, & Sakakibara, 1994; Hair, Anderson, Tatham, & Black, 1998). Reliability analyses were performed to test whether random measurement errors varied from one question to another (Judd, Smith, & Kidder, 1991). Reliability was measured using Cronbach's alpha internal consistency method where reliability coefficients of 0.60 or higher are considered acceptable (Cronbach, 1951). All of the reliability coefficients are greater than 0.658 after the removal of questions 2 and 3 from the "Human Resource" construct and question 9 from the "Software Selection and Support" construct. Reliability statistics and factor loadings are shown in Appendix A.

All questions were analyzed using a seven point Likert scale with a score of 1 labeled "not important," a score of 4 labeled "neither important nor unimportant," and a scale of 7 labeled "very important."

Table 2. Company profile

Years in Operation	Count	Percent
Less than 5	55	28%
6-15	39	20%
16-30	8	04%
30 or more	95	48%

2	35	18%
3 or more	8	04%
Multiple ERP Systems in the Same Facility	Count	Percent
No	171	87%
Yes	26	13%

This study uses simple mean-based ranking of the indicators within each theoretical construct. Further analysis was conducted to provide additional insight into the results. The following sub-sections present the current state of practice for each of the theoretical constructs.

Strategic Initiatives

Table 3 presents the results for strategic initiatives. The mean response for the seven indicators ranged from 5.33 to 5.79. This result is a pleasant surprise in that many researchers have written about ERP implementations being relegated to the information technology departments; to the contrary, this research shows that firms are now attaching a strategic component to their ERP implementations and that the decision to implement an ERP system is now being made at a cross functional executive level which includes inputs from all functional business areas. Further, the respondents concur that the ERP implementation should be tied to achieving strategic goals. The fact that two-thirds (67%) of the respondents came from firms with sales in excess of $500 million may further explain the increased desire for a strategic component. Larger firms have the resources to fully integrate ERP systems as opposed to just automating processes (Muscatello, 2002). These larger firms may have access to information and research that smaller firms do not and thus have common strategic goals and when goals are common, improvement becomes a shared task (Hill, 2000). The low standard deviation further shows the uniformity of this opinion.

Executive Commitment

Executive commitment has been documented to be of great importance in achieving any major business improvement project. The response to this survey re-confirms the need for executive commitment for ERP implementations identified by on past research. Seventy three percent (73%) of the respondents classified themselves as middle-managers and 17% classified themselves as director or above. However, a test of the means between the respondents produced no discernable difference, verifying that all levels of management consider executive commitment important. Table 4 presents the results for executive commitment and support. The mean response for the seven indicators ranged from 4.68 to 5.53. The highest responses came from the question on long-term executive commitment showing the high regard they have for executives who realize the complexity and time commitment necessary for a successful implementation. The lowest indicator showed that while executives deemed the ERP implementation very important, they still expected the operational concerns to be addressed in the interim.

Table 3. Strategic initiatives

Indicator		Mean	Std Dev
1)	IT capabilities are constantly reviewed against strategic goals	5.79	1.148
2)	Strategic IT planning is a continuous process	5.60	1.260
3)	Written guidelines exist to structure strategic IT planning in our organization	5.33	1.369
4)	Strategic IT planning includes inputs from all business functional areas	5.49	1.244
5)	ERP is integrated into the strategic plans of all business functional areas	5.53	1.210
6)	ERP was chosen to support the organization’s strategic plans	5.59	1.124
7)	Managers evaluate the potential of ERP when building strategic plans	5.40	1.181

Human Resources

Indicator number 2, ‘low IT skills are an obstacle to successful ERP implementations’ and Indicator 3, ‘executives with little knowledge of ERP should be minimally involved’ were eliminated from the research to improve the Cronbach’s alpha to 0.677 from 0.606. The mean responses of the remaining six indicators ranged from 4.57 to 5.76 and are presented in table 5. From the human resource side, there appears to be strong commitment to gaining the knowledge required to successfully implement ERP systems via training and education of current employees or hiring of outside consulting help. Significant research has noted that ERP education and training is required for successful implementation. This research offers a new insight: respondents saw little difference between gaining the knowledge via education and training or through consulting help. The lowest responses came from the idea of replacing ineffective employees or managers who are not able

Table 4. Executive commitment

Indicator		Mean	Std Dev
1)	The need for long term ERP support resources is recognized by management	5.53	1.100
2)	Executive management is enthusiastic about the possibilities of ERP	5.29	1.144
3)	Executives have invested the time needed to understand ERP’s benefits	5.23	1.222
4)	Executives mandate that ERP requirements have priority over functional concerns	4.68	1.387
5)	Top management has clearly defined the ERP entity’s business goals	5.31	1.378
6)	All levels of management support the overall goals of the ERP entity	5.24	1.313
7)	Executives continuously champion the ERP project	5.07	1.356

Table 5. Human resources

Indicator		Mean	Std Dev
1)	The ability of the IT workforce to learn is critical to an ERP implementation	5.64	1.076
2)	Low IT skills are an obstacle to successful ERP implementations	5.35	1.179
3)	Executives with little knowledge of ERP should be minimally involved	4.86	1.711
4)	Ineffective employees are moved or replaced if they are not able to adapt	4.57	1.396
5)	Ineffective managers are moved or replaced if they are not able to adapt	4.83	1.445
6)	The ERP team members need to understand the project has priority	5.74	1.040
7)	Consultants are used where in-house knowledge is inadequate or not available	5.76	1.135
8)	Compensation and incentives should be given to high achieving team members	5.57	1.170

to adapt to the new system. This could present a problem in some smaller firms where key managers have multiple tasks. Possible explanations for the low response rate for employee replacement includes the reluctance of many firms to terminate people for incompetence if they are well liked and committed. It is noted that Hammer and Champy (1993) also openly reject the idea of eliminating jobs through reengineering. Thus, many managers and consultants may still hold true to this idea.

Project Management

Respondents were asked about ERP project management issues including the responsibilities of project team members and the capabilities of the project leader. Table 6 presents the results for project management. The mean response for the seven indicators ranged from 5.51 to 5.64. This shows a strong commitment for project management skills in project definition, scope, tracking, and status. It reveals that project management skills were grossly underestimated in ERP implementation in the past and are now becoming a critical skill set for ever changing business needs. The fact that 81% of the responding firms had more than 500 employees could also explain this response. Larger firms have more internal expertise to draw from and thus are more likely to be equipped with project management champions.

Information Technology

Software and hardware expertise has been documented to be of great importance to a successful ERP implementation and this survey shows the same high level of importance with a range of the means from 5.41 to 5.69 with very low standard deviations. The results are presented in Table 7. Somewhat unique to this research is the attempt to find out the importance of the skill sets of the current information technology (IT) staff, which are deemed very important, and the use of consultants if the skill sets are not internal. The results show that firms are willing to supplement their IT staff with consultants when necessary. This acceptance of outside help shows an understanding of internal limitations of a firm and a sense of urgency and willingness to acquire it externally.

Business Process

ERP implementation has been referred to as an "organization wide revolution" due to the large number of changes it brings to an organization (Hammer & Stanton, 1999; Bingi et al., 1999). The

Table 6. Project management

Indicator		Mean	Std Dev
1)	The tasks to be performed during the ERP project are clearly defined	5.61	1.149
2)	The responsibilities of project team members are clearly defined	5.64	1.167
3)	There is a formal management process to track external contractor activities	5.59	1.173
4)	Measurements are used to determine the status of project tasks	5.51	1.105
5)	The ERP project leader is able to track project tasks to completion	5.58	1.102
6)	The ERP project leader is experienced in project management	5.60	1.128
7)	The ERP project leader is able to minimize project scope creep	5.57	1.031

Table 7. Information technology

Indicator		Mean	Std Dev
1)	There is a high degree of technical expertise in the IT organization	5.49	1.137
2)	Internal It members understand custom ERP software programs	5.52	1.062
3)	The IT staff are able to efficiently implement ERP system upgrades	5.65	1.036
4)	The IT staff are able to analyze the technical impact of proposed system changes	5.53	1.268
5)	The IT organization provides a service to the business	5.47	1.296
6)	Consultants are hired to supplement internal IT staff when necessary	5.63	1.165
7)	The IT staff is continuously updating their technical skills through training	5.74	1.092

strong connections that researchers have proposed between business process redesigns and successful ERP implementation have been confirmed by our results. The means ranged from 5.45 to 5.74 with low standard deviations are presented in Table 8. Interestingly, the high means for all seven indicators suggest that the connection researchers have preached is being accepted by the practitioners. Ross (1999) suggested that firms believed that ERP software would solve their problems by imposing discipline and process integration on their organization. This research confirms that practitioners now disagree with that assessment and realize that software is not a substitute for good business processes. The "business process" indicators indicate that process knowledge and redesign, cross functional management and driving out inefficiencies that improve customer benefits are all strongly accepted as necessary for a successful implementation. Hammer and Champy's (1993) work on reengineering and the wide-spread use of their practices as a change enabling tool helps confirm the positive use of reengineering in ERP implementations.

Training

The importance of training was echoed by most of our respondents. As expected, based on current research, training was a highly regarded component of ERP implementations. The means of the eight indicators ranged from 5.45 to 5.70 with low standard deviations and are presented in Table 9. Again, the question if external expertise in the form of consulting should be used to supplement internal knowledge was asked and the answer was

Table 8. Business process

Indicator		Mean	Std Dev
1)	Employees understand how their actions impact the operations of other functions	5.45	1.171
2)	There is a high level of business process knowledge within the ERP entity	5.52	1.123
3)	Managers are skilled at analyzing business processes for customer benefits	5.65	1.036
4)	Business process redesign is performed before ERP implementation	5.53	1.268
5)	The operational processes of the ERP entity are formally documented	5.47	1.296
6)	Business process redesign teams are cross functional	5.63	1.165
7)	Redesigned business processes are used to drive out inefficiency	5.74	1.092

Table 9. Training

Indicator		Mean	Std Dev
1)	Specific user training needs were identified early in the implementation	5.70	1.020
2)	A formal training program has been developed to meet the ERP users requirements	5.53	1.276
3)	Training materials have been customized for each specific job	5.45	1.158
4)	Training materials target the entire business task, not just the ERP screens/reports	5.49	1.284
5)	Employees are tracked to insure they have received the appropriate ERP training	5.51	1.194
6)	All users have been trained in basic ERP system skills	5.69	1.130
7)	Consultants are used to supplement training when internal expertise does not exist	5.55	1.239
8)	ERP training and education is ongoing and available to refresh users skills	5.60	1.194

strongly yes. Firms supported the need for formal, customized training on both ERP knowledge and specific job duties. They also strongly supported on-going education programs which has not always been the case for some firms who are risk adverse. The high percentage of respondents in larger firms (81% had 500 or more employees, and 86% had sales over $100 million) may explain the high level of interest in outside consulting help, since larger firms usually have greater access to resources. Smaller firms, without the access to ERP resources, need to establish whether or not they can obtain the resources or postpone the implementation since it is documented that overcoming an ERP failure is difficult and often fatal (Muscatello et al, 2003).

Project Support and Communications

Lack of strong support for a massive project like ERP creates enormous challenges for the project team such as buy-in from users. A recent study revealed that 25% of organizations adopting ERP systems faced significant resistance from staff and that 10% of the organizations also encountered resistance from managers (Kumar et al., 2003). Table 10 presents the results for project support and communication. The means range from 5.57 to 5.86. This research supports extant research on employee relations and change management in that the respondents felt it very important to actively communicate how employees fit into the new ERP-oriented environment and to actively work to alleviate employee concerns. Respondents also agree that cultural changes need to be managed to ensure shared values and common aims conducive to both employee and firm success. A user support group with employee comments and reactions should be used to help employees manage through the cultural changes.

Software Selection and Support

Even with today's state of the art technology, organizations find that not all their requirements are met by the ERP systems they adopt. The remaining nine indicators are strong with means from 5.64 to 5.86 and the results are presented in Table 11. These indicators confirm current research that shows a strong relationship between successful ERP implementations and software fit. Interestingly, the research again confirms that firms are willing to use outside consultants if software selection experience is not available internally. Again, this set of indicators show a new willing-

Table 10. Project support & communications

Indicator	Mean	Std Dev
Employees understand how they fit into the new ERP entity	5.71	1.112
Management actively works to alleviate employee concerns about ERP	5.65	1.153
The roles of all employees under the ERP system have been clearly communicated	5.57	1.161
An ERP support group is available to answer concerns about ERP job changes	5.57	1.093
Effective communication is critical to ERP implementations	5.63	1.110
User input should include requirements, comments, reactions and approvals	5.86	1.025
Enterprise wide culture and structure change should be managed	5.77	1.033
A culture with shared values and common aims is conducive to success	5.66	1.111

Table 11. Software selection & support

Indicator		Mean	Std Dev
1)	An analysis should be performed to select the appropriate business modules	5.86	1.079
2)	The modules selected should be able to share information freely	5.80	1.137
3)	The ERP system should eliminate the need for redundant entry of data	5.79	1.033
4)	If ERP experience does not reside in house then consultants should be used	5.79	1.135
5)	The overall ERP architecture should be established before deployment	5.66	1.134
6)	The firm should work well with vendors and consultants to resolve software issues	5.64	1.101
7)	Vigorous and sophisticated software testing eases implementation	5.85	1.085
8)	There should be a plan for migrating and cleaning up data	5.64	1.062
9)	ERP software development, testing and troubleshooting is essential	5.83	1.310

ness amongst ERP implementers to realize their firm’s limitations in this difficult endeavor. Also of note is a strong resolve to work with vendors to ensure proper module and process fit, as well as vigorous software testing, troubleshooting, and a plan for migrating and data clean up after the initial installation.

CONCLUSION

Enterprise resource planning systems have experienced a phenomenal growth over the past decade. While some firms declared their ERP implementation success, many others reported negative results. With these developments, there has been a significant amount of research that seeks to identify the success factors associated with the implementation of ERP systems. Most of these authors, however, have based their research on a small number of case studies. This study, therefore, aimed to understand the critical constructs of ERP implementation using a large scale survey. A cross sectional mail survey of business executives with ERP implementation experience was used to capture the degree of adoption of these concepts. Basic statistical methodology was used on this empirical data to examine the adaptation of the various concepts. Although this analysis was based on simple statistical methods, it provides a clear picture of the beliefs of current ERP implementation. These constructs can also help guide future research for academics and practitioners in the ERP environment.

In summary, the results show that the implementation of ERP systems has grown from the belief that it was a simple information system implementation of new software into a realization that it is a strategic and tactical revolution which requires a total commitment from all involved. This is in stark contrast to studies as recent as 5 years ago, which concluded that firms believed that the ERP software would automatically drive the strategic and tactical changes. Firms now realize that business process changes and project management are strongly linked to the success of the ERP implementation. Moreover, they are as important as software and hardware knowledge. Another new finding is that firms now strongly believe that the use of outside consultants to supplement internal staff is an acceptable and desirable practice. This is likely a result of the documented cases of ERP implementation failure where firms failed to take stock of their internal competencies and shortcomings. Taken together, these results suggest that firms are realizing that ERP implementations are a long journey and that results may not be readily apparent until well into the future.

This research has provided insight into the current practice of ERP implementations. It has paved a solid foundation on which to build future research in this area. Nevertheless, it is realized that this effort cannot completely explain all of the issues surrounding an ERP implementation. Additional insights may be revealed through longitudinal studies and by building empirical models.

Diffusion of Enterprise Resource Planning Systems in Taiwan:

Influence Sources and the Y2K Effect

ABSTRACT

ERP was one of the important developments in the use of information technology for organizations in the 1990s. Y2K rectification was a key driver in the decision to move to ERP software. Based on diffusion-of-innovation models, in this study, the sources of influence of ERP adoption in Taiwan are investigated and if the dawning Y2K can be viewed as a critical point is explored. The results demonstrate that the main influence source of ERP adoption is a mix of influence sources for all adopters. Before the millennium, the internal model shows the higher power of explanation. And after the millennium, the main influences become external influence sources. With different diffusion patterns between, before, and after the millennium, the analysis results confirm that the millennium is a critical point. Besides contributing to the application of diffusion-of-innovation in Taiwan's ERP adoption, the results of this study can provide suggestions for ERP suppliers' marketing strategy.

INTRODUCTION

In the age of the information and knowledge, organizations depend heavily on information systems to support regular operations, solve problems, and make flexible responses to the competition around the world. In the early stages, organizations tended to develop stand-alone systems for a single functional area or business unit; maintaining many different systems led to enormous costs. Organizations faced many problems because of the lack of integration, especially at the global level (Ives & Jarvenpaa, 1993). Recently, enterprise resource planning systems (ERP) which incorporate commercial software packages, also known as integrated enterprise computing systems, attempt to integrate all departments and functions across a company, constitute one of the fastest growing segments in the software market and one of the most important developments in recent years (Sprott, 2000; Seethamraju, 2005). Most of this was clearly attributable to the Y2K effect (Sprott, 2000). Y2K rectification was a key driver in the decision to move to ERP software (Scott & Kaindl, 2000).

The market for ERP software grew a surprising 14% in 2004 to become a $23.6 billion business (Woodie, 2005). And in Taiwan, according to the investigation of MIC, the market for ERP grew from 2.1 billion NT dollars in 1997, to 4.6 billion NT dollars in 1998. During the year 2000, the ERP market grew 26% and the market scale was up to 7.7 billion NT dollars. Nevertheless, the ERP market has generated 9.5 billion NT dollars in year 2003 and only up to 9.8 billion NT dollars in year 2004. MIC indicated that the CAGR (compound annual growth rate) of the ERP market scale would reach 28% for 3 years after 2001, but also that the growth of the ERP market would decrease below 5% after 2004 (MIC, 2004).

The ERP system is the most important development in information technology use in the 1990s (Davenport, 1998). ERP systems have developed for several years, and the number of adoption firms is growing. The diffusion of innovation model (DOI model) is usually applied to explore the spread of new technology. For example, Anat, Ravi, and David (2004) applied the DOI model to investigate adoption of Internet standard IPV6. The DOI model has the potential to investigate ERP adoption. The imitation hypothesis has generally guided researches on the organizational adoption of administrative innovations. The hypothesis states that, within a relevant population of firms, such adoption results in a predictable diffusion pattern. Members of a social system have different propensities for relying on mass media or interpersonal channels when seeking information about an innovation (Mahajan, Sharma, & Bettis, 1988; Rogers, 1995; Rogers, 2003).

In this study, the diffusion-of-innovation perspective to examine the impact of various forms of influence in the adoption of ERP in Taiwan is applied. First, the sources of influence (internal, external, and mixed) that could explain the diffusion pattern of ERP by adopting ordinary least square (OLS) estimation methods and specification tests are examined. Second, because previous research showed that the Y2K effect is a key driver for the adoption of ERP; the millennium is treated as a ‘critical point’ in delineating two regimes: “pre-millennium” and “post-millennium,” to assess the different impacts of the influence sources within each of the regimes.

THEORETICAL PERSPECTIVES

The theoretical perspectives begin with the introduction of ERP system and diffusion of innovation in first two sections, and then why the study regards ERP as an administrative innovation is explained in next section. This is followed by a description of three diffusion models, namely influence sources. In the end, the theoretical perspectives highlight the crucial role that Y2K has had in driving the diffusion pattern of ERP.

Enterprise Resource Planning (ERP)

The term “ERP” was addressed first by the Gartner Group in the early 1990s. It evolved from MRP, closed-loop MRP in the 1970s and MRP II in the

1980s. ERP is designed to manage a production facility's orders, production plans, and inventories. ERP integrates inventory data with financial, sales, and human resources data, and has become the pervasive infrastructure (Markus et al., 2000; Moller, 2005; Seethamraju, 2005).

Unlike the requirements of other IT tools, companies should move out of their traditional "functional silo" mode of thinking to an organizational mode of planning and thinking in the implementation of ERP, because ERP will impact the entire organization (Palaniswamy & Frank, 2002), radically reshaping how business is done and exploiting the new automated, seamless enterprise system capabilities in the process—the real value-adding opportunity offered by ERP. To improve "how business is done" is not just about integrating and creating more efficient transactional processes, the ERP route to business value is dependent also on major human, culture, and organizational changes (Willcocks & Sykes, 2000), see Figure 1.

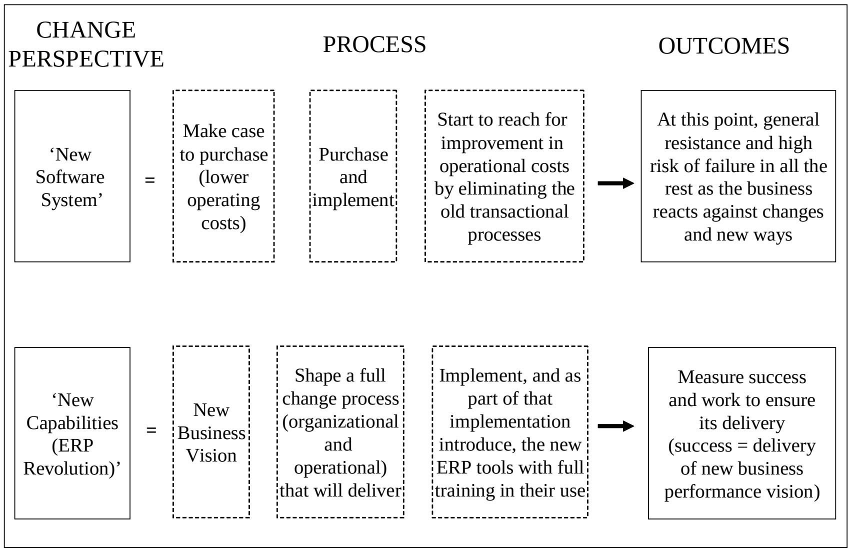
Diffusion-of-Innovation

Since Rogers addressed the diffusion concept in 1962, research on the diffusion of innovations has resulted in a large body of literature. According to Rogers' (1995) definition, "An innovation is an idea, practice, or object that is perceived as new by an individual or other unit of adoption." The perceived newness of the idea determines the individual's reaction to it. Rogers (1995) stated that "Diffusion is the process by which an innovation is communicated through certain channels over time and among the members of a social system." This definition indicates that diffusion is a special type of communication, in that the messages concern a new idea. According to the definition, there are four main elements in the diffusion of innovations: (1) the innovation, (2) communication channels, (3) time, and (4) the social system (Rogers, 1995). These elements are described.

Innovation

A new product or service, a new production process technology, a new structure or administrative system, or a new plan can all be viewed as innovation. Damanpour (1991) argued that an innovation is a means of changing an organization, either as a response to changes in its internal or

Figure 1. ERP: comparing change equations (Source: Willcocks & Sykes, 2000)



external environment or as a preemptive action taken to influence an environment.

Communication Channels

The essence of the diffusion process is the information exchange through which individuals communicate a new idea each other. A communication channel is the means by which messages get from one individual to another. It takes two forms: mass media channels and interpersonal channels. Mass media channels, involving all those means of transmitting messages such as radio and television are often the most rapid and efficient means to inform an audience of potential adopters about the existence of an innovation. Interpersonal channels, involving face-to-face exchanges between individuals, are more effective in persuading individuals to accept a new idea (Rogers, 1995).

Time

Rogers (1995) states that "the time dimension is involved in diffusion (1) in the innovation-decision process by which an individual passes from first knowledge of an innovation through its adoption or rejection, (2) in the innovativeness of an individual or other unit of adoption, that is, the relative earliness/lateness with which an innovation is adopted, compared with other members of a system, and (3) in an innovation's rate of adoption in a system, usually measured by the number of members of the system who adopt the innovation in a given time period."

The Social System

A social system is a set of interrelated units that are devoted to joint problem-solving, to accomplish a common goal (Rogers, 1995). In the diffusion of innovation, it means the community of individuals and/or organizations that are potential adopters of the innovation (Loh & Venkatraman, 1992).

In this study, the innovation is the ERP system and the relevant social system is the set of Taiwanese organizations that potentially adopt ERP systems. The communication channels in ERP take two forms: mass media channels (for example, through promotional efforts by ERP vendors, consulting firms, or trade periodicals) and interpersonal channels (for example, through the members of a social system interacting with one another).

The innovation can be distinguished into two types: administrative innovation and technical innovation. According to Damanpour's (1991) conceptualization, "technical innovations pertain to products, services, and production process technology; they are related to basic work activities and can concern either product or process," whereas "administrative innovations involve organizational structure and administrative processes; they are indirectly related to the basic work activities of an organization and are more directly related to its management."

Similarly, Venkatraman, Loh, and Koh (1994) defined an administrative innovation as "involving significant changes in the routines (or behavioral repertoires) used by the organization to deal with its tasks of internal arrangements and external alignments." Furthermore, the implementation of administrative innovations often involves an enormous change in functions, tasks, responsibilities, systems, and culture (Mahajan et al., 1988).

The diffusion of innovation perspective has been utilized for this study of technical innovations and administrative innovations. Detecting types of innovation is necessary for understanding organizations' adoption behavior and identifying the determinants of innovation in organizations (Downs & Mohr, 1976; Knight, 1967; Rowe & Boise, 1974). The decision-making processes are different between administrative with technical innovations (Daft, 1978).

ERP as an Administrative Innovation

According to the definitions of administrative innovation as described, it captures: (1) the critical opinion of first-time adoption by the organization (Rogers, 1995), (2) the changes in the routines and procedures of organization and management that involve significant "set up" costs and organizational disruption (Teece, 1980), and (3) a broader view of administrative tasks as an organization-environment co-alignment, that reflect both internal arrangements as well as external alignments (Thompson, 1967; Snow & Miles, 1983).

The arguments supporting the consideration of ERP as administrative innovations are described. First, it represents a significant shift in the mode of governance: ERP permits the injection of more discipline into their organizations. Some companies exert more management control and impose more-uniform processes on freewheeling, highly entrepreneurial cultures. Nevertheless, some companies use ERP to break down hierarchical structures, freeing their people to be more innovative and more flexible (Davenport, 1998). For example, a semiconductor company says, "We plan to use SAP as a battering ram to make our culture less autonomous." Union Carbide uses ERP to give low-level managers, workers, and even customers and suppliers much broader access to operating information (Davenport, 1998). In fact, such a shift in the mode of governance is an ally in achieving profound transformations in the strategic and operational mechanisms that are necessary for an organization to position itself within its current mission or scope (Markus et al., 2000; Loh & Venkatraman, 1992).

Second, ERP represents significant changes in the internal processes of the organizations. Generally, business often modified itself to fit the ERP. Therefore, ERP could drive the business process reengineering. Lee (1998) argued that organizations should make reengineering and ERP implementation simultaneously, to maximize value derived from the implementation. Besides, ERP is a software package that manages and integrates business processes across organizational functions and locations. It costs millions of dollars to buy and necessitate disruptive organizational change (Soh, Kien, & Tay-Yap, 2000). It is consistent with Teece's (1980) view of administrative innovation as often involving significant "set up" costs and organizational disruption.

Third, ERP constitutes a significant change in the organizational routines used to deal with the external environment. ERP is evolving to support other functionalities that were offered separately, like supply chain management (SCM), customer relationship management (CRM), professional service automation (PSA), and others (Shakir, 2000). ERP could integrate planning and resources of financial procedures and inter-enterprise collaborative operations. It emphasizes integration enterprise, customers, and supplier chains. Organizations build long-term relationships with partners through the sharing of information.

Influence Sources

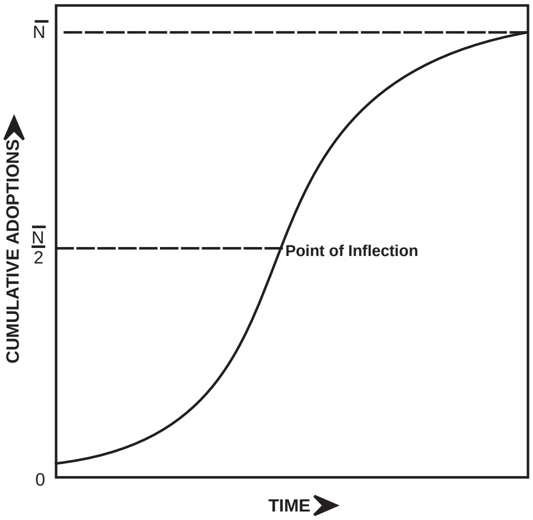
Traditionally, diffusion model has three basic models: internal influence (word-of-mouth or interpersonal communication), external influence (mass-media communication), and mixed influence (Rogers, 1995; Venkatraman, Loh, & Koh, 1994; Loh & Venkatraman, 1992; Mahajan, Muller, & Bass, 1990). A diffusion model permits prediction of the continued development of the diffusion process over time as well as facilitates a theoretical explanation of the dynamics of the diffusion process in terms of certain general characteristics (Mahajan & Perterson, 1985). The essence of the diffusion is the information exchange through which one individual (or other unit) communicates a new idea (or an innovation) to one or several others (Rogers, 2003). Internal and external sources are two influences for adopters. Internal influence source means the unit adopted an innovation that was influenced by the member of the social system (inside). External influence source means the unit adopted an innovation was influenced from outside of the social system. Mass media, vendors, consulting firms, or trade periodicals are usually external influence sources outside of the social system. These factors are explored by an estimation of model fit.

Internal influence. Mansfield (1961) suggested the internal-influence model. It purports that diffusion occurs through channels of communication within a social system and is appropriate for testing the imitation hypothesis. The diffusion is driven from imitative behavior within the social system. The model can be stated as:

$$\frac{dN(t)}{dt} = qN(t)[m - N(t)] \qquad (1)$$

where *N(t)* is the cumulative number of adopters at time *t*, *m* is the total number of adopters who will eventually adopt the innovation, and *q* is the coefficient of internal influence. In this model, the diffusion rate is a function of the number who have already adopted the innovation, and the remaining number of potential adopters. Mahajan and Peterson (1985) argued that the model is structurally equivalent to the imitation model, as seen in Figure 2. Applied to the study, the adoption of ERP in an organization may imitate other organizations which have adopted it.

Figure 2. Internal influence diffusion curve (Source: Mahajan & Peterson, 1985)



External Influence

Much of the popularity of the external-influence model is due to the work of Coleman et al (1966). Diffusion processes are hypothesized as only being “driven” by information from a communication source external to the social system. The model assumes that the rate of diffusion at time *t* is dependent only on the potential number of adopters present in the social system at time *t*. That is to say, the model does not consider interaction between prior adopters and potential adopters (Mahajan and Peterson, 1985). The model can be represented as:

$$\frac{dN(t)}{dt} = p[m - N(t)] \qquad (2)$$

where *p* is the coefficient of external influence and a nonnegative constant. *N*(*t*) with t results in a curve that increases at a decreasing rate, as shown in Figure 3. In our study, external influences on the potential adopters of ERP includes: mass media, vendors, consulting firms or trade periodicals.

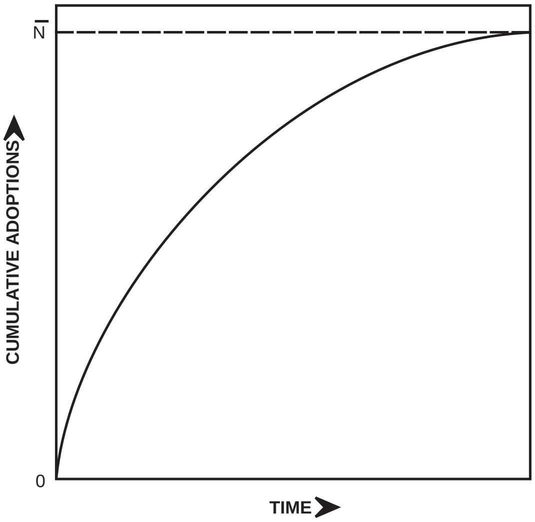
Mixed Influence

This formulation combines both the internal- and external-influence models (Bass, 1969). The mixed-influence model can be stated as:

$$\frac{dN(t)}{dt} = [p + qN(t)][m - N(t)] \qquad (3)$$

The cumulative distribution of the model brings about a generalized logistic curve whose S-shape depends on the coefficients *p* and *q*. The model is the most general form and is widely used to combine both internal and external influences

Figure 3. External influence diffusion curve (Source: Mahajan & Peterson, 1985)



concurrently. The diffusion of the model was due to a combination of coverage by the media and early adoption.

Research Questions

The internal, external, and mixed influence equations provide the foundation for two research questions:

- Research Question #1: *What source of influence best characterizes the diffusion of ERP?*

A second research question looks at the importance, as the literature suggests, of Y2K as an important inflection point in the evolution of ERPs. In the late 1990s, most enterprise information systems included some legacy systems; Y2K was a serious problem for these old systems. ERP systems could provide a solution to fix the Y2K problem for firms. During the last 3 years of the 1990s, the ERP market was one of the fastest growing and most profitable areas of the software industry (Davenport, 1998). Sprott (2000) indicated that most of this was clearly attributable to the Y2K effect. The package software got a huge boost when companies began to realize the full impact of the Y2K problem.

By 1998, nearly 40% of companies with annual revenues of more than $1 billion had implemented ERP systems (Caldwell & Stein, 1998). The largest ERP vendor, SAP Inc., had revenues of $3.3 billion in 1997, which had soared from less than $500 million in 1992 (Davenport, 1998). AMR research predicted that the ERP market would reach $66.6 billion by 2003. But, because many companies have already implemented ERP in response to Y2K concerns, the ERP systems and services of market have cooled somewhat at present (Markus & Tanis, 2000). The Y2K issue provided an added incentive to address the inflexibility of legacy systems, enabling the introduction of ERP. That is, the Y2K problem drove the demand for ERP software packages (Scott & Kaindl, 2000). Based on the discussion, the Y2K is treated as a critical point in the adoption of ERP. In particular, whether the types of underlying influence differ before and after this critical point is tested.

The term “Y2K effect” is used to signify the importance of the Y2K critical point in driving the diffusion pattern of ERP. For this purpose, the period: January 1997 to December 2000 is considered as the first diffusion regime and the period: January 2001 to December 2004, as the second diffusion regime.

A research question to explore the impact of Y2K follows:

- Research Question #2: *What source of influence best characterizes the diffusion of ERP before and afterY2K?*

RESEARCH DESIGN

Based on the discussions, the research methodology used in the study is described.

The Adoption Data

The sample comprises companies which have adopted ERP in Taiwan. The data are collected from the TTS (transmission text retrieval system) Web server. TTS is the products of Transmission Books and Microinfo Co., Ltd. (TBMC). It has been providing various publications and services to academic libraries since 1981. TTS contains indexes of several major daily newspapers in Taiwan (such as United Daily News, Economic Daily News, China Times, and The Commercial Times). Related reports and statistical data on ERP in Taiwan mostly begin from 1997 (MIC, 2004). Besides, since the millennium is viewed as a critical point, a search of related information sources from 1997 to 2004 is performed. Time-series adoption data are developed by the year function.

Table 1 shows these data (on 82 firms), and by year, provides the number of firms that adopted the ERP system. Figure 4 illustrates the non-cumulative number of adopters. Figure 5 shows the cumulative number of adopters. It shows a clear "S" curve and the pattern of diffusion process. The pattern shows a typical diffusion process. It also finds that the inflection point of the curve is on Y2K in the figure. That means the increasing rate is different before and after Y2K. The curve also shows the increasing rate is positive before Y2K and negative after Y2K.

Analytical Framework

The Bass model assumes that potential adopters of an innovation are influenced by two means of communication: (1) mass media and (2) word of mouth. This further assumes that the adopters of an innovation comprise two groups: (1) those influenced by mass media communication, an external influence; and (2) those influenced by interpersonal communication, an internal influence (Mahajan et al., 1990). Mahajan et al. (1988) studied the adoption for the M-form organization structure and used linear regression analogue equation (ordinary least square: OLS estimation) to test different models. Based on the Bass model and Mahajan et al. (1988) analysis methods, the analysis method of this study adopted the OLS method.

Research Procedures

The Null Hypothesis

A stringent null hypothesis assumes that the diffusion pattern follows a white-noise or a random walk process (Majahan et al., 1988; Loh & Venkatraman, 1992). The white-noise process clarifies the difference between the numbers of adopters at t and $(t\text{-}1)$ is random. That is, in time-series data, the rate of diffusion will be driven by the error term only when:

$$x(t) - x(t-1) = \varepsilon(t) \text{ or } x(t) = x(t-1) + \varepsilon(t) \qquad (4)$$

where $x(t)$ is the number of adopters at time t, and the residuals $\varepsilon(t)$ have a zero mean that is uncorrelated with $\varepsilon(t-k)$ for all nonzero k. The model indicated that in the adoption of time-series, progression occurs via a sequence of unconnected steps, starting each time from the previous value of the adoption time-series.

Table 1. Adoption data (non-cumulative)

Year	1997	1998	1999	2000	2001	2002	2003	2004
Number of adopters	1	1	11	24	15	13	11	6

Figure 4. Non-cumulative adoption

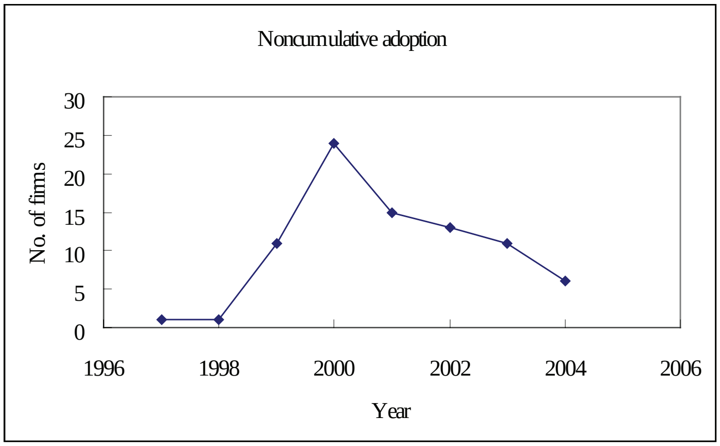


Figure 5. Cumulative adoption

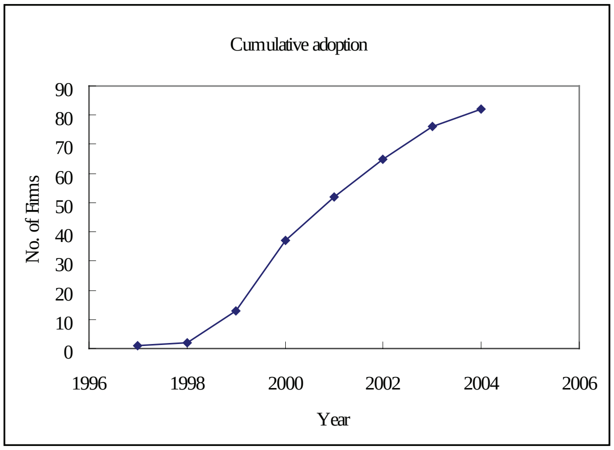

The External-Influence Model

The regression analogue of the external-influence model, equation (2), for describing a time-series adoption pattern, can be stated as (Mahajan et al., 1988):

$$x(t) = \beta_2 x(t\text{-}1) + \varepsilon(t) \qquad (5)$$

where $x(t) = N(t)\text{-}N(t\text{-}1)$ is the number of adopters at time t, $N(.)$ is the cumulative number of adopters, $\beta_2 = (1\text{-}p)$ and $\beta_2 < 1$, and the residuals, $\varepsilon(t)$, have zero mean, and $\varepsilon(t)$ is uncorrelated with $\varepsilon(t\text{-}k)$ for $k \neq 0$. Besides, if β_2=1, equation (5) is reduced to the white noise model.

The Mixed-Influence Model

Two popular innovation diffusion models that generate the S-shape adoption pattern and, in particular, capture the imitation behavior, are those suggested by Mansfield (1961) and Bass (1969). The Bass model can be stated as:

$$\frac{dN(t)}{dt} = p(m - N(t)) + \frac{q}{m}(m - N(t))N(t) \qquad (6)$$

where the second term in equation (6) represents the "contact" between adopter and non-adopters and reflects the imitation behavior. Consequently, the non-negative constant q is usually defined as the coefficient internal influence. Note when q=0 and $\beta_2 < 1$, as in equation (6), it yields the Coleman model (external-influence), equation (3).

One possible regression analogue of both imitational (mix and internal) models can be derived as:

$$x(t) = \beta_2 x(t-1) + \beta_3 N^*(t-1) + \varepsilon(t) \qquad (7)$$

where $\beta_2 = 1+q-p$ for the Bass (mixed-influence) model and $\beta_2 = 1+q$ for Mansfield (internal-influence) model and $\beta_2 > 1$, $\beta_3 < 0$, and $N^*(t-1) = N^2(t-1) - N^2(t-2)$ (Mahajan et al., 1988).

The Internal-influence Model. In the mixed-influenced equation (7), $\beta_2 = 1+q-p$ for the Bass (mixed-influence) model and $\beta_2 = 1+q$ for the Mansfield (internal-influence) model and $\beta_2 > 1$, $\beta_3 < 0$. In the external-influenced equation (5), $\beta_2 = (1-p)$ and $\beta_2 < 1$. So, it is derived that internal-influenced β_2 is 1+ (mixed-influenced β_2) - (external-influenced β_2).

$$x(t) = \beta_2 x(t-1) + \beta_3 N^*(t-1) + \varepsilon(t) \qquad (8)$$

where $\beta_2 = 1 + (1+q-p) - (1-p)$ and $\beta_2 > 1$, $\beta_3 < 0$. Table 2 summarizes the model specification and parameter values.

Evaluating the Two Research Questions

The first research question, based on the analytical framework, is employed to test the entire diffusion regime, to assess the relative adequacy of an influence model against the white-noise model with the three influence models. The second research question is appraised in the two regimes. According to Loh and Venkatraman (1992), the approach used is in accordance with the standard econometric technique of testing structural change by breaking up a full-time series into separate regimes, using some conceptually conceived cutoff points. The research question is to be evaluated by comparing the separate analysis results within each of the regimes, and to interpret the results in terms of the dominant type of influence in the two regimes.

RESULTS

Research question 1: Influence sources in the diffusion of ERP

Table 3 summarizes the parameter estimates and the fit statistics (R^2 and significance values) for the three alternative models and white noise model. The white noise's R^2 value is smaller than those of other models. Three alternative models are significant. Main influence sources are mixed influence sources. It may be thought that external influence has more influence if it is considered that mixed sources are combined with internal and external influence sources; however, there is no significant difference compared with internal and external models.

Table 2. Summary of hypothesized model specifications

Hypothesis	Model name	Model Specification	Parameter Values - - β_2 β_3
Null	White-noise	$x(t) = x(t-1) + \varepsilon(t)$	- - =1 -
Alternative	External mixed Internal	$x(t) = \beta_2 x(t-1) + \varepsilon(t)$ $x(t) = \beta_2 x(t-1) + \beta_3 N^*(t-1) + \varepsilon(t)$ $x(t) = \beta_2 x(t-1) + \beta_3 N^*(t-1) + \varepsilon(t)$	- - <1 - - - >1 <0 - - >1 <0

Table 3. Parameter estimation of ERP diffusion

Model	Coefficients				
	β_2	β_3	R^2	F	*Sig.*
White-noise	1.00	−	0.649	15.768	0.063*
external	0.857	−	0.672	17.369	**0.004*****
mixed	1.270	-0.006	**0.675**	9.326	**0.014****
internal	1.413	−0.007	0.670	9.120	**0.015****

** p<0.1; ** p<0.05; *** p<0.01*

Table 4. Parameter estimation of ERP diffusion before the millennium

Model	Coefficients				
	β_2	β_3	R^2	F	*Sig.*
White-noise	1.00	−	0.485	1.589	0.297
external	1.00	−	0.485	1.589	0.297
mixed	6.119	-0.262	**0.838**	11.364	0.081*
internal	6.119	-0.262	**0.838**	11.464	0.081*

** p<0.1; ** p<0.05; *** p<0.01*

Research question 2: What source of influence best characterizes the diffusion of ERP before and after the millennium?

Table 4 summarizes the parameter estimates and fit statistics for the three alternatives model and the white-noise model before the millennium (included 2000). The results show that white-noise and external models are not significant, while mixed and internal models are significant (significance level 0.1). Mixed and internal models have the same influence (equal R^2 value), explaining the quite high variance (about 84%). From the analysis, the main influence sources are internal channels before the millennium.

Table 5 summarizes the parameter estimates and the fit statistics for the three alternatives model and the white noise model after the millennium. Only the external model is significant with 5% significance level (mixed model is significant with 10% significance level). The results show that the main influence sources are the external channels. It explains the 96.1% variance. Table 4 and Table 5

Table 5. Parameter estimation of ERP diffusion after the millennium

Model	Coefficients				
	β_2	β_3	R^2	F	*Sig.*
White-noise	1.000	−	0.724	3.833	0.145
external	0.700	−	**0.961**	33.438	**0.010****
mixed	1.000	-0.003	0.855	12.830	**0.072***
internal	1.300	-0.006	0.669	4.861	0.171

*p<0.1; ** p<0.05; *** p<0.01*

show the main influence sources differing before and after the millennium. These results confirm that the millennium is a critical point.

DISCUSSION AND CONCLUSION

An innovation is an idea, practice, or object perceived as new by an individual or other unit of adoption (Rogers, 2003). In this study ERP is viewed as administrative innovation and the unit of adoption is an organization. The influence sources of the adoption of ERP were explored and the Y2K effect in Taiwan was also examined by different diffusion models. The results show that the mixed model is a better fit for the total period. More specifically, external communication channels showed more influence. Perhaps mass media reports about the Y2K effect and the benefits of ERP created effective innovation knowledge and change attitudes toward ERP adoption. Considering the Y2K effect, before the millennium, the mixed model and internal model showed the same power of explanation (R^2 = 83.8%). While the internal communication channels were important influences behind ERP adoption before the millennium, interpersonal channels were more effective in forming and changing opinions concerning the adoption of ERP. However, after the millennium, the external influence sources became the main influences (R^2 =96.1%). That suggests that mass media and other external channels (such as consulting firms) are major influences for ERP adoption in this period.

After Y2K, the ERP concept and ERP market reached maturity. The Y2K effect was not an important factor any more for ERP adoption. Enterprises focused on business strategy planning, critical process reengineering, and organization change management for adopting ERP. External channels, such as reports about ERP in the mass media, promotion of ERP providers, and consulting firms were the major influence sources. The external diffusion model showed an exponential distribution, but also showed slow growth at a later stage. The sample data also shows this trend, and this finding is in accord with the MIC annual report about software industry development (MIC, 2006). The report also indicates that most large-sized companies have already implemented ERP systems.

This study expanded the application of the diffusion model to ERP adoption. The research results indicate when the Y2K is the critical point and that can significantly differentiate the pattern of influences in the diffusion of ERP. They also reveal that the market of ERP is decreasing in Taiwan. In particular, large firms turned their software system demands to other systems, such as customer relationship management, business intelligence, and so forth. Comparatively, medium and small-size firms have still been demanding ERP systems recently (MIC, 2006). For practitioners, because of the slow growth of the ERP market, ERP providers should provide multiple services and continue to maintain original customers. Moreover, because of the lower demand of large firms, they could exploit ERP applications for small and medium-size firms.

There are some limitations to this study. The sample is collected from the TTS Web server, perhaps inducing some biases in terms in that almost large companies reported in these sample sources. Some medium or small companies could have been missed. Nevertheless, due to their lower visibility, it could be believed that smaller companies are not a critical impetus underlying imitative behavior in ERP diffusion. This study does not consider several dimensions, such as incorporating the effects of social structure and organizational characteristics. Future researchers could expand the scope of the constructs considered.

Enterprise Resource Planning (ERP):

A Postimplementation Cross-Case Analysis

Joseph R. Muscatello

ABSTRACT

In today's intensely competitive marketplace, companies can benefit strategically and tactically from enterprise resource planning (ERP) systems, if implemented correctly. However, with failure rates estimated to be as high as 50% of all ERP implementations, companies can be negatively impacted by a poorly performing ERP system. The research on ERP has focused on events leading to the selection, evaluation, and implementation of the ERP system. The intent of this research is to identify new or lightly researched theories regarding the difficulties of ERP implementations that can help practitioners successfully manage ERP implementations by performing a post-ERP implementation examination of eight corporations. We examine operations management (OM) literature rather than information systems (IS) literature in order to provide IS readers with an alternative yet valuable analysis. Further, we purposely avoid well-established findings by performing a large literature review. This article is based on a qualitative research design using case-study methodology. The propositions derived from the case studies form solid insight into the considerations that may influence the success of an ERP system.

INTRODUCTION

In today's highly competitive manufacturing environment, firms are implementing enterprise resource planning systems to address the problem of fragmentation of information or "islands of information" in business organizations. ERP systems promise to computerize an entire business with a suite of software modules covering activities in all areas of the business. Furthermore, ERP is now being promoted as a critical link for integration between all functional areas within a firm's supply chain, and has shown to be a significant contributor to a corporation's success, if implemented correctly. ERP systems improve efficiency within the four walls of an enterprise by integrating and streamlining internal processes (Anderson, 2000; Koch, 1999). Kalling (2004) has also speculated that ERP may be a source of competitive advantage.

The ERP implementation efforts of many manufacturing companies have resulted in partial failure and, in some cases, total abandonment. Trunick (1999) reports that 40% of all ERP installations only achieve partial implementation, and nearly 20% are scrapped as total failures. Some of the failures have been shown to be user related in that new technology is not always acceptable (Nah, Tan, & Teh, 2004). An American Production and Inventory Control Society (APICS) Conference Board report issued in June 2001 stated that 40% of participants failed to achieve their business case after having implemented ERP for at least 12 months (Salopek, 2001). Other authors have suggested that the failure rate may be higher than 50% (Escalle, Cotteleer, & Austin, 1999). In a recent survey by Deloitte Consulting LLC, 25% of the 64 Fortune 500 companies surveyed said they suffered a drop in performance when their ERP systems went live (Evangelista, 1998). This is after believing that they had successfully installed the system. A recent study conducted by Professors Austin and Nolan of the Harvard Business School reveals that a remarkable 65% of executives believe ERP systems have at least a moderate chance of hurting their business because of implementation problems (Cliffe, 1999). At present, ERP is a new phenomenon and the research relating to ERP implementations is very limited (Al-Mashari, 2000; Dong, 2001; Nah, Lau, & Kuang, 2001; Parr, Shanks, & Drake, 1999). Most of the research to date focuses on preimplementation activities and provides some answers to a successful "path forward" for firms wanting to implement an ERP system. Research shows that some firms have successfully implemented ERP systems with some excellent performance improvement (Anderson, 2000; Melnyk & Stewart, 2002). However, since many ERP systems fail to meet their objectives after going live (Cliffe, 1999; Salopek, 2001), it is logical to conclude that there must be postimplementation improvements being performed by firms committed to using ERP as a successful business tool. This research seeks to uncover new information about the successful implementation and management of ERP systems by analyzing eight firms who have multiple years' experience, with varying degrees of success, with ERP systems.

The intent of this research is to identify new or lightly researched theories regarding the difficulties of ERP implementations that can help practitioners successfully manage ERP implementations by performing a post-ERP implementation examination of eight corporations. Our findings are formed into propositions. We examine operations management literature rather than information systems literature in order to provide IS readers with an alternative, yet valuable analysis. Further, we purposely avoid well-established findings by performing a large OM literature review.

LITERATURE REVIEW

OM ERP implementation literature can be segmented into five major areas, with each addressing several subtopics. These areas include strategic considerations, costs, training, project management, and the implementation process. Since our goal is to provide new ideas and theories, we reviewed the existing OM literature to gain insight into established theory on why ERP

Table 1. ERP implementation literature review

Research Area	Application	Literature Support
Strategic		
Strategic Assessment of ERP and Management Support	ERP adoption should be seen as a business decision rather than a pure technology decision. Top level managers must understand and appreciate the strategic value of ERP and be willing to provide unswerving support for the project.	Anderson, 2000; Brakely, 1999; Davenport, 2000; Griffith et al., 1999; Ng and Ip, 1998; Shulman, 1998; Vasilash, 1997; Volkoff et al., 1997.
ERP Package and Module Selection and Subsequent Technical (Information Technology) Issues	If the firm decides to implement an ERP, the information gathered in the needs assessment will provide a ready checklist for configuring an ERP system with all the necessary modules and their associated subsystems. If the expertise is not located internally it should be solicited from a third party.	Booker, 1999; Davenport, 2000; Holland and Light, 1999; Koch, 1999; Lail, 1999, Nah, et al, 2001; Shulman, 1998; Travis, 1999, Trepper, 1999.
Economic/Financial and Strategic Goals of ERP	Many ERP projects proceed without a formal analysis of costs and benefits. Major strategic benefits such as improved response to customer demands, improved and streamlined internal and external communication, and improved customer-supplier relationships should be factored into the expected benefits.	Davenport, 1998; Herr, 1994; Koch 1999; Maxwell, 1999; Melnyk and Stewart, 2002, Schaeffer, 1999; Vasilash, 1997.
Top Management Support	Top management commitment is much more than a CEO giving his or her blessing to the ERP system and then moving on to other projects. Management commitment should look beyond the technical aspects of the project to the organizational requirements for a successful implementation.	Cotteller et al., 1999; Dong, 2001, Herr, 1999; Maxwell, 1999. Oliver, 1998; Rausch, 1994.
Cost Considerations		
Economic and Strategic Justification of ERP	Economic and strategic justification for an ERP project, prior to installation, is necessary because of the enormous investment and risk involved. Moreover, the justification process helps identify all the potential costs as well as the strategic and economic benefits that can accrue from the ERP implementation.	Cliffe, 1999; Cotteler et al., 1998; Herr, 1994; Koch, 1999; Schaeffer, 1999; Vasilash, 1997.
ERP Implementation Costs	Many firms budget for these systems without adequate appreciation for the full costs of an implementation. Systems integration costs are often more difficult to predict. Often training and education costs are grossly underestimated.	Bradley et al., 1999; Koch, 1999; The Meta Group;
Training		
Training and Education	Extensive training and education are considered to be critical for the success of an ERP implementation. Training of both management and employees is required.	Al-Mashari, 2000, Appleton, 1997; Capron and Kuiper, 1998; Griffin, 1998; Griffith et al., 1999; Schaaf, 1999; Trunick, 1999.
ERP Skill Assessment and Training Needs	Formal assessment of the knowledge and understanding of ERP principles for all levels of employees is required to evaluate the amount of training required. It is also critical in establishing who has the ability to learn and change and if they can survive in the new organization.	Cliffe, 1999; Herr, 1994; Koch, 1999; Kropp, 1994; Muscatello 2002.

Table 1. ERP implementation literature review (cont.)

Research Area	Application	Literature Support
Project Management		
ERP Project Scope	"Scope creep" can create a project that never ends. The functional departments and processes that will be affected by the ERP installation should be selected at the beginning of the project and jealously guarded against additions.	Delaney and Mabary, 1994; Herr, 1994; Holland and Light, 1999; Lewis, 1993; Trepper, 1999
ERP Project Management and Team Structure	A project management structure that includes an executive steering team, a full-time project manager, a project management team and process teams is recommended.	Cotteller et al., 1999; Dong, 2001, Herr, 1994; Koch, 1999; Lewis, 1993; Nah, et al, 2001; Trepper, 1999; Vasilash, 1997, Volkoff et al., 1999; Welti, 1999.
Project Management Tools	The implementation of an ERP package is a complex task requiring specific project management skills and knowledge. As with every project, timely reports and updates are needed to evaluate ERP project progress in terms of time, cost targets and achieved benefits.	Lewis, 1993; Trepper, 1999; Wight, 1993; Welti, 1999.
Managing an ERP project Time Line	Implementing an ERP system in phases allows the executive management team to evaluate the current project phase's success or failure. This allows them to make business decisions without jeopardizing the full project cost.	Cliffe, 1999; Ferman, 1999; Frank, 2000; Holland and Light, 1999
Implementation		
Quality Assurance Methods for an ERP Implementation	Developing a "day in the life of" business case for key functions such as order entry, billing, shipping, etc. and piloting them in a conference room can drive out problems before the module is fully activated.	Benjamin and Levinson, 1993; Herr, 1999; Holland and Light, 1999; Lewis, 1993.
Process Reengineering	Companies need to integrate their core processes, combine related activities and eliminate those activities that do not add value prior to adopting the any new manufacturing or information technology.	Al-Mashari, 2000; Chalmers, 1999; Davenport, 1993; Dickey, 1999; Hammer and Champy, 1993; Hammer and Stanton, 1999; Jenson and Johnson, 1999; Nah, et al, 2001; Muscatello, 2002; 1999; Smith, 1999.

implementations are so difficult and often fail. This analysis allowed us to refrain from publishing heavily researched areas that may not make much of a contribution. Table 1 provides a summary of an extensive and critical review of the OM literature.

ERP adoption must be seen as a business decision (See for example: Anderson, 2000; Brakely, 1999; Ng & Ip, 1999) and not as a technology decision. This viewpoint will be helped along in the organization if strategic benefits are identified initially (i.e. response to customer demands, improved communications within and outside the firm, and improved customer and supplier relationships (See for example: Davenport, 2000; Herr, 1994). Top management support is not only necessary but critical in a project of the scope of an ERP system (See for example: Cliffe, 1999; Cotteller, Austin, & Nolan, 1998). Management commitment is essential not only in providing the financial support, but in providing the organizational processes that will ensure the success of the implementation. Package selection and identification of the features and functionality required is a tedious and resource-consuming task. Providing resources initially for the preparation of the needs assessment also requires top management support (See for example: Booker, 1999; Travis, 1999).

The second area of cost consideration is also shown in Table 1. Economic and strategic justification must be detailed and accurate in a project of the scale of ERP. Costs and benefits are critical, and must include contingencies and timing of both costs and benefits. While costs may be estimated, there are two categories of costs that are commonly underestimated. These include systems integration and training (See for example: Bradley, Thomas, Gooley, & Cooke, 1999).

Training and education are critical for the success of ERP (See for example Al- Mashari, 2000; Griffith, Zammuto, & Aiman-Smith, 1999). Skills and needs assessment must be done for all levels in the organization. Several authors identify the need to assess an employee's readiness for organizational change (See for example Cliffe, 1999; Muscatello, 2002).

Project management skills and abilities are also important in a high-profile project such as an ERP implementation. These include project structure (See for example Dong, 2001; Koch, 1999), managing scope (See for example Delaney & Mabary, 1994), managing the project time line (See for example Ferman, 1999), and overall project communication (See for example Welti, 1999).

Finally, process reengineering (See for example Chalmers, 1999; Smith, 1999) and quality assurance (See for example Holland & Light, 1999) are but two of the implementation issues that require attention in an ERP implementation.

The gap that exists in current research has to do with the postimplementation ERP effects on a business. What processes, programs, or duties changed post-ERP implementation? What interdisciplinary effects were observed? What are the observed ongoing effects? This research extends the theories on ERP implementation by exploring the selected case studies, both pre- and postimplementation.

METHODOLOGY

Case-study research methodology has been highly recommended by many researchers as an ideal tool for improving conceptual and descriptive understanding of complex phenomena (Flynn, Sakakibara, Schroeder, & Bates, 1990; McCutcheon & Meredith, 1993; Meredith, 2002; Stuart, 2002; Yin, 1994). The case-study method also offers many benefits, such as the ability to directly observe causality, and combine evidence and logic to build, develop, or support theories that are not available using other research methods (Maffei & Meredith, 1995). In contrast to survey research formats, it allows for more meaningful follow-up questions to be asked and answered, and can result in more extensive findings and insights that are valid, generalizable, and rigorous (Meredith, 1998).

ERP implementation is an expensive and extensive undertaking involving all activities related to planning, justification, installation, and commissioning of the installed system. An ERP system extends across the entire organization and beyond to cover integral partners in the supply chain. Furthermore, ERP projects can take two, three, or more years to fully implement (Parker, 1999). All of the above factors contribute to the complexity of ERP installations, and make snap-shot/cross-sectional approaches unsuitable for investigating the entire ERP implementation process. We adopt a case-study methodology to create propositions based on a longitudinal analysis of postimplementation factors that contribute to the successful installation and management of an ERP system. However, unlike the majority of studies in this area that focus on single case studies or survey information based on a specific ERP process or implementation plan, we develop propositions based on ERP implementations at eight diverse manufacturing facilities.

Selection of organizations is a very important aspect of building theory from case studies. While the cases may be chosen randomly, random selection is neither necessary, nor even preferable. Given the limited number of cases that can be studied, it has been suggested that researchers choose extreme situations and polar types in which the process of interest is transparently observable (Eisenhardt, 1989). Of the eight ERP implementation projects included in this study, four were successful, two are partially completed with low to moderate success, and two were eventually abandoned with very little gain. It was difficult to assess whether the abandoned projects should be included in a postimplementation study since obviously, their postimplementation was a failure. However, after reviewing the supporting documents and conducting preliminary interviews we decided to include them since they believed they had implemented the ERP system and abandoned it after the project team was disbanded. The author of this study served as a team member on six of the eight projects, with different roles on each project. His roles included Executive Sponsor, Project Manager, Subject-matter Expert, and Project Team Member. On the other two studies, the author had follow-up access to the project charter, plan, reengineering records, scope, quality plan, meeting minutes, consultants, project manager, team members, and executive sponsors.

Multiple methods were used to generate the data including the principle author's observations and constant interactions with ERP project team members during and after implementation. As an integral member of the pre- and postimplementation project team for six projects, and as a postimplementation advisor to the remaining two businesses, the principle author had unlimited access to historical documents and other records, financial data, and operations statistics. Open-ended interviews were also held with corporate officers, divisional managers, project leaders, super-users, and various project team members. A minimum of 10 interviews was held for each case study. These interviews included opening statements by the interviewer, open-ended questions, and nonsolicited interviewee statements. These interview techniques permitted the project participants to identify and frame the important issues and factors that affect ERP implementation success, as also suggested in Maffei and Meredith (1995). This approach is consistent with the recommendation that, in an area where theory is relatively undeveloped, researchers should use an inductive approach to the process of identifying issues for inclusion in the study (Flynn, Schroeder, & Sakakibara, 1994; Hensley, 1999; Spector, 1992). The written records, project plans, interview findings, and financial data were sorted for relevancy and completeness, and placed into tables that are referenced later in this paper. Sorting data into well-defined components in order to perform cross-case analysis follows the case-study analysis recommendations of Maffei and Meredith (1995).

COMPANY BACKGROUND AND DATA

Four of the companies covered by this study were divisions of larger companies. Four were stand-alone companies. They represented a range of firm sizes, products, types of manufacturing (continuous process, batch, and job shop) markets, and organizational arrangements, as shown in Table 2. The companies also had different prior experiences with manufacturing and information technology. The financial performances of seven of the eight companies were below the expectations of their corporate headquarters. Company G had average profits compared to the industry. Four companies (A, B, E, and F) were recording consistently declining profits. Company C was just breaking even in a growing market, and companies D and H were losing money. In addition, they were all experiencing problems with excessively highinventory levels and low inventory turnover rates. Only companies D and H had on-time delivery performances better than the industry average, while the remaining six were below average. Corporate and divisional management for all the companies recognized the need for immediate strategic and operational responses to these problems.

All eight of the companies entered their ERP decision process under directives from corporate headquarters or the company's executive management team. Companies A and G had been threatened with widespread divisional management changes if the decline in profitability was not reversed. Company B's corporate management had stated that it would close down the division and transfer the work to a foreign division of the company. Executive management of company C had threatened to find an external source for this division's products, and the corporate management of companies D and H indicated that they were going to close the division/company if the losses continued. Company E's management required improvements or underperforming divisions would be closed or sold. Executives at company F required improvement or the acquisition plan would be scuttled, leaving fewer opportunities for middle management. Corporate management of four of these companies had recent encouraging experiences with enterprise system (ES) installations at their headquarters or in other divisions; they were favorably disposed to ES solutions for streamlining divisional operations. Experienced internal managers and consultants, vendors, board members, or other professionals who had an understanding of ERP systems influenced the companies who were not divisions or subsidiaries. Corporate management at all firms viewed integrated enterprise systems as a means of improving efficiencies and communications across all their divisions, and between the divisions and corporate headquarters. Corporate management was also the primary selector of the project sponsor and senior project team members.

A detailed business profile and the findings of each case study are shown in Table 2. To maintain anonymity, the names of the corporations have been removed. The intent of this case analysis is to infer relationships between project interdependencies and project performance. Therefore, each case is akin to a laboratory or complete survey experiment (Meredith, 1998).

PROPOSITIONS AND THEORETICAL FRAMEWORK

The author derived eight propositions based on the eight case studies. Each proposition will be presented at the end of the discussion. Propositions were developed based upon the analysis of the grouped company profile data, the supporting case-study documents, financial records, project plan and meeting notes, interviewer findings and,

Table 2. Company profiles and analysis (cont.)

Current status of Firm	Company A is still in business and has increased market share and profits faster than their competition. They are expanding into TQM and Lean Manufacturing principles	Company B is the largest producer in a market that is replaced by plastics. They feel their ERP system has allowed them to remain competitive	Company C lags the market in both sales and revenue. Only the accounting modules of the ERP system are implemented	Company D closed its doors in 1999. Fortunately for the researchers, we were able to locate several of the senior managers and ERP implementers
	Company E enjoys and increased reputation in the market for both low price and high service	Company F has declined in profitability and has now implemented plans to use off-shore manufacturing	Company G has a strong financial statement and enjoys profits higher than the industry average. They have also implemented Six-Sigma improvement practices	Company H is losing money and closed a division in 2000.

if any, relevant OM literature. The supporting statements made before each proposition are an accumulation of ideas/statements formed into a single like-minded expression. The development of generalities is acceptable for developing propositions when a rigorous case-study analysis has been carried out. (Maffei and Meredith (1995). The companies who contributed to each statement are noted after each statement.

Participants were very vocal about the need to assess the skill and training level of the existing employees after the implementation. There was a general dismay at the lack of ERP and business knowledge residing in companies that implemented ERP systems. One participant stated: “People don’t understand how the whole company operates, just their little corner of the world. They need to understand that an ERP system requires timely and accurate data in order to perform the planning functions. They view transactions as an afterthought and not ‘real work’ like production. This mentality is killing our ERP system.”

Three companies (C, D, and F) performed no formal review of their existing employees’ skill levels until after the implementation. Companies A and B did the skill review with in-house senior managers who had successfully transformed other divisions, and two managers with multiple ERP systems installations. Three companies (E, G, and H) used outside consultants to assess the current skill level, ability to grow, and amount of education and training necessary to grow. The assumption from most management is that after implementation, a person is fully trained. This reasoning is misguided because it assumes that once an employee has gone through an ERP training program, they now understand the business philosophy behind an ERP system. This analysis found that in all eight firms, process and job functions changed so radically in the areas of customer service, production scheduling, purchasing, inventory, and logistics that some employees who were deemed adequate or better performers before the implementation were not able to satisfactorily grasp the new procedures. Human-resource administrators in all eight companies stated they had significantly changed the job descriptions, requirements, and interview procedures after implementing ERP. All of the firms felt they had grossly overestimated the abilities and current job knowledge of at least a few of their employees. Thus,

Proposition 1: Firms who implement ERP systems will significantly change the education, training, and experience requirements for future hires.

Also, after the "go live" date, five firms (A, B, C, E, and G) reported that they implemented more functionality of their ERP systems than planned, and had to conduct further training and education of their employees. Some of the postimplementation functionality implemented included advanced planning systems (APS), distribution requirements planning (DRP), desktop report writers, online costing systems, Internet integration, engineering configurators, and bolt-on software such as timekeeping systems, amongst others. This caused a further gap in the abilities of current employees, and lead to management having to go through the painful process of re-evaluating employees again. However, six firms (A, B, C, E, F, and G) all stated that without the continuous upgrade in employee skills through hire/fire, training and education, or outsourcing, their ERP implementation would have failed, been less successful, or taken longer and been more expensive. So, we propose,

Proposition 2: Firms who address the gap in employees' abilities and performance after the ERP implementation, through an ongoing analysis, will have a greater likelihood of successfully implementing ERP than those who do not.

All eight of the companies performed "needs" assessments. However, there were some differences in their approaches. Company D used an in-house team and examined software packages from various vendors. The remaining companies used independent, third-party consultants to assist in their assessments, and used the results of their reengineering efforts to develop the configuration for their ERP packages. They performed a checklist assessment provided by the consultants to determine the best-fitting software. Company B used a similar checklist and was aided by an outside consultant on their selection of a package. Since they had not yet performed their process reengineering, they selected a package based only on an evaluation of their current processes. After company B's reengineering efforts, changes had to be made to the chosen ERP system to incorporate the requirements of expected future processes. The checklists used by all three companies included questions on

(1) Current IT systems (including hardware)
(2) Type of business (continuous, repetitive, batch, job shop)
(3) Market analysis (demand management, forecasting, customer relationship management, etc.)
(4) Scheduling (MPS, MRP, and BOM requirements; shop floor scheduling, etc.)
(5) Logistics (warehousing, transportation scheduling, etc.)
(6) Purchasing (EDI, Internet, integration to inventory, and MRP, etc.)
(7) Inventory (transactions, bar codes, package types, analysis, etc.)
(8) Performance measurements (types of measurements)
(9) Financial and accounting (GL, AP, AR, credit, online banking, depreciation, aged inventory, budget control, costing, etc.)
(10) Other

All companies came to the conclusion that they needed to install modern information systems, and that this was at least part of the answer to their problem. This conclusion was reached after examining current trends in the marketplace, and after careful consideration of IT needs for their current or reengineered processes, their current IT systems (including hardware), and available IT solutions. The firms all reached several common conclusions about their existing systems that suggested a need for the implementation of new information technologies and ERP systems. We list some of these conclusions drawn by our study participants, as well as supporting research for each conclusion:

- The existing systems required multiple points of input and there was significant duplication, with the same data being entered at multiple points in the system (Davenport, 1998).
- The organization's information and manufacturing technology needs were not adequately being met by the existing systems (Chalmers, 1999; Cliffe, 1999).
- Maintenance and support for the existing systems required significant effort both in terms of time and human resources (Capron & Kuiper, 1998; Griffith et al., 1999).
- The enterprise had islands of information, and many of these systems were incompatible (Muscatello, Chen, & Small, 2003).
- Too much information was stored informally, and “fire fighting” and “expediting” had become the norm (Davenport, 1998; Dickey, 1999).
- In too many instances, employees were unable to respond easily and quickly to questions or information requested by key customers or suppliers (Escalle et al., 1999; Jenson & Johnson, 1999).

The companies expected the ERP systems to provide the required crucial links between factory floor operations and information requirements across all the support functions of the business. The fact that these systems could also be extended to cover partners in the supply chain was also appealing to these companies. The decision to implement ERP was also due, in large part, to the influence exerted by corporate management.

Although all eight companies felt that their ”needs assessment” efforts helped them to configure and select ERP systems that would provide a good fit with their operations, it is clear from the postimplementation respondents that ”needs assessment is ongoing in an ERP project.” The six firms who had some success with their ERP implementation added additional hardware and/or software after the project ”go–live” date. In two instances, the main information systems had to be upgraded due to an unforeseen increase in the usage of the system. Also, five firms (A, B, C, E, and G) decided to install additional modules and/or peripheral devices such as radio frequency (RF) controllers, advanced planning modules, payroll systems, electronic data interchange (EDI), and Internet electronic commerce capabilities. These additional tools were deemed unnecessary or too costly at the beginning of the project. However, after implementation, the value of these technologies was uncovered, and they were subsequently added to the business system.

Proposition 3: A firm's ability to successfully implement an ERP solution requires an ongoing assessment and implementation of technical and functional capabilities beyond the initial scope of the ERP project.

In all eight cases, the manufacturing-marketing interface became much more scrutinized after the implementation of ERP. Current research shows this to be an issue in many organizations (Calantone, Droge, & Vickery, 2002; Parker, 1999). Our study found that the implementation of an ERP system magnifies the diverse perspectives and motivations of manufacturing and sales.

The causes for this increase in potential conflict arise from a variety of factors. First, there is an increased scrutiny of inventory investment since it is one of the leading cost-reduction areas used to justify the implementation. Second, salespeople are rewarded for increasing volume, and this was a project justification factor for all but firm C. In six firms (B, C, D, F, G, and H), manufacturing and sales did not have common performance measurements or goals. Manufacturing was judged on labor cost models, leading to a big run size, lowchangeover philosophy. The sales function was judged on total sales dollars and gross margins, leading to a high stocking philosophy. It was also observed that in five firms (A, C, D, F, and H), there was no formal notification system of changes to the sales plan such as incentive programs, advertisement, and so forth. This led to inventory spikes and stock-outs due to the manufacturing's mandate to lower inventory.

Our study found that postimplementation issues between manufacturing and sales were resolved in several ways. First, five firms (A, B, C, E, and G) created joint performance objectives for all levels of management in the areas of manufacturing and sales. The manufacturing managers had a review component consisting of total sales dollars, gross margins, lost sales, and customer complaints related to customer-service delivery issues. The sales managers had a review component consisting of total inventory dollar investment, schedule changes after freezing the master scheduling, and activity-based product costing. As one executive from firm E described it, both manufacturing and sales had "skin in the game." The same five firms (A, B, C, E, and G) all felt that after they implemented joint performance measurements, manufacturing and sales worked in greater harmony and morale increased in both groups.

Proposition 4: Firms that use ERP functionality to improve performance objectives shared by manufacturing and sales will strengthen the manufacturing-sales interface.

Firms (A, B, C, E, and G) who relied on product forecasts took an integrated role to forecasting. The sales managers were given a forecast variance, plus or minus, that they were expected to adhere to. Manufacturing managers were required to meet the forecast, plus or minus variance, without raising product costs. This created a measurement system that both manufacturing and sales had input into, and the consequences were established. This performance objective helped minimize the after-the-fact arguments between manufacturing and sales.

Proposition 5: Firms that use ERP functionality to create relevant performance objectives for sales forecasting will strengthen the manufacturing-marketing interface.

In summary, the extended theory of ERP implementations reveals that the processes changes forced by an ERP implementation, if acted upon, will strengthen key interfaces and improve the general communication between manufacturing and sales.

Proposition 6: ERP functionality will strengthen the manufacturing-sales interface and increase morale in both areas.

Six firms (A, B, C, E, F, and G) found that the implementation of an ERP system had a dramatic impact on purchasing's role in the corporation, regardless of whether the firm had a centralized or decentralized purchasing function. Five firms (A, B, C, E, and G) reported that the increased pressure to reduce total inventory dollar investments and total product costs caused a greater role for purchasing. In six firms (A, B, C, E, F, and G), purchasing went from a quasiclerical function to a highly skilled professional function because of the emphasis placed on material requirement plans, just-in-time deliveries, and the increased cost of material shortages due to the minimization of raw and component inventory.

Six firms (A, B, C, E, F, and G) agreed that purchasing's role became more strategic after the implementation of the ERP system because of the overall impact to the effective management of the supply chain, and the direct impact to product costing, financial performance measures (inventory turns, etc.), and shop-floor disruption costs.

Proposition 7: Purchasing's strategic and tactical value increases with the implementation of an ERP system

Interestingly, those same six firms (A, B, C, E, F, and G) showed an increase in the amount of time purchasing managers were involved in marketing, financial-, and operations-planning meetings. This also corresponded with an increase in participation from nonpurchasing managers in purchasing meetings, creating more formal integrated purchasing teams. This is interpreted as further proof that purchasing's strategic and tactical value increases with the implementation of an ERP system.

Proposition 8: The Use of Integrated Purchasing Teams Increases with the Implementation of an ERP System

CONCLUSIONS, IMPLICATIONS AND FUTURE RESEARCH

Many researchers have argued that firms implementing ERP systems would benefit from a better understanding of how to implement an ERP system and how will it change their business. This paper conducted an intensive review of OM current literature, academic and practitioner, to determine what theories have been established, and to create groundwork for managing the case studies. We purposely stayed away from areas that have been researched in an attempt to provide new insight into the transforming that takes place with an ERP implementation.

While this study is exploratory in nature, the results provide a number of insights that contribute to ERP strategy research and practice. Current ERP theories showed a strong link between the amount and level of ERP training and implementation success. Our findings conclude that training and education cannot be shorted even after the ”go live” date of an ERP implementation. Also, firms implementing ERP systems must realize that future employees will have to have a significantly greater skill set than previous employees, and that human resources must react to the change. Second, the study demonstrates that there is no single, proven path that a firm can take regarding hardware, software, and other functional capabilities. Each firm has to remain flexible after the ”go live” date, and tune the technical and functional capabilities of the system. Also, a firm should remain flexible and be willing to revisit current processes to establish a better fit between business processes and the hardware and software technology. This point builds upon the findings in OM literature that strong project management skill sets are required for success.

The third conclusion is the suggestion that an ERP system will increase the harmony between manufacturing and marketing. To receive business benefits from an ERP system, manufacturing and marketing need to understand that they both strongly influence the likelihood of success. While this perspective is advanced in the emerging manufacturing strategy literature, it is not found to be uniformly prevalent in practice (Hausman, Montgomery, & Roth, 2002). Hence, firms should strive to increase the harmony between manufacturing and marketing, by integrating performance metrics, to achieve the benefits of ERP.

Fourth, this study highlights the increasing strategic and tactical role purchasing is responsible for in the new supply-chain models. The implementation of an ERP system should increase the visibility and authority of current purchasing managers and their processes, and elevate the need for cross-functional purchasing teams. This is a solid contribution to the emerging practice of strategic purchasing.

Despite the merits of this study, it has certain limitations that should be recognized. First, the study is exploratory and introduces new concepts that need to be verified by further research. Second, we examined only eight companies, and it limits our responses. This research should spawn studies that examine different contextual factors such as SIC codes, firm size, and international firms, amongst others, which may find different results.

Clearly, the effects of an ERP system need to be studied further, especially in light of its pervasive system of choice among operation and service organizations. In summary, this study calls for the extension of current research, and identifies new areas of interest for both researchers and practitioners interested in ERP.

Chapter 4.12

Information Technology Adoption and the Role of Organizational Readiness:

The Case of an Indian Bank

Monideepa Tarafdar
University of Toledo, USA

Sanjiv D. Vaidya
Indian Institute of Management, India

EXECUTIVE SUMMARY

This case describes the evolution of the use of information technology (IT) at National Banking Services, one of the oldest banks in India. It describes the bank's response to economic liberalization and the resulting initiatives for IT adoption. It highlights the influence of organizational readiness on IT adoption. In particular, it describes the negative influence on IT adoption of conditions such as the lack of top management support, skeptical end-user attitudes about the benefits of IT, and resistance from employee unions. The case ends with a description of the changing role of IT in the banking industry in India and the challenges confronting the bank.

ORGANIZATIONAL BACKGROUND—PRIOR TO 1985

Many countries around the world have undergone economic liberalization in the last two decades. As a result, organizations in these nations have been faced with changing industry structures, new policy directives, and greater competition. These changes have resulted in significantly higher levels of information technology (IT) adoption, prompted by requirements for greater process efficiency and better operational and management control. For instance, firms in China have experienced higher levels of IT investment as a result of increased competition (Kunnathur & Shi, 2001). Similarly, Montealegre (1998) describes a case of increased IT adoption in a Guatemalan organization, influenced by changes in the economic environment. Similar findings have been reported from other countries as well (Saxena & Sahay, 2000; Wolcott & Goodman, 2003).

However, all organizations have not adopted IT to the same extent, even in similar industries. While some firms have used IT to achieve significant competitive advantage, others have implemented IT only to the extent required, often only in compliance with regulations (Tarafdar & Vaidya, 2004). This is because there are significant challenges in firms in these countries, in terms of required organizational support, availability of information systems (IS) related to technical and human resources, and appropriate management of change that needs to accompany the transition to higher levels of IT adoption. For instance, studies have shown that it is difficult to acquire and manage IS-related resources because of inadequate physical and information infrastructure as well as social and cultural diversity (Montealegre 1998). There is also a paucity of adequate IS personnel and support (Jain 1997; Ranganathan & Kannabiran, 2004). Moreover, cultural and organizational issues, such as resistance to IT adoption and use and the existence of employee unions, have been challenges, as has been the frequent absence of top management support for the acquisition of IT (Dasgupta, Agarawal, Ioannidis, & Gopalakrishnan, 1999; Kanungo, Sadavarti, & Srinivas, 2001).

A number of studies (see Chwelos, Benbasat, & Dexter, 2001; Iacovou, Benbasat, & Dexter, 1995; Kuan & Chau, 2001; Mehrtens, Cragg, & Mills, 2001) have analyzed IT adoption using a framework that takes into account three antecedent factors: perceived benefits from IT adoption, organizational readiness for IT adoption, and external pressure for IT adoption. Perceived benefits describe advantages that organizations perceive from the adoption of IT, such as increased process efficiency and lower cycle times. Organizational readiness refers to the availability of adequate organizational resources as well as the presence of appropriate supporting conditions (such as top management support and a proactive approach, for instance) required for IT adoption. External pressure refers to influences outside the organization (such as, competitive pressures and government regulation) that lead to IT adoption. Using this framework, this case highlights challenges and issues in IT adoption in one of the largest public banks in India.

National Banking Services (NBS) was one of the largest public banks in India. The company was founded in 1906 and had its corporate headquarters in Mumbai. It had more than 2,500 branches in India and 19 foreign branches in 10 other countries. It employed more than 50,000 employees. The mission statement of the bank was:

…to provide superior, proactive banking services to niche markets globally, while providing cost-effective, responsive services to others in our role as a development bank, and in so doing, meet the requirements of our stakeholders.

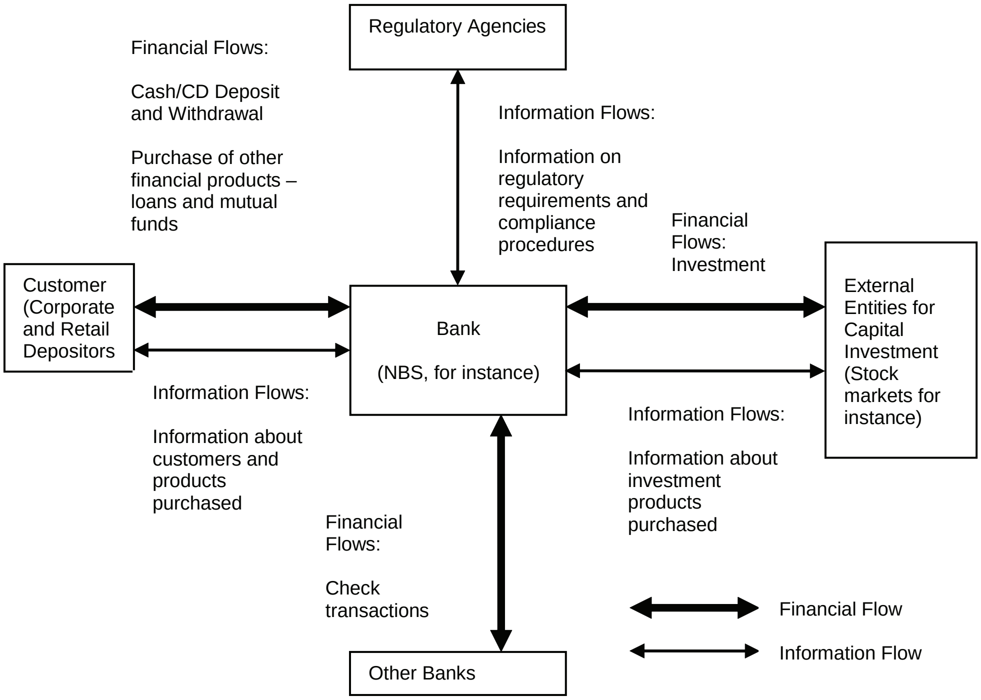
The Indian banking sector was divided into three categories. There were 27 "public sector," or government controlled, banks, 31 private banks owned by Indian companies, and 29 banks owned by foreign companies. The larger ones, usually public banks, operated on a large, nationwide scale. They had on an average, more than 2,000 branches, more than 50,000 employees, and assets of more than 50,00,00 million INR. The smaller banks had, in general, less than 1,500 branches, and assets less than 15,00,00 million INR. Some of the smaller private banks had less than 100 branches, assets less than 70,000 million INR, and less than 700 employees. The public banks were under the jurisdiction of the Reserve Bank of India (RBI), which determined broad strategic directions and formulated policy decisions. All banks operated under broad financial and economic policies specified by RBI and the Ministry of Finance (MOF).

Products and Processes

NBS served two kinds of markets: corporate and retail. Corporate banking products included corporate loans and advances, current account facilities, bill discounting, opening of letters of credit, and overdraft facilities. Retail banking products included savings accounts, current accounts, fixed deposits, and long-term advances as well as loans for houses, automotive vehicles (cars, trucks, and tractors), farm machinery, and white goods. Many of its customers, especially in the rural segment, were small farmers and owners of small-scale business units. Hence, the bank had 70% of its branches in rural areas, so that farmers could have access to capital when required and could also have an avenue to save money. These branches made credit for development and other business opportunities available in the economically backward areas. Along with its commercial objectives, therefore, there had historically been a strong social motive to the bank's operations.

The value chain of a typical bank is described in Figure 1. Important flows relate to the *financial* inflows and outflows of the bank, as well as the flow of *information* to and from external entities, such as other banks and regulatory agencies. NBS interacted with four entities: customers, other banks, investment institutions, and regulatory agencies. First, two-way financial flows with corporate and retail customers included deposits and withdrawal of cash and disbursement of loans. Two-way information flows included customer and product information. Second, NBS had two-way financial flows with other banks, when it cashed a check from another bank or another bank received and honored a check drawn on NBS. Third, NBS had two-way financial and information flows with investment institutions, such as the stock markets. Financial flows were related to capital investment activities, and information flows included

Figure 1. Value chain of NBS



information about investment products that NBS purchased from these institutions. Finally, there were two-way information flows with regulatory agencies, such as the RBI and the MOF, regarding regulatory policy directives and compliance procedures and activities.

The processes at NBS were by and large routine and standardized, with well-defined work procedures. Decision making and policy formulation were centralized. Top management provided clear operating instructions to middle and junior management. Branches worked within well-defined parameters and did not have much scope for making independent decisions. Official communication was written and extensively archived. At the same time, however, information was not stored in a systematic manner, and it was not possible to quickly retrieve information required for task performance. According to a counter clerk at one of the larger branches, "Before branch computerization, information was missing about 70% of the time. We were often not able to trace the account number, or else the account balance was not correct ... some problems were always there."

This was reflective of the general nature of operations of banks during the 1970s and most of the 1980s. At the end of the 1970s, public banks in India had more than 10 million customers. Each day, an estimated 3 million intrabranch transactions and 1 million interbranch transactions took place. This generated acute requirements for complex information processing systems for housekeeping, internal control, and auditing and macrolevel information for policy formulation and control by the government. Throughout this period, information processing techniques in the banking sector remained manual. Consequently, services degenerated and there were delays in settling transactions. The banking control system was suboptimal, leading to possibilities for forgery, fraud, and malpractice. Indeed, the only element of automation that was introduced before 1985 was the introduction of magnetic ink character reader (MICR) checks, to assist in speedier clearance of checks.

Organization Structure

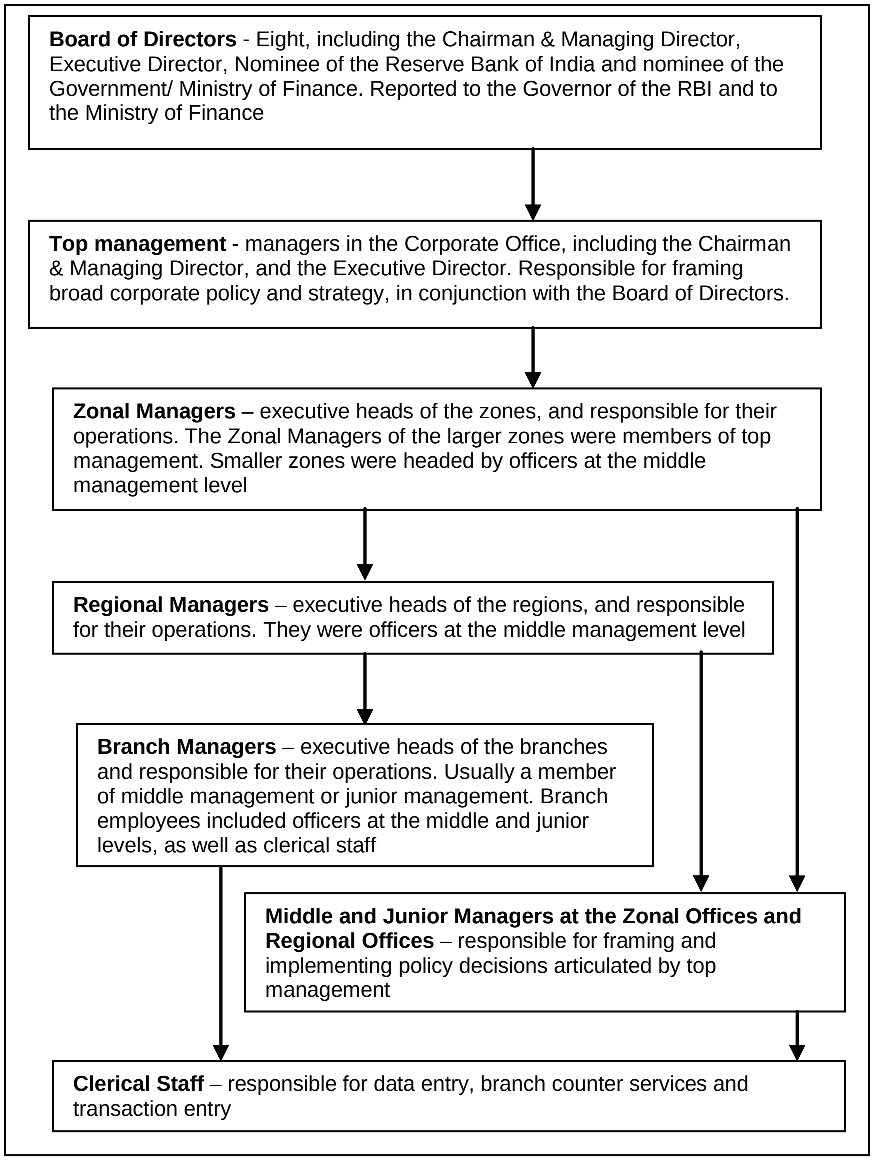
NBS was a headed by a senior government employee, who was the chairman and managing director. He was a professionally qualified bureaucrat or a career banker, specializing in economics and finance, and was appointed by the MOF. The main governing body was the board of directors, which consisted of eight people, including one nominee of the government and another nominee of the RBI. The top management functioned out of the corporate office in Mumbai. The operations were divided into 17 zones and 60 regions. Each zone and region was headed, respectively, by a zonal manager and regional manager. The zonal managers of the larger zonal offices were members of top management, while middle managers headed the smaller zones and regions. Each zone was responsible for three to four regions. At the senior, middle, and junior management levels, the zonal and regional offices were largely staffed by professional bankers, selected competitively from a central pool of applicants. Each region was responsible for a given number of branches. Each branch was headed by a branch manager, who was either a middle or junior manager, depending on the size of the branch.

Zonal managers of the larger zones, along with the corporate top management were responsible for framing overall strategy and policy. Middle and junior managers framed and executed implementation strategies for these policies. Clerical staff was responsible for line operations such as data entry, counter services, and transaction entry. The organization structure is shown in Figure 2.

Regulatory Environment

Traditionally, NBS had functioned in a protected environment. The Indian banking sector, like the rest of the Indian economy, was regulated until

Figure 2. Organizational structure



Board of Directors - Eight, including the Chairman & Managing Director, Executive Director, Nominee of the Reserve Bank of India and nominee of the Government/ Ministry of Finance. Reported to the Governor of the RBI and to the Ministry of Finance

Top management - managers in the Corporate Office, including the Chairman & Managing Director, and the Executive Director. Responsible for framing broad corporate policy and strategy, in conjunction with the Board of Directors.

Zonal Managers – executive heads of the zones, and responsible for their operations. The Zonal Managers of the larger zones were members of top management. Smaller zones were headed by officers at the middle management level

Regional Managers – executive heads of the regions, and responsible for their operations. They were officers at the middle management level

Branch Managers – executive heads of the branches and responsible for their operations. Usually a member of middle management or junior management. Branch employees included officers at the middle and junior levels, as well as clerical staff

Middle and Junior Managers at the Zonal Offices and Regional Offices – responsible for framing and implementing policy decisions articulated by top management

Clerical Staff – responsible for data entry, branch counter services and transaction entry

1991. All banks were governed and administered by the central government, which mandated the nature of activities they could undertake and the financial products and services that they could provide. The government also determined the macro-economic framework within which banks operated. One of the most important aspects of banking policy, historically, had been the concept of "deposit mobilization." As part of this policy, banks were vehicles for generating savings within the economy. One of the measures of their performance, therefore, was the amount of retail "savings" or "deposits" that they were able to generate, especially in the rural sector. Another important parameter was the disbursement of "microcredit," loans for individual entrepreneurs and small businesses that encouraged and generated commerce and economic activity in the rural sector. These objectives were in line with the nation's development goals following political independence in

1947. In addition to their financial and monetary role, therefore, banks were also expected to perform a "service" role. During the 1970s and 1980s, NBS pursued deposit mobilization in the rural areas and provided credit to small-scale sectors, farmers, and agricultural co-operative societies, in keeping with this role.

SETTING THE STAGE—1985-1991

Nature of Information Processing Activities: Perceived Benefits from the Use of IT

The processes of NBS had three characteristics. First, the information processing requirements were quite high. This was because of the sheer size of the bank, which had 2,500 branches, and the volume of transactions handled. The number of branches, total assets, and deposits were among the largest in the country, and almost four times that of the smaller banks. Further, given that products and services were information based, all functions and processes involved the transfer of information (amount of money, interest rates, loan and deposit schemes, account balance, exchange rates) from one point to another. Also, customers had to process significant amounts of information in order to acquire and use the products of the bank. On the whole, therefore, operations of the bank required huge amounts of information to be processed. The adoption and use of transaction processing systems, therefore, would result in significant efficiencies in information processing.

Second, information processing had to be accomplished quickly, especially during counter operations when information regarding bank balance, credit balance, and so forth had to be furnished and retrieved very quickly at the point of service. Operations, such as loan approval and credit appraisal, also had to be completed quickly since customers' decisions depended on the outcome of these activities. The same was true for transactions related to stock exchange services. The use of databases would lead to better access to information and would considerably help speed up these processes.

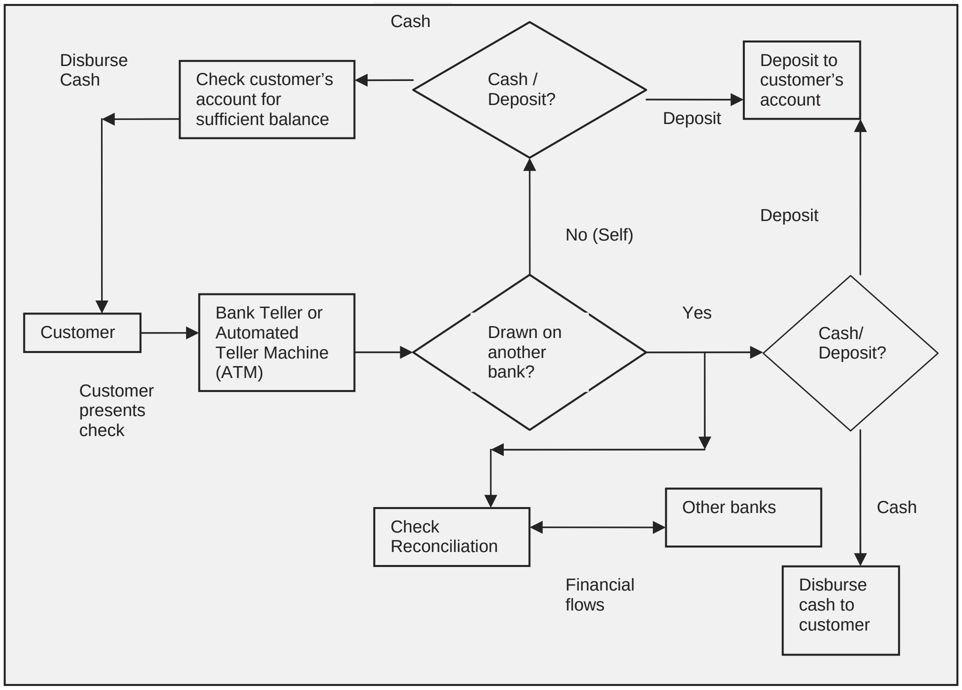
Third, there were significant interdependencies in information processing activities because many of the activities were sequential. For example, Figure 3 shows a typical check processing transaction at NBS. Customers presented their checks at the counters or at the automated teller machines (ATMs). The check was then scrutinized for authenticity, after which an amount of money corresponding to the check was either disbursed as cash (to the customer) or transferred to the customer's account. If the check was drawn on another bank, NBS transferred "reconciliation" information about the check to the bank on which it had been drawn, and received financial flows of the corresponding amount. When other banks honored checks drawn on NBS, they sent in similar information, and received financial flows from NBS of the corresponding amounts. As Figure 3 shows, the speed with which a customer could withdraw money depended on the speed with which the account number was matched and the account balance checked. Similarly, for loan approvals, the time taken to approve a particular loan depended on the speed with which the credit appraisal process was carried out. The use of centralized databases and networked computers would help in this context.

From the above descriptions, it is clear that because of the nature of its processes, the perceived and possible benefits from the adoption of IT at NBS were high, and included better customer services, housekeeping, and control over operations.

IT Deployment During this Period

IT deployment during this period was a result of government directives. In the 1980s the government appointed a committee (Joshi & Joshi, 2002)

Figure 3. Check processing transaction at NBS



to frame guidelines for addressing the information processing requirements of the banking sector. Subsequent to this, and in order to address the major recommendations of the committee, the Indian Banks Association (IBA) reached an agreement with the staff union for introducing electronic ledger posting and accounting machines. These were to be used for updating transactions related to current and savings accounts, general ledger accounts, and cash credit and loan accounts. The process of computerization at NBS and other public banks was initiated against this back drop. A computer department, consisting of senior managers from the administration and internal audit departments, was set up in NBS in 1984.

In 1985-86, automated ledger posting machines (ALPMs) were introduced as part of the computerization efforts in the branches. The RBI coordinated this effort and helped decide on vendors and software. Activities having heavy information processing requirements, such as ledger posting, financial accounting, and payroll processing, were computerized. Initially ALPMs were introduced only in those branches that had greater than 750 transactions in a day. They were located mostly in the larger cities. The ALPMs were stand-alone terminals where transactions were entered at the end of the day to generate the ledger. Data entry was performed offline, and counter clerks were trained in operating the ALPMs. ALPMs were not well received by the employees. Their implementation and adoption were fraught with set backs, mainly because of hardware problems. A teller at one of the branches mentioned: “Initially, we found it frustrating to use ALPMs. They were difficult to operate and would frequently break down. We always kept manual back ups of the data.”

On the whole, during this period, the IS were rudimentary, and used primarily for increasing the speed of existing processes. The total monetary investment in IT deployment during this time was 5 million INR.

Environmental Conditions

Before 1991, given the larger economic perspective of increasing consumer savings, there was a strong thrust for branch expansion in the rural and semi-urban areas and on rural credit disbursement. As a result, branches were opened even in those places where there was little possibility of generating profit. The government provided financial support to offset losses from these branches. About half of the loans given to the agricultural sector were bad debts because of calamities, poor supervision, and willful defaults. The social objectives of the bank took precedence. There was no flexibility in lending, and borrowing rates were fixed. The performance of the bank was judged by the extent to which it had been successful in mobilizing savings. Therefore, "total deposits," rather than "profit," was the primary indicator of the company's performance. Deposits grew by 15 times from 1970 to 1990.

Moreover, the bank did not make any attempts to market its products and services. According to the branch manager of one of the largest branches in the country,

> *We regarded ourselves as a bank as well as a kind of social institution. There was no concept of marketing in this bank. The idea was that we would open shop, customers would come, and we would disburse credit or deposit their money.*

There was no competition from the private sector, since only the nationalized banks could offer loans, take in deposits, and carry out foreign exchange transactions. Additionally, entry barriers were high because of government regulations, so new banks did not emerge. The capital market as an alternative source of savings was perceived to be speculative and unsafe. Alternatives in the rural areas were the post office, money lenders, and unorganized depositors. For the large middle and lower-middle class population of the country, therefore, NBS and other similar banks provided the only organized, regulated, and secure channels through which they could manage their personal finances. Given all this, NBS had an assured customer base and almost no competition. External competitive pressures, therefore, were low.

Impending Changes—Economic Liberalization

In 1991, the government of India started the process of economic liberalization. A number of significant changes ensued in the banking and financial services sectors. Interest rates were liberalized, and the government loosened its control over the operations of banks. Private investment in banking and financial services was allowed. Norms for foreign investment also were eased. At a broad level, this resulted in the entry of new competition in the form of private and foreign banks. At a more specific level, the increased competition forced NBS to re-examine its key products and operations. There was a need for improving efficiencies and lowering costs through automation and modernization, and this had implications for considerably increased use of IT.

CASE DESCRIPTION—1992-2003

Changes in the Industry: External Pressures

NBS faced a number of changes after liberalization. First, regulations changed. The interest rate was partially deregulated. International prudential norms for income recognition, asset classification, delinquent loan provisioning, and capital adequacy were introduced. Whereas earlier, the most important performance criterion had been the *quantum* of deposits; after 1991, the *quality* of deposits, as well as profits, became measures of performance. Interest rate subsidy on rural credit was lowered, and categories for required directed credit were rationalized and reduced.

NBS was required to classify its assets into separate categories, depending on the probability of recovery. The maximum allowable percentage of nonperforming assets (NPAs or loans which had a low probability of being recovered) also was fixed. The government reduced its control over the bank's operations and significantly lowered its financial support. The bank also was allowed to raise equity from capital markets, and offloaded 26% of its shares to retail and institutional investors in the mid 1990s.

Second, competition emerged as entry of private banks, investment banks, and nonbanking financial companies (NBFCs) were allowed by the government. These companies not only offered products and services traditionally offered by public banks like NBS, but they also presented new ones of their own. NBS faced competition from private banks, mutual fund companies, NBFCs, and investment banks for saving accounts, current accounts, and certificates of deposit. For asset lending, NBS faced competition from venture capital funds, investment banks, and housing finance companies. Mutual funds and capital markets emerged as substitute avenues for retail investments.

Third, the power of retail customers increased and their demographics changed. There emerged a section of consumers who were urban, upwardly mobile, young, and educated, and had large disposable incomes. They expected innovative loan and deposit schemes, convenient, single-window services for short and long term investment requirements, and superior customer service from banks. Moreover, they had alternative banks from which to choose. Corporate customers wanted more personalized and differentiated offerings. The new banks had modern technology, efficient processes, and lower operating costs. They provided differentiated products and better customer service. They were smaller and had lower overheads. They, therefore, were well positioned to serve the increasingly sophisticated requirements of the new-age urban customers as well as the small and medium corporate customers.

For NBS, access to cheap funds and protection from competition had resulted in considerable operational and managerial inefficiencies. Its profitability had declined over the years, as shown in Table 1. It was now faced with the prospect of having to reduce costs, increase the quality of its assets, improve customer service, and develop more innovative products and services.

The head of one the zonal offices said that:

Earlier we were not a commercial organization, and it was not required of us to show profit. Now, for our own survival, we have to compete with other private banks and foreign banks. We have been forced to change. Moreover, ours being a big organization, it is difficult for us to change quickly. Senior managers are under pressure to expedite the change process. Indeed, after liberalization, pressures have increased tremendously.

Table 1. Financial performance of NBS

NBS	**2001-2002**	**2000-2001**	**1999-2000**	**1998-1999**	**1997-1998**	**1996-1997**	**1995-1996**	**1994-1995**	**1993-1994**	**1992-1993**	**1991-1992**
Revenues (Rs. 10 million)	6,178	5,535	5,164	4,590	3,935	31,513	2,890	2,338	2,318	2,657	1,885
Profit (Rs. 10 million)	252	173	202	201	364	360	276	50	-3,311	56	22
No. of employees	52,500, as of 2001-2002										
No. of branches	2,515, as of 2001-2002										

From a mobilizer of rural savings, we have had to become a competitive and commercial, profit oriented business enterprise.

As these descriptions show, external pressures increased significantly during this period, due to competitive and government policy changes. Competitive pressures have widely been seen to be one of the most immediate and important reasons for IT adoption. Organizations respond to the demands of the business environment and adopt IT-related and other innovations (Subramanium & Nilakanta, 1996), and increased competition leads to IT adoption (Caldeira & Ward, 2002; Iacovou et al., 1995; Premkumar & Roberts, 1999; Thong 1999,). IT adoption at NBS during this period was primarily due to competitive pressures and the consequent need for increasing operational efficiency. In addition, in the later part of the 1980s and early part of the 1990s, there was a nationwide government policy initiated to modernize the functioning of nationalized banks. Existing studies (see, for example, Mustonen-Ollila & Lyytinen, 2003) mention that changes in government regulation serve as important external impetuses for IT adoption, especially in organizations that are partly or wholly controlled by the government.

IT Deployment in NBS During this Period

The Saraff Committee was set up by the MOF and RBI in the early 1990s, to look into various aspects of computerization of the public banks. It recommended in 1994 the use of IT in activities related to fund transfer, check clearing, and the payment of interests, dividend, pensions, and bills.

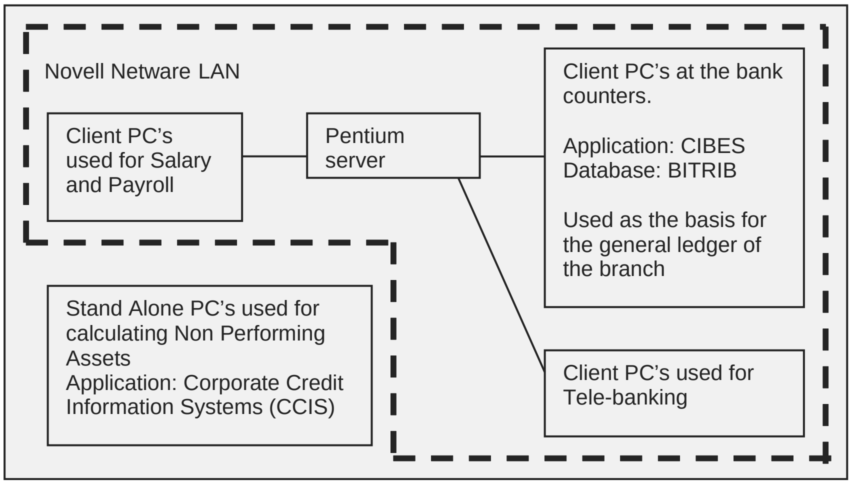
Consequent to these recommendations, and in preparation for imminent computerization, changes were introduced in the IT department. A new position, designated as the general manager (IT) was created to head the department, which reported to the chief general manager (finance). There were about 150 employees in the IS department at the corporate office. About 30% of them were assigned to technical jobs, like software development and hardware maintenance. These employees were recruited in the technical cadre and had IT and software diplomas. The rest of the employees from other administrative departments were transferred and retrained, and were assigned to semitechnical jobs, like report generation, simple maintenance jobs, and vendor management. A team of senior managers were responsible for overall IS planning, hardware acquisition, software development, maintenance, and training. Each zone had an electronic data processing (EDP) department that was staffed largely by junior managers. They maintained existing hardware and software, liaised with vendors and third party maintenance contractors, provided end-user technical support, analyzed data from regions and branches, generated reports, conducted training programs, and looked after the overall functioning of IS within the zone. All computerized branches had one system administrator and one back-up system administrator. Their functions were to maintain hardware and software, liaise with vendors, communicate branch requirements to the regional or zonal offices, and provide training and technical assistance to end users.

The IT investment during this period was 100 million INR, and there was considerable deployment of IT. First, in 1991-92, automation of back office and offline operations, like payroll and general ledger posting, was introduced in the branches. Initially, stand-alone terminals were set up at the service counters. These terminals housed proprietary banking software and entries were made online. The data from the terminals was transferred into the back office servers through floppy disks. Server computations were then performed offline, that is, there was no physical connection between the front office and back office computers. Simultaneously, minicomputers running SCO Unix were installed at each of the zonal offices, for compilation of the data from branches and regional offices within each zone. Reports showing total deposits, total advances, and so forth were created for each zone and sent to the corporate office in floppies and on paper.

Second, in 1996-97, total branch mechanization (TBM) was introduced in branches that had deposits ranging from 500 million INR to 1 billion INR. As part of this, local area networks (LANs) were installed to facilitate real-time transaction processing and integration between the front and back ends at the branches. A number of standardized applications also were developed. First, the *computerized integrated banking executive system* (CIBES) was the primary COBOL-based transaction processing system. The counter personnel used it to post transactions related to savings and current and corporate accounts. The database used was BITRIB. CIBES formed the basis of the general ledger of the bank. Second, the *corporate credit information system* (CCIS), introduced in 1998, was another COBOL application used for recording NPAs. Third, corporate customers used *telebanking software* to obtain and request information about their accounts. It was linked to CIBES. Fourth, the *Equifax* software was used to store transactions related to credit cards payments. This was a stand-alone application. Finally, salary and payroll processing was done through an application developed in FoxBASE. The IT deployed in a typical branch has been described in Figure 4. There were typically two to four Pentium servers and a Novell NetWare LAN, having around 20 diskless nodes and four personal computers (PCs). The diskless nodes were used for counter operations. The use of IT was limited to transaction processing, and there were no operations relating to decision support or other higher level functions. Further, although individual branches were computerized, there was no connectivity among different branches or from the branches to the corporate office.

At around the same time, IS were introduced in the corporate, zonal, and regional offices. The basic infrastructure in the regional and zonal offices was a Novell NetWare based LAN. The regional offices usually had one server and about 10 Pentium II PCs. The zonal offices had two servers and between 15 and 30 PCs. The servers housed SYBASE databases that stored records of branch, region, and zone operations. There were two kinds of applications. Functional applications such as payroll and accounting were written in house in FoxBASE. They operated on stand-alone machines and were standardized across offices. MicroSoft (MS) Office was used for productivity operations, such as word process-

Figure 4. TBM—IT deployed at a typical NBS branch



ing and spreadsheet analysis. The regional and zonal offices compiled MIS reports and sent them to the corporate office. These reports included consolidated information from the branches about customers, loans, deposits, and other financial information, as well as payroll and human resource information.

Third, interconnectivity among branches was introduced in 1999-2000. NBS installed a very small aperture terminal (VSAT) network. The network had 38 antennas or nodes, which connected through satellite some of the regional offices, the zonal offices, and the corporate office. As Figure 6 shows how the branches compiled their bank statements and sent printouts to the regional offices. The regional offices compiled reports for all branches under them and sent them to the zonal offices, either on floppies or on paper print outs. The zones combined and analyzed the data from the regions in specific formats suggested by the corporate office and sent the reports through electronic transfer. At the time of the study, about 520 branches, which accounted for 66% of the bank's business, had been computerized.

With the introduction of TBM and online transaction processing, the dependence of NBS on computers increased sharply. The computerized branches were completely operationally dependent on IT and could not carry out their operations without it. According to the IT manager of one of the first branches that was computerized, "After the branch was computerized, everyone would leave the office by 5 o'clock, whereas earlier they would stay 'til 10 in the night. Computers became the medium through which we carried out our work."

IT Applications Used by Competitors

Even though there was significant IT deployment at NBS during this period, the outcome of IT implementation was only to achieve a desired level of efficiency and parity with other banks. NBS did not obtain competitive advantage from its IS. This is because many of the private-sector banks that had been set up after economic liberalization were much more sophisticated users of IT, both in terms of infrastructure and manner of use. To give an example, the IS used by one of NBS's private-sector competitors. As shown in Figure 7, each branch had a server that had front-to-back integrated banking software, to which tellers' and other employees' terminals were connected. Another server was connected to ATM terminals. Both servers had real-time connectivity to central database servers at the corporate office through a third server at the branch.

At the corporate office, a central server housed real-time account and transaction data. This was connected to a "hot" standby server for disaster recovery as well as with external stock exchanges for stock trading and depository services. All

Figure 5. IS in regional and zonal offices

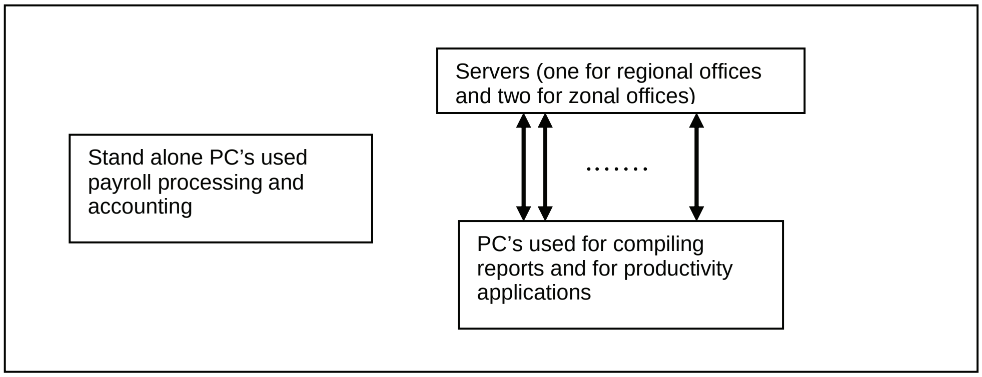


Figure 6. Interoffice connectivity and information flow

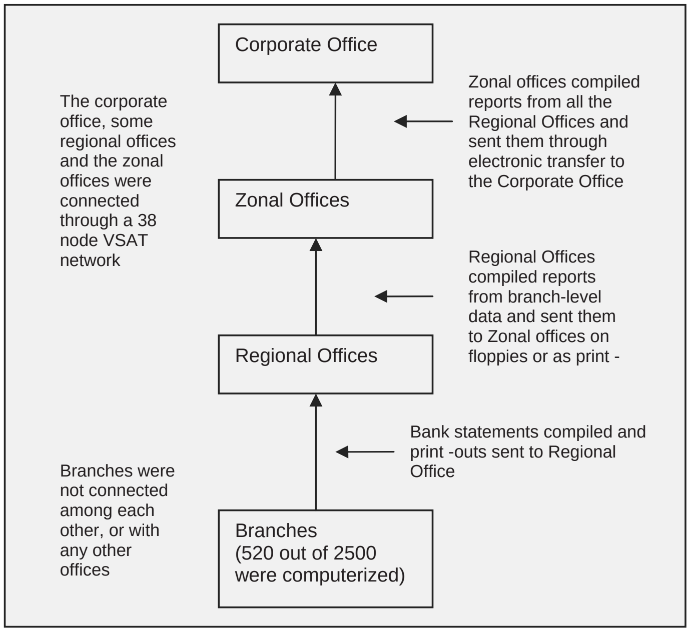

Figure 7. IT infrastructure for a typical private-sector bank

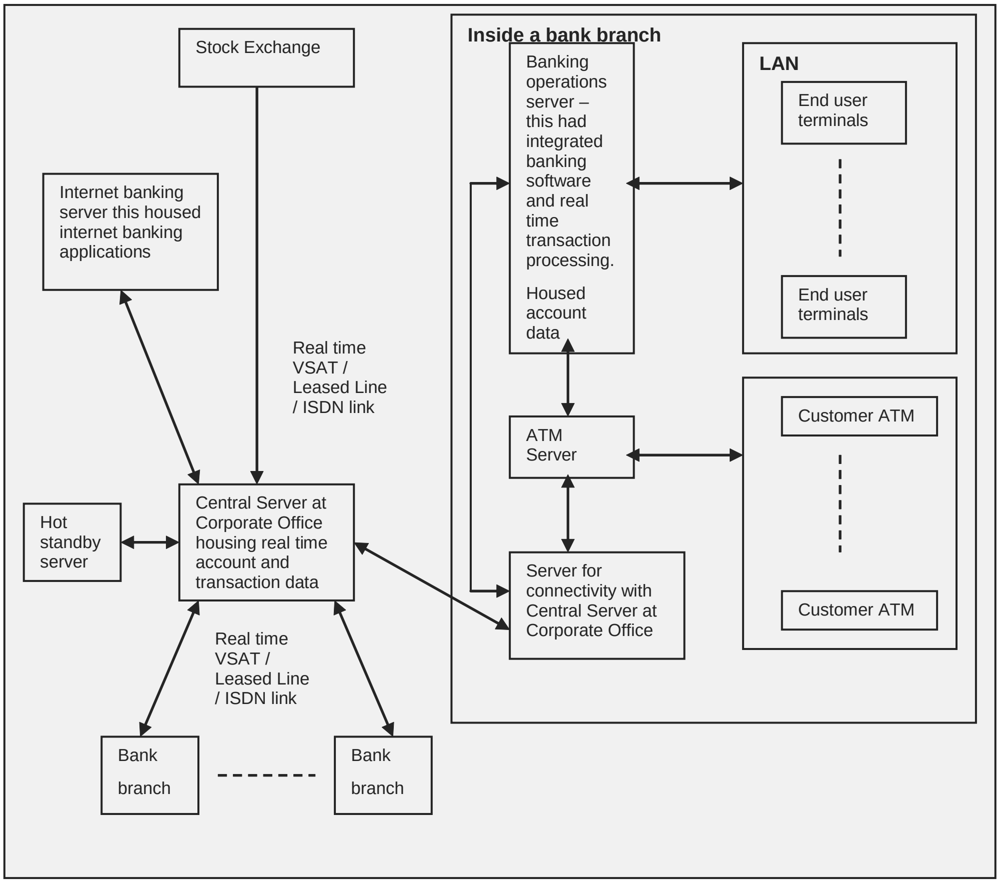

branches and ATMs were connected to the central server in real-time, through VSAT, leased line, and ISDN links. As a result, the bank could provide "anywhere" banking for retail customers and countrywide cash management services for corporate customers. There was separate infrastructure for banking over the Internet. As of 2001, the bank's Web site had information about the organization, its products, branches and ATMs, online banking facilities, annual reports, and news.

Clearly, NBS lagged behind many other organizations in the industry in its use of IT, and, in spite of its considerable capital outlay for modernization and automation, did not derive any competitive advantage from IT. In the next section, we explore possible reasons for this.

Organizational Readiness for IT Adoption

Factors that determine organizational readiness include the availability of technical and managerial IS resources (Iacovou et al., 1995). The former relates to the level of technical expertise and knowledge regarding IT, and the latter describes the level of management understanding and support for the use of IT for competitive advantage (Chwelos et al., 2001). We describe below, three aspects that contribute to the readiness for IT adoption: top management support, organization culture, and characteristics of IS professionals.

Top Management

First, top management support is an important aspect of organizational readiness and leads to higher IT adoption (Lauren & Igbaria, 2001; Nambisan & Wang, 2000; Premkumar & Roberts 1999; Thong, 1999,). Top management support is essential for defining the role of IT in the organization. It also is required for IT planning and in making sure that resources for IT projects are available (Payton, 2000; Premkumar & Ramamurthy, 1995). In this context, senior managers and policy makers at NBS were professional administrators, bureaucrats, and finance professionals. Their average age was more than 45. They were indifferent to computerization and did not show any enthusiasm for it. They had no knowledge about the worldwide use of computers in the industry. Their initiatives towards computerization were driven only by regulatory requirements. The tendency was more for achieving the target in terms of a given number of branches computerized, rather than for proactive changes towards process redesign. One of the branch mangers mentioned, "Many senior managers do not use computers themselves. They delegate computer-related jobs to staff and secretarial personnel."

Another manager, at the middle management level, remarked,

> *We were very focused on the targets given to us in terms of the number of banks to be computerized in a given time period. We did not plan to do anything beyond what was required. We did not, for instance, plan for IT human resource requirements.*

Organization's Culture

Second, elements of the organization's culture influence the organizational readiness to adopt IT. End users' prior exposure to IT increases their inclination to use different IT applications (Lin & Lee, 2005; Mehrtens et al., 2001). Also some organization's cultures offer strong support for the expression and discussion of new and innovative ideas related to IT. This has a positive influence on the ability and inclination of managers to develop and adopt applications with new technology (Hoffman & Klepper, 2000). Organizational support for risk taking and experimentation, and incentives for new ideas hastens the process of adoption of new IT, as observed by Moon and Norris (2005) and Scarbrough and Lannon (1988). The existence of technology champions

(Beath, 1991; Sutcliffe, 1999) is also important for articulating the positive impact of IT (Howell & Higgins, 1990) and for playing the role of opinion leaders in facilitating the choice and evaluation of new technologies. A proactive business strategy also leads organizations to explore different options with respect to innovative and new uses of IT, positively influencing IT adoption (Teo & Ranganathan, 2004).

At NBS, decisions regarding the overall adoption of IT were based on the directives from RBI and the MOF. The specifics of the IT deployment strategy were planned by top management, and the implementation was accomplished by middle and junior management. NBS did not have any innate drive for business excellence and innovation. Of the 50,000 employees in the organization, more than 75% were unionized and performed low skilled and clerical tasks. They perceived computers to be the cause of retrenchment and unemployment. The bank unions were strongly against the use of computers and were determined to block the introduction of any form of computerization. They signed an agreement with NBS, allowing automation and computerization only within certain strict limitations. The agreement emphasized that no ALPM machines would be used at rural branches, and TBM would not be introduced at semi-urban centers. Even so, the unionized staff bitterly opposed the introduction and use of computers. The junior and middle-level managers were apathetic towards it. A counter clerk at one of the branches said, “I am not personally interested in working with computers. However, since it has been mandated by the government, I have to use them. I don’t have a choice.”

Moreover, there were no technology champions to facilitate and expedite the spread of use of IT or encourage innovative uses of IT. The operating-level employees did only what they were asked to. In many branches, benefits in terms of reduced cycle time and improved customer service were not significant, because counter operators were deliberately slow in performing their operations, even while using computers.

Characteristics of IS Professionals

Third, the IS department can play a positive role in influencing IT adoption. IS professionals who understand business needs can increase organizational awareness with respect to IT and actively push for new IT applications. They also can encourage organizational use of IT by providing prompt and effective end-user support (Caldeira & Ward, 2002; Chau & Tam, 2000; Swanson 1994).

At NBS, the general manager (IT) was not an IT professional and did not proactively follow technological developments in the field. He did not independently make crucial decisions relating to IT deployment. He mentioned:

IT related decisions pertaining to resources and budgets are taken at the level of the Chief General Managers. The IS department is given broad guidelines in terms of target deliverables such as the number of branches to be computerized, for example. We then have to frame implementation policies. We do not have independent charge of many of our operations.

The general manager (IT) also could not influence the top management enough to be able to change their inclination towards IT. Most IS personnel had earlier worked in other functions and were subsequently trained to take over the responsibilities of the IS function. They had no formal education in computer hardware or software. IS professionals did not actively push for the development of new applications. They were indifferent and just complied with the instructions that were issued to them. Moreover, IS professionals did not proactively interact with end users; they provided technical support and solved end-user problems only when asked for. They did not try to develop a positive attitude towards IT among the unionized employees.

These discussions illustrate that the organizational readiness to deploy IT was low at NBS.

Therefore, in spite of significant increase in external pressure, NBS adopted IT only to comply with government regulations and to achieve uniformity with other public banks, rather than use IT for achieving a competitively superior position.

CURRENT CHALLENGES

Banking Sector in India—Competitive Challenges

The banking sector in India is widely seen to be headed for consolidation. With the Indian financial sector and stock market experiencing one of the most explosive phases of growth ever (Bellman, 2005a,b), interest rates are expected to rise, and gains from treasury and government bonds are likely to fall. Competition for customers and market share is likely to remain intense.

The private-sector banks had introduced new services since 1996. These included depository services for retail customers and clearing bank services for the major stock exchanges, besides Internet banking facilities, such as bank statements, fund transfers, credit card payment, and general account management. Services intended to be introduced in the future included payments for mobile phone services, insurance premiums, and utility bills through the Internet or by telephone. These banks also had used the Internet to introduce niche products. Citibank, for example, had introduced a special "Women's Account," which used the Internet to provide information about personal finance, savings, investments, loans, insurance, mutual funds, deposits, and stock trading and general education on finances and retirement accounts to women. The account also carried special credit cards linked to shopping outlets and grocery stores.

Clearly, for NBS, external pressures, especially competitive pressures, would continue to remain high. How should it use the Internet to develop more innovative products and services? NBS had, in recent years, taken some steps towards this. In 2001-2002, the company started offering depository services to two of the largest stock exchanges in the country. In 2003, it introduced Internet banking for customers of the networked branches.

Moreover, the operating profit per employee of the bank was 48,000 INR, whereas that of one of the larger private Indian banks, for example, was 1 million INR. How should NBS use the Internet to reduce costs? Build cheaper and more efficient online delivery points and distribution processes? At the time of writing, customers could use the Internet to get statements and account balances and to order checkbooks. NBS also planned to introduce "Any Branch Banking" for its retail customers, cash management services for its corporate customers, and fund transfers for both. NBS had entered a joint venture with five other public banks, to set up and operate a shared ATM network, whereby customers of any of these banks could access ATMs of other member banks. This was called the "Cash Tree" initiative and was expected to include 1,200 ATMs.

Given the high information intensity of the banking sector, the perceived benefits to adopting IT were high. However, based on policy guidelines laid down by the RBI and the MOF, all banks in India had computerized transaction processing, electronic funds transfer, automation of generic banking processes, and local and wide area networking. These applications were "factory" systems (McFarlan, McKenney, & Pyburn, 1983); they were for achieving competitive parity and did not provide any competitive edge. To get competitive advantage out of IT, NBS would need to develop distinctive and proprietary applications that could be used for differentiation in customer service, developing decision support models for market research and financial research, and market development. These applications would enable the development of new products. For setting up Web-based banking systems, the branches and the corporate treasury offices would have to be connected to a single data center through a centralized banking system, using the VSAT network. Real-time connectivity to external stock exchanges was required, as was Web-based infrastructure for linking the Web site to back-end databases. IT management would need to be that of the "strategic" sector (McFarlan et al., 1983), where IT planning would need to be aligned with business planning.

Organizational Challenges

What then were the organizational challenges that NBS faced for developing and implementing "strategic" IT applications? Of the three antecedents to IT adoption, external pressures and perceived benefits were high. However, organizational readiness for IT adoption was low. An important challenge before NBS was, therefore, to increase organizational readiness. There were a number of aspects important in this context.

First, top management had an indifferent attitude towards IT adoption. Senior managers were either appointed by the RBI or consisted of officers who had risen through the ranks. Given the long history of the bank, its historical resistance to change, its formalization, and its bureaucracy, the attitude of top management towards IT could be difficult to change. Second, there was a need to bring about appropriate changes in the overall organizational climate and attitude with respect to IT. There was a need to increase the level of knowledge and awareness about IT and to encourage IT-related innovation that would generate and develop ideas for new and strategic applications in areas such as customer service and the market. The power of unions also would have to be addressed. A lot of new technology implementation and the related learning mechanisms in large, bureaucratic organizations take place through "programs" or well-publicized organization wide procedures (Earl, 1989). In this context, institutional support mechanisms, such as creating an understanding of the business role of IT, encouraging learning, training, and the use of consultants, can increase end users' awareness of IT and help create more opportunities for its use. Finally, the IS function would need to be given greater prominence and say in business decisions. One of the ways of accomplishing this could be to include the general manager (IT) in the top management team, with increased autonomy in IT-related decision making. Moreover, given the role of IT as a service department, effective interaction would be required between IS professionals and top management, as well as between IS professionals and end users. Most IS personnel at NBS were employees from other departments who had been retrained and redeployed; they were not career IS professionals and did not know how to effectively deal with end-user problems or interact with top management. They would have to be re-oriented towards greater end-user or "customer" satisfaction, through training and exposure to best practices of other IS departments in comparable organizations.

WHAT NEXT?

NBS had faced a number of environmental changes in the last 15 years. These included changed regulations and increased competition that has led to imperatives for increased product innovation and process efficiency. So far, in its use of IT, NBS has achieved uniformity and standardization compared to most other banks. However, in order to achieve differentiation and competitive advantages from the use of IT, it faces a number of challenges. How should it use the Internet to develop new products and increase market share? How would banking processes need to be redesigned for reducing costs? How would the required organizational changes be implemented? These are the options that face the executive leadership of the company.

Chapter 4.13

Building Enterprise Network Infrastructure for a Supermarket Store Chain

Beomjin Choi

Tom Jones
University of California – Berkeley, USA

EXECUTIVE SUMMARY

Enterprise network infrastructure has served as a vehicle on which data and information can be transferred between functional units regardless of their location. Creating the network infrastructure that enables firms and organizations to adapt to rapidly changing business needs has never been more important than now. Building the enterprise network infrastructure requires careful planning, effective design, and appropriate strategies for successful implementation. The current case study examines how a regional supermarket store chain in the retail food industry develops its enterprise network infrastructure to outperform its larger competitors. A detailed description of the evolution of the company's enterprise network infrastructure is presented to show how the strategy of network infrastructure development has aligned with the organization's growth strategy for the past two decades. The current case study highlights critical success factors for firms to build an effective enterprise network infrastructure that include IS planning firmly tied to critical business goals, strategic collaboration with technology vendors, and careful evaluation and selection of network services and technical details.

ORGANIZATIONAL BACKGROUND

The retail food industry can be broadly defined as businesses that cover diverse aspects of grocery productions and sales, ranging from making, processing, packaging, distribution, to retailing and catering food. In 2004, the retail food industry in the United States took nearly 10% of its Gross Domestic Product. It consists of businesses that include conventional supermarkets, superstores, convenience stores, membership clubs, independent food stores, and dot-coms. While the retail food industry relies on government regulations and administration for establishing an efficient consumer market, it has heavily utilized continuous innovation in the areas of technology, transportation, and logistics for an efficient flow of products and related information (Kahn & McAlister, 1997; Li, Lin, Wang & Yan, 2007; Walsh, 1993). The competition in the industry is extremely high and so typically the management is under constant pressure for sales growth and market share while dealing with competitive challenges.

ABC[1] Corporation is one of the successful privately owned, regional supermarket store chains in the retail food industry in the United States. Headquartered in one of the cities in Northern California, ABC employs more than 16,600 employees and owns 139 grocery stores and one distribution center in several West Coast States of the United States. Its store chains sell groceries including bakery, dairy, deli, frozen foods, general grocery, meat, liquor, natural foods, pharmacy, produce, seafood, snacks, and so forth. In the fiscal year of 2006-07, the estimated sales of the company were $3.4 billion with its annual growth rate of 2.1%, thus placing the company in the upper 50% of the "Top 75 North American Food Retailers" (Supermarket News, January 2006). ABC Corporation is currently under the management team of two owners, a president as CEO, and a CFO. The mission of the company is to be "the place where customers love to shop and employees love to work". The company values "excellence in business practices" such as leadership, accountability, respect, teamwork, excellence, responsibility, learning, and integrity.

As part of a growth strategy, ABC Corporation has made some serious acquisitions in its history that led the company to be one of the leading supermarket store chains in the region. In 1956, the company operated just nine grocery store sites with around $8 million in annual revenues. In 1973, after acquiring ten drug stores put up for sale in the region, the company began to deal with both the grocery and drug items in the same store. The company boosted its annual sales volume up to nearly $1.8 billion after the acquisition of another store chain with 17 grocery store sites, which had developed a reputation for their superb product quality and excellent customer service throughout a West Coast state. By the mid-1990's, the company grew up to operate 81 stores, thus making it one of the giant supermarket chains. In 1998, the company acquired an up scale grocery chain with 27 stores. Again in 1999, the company purchased additional 27 stores from two grocery store chains so that it could compete against larger chains such as Safeway, Albertson, and Lucky.

ABC Corporation has operated under centralized control from its headquarters, which aims at making its operations efficient and cost effective. When a customer buys a specific item from a particular store and pays for the item at the cash register, this information is immediately passed on to the headquarters. At the headquarters, the system reduces the inventory stock level for the purchased item at that particular store by a quantity of one (or whatever quantity is sold) in the central database. By this way, the company can keep a real-time inventory amount of every product item in every store. The ABC's real-time inventory accounting system allows the company to restock the store shelves in an efficient and effective manner. When a reorder quantity reaches an optimum level, the company can immediately place a reorder request to the vendor and receive the merchandise at its warehouse locations. The warehouses can then break up the shipment and distribute the product to the individual store sites that are running low on the shelf inventory. Each store also uploads daily transaction data to the headquarters so that each day, customer buying data can be compiled and analyzed in order to determine buying behavior of the customer to develop marketing schemes or to produce efficient centralized bulk buying.

To support its organizational strategies, ABC Corporation has been active in adopting information systems and communications technologies. According to the management of ABC Corporation, while most grocery chains, on average, spend 1 to 2% of revenues on information technology investment, ABC typically allocates just 0.5% of total revenue to its information technology investment. Yet, the management claims that ABC's enterprise network reportedly has better overall performance and provides lower operational costs than the networks of their larger competitors.

SETTING THE STAGE

Businesses in the retail food industry have actively utilized information and communication technologies to improve its operational efficiency (Barua, Konana, Whinston & Yin, 2004; Kinsey, 2000; Rai, Patnayakuni & Patnayakuni, 1997). Starting from the scanning technology to electronic cash register to computer systems and electronic data interchange (EDI), different combinations of information technology (IT) has helped grocery store chains increase productivity of retail food operations (Chen, Motiwalla & Khan, 2004; Kinsey & Ashman, 2000).

The establishment of reliable network infrastructure has been one of the critical success factors for the ABC Corporation's everyday business operations. Even a small amount of system downtime could lead to lost sales, inaccurate inventory counts, and failure to restock store shelves adequately. To support the communication between the headquarters and the store sites, ABC Corporation has invested in developing enterprise network infrastructure since 1980's. More recent rapid growth of the company in the late 1990's required a more efficient and effective network infrastructure for timely information sharing and dissemination. Building the enterprise network infrastructure however requires careful planning, effective design, and appropriate strategies for successful implementation.

Enterprise Network Planning

Enterprise network planning is a process aimed at meeting the needs of network users in large organizations. It is a critical process that involves not only network technology planning, but also business planning. Creating a business-driven IT infrastructure requires that executives and management thoroughly understand their organization's current and future needs and environment. Drawing on more over 200 on-site interviews with senior business and IT executives, Broadbent and Weill (1997) formulated an IT infrastructure planning methodology, which helps identify the IT infrastructure service needed and its specific design criteria. The framework consists of four components: strategic context, business maxims, IT maxims, and IT infrastructure. It begins with consideration for the organization's strategic context. Searching the answer for the question of "how will the organization achieve the strategic synergy among the business subunits to maximize the effectiveness for the entire organization as a whole?" is the first and most essential task when formulating strategic context. The current and long-term strategies of the entire organization including each business unit can then be translated into what is called business maxims. The purpose is for business and IT managers to articulate an agreed-on position in a form that executives can readily understand and act on.

IT maxims are identified from the business maxims. IT maxims describe clearly and concisely how a firm will meet business maxims through the use of IT, or more specifically how a firm will connect, share, and structure information and deploy IT across the firm (Haeckel & Nolan, 1993). IT maxims must specify the firm's approach regarding the role of IT and levels of investment relative to competitors, transaction processing (standardization, common interfaces, or local tailoring), and access and use of different types of data (e.g., financial, product, or consumer (Broadbent & Weill, 1997, p. 82-83).

Also, an organization should determine how IT infrastructure is used; there are four views of firmwide IT infrastructure: none, utility, dependent, or enabling (Weill, 1993) (Table 1). One of these four views is typically taken with individual firms. No particular view is best for all firms, but typically one view is more appropriate for a business according to their business and IT maxims. There are two different approaches in enterprise IT infrastructure planning: maxim route and deals making route. The maxim route assumes that both business and IT management look at the company as a whole. The deal making route focuses on a more immediate need of a business. In the deal-making route, typically there are only three views: none, utility, or dependent.

Enterprise Network Design

A typical enterprise network design involves a three-step cycle: needs analysis, technology design, and cost assessment (FitzGerald & Dennis, 1999). The cycle is repeated as necessary to complete the design. After the firm-wide infrastructure planning is conducted, the project team starts with a needs analysis of the overall goals of IT maxims. Needs analysis is typically concerned about factors such as geographic scope, application systems to be served using the network, number and types of network users, a rough assessment and classification of the network capacity needs, and so forth.

Technology design builds on the network diagrams created in the needs analysis phase. At this phase, the network diagrams include information on the type and quantity of all users' computers and network servers, network circuits and devices (e.g., hubs, routers, switches), the fundamental technology and protocols (e.g., Ethernet or token ring, TCP/IP or SNA), and the capacity of each circuit (e.g., 64 kbps, 10Mbps, 1Gbps). Network capacity planning is required for the assessment of circuit loading. Circuit loading is the amount of data transmitted on a circuit. Analysis can focus on average or peak circuit traffic. If an existing network is in place, network monitors usually can provide such information.

Table 1. Four views of firm-wide IT infrastructure

View	Description	Note
None	• No firm-wide IT infrastructure	• No synergetic effect
Utility	• Firm-wide IT infrastructure provides a necessary, unavoidable service that incurs administrative expenses.	• Spending on IT in this view is only a way to reduce costs through economies of scale and sharing. • Maximizing return on assets while minimizing costs is a high-priority.
Dependent	• Firm-wide IT infrastructure investment is a response to a specific current strategy.	• IT infrastructure investments are derived directly from business strategies that specify IT needs. An example is the need for an e-business to have Web application servers.
Enabling	• Firm-wide IT infrastructure expands a dependent infrastructure beyond the current requirements of the business.	• The purpose is to achieve the firm's long-term goals. • Executive officers must justify enabling infrastructure spending as a core competence that provides competitive advantage. • Typically enabling technologies are highly centralized.

Finally, the team moves on to the costing of a network project, which typically includes hardware, software, and circuit connections. Businesses rarely have the resources to develop and implement their own large-scale network so outside vendors are often called to complete the project. In many cases, network designers will compose a request for proposal (RFP) that incorporates all desired specifications of the network being built.

Enterprise Network Implementation

Rapid technological advances on many fronts have made it less feasible for firms and organizations to internally maintain all the technological expertise. As a result, firms increasingly seek the use of outside suppliers for IT related services which were previously supplied internally. An effective supplier management strategy has become critical to maximize the business value of purchased IT products and services (Heckman, 1999). Heckman further states that this has created a "gamut of possible supplier relationships" ranging from "purely transactional, price-based interactions to highly interdependent partnerships and alliances" (1999, p. 142). The "purely transactional, price-based interactions" view posits that the process of IT supplier management requires discipline, structure, and that successful buyer-seller relationships are based on semi-distant, rigorously negotiated contractual understandings. In this regard, contracted IT products and services should result from rigorous and professional contract management, usually involving multi-skilled contract management teams (Lacity, Willcocks & Feeny, 1995, 1996). On the other hand, the "highly interdependent partnerships and alliances" view posits that buyer-seller relationships are more effective when based on less formal notions such as commitment, trust, and partnership. Heckman (1999) argues that because the complexity of any large IT vendor/outsourcing arrangement makes it extremely difficult to specify in advance all the possible future contingencies, customer and supplier alike are best served when they enter into such relationships expecting to live by the spirit rather than the letter of the contract (Sabherwal, 1999; Sawhney, 2002).

CASE DESCRIPTION

The central information processing system at the ABC's headquarters consists primarily of two mainframes run by Unix and two communications controllers. Unix provides the high reliability required for mission-critical applications and the high functionality needed for complex server situations. The mainframes are used to process transactional data. The first mainframe is used to process all transactions that occur at the regular checkout line. This mainframe processes transactions on general merchandise and other food items. It accesses, processes, and stores the database that tracks real-time inventory of every shelf item in every store. The database keeps detailed records of sales from individual stores. The data stored are used for statistical analysis in order to determine buying behavior and develop marketing schemes to better promote a wider range of products.

The second mainframe is used by the pharmacy. This mainframe houses transactional data from pharmacy purchases and provides real-time inventory of all pharmaceuticals in every store. This data are used to produce efficient buying and restocking of pharmaceuticals. This mainframe is also used to house a database of customer information, which is used to keep track of prescription refill orders, additional drug sales, and medical reasons used by the pharmacists. Two communications controllers conduct front-end processing that operates in tandem to provide redundancy for the mission critical connections to store sites. Communications controllers are located between the mainframes and cluster controllers in store sites. They manage communications with cluster controllers, thus freeing up the mainframe to focus on file and database processing.

In the late 1980's and early 1990's ABC Corporation used dial-up network to connect the data communication devices. Systems network architecture (SNA) protocol was used to provide high reliability and centralized control for real-time terminal-host interactions. ABC's each store site dialed in directly to ABC's headquarters. The maximum upload data speed for this dial-up connection was 33.6 kbps and maximum download speed was 56 kbps. Long distance charges were applied to each dial-up connection from a store site to ABC's headquarters. All voice connections between the store sites and headquarters were held at an additional expense to the network connection. ABC's dial-up was very advanced compared to other supermarket networks at that time but still was not on the leading edge of technology. In 1993, ABC decided to do away with the dial-up connections and build their own private frame relay network, which was called ABC's Net I.

ABC's Net I Period (1993-1997):

In the mid 1990's ABC Corporation grew up to operate 81 stores. It became obvious that ABC's dial-up network could not support the company's rapidly growing business operation. Net I project was initiated to create a firm-wide enterprise network infrastructure that connects all store sites to the headquarters utilizing the mainframe computers. The primary goal of Net I was to provide faster, integrated communications services that allow voice-over-data transmission services. ABC took the total responsibility for the entire project; its project team conducted a range of activities including network planning, analysis, design, and implementation of the enterprise network infrastructure utilizing leased lines and its own network equipments.

Net I - Wide Area Network (WAN)

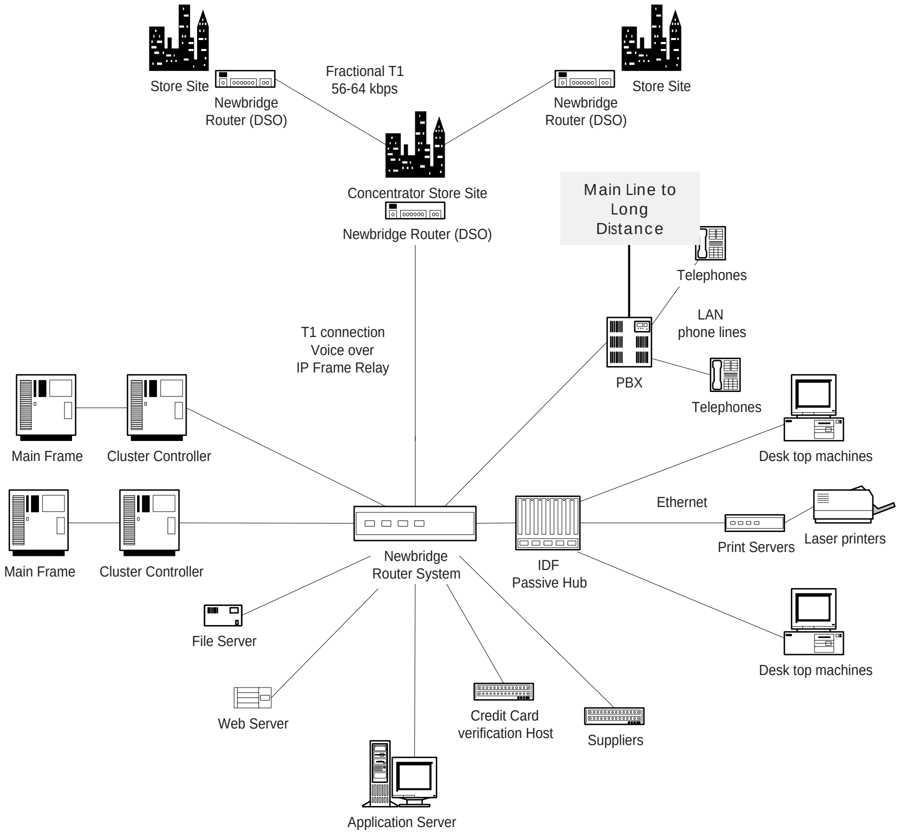
Network connections between all store sites and headquarters formed the WAN of ABC's Net I. The team decided to construct a private frame relay network along with IP protocol as its WAN solution. Compared to other communication technologies such as X.25 packet switching network, frame relay was more appropriate technology than other alternatives to meet the needs of the company for faster data communication between store sites and headquarters. The team designed the frame relay network configuration in which groups of individual store sites were linked to a central store in the region called a concentrator site, which was then connected to the headquarters. The connections between store sites and a concentrator site were established by fractional T1 leased lines with 56 kbps data transmission rate whereas each concentrator site was connected to the headquarters by a full T1 leased line. All the network components of ABC's Net I were owned or leased by ABC, which include routers, leased lines, and other communication devices. Figure 1 illustrates a schematic view of ABC's Net I. Note that in actuality, more than two stores were connected to a concentrator site, and more concentrator sites, desktop machines, and phones were present than are depicted in this diagram.

ABC's Net I also provided the capability of transmitting voice traffic over the frame relay network in order to meet the needs of the company. Telephone services between any store sites and headquarters or between any two store sites could be provided at no additional charge. This gave ABC the capability to route all long distance calls through one central connection to a long distance carrier, thus allowing a sizable cost savings of telephone communication payment.

Net I - Local Area Network (LAN)

The local area network at that time consisted of client stations located on three floors of the

Figure 1. ABC's Net I network diagram (simplified version)



headquarters. Each client station was connected to one of two hubs located on each floor. ABC's Net I LAN used Ethernet protocol by which data traffic was broadcasted to every desktop machine at the headquarters.

Net I – Challenges and Issues

ABC's Net I was an improvement over its dial-up network because it had the potential to deliver faster data as well as voice-over-data communications. These improvements were recognized when Net I was operational. However, ABC's Net I WAN was not extremely reliable. For example, if a router was down at a concentrator site, the whole group of stores connected to that concentrator site could have been down. Also, since ABC's Net I operated using leased lines, the company was totally responsible for maintaining all site-to-site connections. Leased lines were expensive and difficult to maintain because the lessee must perform all the labor required to make the leased lines available. Voice connections over the network were less than satisfactory. Many staff bypassed the network all together and simply dialed nine to reach an outside line to complete the call over the conventional public switched telephone network, which defeated the purpose of placing voice over data and lowering long distance telephone costs.

ABC's Net I LAN was not extremely reliable either. The hub technology with Ethernet broadcasting protocol frequently caused network congestion which brought LAN communications to a near stand still at times. Moreover, ABC's Net I was using multiple protocols which further caused network congestion. Some of the protocols were characterized as "chatty" that produced multiple data exchanges between hosts.

In the late 1990's, the amount of downtime of Net I was determined to be unacceptable. In 1998, ABC initiated a major overhaul to its LAN and WAN and initiated a new project called Net II. ABC's Net II is currently operational and has many advantages over its Net I.

ABC's Net II Period (1998-Present):

By late 1990's, the ABC's mainframes were upgraded using the latest version of mainframe operating systems, which were then supported by the backbone of a gigabit fiber optic connection, thus creating what is called the data center. With additional processing power, all the functions of the mainframe computers, such as database processing for all inventories, transaction data, and the pharmacy database, could be performed more effectively and efficiently. While the company depended on ABC's Net I to run its daily routine business, it became increasingly challenging to operate ABC's Net I with regards to its reliability, quality, and the cost of maintenance, which posed a great threat to the company to grow through rapid expansion.

In 1998, a network development team led by ABC's chief information officer (CIO) initiated a major overhaul to its enterprise network infrastructure, thus initiating ABC's Net II project. The team consisted of members from WAN Support, Voice Support, LAN Support, and Technical Advisory Committee. The team started off with defining the goals for Net II: (1) reducing network operational costs, (2) decreasing network downtime, (3) cutting down network latency, and (4) providing usable voice connections through network. Given the goals, the team made detailed tactical decisions on design criteria such as network protocol to be used, bandwidth, services provided, equipment, and deployment method. The CIO made sure to keep the decision making process open. "Where all participants sought a limited number of relevant alternatives that provide a satisfactory solution," the CIO recalled, "the team selected a satisficing solution that was more ethically and rationally relevant to ABC that either maximization or optimization could deliver".

The ABC's team was very knowledgeable and did well on needs analysis to understand basic network requirements without being experts on the engineering issues related to technical network design. The team discussed a variety of network technology alternatives in terms of their capabilities, expected costs, and the expected fitness with the needs of the company. For example, the team seriously considered using satellite technology as a WAN solution. But because the bandwidth was shared and some of ABC's data traffic was bursty with large payloads, satellite was only considered for disaster recovery. Asynchronous Transfer Mode (ATM) technology, a special type of packet switching network that delivers small fixed-size data packet across a network, was also considered, but was not considered appropriate due to various reasons. For instance, ATM works well with live video and audio due to its low latency and very high quality of service. However, ATM technology has largely been implemented by large carriers for their wide area network cores, thus making this technology less feasible both technologically and economically.

The team however was not as knowledgeable about design specific details of the technologies required for network implementation. The CIO and the team decided to partner with a technology vendor to create the technology design for the network upgrade. The team ended up focusing on the identification and development of business and IT requirements of the company, as well as the development of basic design for network upgrade, and handed these off to technology vendors to complete the technical design. Interviews were conducted with various network technology suppliers to assess their capabilities. The team ultimately selected Cisco as its partner not only because Cisco was a well established and internationally known telecommunication products manufacturing company, but also because it was very cooperative and willing to collaborate in efforts to evaluate the capabilities of router, switch and other network technology required for Net II implementation. The ABC's team and its implementation partner Cisco together went over the network analysis and design. Following a top down network design approach (Oppenheimer, 1999), they started with analyzing company's goal and customer's needs and conducted logical/physical network design, testing, optimizing, and documentation. This collaboration helped determine specific features, functions, and networking hardware early on to optimize the network. This enabled ABC to successfully implement enhanced network features shown below unavailable to the company's competitors, in addition to rendering a large amount of cost savings.

- Single protocol technology TCP/IP
- 100% Switched network, no hubs
- Reliable and functional Voice over IP
- Frame relay connections to store sites (no more leased lines)
- ISDN Backup

The team's decision to seek advice from a competent technology vendor as early as possible and having a rapport relationship with the vendor laid the foundation for successful implementation of the network. The CIO recognized the importance of this action, saying "without question (Cisco was) key to the success of the project." The CIO and the team attributed a considerable portion of the successful planning and development of the network to the close relationship established and maintained with the router vendor. The CIO said "Cisco played a large role in the functional assessments, and ultimately was selected as the implementation partner because of their collaborative efforts."

Net II - Wide Area Network

ABC removed the leased T1 lines and went to subcontracted frame relay service from MCI. Subcontracted frame relay is a special type of public switched data network (PSDN). PSDNs are typically portrayed as clouds on network diagrams because the user does not have to know what is going on inside the PSDN. The PSDN service provider handles all switching, management, and maintenance tasks. Overall, PSDNs are easier to use than leased lines, and because of price competition, PSDNs tend to be less expensive than a comparable mesh of leased lines. ABC's Net II used Cisco routers to switch data frames over the frame relay PSDN. The Cisco routers on ABC's Net II followed the frame relay protocol which routes data according to layer two or the data link layer protocol. Once the frame is in the PSDN, it is MCI's responsibility to deliver the frame at the other end of the cloud to the proper Cisco router of ABC's Net II.

Individual store sites have to provide a router and a single leased line to the frame relay network's point of presence (POP) which is a connection location to the PSDN. ABC's Net II frame relay connections are 128 kbps; the cost of each store connection is approximately $400 per month. ABC negotiated this competitive rate by tying the connection of all stores into one large service contract.

The frame relay connections include voice over data frame capability. Cisco 7204 routes voice frames directly to PBX. Net II used integrated Voice over Internet Protocol (VoIP) to provide completely meshed, 4 digit dialing from store to store, as well as the headquarters to store and vice versa. Unlike Net I, ABC's Net II actually provides clear usable telephone connections. The CIO recalled, "That was huge and we were the first retail chain in the world to do it".

Because the network connections to ABC's stores are mission critical, ABC's Net II has included a back-up network connection to each store. The back-up connection is an integrated services digital network (ISDN). ISDN differs from PSDN in that it is based on circuit switching, which is expensive for data transmission because it creates and holds an open circuit between hosts. Users must pay to keep this ISDN circuit open, even if no data traffic enters the circuit. The maximum connection speed of ISDN is 128 kbps and the cost for each store's ISDN connection ranges from $1,100 to $3,000 per month depending on the store location.

ABC's Net II has been an overwhelming success. According to the CIO, the cost of the setting up the network was about $1 million, but this cost was recovered one year after ABC's Net II implementation in the form of reduced long distance charges, reduced network connection fees, and most importantly, reduced system downtime. Damages from system downtime could be quite substantial not only because of lost revenues resulting from downtime, but also because of potential changes in future buying behavior of customers who were alienated from system downtime.

Net II - Local Area Network

The MCI frame relay network is connected to ABC's headquarters by two Cisco 7204 routers. Each ABC's store is connected to the headquarters by a Cisco 2610 router. There are no more concentrator sites with ABC's Net II—each store is directly connected to the headquarters through the cloud. In this regard, this is a star shaped connection. The Cisco 7204's route data frames to the switch which replaced the hubs on ABC's Net I.

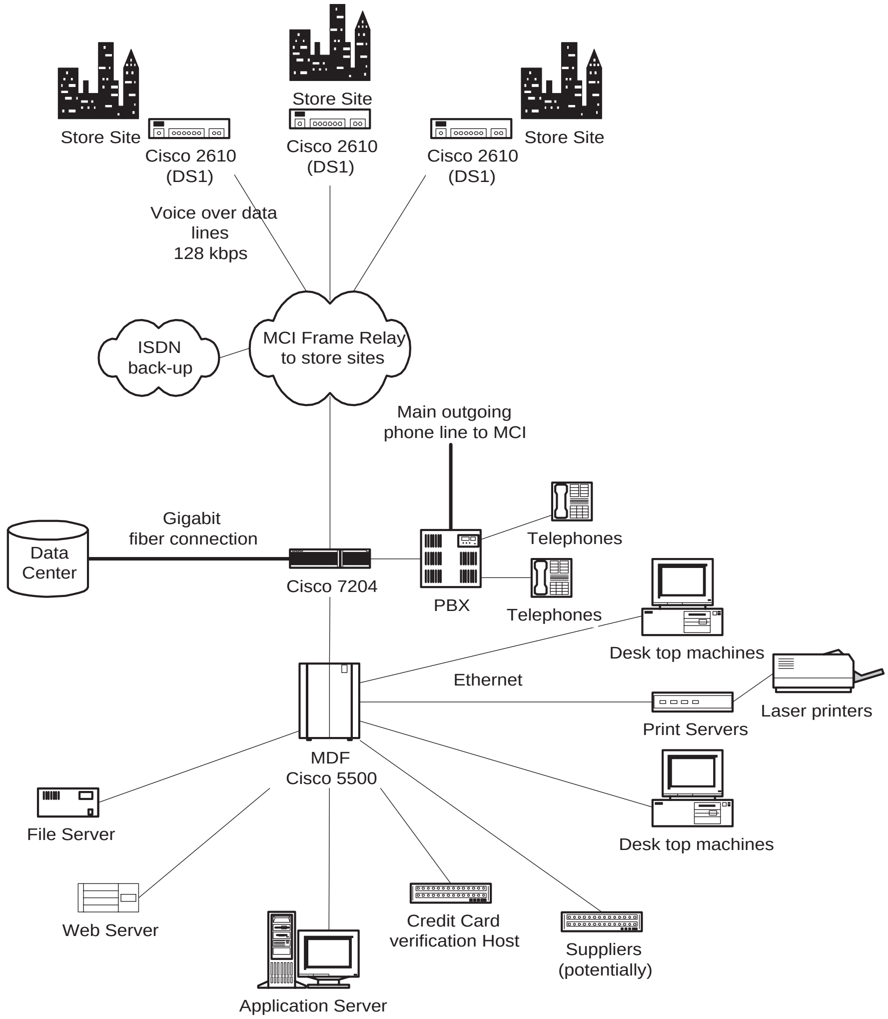
The team removed all non-IP protocols on the ABC's Net II LAN. It was determined that the mixing of various protocols on the LAN turned out to be a major cause of network congestion. Switching to all IP protocol substantially reduced network congestion and decreased latency but unfortunately was very difficult to install. The system had issues with legacy applications and data sources that were not IP compatible. Substantial work had to be done to convert these applications and data sources to IP, and, in some cases, new software had to be installed to convert these applications.

Figure 2 illustrates a schematic view of ABC's Net II. Note that in actuality there are more than three stores connected to the frame relay network, that there are two Cisco 7204 routers, and that there are more applications, applications servers, desktop machines, and phones than depicted in the diagram.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

ABC's current Net II has started facing with challenges in providing enterprise IT network infrastructure services for the company. As the company continues to grow, the needs and requirements from network users, including business subunits and partners, are constantly evolving. For example, ABC's Net II network infrastructure has had difficulties in providing the quality of service demanded by end-users and voice and data applications. Prioritizing network traffic is almost impossible using the current frame relay network, which tends to become increasingly expensive as compared to other emerging communications technologies. Moreover, ABC Corporation has started seeing some potential in deploying supply chain technology with partners in the retail food industry and attempts to capitalize on it when its suppliers are ready. The supply chain network links businesses with their suppliers, customers, or other businesses that share data and applications. Typically extranets connections are deployed over the Internet connecting personnel and applications from different organizations. It is a collaborative network, extending a company's internal network out onto the Internet, which

Figure 2. ABC's Net II network diagram (simplified version)



requires careful planning that should be made by a group of concerned stakeholders and supported by appropriate network infrastructure.

As part of the strategy to address the problems, ABC Corporation started considering another network upgrade to the Multiprotocol Label Switching (MPLS) technology using ATT. MPLS is a networking technology similar to the concept of the frame relay technology, but uses packet labels to prioritize network traffic to optimize network performance, thus enabling the company to meet the business needs. The primary difference is that user organizations like ABC Corporation can purchase quality of service (QoS) for applications across the MPLS network. Some of the expected benefits for ABC Corporation include reduced costs, improved manageability, and enhanced performance of its wide area networks, as well as better alignment with current and future business needs. While the benefits from migrating to MPLS are quite attractive, there is a caveat that the user may lose visibility into the MPLS cloud, which will challenge IT professionals in ABC Corporation.

GLOSSARY

ATM: Asynchronous Transfer Mode (ATM) is a special type of packet switching network that delivers small fixed-size data packet across a network. It works well with live video and audio due to its low latency and very high quality of service.

EDI: Electronic Data Interchange (EDI) is an international standard format for exchanging business data. It is a set of standards for structuring information that is to be electronically exchanged between and within businesses and other organizational entities.

Ethernet: Ethernet is another name for the IEEE 802.3 protocol. This network protocol operates at Layers 1 (physical layer) and 2 (data link layer) of the TCP/IP architecture.

Frame Relay: Frame relay is a telecommunication service designed for cost-efficient data transmission over a wide area network (WAN). It is effective for intermittent traffic between local area networks (LANs) across a WAN.

Fractional T1: Fractional T-1 refers to any data transmission rate between 56 Kbps and 1.544 Mbps in the North American T-carrier system. It is typically provided by a carrier in lieu of a full T-1 connection and is leased to a customer for a point-to-point connection arrangement.

ISDN: Integrated Services Digital Network (ISDN) is a set of standards for digital transmission over ordinary telephone line as well as over other media. ISDN allows home and business users to transmit data at up to 128 Kbps. ISDN service is generally available from phone companies in most urban areas.

MPLS: Multiprotocol Label Switching (MPLS) is a data-carrying mechanism that belongs to the family of packet-switched networks. MPLS speeds up network traffic flow and makes it easier to manage. MPLS saves the time needed for a router to look up the address by setting up a specific path for a given sequence of packets identified by a label put in each packet.

PSDN: Public Switch Data Network (PSDN) is a publicly available network based on packet switching technology. Packet switched networks do not establish physical communication channels between communicating devices. In packet-switched networks, data packets from different sources going to different destinations can share common data pathways.

QoS: QoS is an acronym for Quality of Service. It is a networking term that specifies a guaranteed throughput level. QoS is the ability to provide different priority to different applications, users, or data flows.

SNA: Systems Network Architecture (SNA) is a proprietary networking architecture designed in 1974 for IBM's mainframe computers. It is a set of network protocols for interconnecting IBM computers and their resources.

Switch: A switch is a special-purpose computer that receives and transmits data across a network.

T1: T1 is a part of T-carrier system. It is the most commonly used digital transmission service for businesses to connect to an Internet access provider or other entities. T1 allows the data transmission speed of up to 1.544 million bits per second (Mbps).

TCP/IP: Transmission Control Protocol/Internet Protocol (TCP/IP) is a protocol architecture used as part of the TCP/IP architecture. This is used on the Internet.

Token ring: A Token Ring network is a type of local area networks (LANs) in which all computers are connected in a ring topology. A token-passing scheme is used in order to control the flow of data between computers.

Unix: Unix is an operating system developed at Bell Labs. It has been used for the scientific and engineering communities since 1970's. It has evolved over time with many extensions provided in a variety of versions of Unix. The Unix environment and the client/server model were important elements in the development of the Internet.

VoIP: Voice over Internet Protocol (VoIP) is a protocol optimized for providing voice communication service through the Internet or other packet switched networks. VoIP enables people to use the Internet as the transmission medium for telephone calls.

X.25: 25 is a widely-installed commercial wide area network protocol based on packet switching technology. A packet switching network describes the type of network in which relatively small units of data called packets are routed through a network based on the destination address contained within each packet.

Chapter 4.14

Managing the Implementation of Business Intelligence Systems:

A Critical Success Factors Framework

William Yeoh
University of South Australia, Australia

Andy Koronios
University of South Australia, Australia

Jing Gao
University of South Australia, Australia

ABSTRACT

The implementation of a BI system is a complex undertaking requiring considerable resources. Yet there is a limited authoritative set of CSFs for management reference. This article represents a first step of filling in the research gap. The authors utilized the Delphi method to conduct three rounds of studies with 15 BI system experts in the domain of engineering asset management organizations. The study develops a CSFs framework that consists of seven factors and associated contextual elements crucial for BI systems implementation. The CSFs are committed management support and sponsorship, business user-oriented change management, clear business vision and well-established case, business-driven methodology and project management, business-centric championship and balanced project team composition, strategic and extensible technical framework, and sustainable data quality and governance framework. This CSFs framework allows BI stakeholders to holistically understand the critical factors that influence implementation success of BI systems.

BACKGROUND

Engineering asset management organizations (EAMOs), such as utilities and transportation enterprises, store vast amounts of asset-oriented data (Lin et al., 2007). However, the data and information environments in these organizations are typically fragmented and characterized by disparate operational, transactional and legacy systems spread across multiple platforms and diverse structures (Haider & Koronios, 2003). An ever-increasing amount of such data is often collected for immediate use in assessing the operational health of an asset, and then it is either archived or deleted. This lack of vertical integration of information systems, together with the pools of data spread across the enterprise, make it extremely difficult for management to facilitate better learning and make well-informed decisions thus resulting in suboptimal management performance. Yet large volumes of disperse transactional data lead to increased difficulties in analyzing, summarizing and extracting reliable information (Ponniah, 2001). Meanwhile, increased regulatory compliance and governance requirements have demanded greater accountability for decision making within such organizations (Logan & Buytendijk, 2003; Mathew, 2003). In response to these problems, many EAMOs are compelled to improve their business execution and management decision support through the implementation of a BI system.

According to Negash (2004), “BI systems combine data gathering, data storage, and knowledge management with analytical tools to present complex and competitive information to planners and decision makers.” Implicit in this definition, the primary objective of BI systems is to improve the timeliness and quality of the input to the decision making process (Negash, 2004). Data is treated as a corporate resource, and transformed from *quantity* to *quality* (Gangadharan & Swami, 2004). Hence, actionable information could be delivered at the right time, at the right location, and in the right form (Negash, 2004) to assist individual decision makers, groups, departments, divisions or even larger units (Jagielska et al., 2003). Fisher et al. (2006) further posited that a BI system is primarily composed of a set of three complementary data management technologies, namely data warehousing, online analytical processing (OLAP), and data mining tools.

A successful implementation[1] of BI system provides these organizations with a new and unified insight across its entire engineering asset management functions. The resulting unified layer, in reporting, business analysis, and forecasting assures consistency and flexibility (Gangadharan & Swami, 2004). Critical information from many different sources of an asset management enterprise can be integrated into a coherent body for strategic planning and effective allocation of assets and resources. Hence, the various business functions and activities are analyzed collectively to generate more comprehensive information in support of management’s decision-making process.

BI systems come as standardized software packages from such vendors as Business Objects, Cognos, SAS Institute, Microstrategy, Oracle, Microsoft and Actuate, and they allow customers to adapt them to their specific requirements. In recent years, the BI market has experienced extremely high growth as vendors continue to report substantial profits (Gartner, 2006a; IDC, 2007). Forrester’s recent survey indicated that for most CIOs, BI was the most important application to be purchased (Brunelli, 2006). The results of the latest Merrill Lynch survey into CIO spending similarly found that the area with the top spending priority was BI (White, 2006). These findings are echoed by Gartner’s CIOs priorities surveys in 2006 which revealed that BI ranked highest in technology priority (Gartner, 2006b). In the most recent survey of 1400 CIOs, Gartner likewise found that BI leads the list of the top ten technology priorities (Gartner, 2007).

INTRODUCTION AND RESEARCH MOTIVATION

While BI market appears vibrant, nevertheless the implementation of a BI system is a financially large and complex undertaking (Watson et al., 2004). The implementation of an enterprise-wide information system (such as a BI system) is a major event and is likely to cause organizational perturbations (Ang & Teo, 2000). This is even more so in the case of a BI system because the implementation of a BI system is significantly different from a traditional operational system. It is an infrastructure project, which is defined as a set of shared, tangible IT resources that provide a foundation to enable present and future business applications (Duncan, 1995). It entails a complex array of software and hardware components with highly specialized capabilities (Watson & Haley, 1998).

BI project team need to address issues foreign to the operational systems implementation, including cross-functional needs, poor data quality derived from source systems that can often go unnoticed until cross-systems analysis is conducted; technical complexities such as multidimensional data modeling; organizational politics, and broader enterprise integration and consistency challenges (Shin, 2003). Consequently, it requires considerable resources and involves various stakeholders over several months to initially develop and possibly years to become fully enterprise-wide (Watson & Haley, 1997). Typical expenditure on these systems, includes all BI infrastructure, packaged software, licenses, training and entire implementation costs, may demand a seven-digit expenditure (Watson & Haley, 1997). The complexity of BI systems is exemplified by Gartner's recent study that predicted more than half of systems that had been implemented will be facing only limited acceptance (Friedman, 2005).

Much IS literature suggests that various factors play pivotal roles in the implementation of an information system. However, despite the increasing interest in, and importance of, BI systems, there has been little empirical research about the critical success factors (CSFs) impacting the implementation of such systems. The gap in the literature is reflected in the low level of contributions to international conferences and journals. Although there has been a plethora of BI system studies from the IT industry, nonetheless, most rely on anecdotal reports or quotations based on hearsay (Jagielska et al., 2003). This is because the study of BI systems is a relatively new area that has primarily been driven by the IT industry and vendors, and thus there is limited rigorous and systematic research into identifying the CSFs of BI system implementation. Therefore, the increased rate of adoption of BI systems, the complexities of implementing a BI system, and their far-reaching business implications justify a more focused look at the distinctive CSFs required for implementing BI systems.

Research Objective

Given the background and motivation of this research, the authors used Delphi method to:

- explore and identify the CSFs, and their associated contextual elements that influence implementation of BI systems
- consolidate a CSFs framework for BI system implementation

Essentially, the authors argue that there is a set of factors influencing the implementation of BI systems and such antecedents (i.e., CSFs) are necessary. In alignment with Sum et al.'s (1997) argument, this research also recognizes that the associated contextual elements that make up each factor provide more specific, useful and meaningful guidelines for BI systems implementation. As asserted by Sum et al. (1997),

> Top management support has often been cited as a CSF, but what exactly constitutes top management support is not really known. Good performance of the CSFs requires that their elements (or constituents) be known so that management can formulate appropriate policies and strategies to ensure that the elements are constantly and carefully being managed and monitored. Lack of clear definitions of the CSFs may result in misdirected efforts and resources.

Furthermore, the CSFs identified can be consolidated into a framework to provide a comprehensive picture for BI stakeholders, and hence allowing them to optimize their resources and efforts on those critical factors that are most likely to have an impact on the system implementation. Thereby ensuring that the initiatives result in optimal business benefits as well as maintaining effective uptake.

The remainder of this article has been structured as follows. The following section describes the research methodology, before elaborating on the CSFs finding. The next section then presents the CSFs framework and detail of each CSF. In the last section the authors state the conclusion, research contribution and future study.

RESEARCH METHODOLOGY

In the absence of much useful literature on BI system, this study seeks to explore and identify a set of CSFs that are jointly agreed by a group of BI system experts who possess substantial experience in EAMOs. The Delphi method was deemed to be the most appropriate method for this study because it allows the gathering of subjective judgments which are moderated through group consensus (Linstone & Turoff, 1975; 2002; Helmer, 1977). Moreover, this research assumes that expert opinion can be of significant value in situations where knowledge or theory is incomplete, as in the case of BI systems implementation in EAMOs (Linstone & Turoff, 2002). Unlike focus group method, this Delphi method is particularly suitable for this research situation where personal contact among participants and thus possible dominance of opinion-leaders is not desirable because of concerns about the difficulty of ensuring democratic participation.

For this study, a Delphi panel composed of fifteen BI systems experts in EAMOs was established. Ziglio (1996) asserts that useful results can be obtained from small group of 10-15 experts. Beyond this number, further increases in understandings are small and not worth the cost or the time spent in additional interviewing (Carson et al., 2001). Thus, the size of such a Delphi panel is deemed suitably representative. As shown in Table 1, the Delphi participants have all been substantially involved in the implementation of BI systems within EAMOs in Australia and the United States.

In addition, the range of engineering asset management organizations represented by these experts was diverse and included public utilities (such as electricity, gas, water, and waste management) and infrastructure-intensive enterprises such as telecommunications and rail companies. It should be noted that some of the large organizations in which the participants have been involved have implemented BI projects in a series of phases. Most of the EAMOs are very large companies with engineering assets worth hundreds millions of dollars and have committed immense expenditure to BI projects. So the expertise of the Delphi participants represents ‘state of the art’ knowledge of BI systems implementation in a broad range of engineering asset-intensive industries.

The Delphi study comprised three rounds. During the first round the authors conducted face-to-face interviews with each participant (and phone interviews in some cases due to geographical constraints), and these varied in duration from one to one and half hours. Rather than having an open-ended question, the authors adopted a different approach from traditional Delphi methods by beginning with a list of factors derived from data warehousing literature, which is the core component of a BI system. Having a prior theory has advantages such as allowing the opening and probe questions to be more direct and effective, and helping the researcher recognize when something important has been said (Carson et al., 2001). However, the existing literature is not comprehensive in regard to CSFs for an entire BI system, but mainly focuses on data warehousing. Therefore, those factors were mainly used to start each discussion. When the mention of particular factors elicited relevant responses then further

probing questions would follow in order to gather more details on those factors. The panelists were indeed encouraged to suggest other factors that they deemed critical.

At the commencement of the interviews, it was explained that the study focused on CSFs that facilitated the implementation success of BI systems in terms of infrastructure performance and process performance. The infrastructure performance consists of three major IS success dimensions proposed by Delone and McLean (1992; 2003), namely system quality, information quality, and system use, whereas process performance is composed of meeting time-schedule and budgetary constraints (Ariyachandra & Watson, 2006). After the interview, further clarifications (if any) were made by follow-up phone calls and e-mail communications. Subsequently, the data gathered from the first round of interviews were analyzed thoroughly by content analysis technique, a constant comparison ('grounded') technique, to identify major themes (Glaser & Strauss, 1967). This technique encourages the emergence of a finding from the data set by constantly comparing incidents of codes with each other and then abstracting related codes to a higher conceptual level (Glaser, 1992; 1998). In other words, the qualitative data were examined thematically and emergent themes were ranked by their frequency and later categorized. The objective of the present research was to identify the CSFs that influence the implementation of BI systems. Hence, it is considered to be very important to determine what emerges from the data regarding interpretations of the CSFs for implementing BI systems.

In the subsequent round, the suggested factors of all the participants were consolidated into a single list. The list was then distributed among the participants to facilitate comparison of the expert's perceptual differences. However, none of them nominated any additional factors of their own. Also, based on feedback from participants, some further minor changes were incorporated. In addition, the participants confirmed that the classification of factors and their associated contextual elements is appropriate. For instance, several elements are grouped together because of the closed interrelationship. During the third round, the list of candidate CSFs was surveyed by the Delphi participants using a structured questionnaire survey approach. Specifically, a 5-point Likert scale was applied to rate the importance of the candidate CSFs in the process of seeking statistical consensus from the BI experts. The purpose of using a 5-point scale from 1 to 5 (where 1 meant 'not important,' 2 of 'little importance,' 3 'important,' 4 'very important,' to 5 'critically important') was to distinguish important factors from critical success factors. From the survey feedback, only those factors with average rating of 3.5 and above were shortlisted as CSFs (as shown in Table 2). These CSFs ratings are considered legitimate because the participants were directly drawing on their hands-on experience in EAMOs' BI system implementations. The details of the results are discussed below.

CSFS FINDING AND DISCUSSION

Table 2 depicts the average rating results for the respective CSFs in descending order of importance. It contains the consensus outcomes and shows that the Delphi study captured the importance of the seven critical factors, namely committed management support and sponsorship, business user-oriented change management, clear business vision and well-established case, business-driven methodology and project management, business-centric championship and balanced project team composition, strategic and extensible technical framework, sustainable data quality and governance framework.

Notably, data and technical-related factors did not appear to be the most critical in relation to

Table 2. Ratings of critical success factors by Delphi participants

Critical Success Factors	Mean	Std. Dev
• Committed management support and sponsorship	4.16	0.99
• Business user-oriented change management	4.10	1.00
• Clear business vision and well-established case	4.09	0.90
• Business-driven methodology and project management	4.08	0.88
• Business-centric championship and balanced project team composition	3.94	0.89
• Strategic and extensible technical framework	3.90	0.89
• Sustainable data quality and governance framework	3.82	0.91

other organizational factors. According to most interviewees, technological difficulties can be solved by technical solutions. However, it was found that achieving management and organizational commitment for a BI initiative poses the greatest challenge, because the BI teams considered them to be outside their direct control. The organizational support is reflected in the attitudes of the various business stakeholders; that is, their attitudes to change, time, cost, technology, and project scope. Based on a large-scale survey result, Watson and Haley (1997) pointed out that the most critical factors for successful implementations were organizational in nature. Committed management support and adequate resources were found to determine the implementation success, because these factors worked to overcome socio-political resistance, address change-management issues, and increase organizational buy-in. This finding was also converging with Gartner's recent observation that "overcoming complex organizational dynamics will become the most significant challenge to the success of business intelligence initiatives and implementations" (Burton et al., 2006).

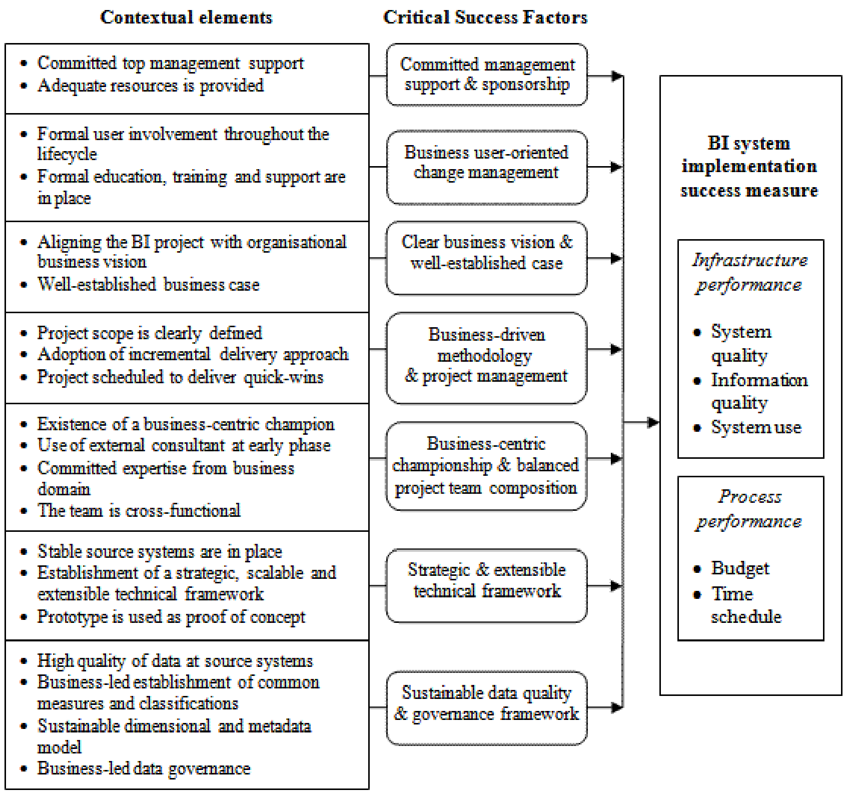
In fact, the effort of implementing BI systems is highly regarded by the Delphi participants as a business-driven program as opposed to a technological one. The fulcrum of BI program success is thus dependent on the business personnel, whereas technical people are expected to support the analytical requirements via technologies and tools. The definition of strategic BI framework, project scoping and data quality initiatives were considered within the realm of business personnel. That is, this new understanding emphasizes the priority of business aspects, not the technological ones, in implementing BI systems.

While the specific CSFs may seem to vary slightly between BI systems and general IS studies, the actual contextual elements of these CSFs are substantially different from the implementation effort required for conventional operational systems. Unlike those transactional systems, business stakeholders need to be involved interactively in order to meet their dynamic reporting and ever-changing analytical needs. Owing to the evolutionary information requirements, the BI team has to provide continual support not only on tools application, but also at broader data modeling and system scalability issues. This is in line with the adoption of an incremental delivery approach for implementing an adaptive decision support system, such as a BI system (Arnott & Pervan, 2005). Moreover, organizational and business commitment to a BI system implementation is critical to solve the complex organizational issues, especially in the democratization process of data ownership, selection of funding model, change of business process, definition of the scoping study, data stewardship and quality control, and the provision of domain expertise and championship. The following section presents the CSFs framework consolidated from these CSFs findings.

DEVELOPMENT OF A CRITICAL SUCCESS FACTORS FRAMEWORK

Based on the research finding, these seven critical factors were integrated with the implementation success measures to provide a comprehensive CSFs framework for implementing BI systems. As illustrated in v below, this CSF framework outlines how a set of factors contribute to the success of a BI system implementation. It postulates that there is a set of CSFs influencing the implementation success that takes into account two key measures: infrastructure performance and process performance. The infrastructure performance has parallels with the three major IS success variables described by (Delone & McLean, 1992; 2003), namely system quality, information quality, and system use, whereas process performance can be assessed in terms of time-schedule and budgetary considerations. Specifically, system quality is

Figure 1. A critical success factors framework for the implementation of business intelligence systems



concerned with the performance characteristics of the information processing system itself, which includes ease-of-use, functionality, reliability, flexibility, integration, and response time (Delone & McLean, 1992; Rai et al., 2002). Information quality refers to accuracy, timeliness, completeness, relevance, consistency, and usefulness of information generated by the system (Delone & McLean, 1992; Fisher et al., 2006). System use is defined as "recipient consumption of the output of an information system" (Delone & McLean, 1992). These success criteria serve as the operationalizations of this study's dependent variables (i.e., the critical success factors).

In brief, this framework treats the CSFs identified as necessary factors for implementation success, whereas the absence of the CSFs would lead to failure of the system (Rockart, 1979). Within the framework, each of the CSFs identified by the Delphi study is described as follows.

Committed Management Support and Sponsorship

Committed management support and sponsorship has been widely acknowledged as the most important factor for BI system implementation. All Delphi participants agreed that consistent support and sponsorship from business executives make it easier to secure the necessary operating resources such as funding, human skills, and other requirements throughout the implementation process (Watson et al., 2001). This observation is reasonable and expected because the whole BI system implementation effort is a costly, time-consuming, resource-intensive process (Watson et al., 2004).

Moreover, the Delphi experts further argued that BI system implementation is a continual information improvement program to leverage decision support. They believed that the typical application-based funding for implementation of transactional systems does not apply to BI systems that are adaptive in nature. That is, a BI system evolves through an iterative process of systems development in accordance to dynamic business requirements (Arnott & Pervan, 2005). Therefore the BI initiative, especially for the enterprise-wide scale, requires consistent resource allocation and top-management support to overcome organizational issues. These organizational challenges arise during the course of the cross-functional implementation, as it often uncovers many issues in such areas as business process, data ownership, data quality and stewardship, and organizational structure. Many functional units tend to focus on tactical gains, ignoring the rippling effects imposed on other business units, and one expert observed that,

The whole BI effort cut across many areas in the organization that's making it very difficult, it hits a lot of political barriers. For instance, for a systems owner, they are only interested in delivering day to day transaction, as long as all that done… that's what they care about.

Also, without dedicated support from top management, the BI project may not receive the proper recognition and hence the support it needs to be successful. This is simply because users tend to conform to the expectations of top management and so are more likely to accept a system backed by their superiors (Lambert, 1995).

Business User-Oriented Change Management

Having an adequate user-oriented change management effort was deemed critical by the Delphi participants. The experts perceive that better user participation in the change effort can lead to better communication of their needs, which in turn can help ensure the system's successful implementation. This is particularly important when the requirements for a system are initially unclear, as is the case with many of the decision-support applications that a BI system is designed to sustain (Wixom & Watson, 2001). Significant numbers of Delphi participants shared the same view that formal user participation can help meet the demands and expectations from various end users. No doubt, the user groups know what they need better than a secluded architect or developer that does not have day to day user experience. Hence, key users must be involved throughout the implementation cycle because they can provide valuable input that the BI team may overlook. The data dimensions, business rules, metadata, and data context that are needed by business users should be considered and incorporated into the system (Wixom & Watson, 2001). Furthermore, users can provide input to the process through review and testing to ensure that it meets the goals that they think it should.

Furthermore, when users are actively involved in the effort, they have a better understanding of the potential benefits and this makes them more likely to accept the system on completion (Hwang et al., 2004). Thus through this 'implicit' education approach, it create a sense of ownership by the users. Most interviewees also agreed that consistent support for, and systematic training of, end users must not be ignored when aiming for successful BI system implementation (Ang & Teo, 2000). Many participants emphasized that training should focus on the technology itself as well as on the associated management and maintenance issues. This training is important to equip users to understand and experience the features and functions, and to learn about the configured environment and business rules of the BI applications.

Clear Business Vision and Well-Established Case

As a BI initiative is driven by business, so a strategic business vision is needed to direct the implementation effort. The Delphi participants indicated that a long-term vision, primarily in strategic and organizational terms, is needed to enable the establishment of BI business case. The business case must be aligned to the corporate vision because it would eventually impact the adoption and outcome of the BI system. Otherwise they will not receive the executive and organizational supports that are required to make them successful. Consequently, the investment return of a BI system implementation should be included in those of the business process as a whole (Liautaud & Hammond, 2000). Majority interviewees indicated that the mindset of 'setting an excellent system there, then people will come to use it' is totally inappropriate. In fact, one interviewee claimed that:

A BI system that is not business-driven is a failed system! BI is a business centric concept. Sending IT off to solve a problem rarely results in a positive outcome. There must be a business problem to solve.

Most participants stressed that a solid business case that was derived from a detailed analysis of business needs would increase the chances of winning support from top management. Thus, a substantial business case should incorporate the proposed strategic benefits, resources, risks, costs and the timeline. Hence, a solid business case would provide justifiable motivations for adopting a BI system to change the existing reporting and analytical practices.

Business-Driven Methodology and Project Management

The next factor to be considered is business-driven methodology and project management. According to the Delphi experts, adequate project scoping and planning allows the BI team to concentrate on the best opportunity for improvement. To be specific, scoping helps to set clear parameters and develops a common understanding as to what is in scope and what is excluded (Ang & Teo, 2000). For instance, a Delphi expert gave insight into his experience:

The success of 90% of our project is determined prior to the first day. This success is based on having a very clear and well-communicated scope, having realistic expectations and timelines, and having the appropriate budget set aside.

Hence, adequate scoping enables the project team to focus on crucial milestones and pertinent issues while shielding them from becoming trapped in unnecessary events. Many experts further indicate that it is advisable to start small and adopt an incremental delivery approach. Large-scale change efforts are always fraught with greater risks given the substantial variables to be managed simultaneously (Ang & Teo, 2000). Moreover, business changes very fast and is always looking to see immediate impact, and such an incremental delivery approach provides the tools for delivery of needed requirements in a short time (Greer & Ruhe, 2004). Also, an incremental delivery approach allows for building a long-term solution as opposed to a short term one, as is the case for an evolutionary BI system development (Arnott & Pervan, 2005).

Besides that, some interviewees commented that a BI program that starts off on a high-impact area is always valuable to provide tangible evidence for both executive sponsors and key users

(Morris et al., 2002). According to them, adopting this so-called 'low hanging fruits' approach—projects with the greatest visibility and monetary impact— demonstrates to leadership that there is a payback (ROI) for their investment and it shows it in a short timeframe. This will increase leadership support and help the other associated initiatives to be supported readily. One interviewee elaborated that:

You cannot role out the whole BI system at once but people want to see some key areas. You need to do data marts for a couple of key areas and then maybe a small number of other key reports in an attempt to keep all stakeholders happy. Then when the first release is done and you get some feedback, you can work on other data mart areas and enhance existing subject areas over time.

Therefore, a 'low hanging fruits' approach allows an organization to concentrate on crucial issues, so enabling teams to prove that the system implementation is feasible and productive for the enterprise.

Business-Centric Championship and Balanced Project Team Composition

The majority of Delphi experts believed that having the right champion from the business side of the organization is critical for implementation success. According to them, a champion who has excellent business acumen is always important since he/she will be able to foresee the organizational challenges and change course accordingly. More importantly, this business-centric champion would view the BI system primarily in strategic and organizational perspectives, as opposed to one who might over-focus on technical aspects. For example, as noted by an interviewee:

The team needs a champion. By a champion, I do not mean someone who knows the tools. I mean someone who understands the business and the technology and is able to translate the business requirements into a (high-level) BI architecture for the system.

All interviewees also agreed that the composition and skill sets of a BI team have a major influence on the implementation success. The project team should be cross-functional and composed of those personnel who possess technical expertise and those with a strong business background (Burton et al., 2006). As most interviewees stressed, a BI system is a business-driven project to provide enhanced managerial decision support, and so a suitable mix of IT expertise is needed to implement the technical aspects, whereas the reporting and analysis aspects must be under the realm of business personnel.

Furthermore, most experts posited that the BI team must identify and include business domain experts, especially for such activities as data standardization, requirement engineering, data quality analysis, and testing. Many respondents also agreed with the critical role played by external consultants, especially at early phase. They believed that the lack of in-house experience and competencies can be complemented by external consultants who have spent the majority of their time working on similar projects. As well as being a subject matter expert, the interviewees indicated that an external consultant could provide an unbiased view of solution to a problem. This is because the organizational structure of an engineering asset management enterprise is traditionally functional-oriented and culturally fragmented with siloed information systems design (Haider & Koronios, 2003). There may even be situations where the client possesses the expertise to solve a particular problem, but are conflicted on the organizational ground. An external consultant hence can evaluate and propose an unbiased course of action without having fear of political repercussions (Kaarst-Brown, 1999).

Strategic and Extensible Technical Framework

In terms of strategic and extensible technical framework, most experts asserted that stable source/back-end systems are crucial in implementing a BI system. A reliable back-end system is critical to ensure that the updating of data works well for the extraction, transformation and loading (ETL) processes in the staging area (Ponniah, 2001). Hence the data can be transformed to provide a consistent view into quality information for improved decision support. It is therefore crucial for BI team to assess the stability and consistency of source systems before embarking on a BI effort. Otherwise after the system implementation, the cost of changes in terms of time and money can be significant. A BI expert explained the importance of this factor in detail:

It's more important you got a reliable, consistent, stable back-end system, in my experience, I'm working with a mining company now, in their case, they don't have consistent back-end systems, in some departments, they have just large number of spreadsheets, which call production data into their spreadsheets, it is scary. It's a major impediment to BI system, and you got multiple bits over all the places.

Another prime element concerned by the respondents was that the technical framework of a BI system must be able to accommodate scalability and extendibility requirements. Having a strategic view embedded in the system design, this scalable system framework could include additional data sources, attributes, and dimensional areas for fact-based analysis, and it could incorporate external data from suppliers, contractors, regulatory bodies, and industry benchmarks (Watson et al., 2004). It would then allow for building a long-term solution to meet incremental needs of business.

The majority of interviewees also agreed that a prototype is always valuable as proof of a concept. That is, constructing a fairly small BI application for a key area in order to provide tangible evidence for both executive sponsors and general users (Watson et al., 2001). They perceive that a prototype that offers clear forms of communication, and better understanding in an important business area, would convince organizational stakeholders on the usefulness of a BI system implementation. As a result of a successful prototype, senior management and key users would be more likely and more motivated to support larger-scale BI efforts.

Sustainable Data Quality and Governance Framework

The Delphi findings indicate that the quality of data, particularly at the source systems, is crucial if a BI system is to be implemented successfully. According to the interviewees, a primary purpose of the BI system is to integrate 'silos' of data sources within enterprise for advanced analysis so as to improve the decision-making process. Often, much data related issues within the back-end systems are not discovered until that data is populated and queried against in the BI system (Watson et al., 2004). Thus corporate data can only be fully integrated and exploited for greater business value once its quality and integrity are assured.

The management are also urged to initiate data governance and stewardship efforts to improve the quality of the data in back-end systems because unreliable data sources will have a ripple effect on the BI applications and subsequently the decision outcomes (Chengalur-Smith et al., 1999). For instance, an expert expressed his concern:

This is the most underrated and underestimated part of nearly every BI development effort. Much effort is put into getting the data right the first time, but not near enough time is spent *putting in place the data governance processes to ensure the data quality is maintained.*

Some interviewees further argued that a sound data governance initiative is more than ad-hoc data quality projects. Indeed, it should include a governing committee, a set of procedures, and an execution plan. More specifically, the roles of data owners or custodians and data stewards must be clearly defined (Watson et al., 2004). Frontline and field workers should be made responsible for their data source and hence data quality assurance. Meanwhile, a set of policies and audit procedures must be put into place that ensures ongoing compliance with regulatory requirements as most EAMOs like utilities are public-owned company.

Apart from that, the Delphi participants believed that common measures and definitions address the data quality dimension of representational consistency. This allows all stakeholders to know that this term has such definition no matter where it is used across the source systems. Furthermore, it is typical for an EAMO to have hundreds of varying terms with slightly different meanings, because different business units tend to define terms in ways that best serve their purposes. Often accurate data may have been captured at the source level; however, the record cannot be used to link with other data sources due to inconsistent data identifier. This is simply because data values that should uniquely describe entities are varied in different business units. Once an organization collects a large number of reports it becomes harder to re-architect these areas. As a result, a cross-system analysis is important to help profiling a uniform ‘master data set’ which is in compliance with business rules. The development of a master data set on which to base the logical data warehouse construction for BI system will ease terminology problems (Watson et al., 2004).

In order to have consistent measures and classification across subject areas, most interviewees asserted that business-led commitment is pivotal to establish consensus on data measurement and definition. Indeed, a BI system implementation is a business driven initiative to support the reporting and analytical requirements of business. As a result, the BI team would use those common definitions to develop an enterprise-wide dimensional model that is business-orientated. Many participants asserted that a correct dimensional data model is the absolute cornerstone of every BI project. A faulty model will surely lead to failure of the project as it will fail to deliver the right information. As noted by an interviewee:

Not understanding dimensional modeling will cause lots of grief later on and make it difficult to answer some questions. Once you have a large number of reports, it becomes harder to re-architect these areas. Better to get it right the first time with a star schema and well-designed dimensions and fact tables. Good use of aggregates can speed report results and make people happy.

Also, a sustainable metadata model on which to base the logical and physical data warehouse construction for a BI system was deemed critical by many experts. Therefore, the metadata model should be flexible enough to enable the scalability of the BI system while consistently providing integrity on which OLAP and data mining depend (Watson & Haley, 1997).

CONCLUDING REMARKS AND FUTURE RESEARCH

This theory building research presents a CSFs framework derived from a Delphi study with 15 BI systems experts within engineering asset management domain. An analysis of the findings demonstrated that there are a number of CSFs peculiar to successful BI system implementation. More importantly, this study revealed a clear trend towards multi-dimensional factors in implementing BI systems. Organizational factors were perceived to be more important than the technological ones because the BI team considered them to be outside their direct control. Furthermore, the contextual elements of these CSFs appear to be substantially different from the implementation effort of conventional operational systems.

The research is likely to make both theoretical and practical contributions to the field of BI systems implementation. First, this study fills in the research gap by building theory of CSFs, addresses issues of concern to practitioners and supplements the current limited understanding on implementation issues of BI systems. Moreover, this research provides thought-provoking insights into multi-dimensional CSFs that influence the BI systems implementation. The contextual elements identified alongside for each of the critical factors and the consolidated CSFs framework provides a comprehensive and meaningful understanding of CSFs.

Not only does this research contribute to the academic literature but it benefits organizations in several ways as well. Essentially, BI practitioners (both current and potential) will be better able to identify critical factors for successfully implementing BI systems. The findings will enable them to better manage their implementation of BI systems if they understand that such effort involves multiple dimensions of success factors occurring simultaneously and not merely the technical aspects of the system. With the CSFs framework, it could enable BI stakeholders to better identify the necessary factors, and to possess a comprehensive understanding of those CSFs. Such outcomes will help them to improve the effectiveness and efficiency of their implementation activities, by obtaining a better understanding of possible antecedents that lead to successful BI system implementation. For senior management, this research finding can certainly assist them by optimising their scarce resources on those critical factors that are most likely to have an impact on the BI systems implementation. Moreover, the management can concentrate their commitment to monitor, control and support only those key areas of implementation.

In the next stage, it is planned to conduct case study with multiple engineering asset management organizations to further validate the CSFs findings. The multiple case studies will examine whether these critical factors and/or any other alternative factors influence the implementation success of BI systems.

Chapter 4.15

Business Process Management Systems for Supporting Individual and Group Decision Making

Amit V. Deokar
Dakota State University, USA

Omar F. El-Gayar
Dakota State University, USA

INTRODUCTION

The complexities involved in managing intra-functional as well as interfunctional activities have triggered many organizations to deploy large information technology (IT) systems such as ERP and CRM. While such systems have focused mainly on providing solutions to problems such as enterprise-wide application integration and customer driven revenue management, one of the prime issues of managing coordination among activities in organizational processes has not gained adequate attention and support. Business process management (BPM) systems have emerged as a key technology primarily in the past two decades with a goal of providing process support to organizations and supporting better decision making.

This article focuses on highlighting this role of BPM systems while discussing some of the recent advances and approaches from a decision making standpoint, both for supporting individual and collaborative decision making activities.

BACKGROUND

The original ideas upon which BPM systems are founded upon can be traced back to several different areas of computing and management.

It is worthwhile to glance at the history to better understand the motivating factors for the advancement and role of BPM systems. One such area is that of office information systems. In the 1970s and 1980s, researchers like Holt (1985) focused on modeling routine office procedures with mathematical formalisms such as Petri Nets. These efforts did not gain much momentum due to the functional nature of organizations. Later, in the mid-1990s, management initiatives such as Business Process Re-engineering (BPR) (Hammer, 1990), and Total Quality Management (TQM) (Harrington, 1991) highlighted the importance of process oriented thinking in organizations, which helped in rejuvenating the interest in business process modeling and management.

During mid-1980s and early-1990s, another research stream of organizational decision support system (ODSS) emerged. It built upon Hackathorn and Keen's (1981) key ideas of decision support: individual, group, and organizational. From a decision standpoint, it laid out a foundation for focusing on organizational activities and further decomposing them into a sequence of subactivities performed by various organizational actors. Although process coordination was not the primary focus of ODSS, it supported the notion of coordinating and disseminating decision making across functional areas and hierarchical layers such that decisions are congruent with organization goals and management's shared interpretation of the competitive environment (Watson, 1990). The term ODSS was sometimes also referred to as "distributed decision support system" in the literature.

Also in the early 1990s, document imaging and management systems fostered the notion of automation of document-driven business processes by routing documents from person to person in an organization (Smith, 1993).

BPM AND RELATED TERMINOLOGY

The term BPM is often used by commercial vendors with different connotations. It is therefore essential to present operational definitions of related terms. Firstly, the term *process* itself is very broad. Medina-Mora, Wong, and Flores's (1993) classification of organizational processes into material processes, information processes, and business processes is noteworthy here. Material processes relate human tasks to the physical world (e.g., assembly of machine parts). Information processes relate to automated tasks (i.e., performed by computer programs), and partially automated tasks (i.e., tasks performed by people with the assistance of computer programs). Business processes are a higher level abstraction of organizational activities that are operationalized through material processes and/or information processes (Georgakopoulos, Hornick, & Sheth, 1995). The term process in the BPM context relates to business processes implemented primarily as information processes, and is used in the discussion in this article.

Workflow is a related concept to automating business and information organizational processes. The Workflow Management Coalition (WfMC) defines *workflow* as: "The automation of a business process, in whole or part, during which documents, information, or tasks are passed from one participant to another for action, according to a set of procedural rules" (WfMC, 1999). Also, WfMC defines the term *Workflow Management System* (WFMS) as: "A system that defines, creates and manages the execution of workflows through the use of software, running on one or more workflow engines, which is able to interpret the process definition, interact with workflow participants and, where required, invoke the use of IT tools and applications" (WfMC, 1999). It can be seen that WfMC places strong emphasis on the execution aspect, which is limiting in many ways. While managing execution of workflows is essential, making use of information about workflows to analyze, diagnose, and redesign business processes at a conceptual level is critical to reap benefits from the technology, rather than focusing merely on process design, system configuration, and process enactment. With this realization, the term *BPM* has emerged, which involves "supporting business processes using methods, techniques, and software to design, enact, control, and analyze operational processes involving humans, organizations, applications, documents, and other sources of information" (Weske, van der Aalst, & Verbeek, 2004). Similarly, a *BPM system* can be defined as "a generic software system that is driven by explicit process designs to enact and manage operational business processes" (Weske et al., 2004).

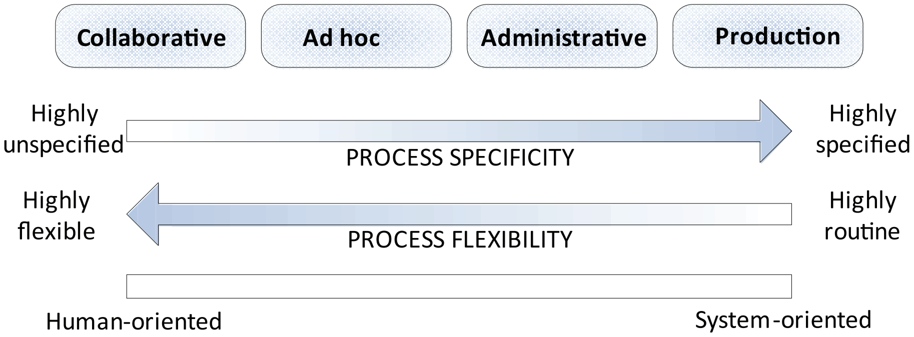
The BPM life cycle can be viewed as the one involving process (re)design, system configuration, process enactment, and diagnosis. Thus, along with a strong workflow management component, BPM systems involve decision-making support for business managers through the diagnosis phase. The diagnosis phase mainly involves *business process analysis* (BPA) and *business activity monitoring* (BAM). In this context, a visionary characterization of workflow management infrastructure provided by Georgakopoulos et al. (1995) fits closely with the current BPM systems characterization. It indicates that workflow management involves a distributed computing infrastructure that is component-oriented (i.e., supports loose coupling between heterogeneous, autonomous, and/or distributed systems), supports workflow applications for accessing organizational information systems, ensures the correctness (in case of concurrency) and reliability (in case of failures and exceptions) of applications, and supports re-engineering business processes through modification of workflows.

WORKFLOW CHARACTERIZATION

Workflows can be classified in several different ways. The most widely accepted classification, one that has been used by the trade press and endorsed by the WfMC, divides workflow in four categories: *production*, *administrative*, *ad hoc*, and *collaborative* (Georgakopoulos et al., 1995; Stohr & Zhao, 2001). Different aspects of these workflows are shown in Figure 1.

Production workflows deal with highly structured and repetitive tasks, providing automation support for which can lead to great improvements in productivity. These workflows are characterized by minimal human intervention in process management (e.g., handling exceptions). From a system support perspective, production

Figure 1. Characterization of workflows. Adapted from Georgakopoulos et al. (1995) and Stohr and Zhao (2001).



workflows are supported as either autonomous workflow engines or as embedded workflow components within enterprise systems such as ERP. Since various decisions in the process are made by the workflow system component, rather than humans, they involve high task complexity in addition to integration and interoperatibility of different enterprise applications. Also, with high transaction volumes, these workflows are mission critical and demand high accuracy, reliability, efficiency, security, and privacy. Typical examples of production workflows are health claims processing and order entry and billing in manufacturing supply chains.

Administrative workflows are characterized by human decision-making and task execution (with the assistance of software applications). They involve simpler task coordination rules as compared to production workflows, thus having relatively less task complexity. Also, the emphasis is on routing and document approval functionalities such as in the case of travel expense reports. Most often, these workflows are nonmission critical from a business value standpoint. Coordination is achieved by prompting users to perform their tasks, most commonly by using electronic mail technology.

Ad hoc workflows are best suited where flexibility in processes is a key requirement. They are often used where spontaneous, user-controlled ordering, and coordination of tasks is needed. A typical example includes a small team of knowledge workers involved in a short term project involving a set of activities. These are most often nonmission critical and do not have high repeatability, thus ruling out the need for an automated task coordination and facilitation system, such as in the case of administrative or production workflows. Electronic mail, group calendaring, and conferencing systems (collectively termed as groupware tools) are commonly used for ad hoc workflows and thus advancements in computer supported cooperative work (CSCW) are relevant for enabling these workflows.

Collaborative workflows are activities which predominantly involve group decision making activities, which are mission critical. Quite differently from ad hoc workflows, collaborative workflows are knowledge intensive with collaborative intellectual problem solving involved, which requires expertise from multiple people. However, they may or may not be repeatable, depending on the process. For example, organizational processes such as strategic planning, engineering design, user requirements gathering, are not repeatable (as compared to production workflows), although they are critical to the business process. Traditionally, these processes have been supported by group decision support systems (GDSS) (Nunamaker, Dennis, Valacich, Vogel, & George, 1991), but deserve a place in the workflow spectrum.

Supporting Decision Making Through Coordination and Control

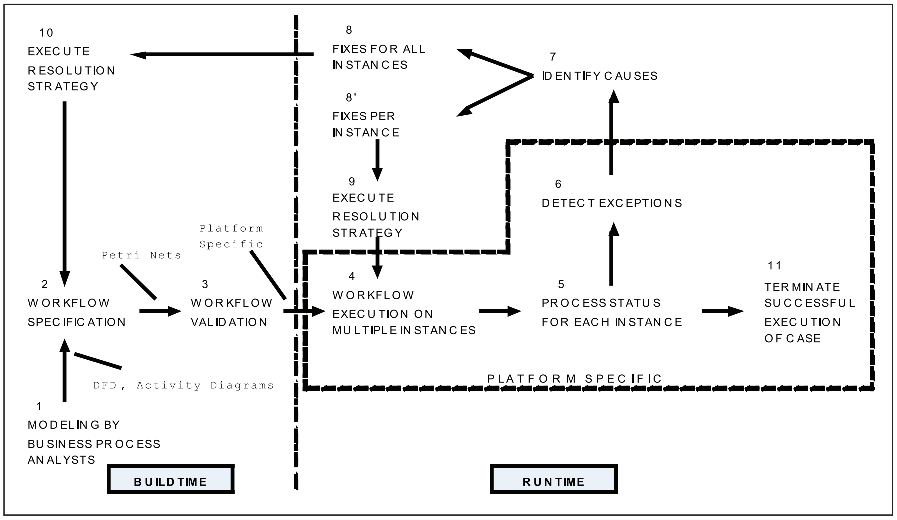
BPM systems can be used for coordinating and controlling interleaved individual and collaborative decision making tasks. With efficient coordination and control of the process, better decision making can be achieved. It is useful to look at a life cycle of a workflow schema to understand this mechanism.

Workflow Management for Coordination and Control of Tasks

The contemporary workflow management approach can be illustrated by considering the lifecycle of a workflow schema (process definition). Figure 2 illustrates the lifecycle of a workflow schema for a business process, through design and deployment, which forms the basis for coordination and control of tasks through workflow management in modern day BPM systems.

The lifecycle begins when business process analysts acquire and structure organizational processes into a workflow (Step 1). Defining a workflow schema involves identifying the differ-

Figure 2. Lifecycle of a workflow schema for a business process



ent tasks that constitute a business process in an organization and then specifying the execution sequences along with the executing agents, control, and data dependencies for the various tasks. The workflow thus defined is verified, tested, and then executed (enacted) in a workflow engine (Steps 2, 3, and 4). A single workflow schema may cater to multiple workflow instances (or cases). Each executing case is monitored and tracked (Steps 5 and 6). Cases may execute normally without any errors or may lead to exceptions of various kinds. These exceptions may have a variety of causes and are handled by manual intervention (Step 7). The failures of the workflow cases are usually caused by underspecified or erroneously defined workflows during the modeling task, as it is usually difficult to acquire comprehensive knowledge to model all possible variations of a business process (which is one of the limitations of the procedural approaches used for workflow management). Further, the workflow implementation environment changes as the business evolves; organizational roles and task assignments change. Repairs may be applied to a single executing instance or organizationally it may be decided to update the initial workflow specification (Step 8, 8'). The process of updating single instances and generic definitions is a highly knowledge intensive task in organizations because of the complexity of the workflows (Steps 9 and 10). The workflow validation/verification step is usually done via simulation/animation.

The lifecycle in Figure 2 also indicates the different process representations that may be used during the various stages of the lifecycle. For example, data flow diagrams (DFDs) and unified modeling language (UML) activity diagrams may be used by business process analysts, which may be then encoded into a specification. Such a specification may be translated into a Petri Net based formalism for analysis. Note that the activities in the Figure 2 are classified into build time (design) and run time (execution) activities. Runtime models are highly dependent on the technology platform used to execute a workflow. Thus, the process of deploying a workflow model into production requires a consistent set of model transformations that need to occur through different stages of the lifecycle.

It can be noted that the contemporary approach presented is fundamentally programmatic or procedural, as the predefined rigid process structures (workflow schemas) rely on the process designer to search the design space (although implicitly) for seeking the right kind of process model to model the business process at hand and achieve the organizational goals. As a result, failure and change management approaches to support adaptive and dynamic processes are largely ad hoc. Once a workflow is deployed, maintenance of the workflow schema (or its instances) is manual and resource intensive. Manual intervention requires knowledge of the business processes as well as the underlying workflow technology. Also, simulation-based validation may not identify all the errors early because of the large number of test cases that need to be checked.

Alternatively, declarative, goal-driven workflow process design approaches have recently been explored for business process management in dynamic settings (Deokar, Madhusudan, Briggs, & Nunamaker, 2004). Instead on deriving generic schemas for business processes, these approaches use instance specific information to generate a customized process model for addressing the business process problem. Automated logic-based algorithms (such as artificial intelligence planning) may be used for these purposes (Myers & Berry, 1999). While these approaches are novel and useful, they involve a knowledge intensive process of encoding task descriptions based on domain knowledge in order for machine to be able to intelligently generate process models.

Individual Decision Making

Administrative workflows are typical examples where individual knowledge workers are involved in decision making in workflows. These decision making tasks are modeled and designed as any other task in a workflow process; however, the execution may be supported with the help of decision support systems (DSS) to aid the individual decision maker. For example, in a loan application process, the manager might have to make decisions based on the applicant's credit history and assets, among other factors. This decision may be facilitated using a DSS that is geared toward this task (Turban, Aronson, Liang, & Sharda, 2007).

Group Decision Making

Collaborative workflows involve group decision making tasks with high process complexity (due to high information unspecificity and flexibility). Systems supporting collaborative workflows are based on GDSS or group support systems (GSS) technology. Traditionally, such systems have been restricted to face-to-face and small group decision making through facilitator guided meeting sessions (e.g., GroupSystems) (Nunamaker et al., 1991). The process structure and support is also not explicated in such systems. To be embedded as a part of a BPM system, such systems need to contain an explicit embedded representation of the underlying group process (Deokar et al., 2004).

Over the past few years, researchers in the area of collaboration technology have been working on finding ways for teams to wield GSS successfully and manage their collaboration tasks for themselves with predictable results. Addressing this challenge is the domain of an emerging field of collaboration engineering. *Collaboration engineering* is an approach for designing, modeling, and deploying repeatable collaboration tasks for recurring high-value collaborative workflows that are executed by practitioners (knowledge workers) without the ongoing intervention of facilitators (de Vreede & Briggs, 2005). *Collaborative workflows* designed through this approach are processes that support a group effort towards a specific goal, mostly within a specific time frame. The workflow is built as a sequence of facilitation interventions that create patterns of collaboration; predictable group behavior with respect to a goal. As can be noted, the research efforts are moving towards making collaborative workflows "process-aware" in the true sense, thus expanding the horizons of typical GDSS systems from face-to-face to virtual collaboration.

The main thrust of the collaboration engineering research is thus on codifying and packaging key facilitation interventions in forms that can be readily and successfully reused by groups in collaborative workflows and that can produce predictable, repeatable interactions among people working toward their goal. These packaged facilitation interventions are termed as *thinkLets* (Briggs, de Vreede, & Nunamaker, 2003). These codified facilitation interventions are based on experiences of professional facilitators in conducting successful collaborative sessions (e.g., Lowry & Nunamaker, 2002). An example of thinkLet is a "LeafHopper" thinkLet, whose purpose is to have a group brainstorm ideas regarding a number of topics simultaneously. The detail description of this thinkLet can be found in Briggs et al. (2003). Each such thinkLet provides a concrete group dynamics intervention, complete with instructions for implementation as part of some group process. Researchers have formally documented approximately 70 such distinct thinkLets to date (Briggs et al., 2003). Field experiences suggest that these 70 thinkLets account for nearly 80% of a given collaboration process design. The other 20% of group interactions need to be designed with customized thinkLets for the group task at hand.

The underlying rationale behind the design of collaborative workflows using thinkLets is that each group task can be represented as a sequence of different collaboration patterns (thinkLets) with the goal of developing a process design (schema), which when executed (possibly repeatedly), can yield a predictable behavior from the group as a whole, while creating the different constituent patterns of collaboration among team members during the execution of a collaborative workflow.

Managerial Decision Support

As noted in earlier discussion, BPM systems involve BPA and BAM as key components for analysis and diagnosis of processes. These components can provide decision support for business managers who can track the performance of the business process from various standpoints such as productivity, and resource allocation. BPA primarily involves simulation of process models to improve the level of understanding of a business process and further assisting in limiting the amount of variation in the business process. BAM can benefit at multiple levels. At the activity level, it can provide the ability to track and monitor individual work requests, while at the process level, it can provide the ability to review resource productivity and work volume analysis.

BPA and BAM collectively can enable (re) engineering and optimization of business processes. Workflow audit history tracked by BAM tools may help in providing feedback on performance issues, which may be further analyzed to indicate bottlenecks in the process. Root causes for bottlenecks (such as ineffective process design and lack of resources) may be determined to reengineer the process.

FUTURE TRENDS

BPM systems are benefiting from advances in related areas of computing and information systems. Services science is one such emerging area where the focus is on provision and consumption of services. Each service is really a wrapper around a set of activities and would involve process-awareness for systems to fulfill and/or consume services.

In the same vein, work system framework, proposed by Alter, situates BPM systems in this broader context of services science. According to Alter, "a work system is a system in which human participants and/or machines perform work using information, technology, and other resources to produce products and services for internal or external customers" (Alter, 2006).

Also, Semantic Web is another area which has implications for BPM systems and decision making. Automated reasoning technologies and ontology-based frameworks founded primarily upon principles of RDF, OWL, and Description Logic, can be useful in improving decision making by associating semantics to process related information. Ongoing research in this area holds promise for the next generation of BPM systems for coordination, control, and decision making in organizations.

CONCLUSION

Recent advances in information technology are delivering decision support tools for enabling a variety of business activities. Hence, effective and efficient coordination and control between these activities is a key requirement of modern day organizations. In this article, we discussed the role of BPM systems in meeting this requirement. The discussion on the lifecycle of a workflow schema illustrates the contemporary workflow management approach. It is noted that facilitating integrated support for individual as well as group decision making involves many challenging issues and remains an open area for further research and development.

KEY TERMS

Business Process Management (BPM): Supporting business processes using methods, techniques, and software to design, enact, control, and analyze operational processes involving humans, organizations, applications, documents, and other sources of information

Business Process Management Systems (BPMS): A generic software system that is driven by explicit process designs to enact and manage operational business processes.

Collaboration Engineering: An approach for designing, modeling, and deploying repeatable collaboration tasks for recurring high-value collaborative workflows that are executed by practitioners (knowledge workers) without the ongoing intervention of facilitators.

Group Support System (GSS): A software system used for improving team productivity in collaboration tasks.

Group Decision Support Systems (GDSS): A type of GSS geared towards collaborative decision making tasks.

Organizational Decision Support System (ODSS): A decision support system focused on coordinating and disseminating decision making across functional areas and hierarchical layers such that decisions are congruent with organization goals and management's shared interpretation of the competitive environment.

Workflow: The automation of a business process, in whole or part, during which documents, information, or tasks are passed from one participant to another for action, according to a set of procedural rules.

Workflow Management System (WFMS): A software system that defines, creates, and manages the execution of workflows through the use of software, running on one or more process engines, which is able to interpret the process definition, interact with workflow participants, and, where required, invoke the use of IT tools and applications.

Chapter 4.16

An Application of Multi-Criteria Decision-Making Model for Strategic Outsourcing for Effective Supply-Chain Linkages

N. K. Kwak
Saint Louis University, USA

Chang Won Lee
Jinju National University, Korea

ABSTRACT

An appropriate outsourcing and supply-chain planning strategy needs to be based on compromise and more objective decision-making procedures. Although factors affecting business performance in manufacturing firms have been explored in the past, focuses are on financial performance and measurement, neglecting intangible and nonfinancial factors in the decision-making planning process. This study presents development of an integrated multi-criteria decision-making (MCDM) model. This model aids in allocating outsourcing and supply-chain resources pertinent to strategic planning by providing a satisfying solution. The model was developed based on the data obtained from a business firm producing intelligent home system devices. This developed model will reinforce a firm's ongoing outsourcing strategies to meet defined requirements while positioning the supply-chain system to respond to a new growth and innovation.

INTRODUCTION

In today's global age, business firms are no longer able to manage all supply-chain processes from new product development to retailing. In order to obtain a successful business performance, appropriate outsourcing and supply-chain practices should be identified, established, and implemented within the firm. The growth of business scale and scope forces business decision-makers to resolve many of the challenges confronting business firms. These tasks and activities are often not well-defined and ill-structured. This new paradigm in business practices can deliver unprecedented opportunities to establish the strategic outsourcing and supply-chain planning in business firms (Heikkila, 2002; Li & O'Brien, 2001). Due to the technology and market paradigm shift, strategic outsourcing and supply-chain planning process in business firms may become more tightly coupled with new product research and development, capacity and financial planning, product launching, project management, strategic business alliances, and revenue planning.

Successful linkages of these complicated processes play a critical role affecting business performance in manufacturing settings (Cohen & Lee, 1988; Fisher, 1997; Min & Zhou, 2002; Quinn & Hilmer, 1994). Strategic outsourcing and supply-chain planning is a growing requirement for improving productivity and profitability. Many outsourcing studies have been conducted with supply-chain linkages directly and indirectly as follows: capacity planning (Lee & Hsu, 2004), downsizing (Schniederjans & Hoffman, 1999), dual sourcing (Klotz & Chatterjee, 1995), information system decision (Ngwenyama & Bryson, 1999), line balancing (Liu & Chen, 2002), service selection (Bertolini, Bevilacqua, Braglia, & Frosolini, 2004), transportation mode choice (Vannieuwenhuyse, Gelders, & Pintelon, 2003), and vendor selection (Karpak, Kumcu & Kasuganti, 1999).

In spite of a plethora of outsourcing studies in the existing literature, multi-criteria decision making (MCDM) applications are scarce and seldom identified as the best practice in business areas. Especially, an integrated MCDM model comprising goal programming (GP) and analytic hierarchy process (AHP) is rarely applied to manage an emerging outsourcing and supply-chain concern. This chapter has dual purposes: (1) to develop a decision-making model that aims at designing a strategic outsourcing and supply-chain plan, and (2) to provide the decision-makers with an implication for effectively managing strategic outsourcing and supply-chain planning in business firms and other similar settings.

The chapter is organized in the following manner. The "Introduction" section presents current research issues in both strategic outsourcing and supply-chain planning and MCDM in a business setting. The next section "Multicriteria Decision Making" provides a review of MCDM models. After that, a problem statement of the case study along with description of data collection is described. The model development to a real-world setting and the model results and a sensitivity analysis are provided, followed by concluding remarks.

MULTI-CRITERIA DECISION MAKING

Multi-criteria decision making (especially integrated MCDM) is defined as an applied linear programming model for a decision process that allows the decision-maker to evaluate various competing alternatives to achieve certain goals. Relative importance is assigned to the goal with respect to a set of chosen criteria. MCDM is appropriate for situations in which the decision-maker needs to consider multiple criteria in arriving at the best overall decisions. In MCDM, a decision-makers select the best strategy among a number of alternatives that they evaluate on the basis of two or more criteria. The alternatives can involve risks and uncertainties; they may require sequential actions at different times; and a set of alternatives might be either finite or infinite. A decision-maker acts to maximize a value or utility function that depends on the chosen criteria. Since MCDM assumes that a decision-maker is to select among a set of alternatives, its objective function values are known with certainty. Many MCDM problems are formulated as multiple objective linear, integer, nonlinear, and/or interactive mathematical programming problems.

One of the most widely used MCDM models is goal programming (GP). Charnes and Cooper (1961) conceptualized the GP technique and applied to an analytical process that solves multiple, conflicting, and noncommensurate problems. There are many different methods and models used to generate solutions for GP models. The natural decision-making heuristic is to concentrate initially on improving what appears to be the most critical problem area (criterion), until it has been improved to some satisfactory level of performance.

Classical GP assumes that there are some absolute target levels that can be specified. This means that any solution cannot always satisfy all the goals. Thus, the objective of GP is to find a solution which comes as close as possible to the target.

The formulation of a GP model assumes that all problem constraints become goals from which to determine the best possible solution. There are two types of constraints in GP: goal constraints and systems constraints. Goal constraints are called the goal equations or soft constraints. Systems constraints are called the ordinary linear programming constraints or hard constraints which cannot be violated.

One major limitation of GP is that the decision-makers must subjectively prioritize goals in advance. The concept of nondominated (noninferior) solutions for noncommensurable goals cannot make an improvement of one goal without degrading other conflicting goals. Regardless of the weighting structures and the goals, GP can lead to inefficient and suboptimal solutions. These solutions are not necessarily optimal for the decision-maker to acquire so that a satisfying solution is provided.

Among the MCDM models, the analytical hierarchy process (AHP) is another popular decision-making tool for multi-criteria decision-making problems. AHP provides a method to assess goals and objectives by decomposing the problem into measurable pieces for evaluation using a hierarchical structure. The procedure requires the decision-maker to provide judgments about the relative importance of each criterion and then specify a preference on each criterion for decision alternatives. The output of AHP is a prioritized ranking indicating the overall preference for each of the decision alternatives. An advantage of AHP is that it enables the decision-maker to handle problems in which the subjective judgment of an individual decision-maker constitutes an important role of the decision-making process (see Saaty, 1980 for a detailed analysis).

PROBLEM BACKGROUND

Problem Statement

A consortium of seven different firms developing and manufacturing the related products of the smart home system for home security was established in Korea. The consortium firm has recently released the smart home system to the general public.

The consortium firm secured $20 million for new product development in the 5-year period (2004-2008). It currently possesses a world-class frontier for developing a smart home system. Each member company has its own unique, special knowledge and human resources to carry on required manufacturing. There are five primary systems for making a smart home system: (1) multifunction home server with an Internet gateway function, (2) intelligent context awareness-based agent system, (3) digital video recorder for home security and applications, (4) biokey system with fingerprint access control solution, and (5) wireless digital home controller functions. It is intended to support a further growth and innovation in home security, home automation, remote controlling, and mobile multimedia functions. The infusion of additional information technology must be consistent with the business mission, strategic direction, business plans, and priorities of the consortium firm.

This special project for an integrated intelligent information technology is intended to address the dramatic growth in information technology use, to foster continued innovation and adoption of new technologies, and to expand information technology foundation for the next-generation smart home system. Thus, the consortium's information technology investment strategies throughout the next five years have been developed.

Data Collection

The data utilized to formulate this MCDM model was collected from the consortium of business firms developing and manufacturing the smart home system for home security. All the necessary data on budget, technical services, and personnel resources was gathered through the consortium's strategic business units. Additional data for establishing the consortium's resource allocation model was collected through the consortium's international business development directors who are in charge of outsourcing and supply-chain management. Project managers participated in the strategic planning process and identified the necessary goals and criteria derived from the proposal for strategic outsourcing and supply-chain planning.

The data was validated by the consortium decision-makers in the outsourcing and supply-chain planning process. The validation of the consortium's resource allocation model is critical to accept the model solutions and to implement the result. The validation process provides the management with a meaningful source to ensure the input, decision-making process, and the outcomes.

The success of the model is based on the accurate measurement of the established goals and criteria. Decision-makers involved in the current outsourcing and supply-chain planning process to complete the validation reviewed the results of both prioritization of the goals, as well as the related projects/alternatives. Figure 1 presents a framework for strategic goals and related criteria.

MODEL DEVELOPMENT

Goal Decomposition and Prioritization

In the MCDM model development of outsourcing and supply-chain planning process, the AHP has been utilized for establishing goal decomposition and prioritization. In order to obtain the overall relative importance of the seven goals, a synthesized priority is calculated for each goal. The proposed model requires the evaluation of goals with respect to how much these goals affect the overall effectiveness of strategic outsourcing and supply-chain planning for resource allocation in the consortium firm. Since no prior quantitative data exists for each goal combination, the decision-maker will make pairwise comparisons of each goal with all others, using the AHP judgment scale.

The AHP values for goal prioritization provide their eigenvalue and consistency ratio. There are four derived criteria, such as financial (C_1), customer (C_2), internal business (C_3), and innovation and learning criteria (C_4).

Strategic outsourcing and supply-chain management is prioritized with AHP weights as follows: quality improvement (G_1), cost effectiveness (G_2), customer satisfaction (G_3), customizing services (G_4), manpower quality (G_5), supplier competency (G_6), and strategic partnership (G_7).

Figure 1. Strategic goals and criteria

Decision Variables

The integrated GP problem consists of two types of decision variables in this study. The consortium firm wants to contract for the supply of five different smart home system components. Five outsourcing suppliers are being considered for contracting on the system components. Tables 2 and 3 present the necessary information for decision variables and constraints. The decision variables are:

X^s_{ij} = decision variables for demand levels assigned to different types of component i (i =1,2,..,5) to be selected with various suppliers j (j =1,2,..,5) in demand capacity

where $X^s_i \geq 0$

X^p_{ij} = decision variables for project i (1, 2, 3, and 4) to which available amounts can be allocated over three-stage period j (1,2 and)

where:

$$X^p_{ij} = \begin{cases} 1 & \text{if ith project is selected} \\ 0 & \text{otherwise} \end{cases}$$

Constraints

The MCDM model has 37 constraints: 14 systems constraints and 23 goal constraints. Systems constraints for this consortium firm's outsourcing and supply-chain planning are (1) demand-supply constraints for each system component, and (2) supply-chain linkages on the number of certain projects development.

Systems constraint 1: Set the demand-supply constraints for five components. 14,400 units [displayed as 144(00)].

$$X^s_{11} + X^s_{12} + X^s_{13} + X^s_{14} + X^s_{15} \leq 144(00) \quad (1)$$

$$X^s_{21} + X^s_{22} + X^s_{23} + X^s_{24} + X^s_{25} \leq 360 \quad (2)$$

$$X^s_{31} + X^s_{32} + X^s_{33} + X^s_{34} + X^s_{35} \leq 380 \quad (3)$$

$$X^s_{41} + X^s_{42} + X^s_{43} + X^s_{44} + X^s_{45} \leq 420 \quad (4)$$

$X^s_{51} + X^s_{52} + X^s_{53} + X^s_{54} + X^s_{55} \leq 320$ (5)

$X^s_{11} + X^s_{21} + X^s_{31} + X^s_{41} + X^s_{51} = 300$ (6)

$X^s_{12} + X^s_{22} + X^s_{32} + X^s_{42} + X^s_{52} = 300$ (7)

$X^s_{13} + X^s_{23} + X^s_{33} + X^s_{43} + X^s_{53} = 300$ (8)

$X^s_{14} + X^s_{24} + X^s_{34} + X^s_{44} + X^s_{54} = 300$ (9)

$X^s_{15} + X^s_{25} + X^s_{35} + X^s_{45} + X^s_{55} = 300$ (10)

Systems constraint 2: Select one project for supply-chain management perspectives in each development stage.

$X^p_{11} + X^p_{12} + X^p_{13} = 1$ (11)

$X^p_{21} + X^p_{22} + X^p_{23} = 1$ (12)

$X^p_{31} + X^p_{32} + X^p_{33} = 1$ (13)

$X^p_{41} + X^p_{42} + X^p_{43} = 1$ (14)

There are seven goals to achieve in this study. Necessary goal priorities are presented next.

Priority 1 (P_1): Avoid overachievement of the financial resource level by providing appropriate system resources in terms of a continuous quality improvement goal (G_1), (See Table 3).

$$150X^p_{11} + 120X^p_{21} + 100X^p_{31} + 150X^p_{41} + 100X^p_{12} + 200X^p_{22} + 60X^p_{32} + 110X^p_{42} + 130X^p_{13} + 130X^p_{23} + 70X^p_{33} + 100X^p_{43} - d^+_1 = 1{,}420 \quad (15)$$

Priority 2 (P_2): Avoid underachievement of the budget level meeting to all outsourcing suppliers of $138(00,000) in terms of cost effectiveness goal (G_2), (See Table 2).

$$80X^s_{11} + 75X^s_{12} + 90X^s_{13} + 90X^s_{14} + 85X^s_{15} + 90X^s_{21} + 85X^s_{22} + 75X^s_{23} + 80X^s_{24} + 90X^s_{25} + 75X^s_{31} + 90X^s_{32} + 80X^s_{33} + 90X^s_{34} + 75X^s_{35} + 85X^s_{41} + 80X^s_{42} + 90X^s_{43} + 75X^s_{44} + 90X^s_{45} + 90X^s_{51} + 85X^s_{52} + 75X^s_{53} + 80X^s_{54} + 90X^s_{55} + d^-_2 = 138 \quad (16)$$

Priority 3 (P_3): Do not overutilize the available market resource level for each product development stage in terms of customer satisfaction goal (G_3), (See Table 3).

$$150X^p_{11} + 120X^p_{21} + 100X^p_{31} + 150X^p_{41} - d^+_3 = 520 \quad (17)$$

Table 2. Estimated price ($) per system component in each supplier group

Monthly Supply Level (00 units)	90	85	75	80	90	320
	300	300	300	300	300	

Table 3. Project categories and available budgets for three stages

Project Category	Product Development			Available Project Budget ($000)
	Stage 1	Stage 2	Stage 3	
Security	150	100	130	380
Automation	120	200	130	450
Remote control	100	60	70	230
Mobile multimedia	150	110	100	360
Total	520	470	430	1,420

$$100X^p_{12} + 200X^p_{22} + 60X^p_{32} + 110X^p_{42} - d^+_4 = 470 \tag{18}$$

$$130X^p_{13} + 130X^p_{23} + 70X^p_{33} + 100X^p_{43} - d^+_5 = 430 \tag{19}$$

Priority 4 (P_4): In terms of customizing services goal (G_4), avoid underachievement of resources to select an outsourcing supplier by using a total budget amount ($000) for (1) a home server outsourcing of $1,200; (2) an awareness agent component outsourcing of $3,060; (3) a digital recorder database component outsourcing of $3,200; (4) a biokey component outsourcing of $3,500; and (5) a controller box component outsourcing of $2,700 (see Table 2).

$$80X^s_{11} + 90X^s_{21} + 75X^s_{31} + 85X^s_{41} + 90X^s_{51} + d^-_6 = 1{,}200 \tag{20}$$

$$75X^s_{12} + 85X^s_{22} + 90X^s_{32} + 80X^s_{42} + 85X^s_{52} + d^-_7 = 3{,}060 \tag{21}$$

$$90X^s_{13} + 75X^s_{23} + 80X^s_{33} + 90X^s_{43} + 75X^s_{53} + d^-_8 = 3{,}200 \tag{22}$$

$$90X^s_{14} + 80X^s_{24} + 90X^s_{34} + 75X^s_{44} + 80X^s_{54} + d^-_9 = 3{,}500 \tag{23}$$

$$85X^s_{15} + 90X^s_{25} + 75X^s_{35} + 90X^s_{45} + 90X^s_{55} + d^-_{10} = 2{,}700 \tag{24}$$

Priority 5 (P_5): Implement projects in the three product development stages in terms of manpower balancing goal (G_5).

$$X^p_{11} + X^p_{12} + X^p_{13} + X^p_{14} + d^-_{11} – d^+_{11} = 1 \tag{25}$$

$$X^p_{21} + X^p_{22} + X^p_{23} + X^p_{24} + d^-_{12} - d^+_{12} = 1 \tag{26}$$

$$X^p_{31} + X^p_{32} + X^p_{33} + X^p_{34} + d^-_{13} - d^+_{13} = 1 \tag{27}$$

Priority 6 (P_6): Determine the demand capacity in each supplier to assign an appropriate outsourcing supplier group in terms of supplier competency goal (G_6).

$$X^s_{11} + X^s_{12} + X^s_{13} + X^s_{14} + X^s_{15} + d^-_{14} – d^+_{14} = 1 \tag{28}$$

$$X^s_{21} + X^s_{22} + X^s_{23} + X^s_{24} + X^s_{25} + d^-_{15} – d^+_{15} = 1 \tag{29}$$

$$X^s_{31} + X^s_{32} + X^s_{33} + X^s_{34} + X^s_{35} + d^-_{16} – d^+_{16} = 1 \tag{30}$$

$$X^s_{41} + X^s_{42} + X^s_{43} + X^s_{44} + X^s_{45} + d^-_{17} - d^+_{17} = 1 \quad (31)$$

$$X^s_{51} + X^s_{52} + X^s_{53} + X^s_{54} + X^s_{55} + d^-_{18} - d^+_{18} = 1 \quad (32)$$

Priority 7 (P_7): In terms of strategic supplier partnership goal (G_7), decision-makers in the consortium firm decide that all suppliers are assigned to supply a certain component.

$$X^s_{11} + X^s_{21} + X^s_{31} + X^s_{41} + X^s_{51} + d^-_{19} - d^+_{19} = 1 \quad (33)$$

$$X^s_{12} + X^s_{22} + X^s_{32} + X^s_{42} + X^s_{52} + d^-_{20} - d^+_{20} = 1 \quad (34)$$

$$X^s_{13} + X^s_{23} + X^s_{33} + X^s_{43} + X^s_{53} + d^-_{21} - d^+_{21} = 1 \quad (35)$$

$$X^s_{14} + X^s_{24} + X^s_{34} + X^s_{44} + X^s_{54} + d^-_{22} - d^+_{22} = 1 \quad (36)$$

$$X^s_{15} + X^s_{25} + X^s_{35} + X^s_{45} + X^s_{55} + d^-_{23} - d^+_{23} = 1 \quad (37)$$

Objective Function

The objective of this MCDM problem is to minimize the sum of the deviational variable values subject to constraints (1)-(37), satisfying the preemptive priority rules. The objective function depends on the preemptive priority sequence of the goals that have seven priorities.

$$\text{Minimize: } Z = \sum_{i=3}^{5}{}_1 d^{+}{}_{1}$$

$$+P_2 d \sum_{i=6}^{10}{}_2 + P_3\ d \sum_{i=11}^{13}{}_i$$

$$+ P_4\ d^{-}{}_{i} + P_5 \left(\sum_{i=14}^{18}{}^{+}{}_{i} + d^{-}{}_{i}\right)$$

$$+ P_6 \sum_{i=19}^{23} (d^{+}{}_{i} + d^{-}{}_{i}) + P_7\ (d^{+}{}_{i} + d^{-}{}_{i})$$

MODEL ANALYSIS

Model Solution and Discussion

In this MCDM model, decision-makers seek a solution that satisfies as close as possible a set of goals. Thus, GP requires the concept of measuring discrepancy from the goals. The concept of nondominated solutions for noncommensurable goals cannot make an improvement of one goal without a trade-off of other conflicting goals. In the GP problem, a nondominated solution is examined. A nondominated solution is defined in the following manner: a feasible solution to an MCDM problem which is efficient, if no other feasible solutions yield an improvement in one goal, without sacrificing another goal. This MCDM model was solved using AB: QM system software (Lee, 1996). Table 4 presents an analysis of the objective function. Table 5 exhibits the results of both decision and deviational variables.

Priority 1 (P_1) is to avoid overachievement of the financial resource level for continuous quality improvement (i.e., G_1). Priority 1 is fully satisfied ($P_1 = 0$). The related deviational variable (d^+_1) is zero.

Priority 2 (P_2) is to avoid underutilization of the budget level for cost effectiveness. Priority 2 is fully satisfied ($P_2 = 0$). The related deviational variable (d^-_2) is zero.

Priority 3 (P_3) is to not overutilize the available market resource level in each product development period for customer satisfaction. The management

* All other deviational variables are zero.

desires that their market resource of outsourcing should not be overutilized in each development stage 1 (d^+_3), stage 2 (d^+_4), and stage 3 (d^+_5). This third priority goal is fully satisfied ($P_3 = 0$), and its related deviational variables (d^+_3, d^+_4 and d^+_5) are zero.

Priority 4 (P_4) is to avoid underachievement of resources to select outsourcing suppliers who have the industrial leading knowledge in five different smart home system components, since the management considers that all five technology resources are highly unattainable. This priority goal is fully satisfied ($P_4 = 0$). Its related deviational variables are all zero: underachievement in home server technology outsourcing resources ($d^-_6 = 0$); underachievement in awareness agent technology outsourcing resources ($d^-_7 = 0$); underachievement in recorder database technology outsourcing resources ($d^-_8 = 0$); underachievement in biokey technology outsourcing resources ($d^-_9 = 0$); and underachievement in controller box technology outsourcing resources ($d^-_{10} = 0$).

Priority 5 (P_5) is to implement appropriately four projects in the three product development periods for securing outsourcing manpower balancing. This priority goal is partially satisfied ($P_5 = 1$). Its related deviational variables are not all zero ($d^+_{11} = 1$, $d^+_{12} = 0$, $d^+_{13} = 0$, $d^-_{11} = 0$, $d^-_{12} = 0$, $d^-_{13} = 0$). There is one project with overachievement. However, this does not mean that the goal is not achieved because four projects should be assigned in any product development stage.

Priority 6 (P_6) is to meet the demand-supply level to select an appropriate outsourcing supplier group for a supplier competency goal. This priority goal is partially satisfied ($P_6 = 1{,}495$). Its related deviational variables are not all zero ($d^+_{14} = 143$, $d^+_{15} = 235$, $d^+_{16} = 379$, $d^+_{17} = 419$, $d^+_{18} = 319$, $d^-_{14} = 0$, $d^-_{15} = 0$, $d^-_{16} = 0$, $d^-_{17} = 0$, $d^-_{18} = 0$). Table 6 indicates demand levels that are assigned to sup-

Table 6. Demand level assigned supplier groups to system components

plier groups for each system component. Supplier 1 is assigned to a demand level of 300 biokey components. Likewise, supplier 2 has demand levels of 280 recorder database and 20 control box components; supplier 3 for a demand level of 300 control box components; supplier 4 for demand levels of 144 home server, 36 awareness, and 120 biokey components; and supplier 5 for demand levels of 200 awareness agent and 100 recorder database components.

Priority 7 (P_7) is to assign certain contracts to supplier groups to achieve a strategic partnership goal. This priority goal is partially satisfied (P_6 = 1,495). Its related deviational variables are not all zero ($d^+_{19} = 299$, $d^+_{20} = 299$, $d^+_{21} = 299$, $d^+_{22} = 299$, $d^+_{23} = 299$, $d^-_{19} = 0$, $d^-_{20} = 0$, $d^-_{21} = 0$, $d^-_{22} = 0$, $d^-_{23} = 0$). Table 7 presents the selected projects assigned to each development stage. In stage 1, remote control function and mobile multimedia function will be recommended to develop. Home automation function will be developed in stage 2 and home security function in stage 3.

Mobile multimedia	X		

Outsourcing and supply-chain planning in supply-chain management perspective has become a significant and integral activity of strategic planning in a firm. The goals surrounding outsourcing and supply-chain planning decisions are complex and conflicting. Like other business decision making problems, outsourcing problems cannot derive a single optimal solution. Most top decision-makers agree that this planning process ultimately depends on a firm's business strategies, competitiveness roadmap, and business value and mission. In order to improve the system's overall effectiveness, decision-makers should recognize the ways to improve product quality, to enhance the internal and external customer satisfaction, to provide more strong commitment to manpower management, and to establish a sound alliance and collaboration with other business partners.

Sensitivity Analysis

Sensitivity analysis is an evaluation tool that is used once a satisfying solution has been found. It provides an insight into how satisfying solutions are affected by changes in the input data. Sensitivity analysis is performed with two scenarios. The management considers three goals (G_1, G_6, and G_7) to be evaluated. Quality improvement goal (G_1) and supplier competency goal (G_6) are changed (i.e., $P_{6\rightarrow} P_1$ and $P_{1\rightarrow} P_6$); and quality improvement goal (G_1) and strategic partnership goal (G_7) are changed (i.e., $P_{7\rightarrow} P_1$ and $P_{1\rightarrow} P_7$).

Table 8. Sensitivity analysis with two scenarios

Original Option		Revised Scenario 1		Revised Scenario 2	
Decision Variables	**Solution Value**	**Decision Variables**	**Solution Value**	**Decision Variables**	**Solution Value**

With sensitivity analysis available for the management, various scenarios can be evaluated more easily at less cost. Table 8 presents the results of two scenarios. It shows an important implication for strategic planning considering effective outsourcing and supplier management. Solution values of supplier decision variables in the original option and the revised scenarios indicate the new demand levels that are assigned to the supplier groups.

The top decision-makers in the consortium firm have accepted the final results as valid and feasible for implementing the outsourcing planning in their real business setting. The consortium firm has started its strategic outsourcing and supplier-customer management planning with ongoing base. The effects from these model outputs will be evaluated in the next fiscal year or two. The future outsourcing and supplier management planning agenda will be identified to compare with this proposed MCDM model for the strategic outsourcing planning. The strategic outsourcing planning based on the proposed MCDM model will provide the management with a significant insight to set an appropriate outsourcing strategy, while enhancing customer satisfaction and relationship management, and improving the firm's global competitiveness. Thus, the consortium firm currently reviews all these alternatives as possible outsourcing strategies.

CONCLUSION

This study presents an MCDM model for outsourcing and supply-chain planning in a smart home system components manufacturing industry in Korea. The proposed MCDM model will provide the management with better understanding of outsourcing and supply-chain planning. This proposed model would give a practical decision-making way for analyzing the outsourcing resource planning. This study indicates that the effective decision-making process in outsourcing and supply-chain planning can enforce the firm's competitive advantages and improve the firm's business performance. It is necessary to be able to assess the relative contribution of the individual member organizations within the supply chain. This requires a performance measurement system that can not only operate at several different levels but also link or integrate the efforts of these different levels to meeting the objectives of the supply chain.

When management considers several conflicting goals to achieve, subject to a set of constraints, MCDM models can provide effective decision-making results for strategic outsourcing and supply-chain planning in business operational environments. Subjective decision-making processes can make the multiple and complicated business problems into the worst situation of both business performance and business partnership due to the potential irrational decision-making. Thus, an appropriate use of MCDM models for effective decision-making is essential to create a long-term strategic plan for a competitive advantage and survival of any business organization in challenging environments.

Chapter 4.17

The Cognitive Process of Decision Making

Yingxu Wang
University of Calgary, Canada

Guenther Ruhe
University of Calgary, Canada

ABSTRACT

Decision making is one of the basic cognitive processes of human behaviors by which a preferred option or a course of actions is chosen from among a set of alternatives based on certain criteria. Decision theories are widely applied in many disciplines encompassing cognitive informatics, computer science, management science, economics, sociology, psychology, political science, and statistics. A number of decision strategies have been proposed from different angles and application domains such as the maximum expected utility and Bayesian method. However, there is still a lack of a fundamental and mathematical decision model and a rigorous cognitive process for decision making. This article presents a fundamental cognitive decision making process and its mathematical model, which is described as a sequence of Cartesian-product based selections. A rigorous description of the decision process in real-time process algebra (RTPA) is provided. Real-world decisions are perceived as a repetitive application of the fundamental cognitive process. The result shows that all categories of decision strategies fit in the formally described decision process. The cognitive process of decision making may be applied in a wide range of decision-based systems such as cognitive informatics, software agent systems, expert systems, and decision support systems.

INTRODUCTION

Decision making is a process that chooses a preferred option or a course of actions from among a set of alternatives on the basis of given criteria or strategies (Wang, Wang, Patel, & Patel, 2004; Wilson & Keil, 2001). Decision making is one of the 37 fundamental cognitive processes modeled in the layered reference model of the brain (LRMB) (Wang et al., 2004; Wang, 2007b). The study on decision making is interested in multiple disciplines such as cognitive informatics, cognitive science, computer science, psychology, management science, decision science, economics, sociology, political science, and statistics (Berger, 1990; Edwards & Fasolo, 2001; Hastie, 2001; Matlin, 1998; Payne & Wenger, 1998; Pinel, 1997; Wald, 1950; Wang et al., 2004; Wilson et al., 2001). Each of those disciplines has emphasized on a special aspect of decision making. It is recognized that there is a need to seek an axiomatic and rigorous model of the cognitive decision-making process in the brain, which may be served as the foundation of various decision making theories.

Decision theories can be categorized into two paradigms: the *descriptive* and *normative* theories. The former is based on empirical observation and on experimental studies of choice behaviors; and the latter assumes a rational decision-maker who follows well-defined preferences that obey certain axioms of rational behaviors. Typical normative theories are the expected utility paradigm (Osborne & Rubinstein, 1994) and the Bayesian theory (Berger, 1990; Wald, 1950). Edwards developed a 19-step decision-making process (Edwards et al., 2001) by integrating Bayesian and multi-attribute utility theories. Zachary, Wherry, Glenn, and Hopson (1982) perceived that there are three constituents in decision making known as the *decision situation*, the *decision maker*, and the *decision process*. Although the cognitive capacities of decision makers may be greatly varying, the core cognitive processes of the human brain share similar and recursive characteristics and mechanisms (Wang, 2003a; Wang & Gafurov, 2003; Wang & Wang, 2004; Wang et al., 2004).

This article adopts the philosophy of the *axiom of choice* (Lipschutz, 1967). The three essences for decision making recognized in this article are the *decision goals*, a set of *alternative choices*, and a set of *selection criteria* or strategies. According to this theory, decision makers are the engine or executive of a decision making process. If the three essences of decision making are defined, a decision making process may be rigorously carried out by either a human decision maker or by an intelligent system. This is a cognitive foundation for implementing expert systems and decision supporting systems (Ruhe, 2003; Ruhe & An, 2004; Wang et al., 2004; Wang, 2007a).

In this article, the cognitive foundations of decision theories and their mathematical models are explored. A rigorous description of decisions and decision making is presented. The cognitive process of decision making is explained, which is formally described by using real-time process algebra (RTPA). The complexity of decision making in real-world problems such as software release planning is studied, and the need for powerful decision support systems are discussed.

A MATHEMATICAL MODEL OF DECISIONS AND DECISION MAKING

Decision making is one of the fundamental cognitive processes of human beings (Wang et al., 2004; Wang, 2007a; Wang, 2007b) that is widely used in determining rational, heuristic, and intuitive selections in complex scientific, engineering, economical, and management situations, as well as in almost each procedure of daily life. Since decision making is a basic mental process, it occurs every few seconds in the thinking courses of human mind consciously or subconsciously.

This section explores the nature of selection, decision, and decision making, and their mathematical models. A rigorous description of decision making and its strategies is developed.

The Mathematical Model of Decision Making

The *axiom of selection* (or *choice*) (Lipschutz, 1967) states that there exists a selection function for any nonempty collection of nonempty disjoint sets of alternatives.

Definition 1. Let $\{A_i \mid i \in I\}$ be a collection of disjoint sets, $A_i \subseteq U$, and $A_i \neq \emptyset$, a function

$$c: \{A_i\} \rightarrow A_i,\ \ i \in I \tag{1}$$

is a *choice function* if $c(A_i) = a_i$, $a_i \in A_i$. Or an element $a_i \in A_i$ may be chosen by c, where A_i is called the set of alternatives, U the universal set, and I a set of natural numbers.

On the basis of the choice function and the axiom of selection, a decision can be rigorously defined as follows.

Definition 2. A *decision, d*, is a selected alternative $a \in \mathcal{A}$ from a nonempty set of alternatives $\mathcal{A}$, $\mathcal{A} \subseteq U$, based on a given set of criteria C, i.e.:

$$\begin{aligned} d &= f(\mathcal{A}, C) \\ &= f: \mathcal{A} \times C \rightarrow \mathcal{A},\ \ \mathcal{A} \subseteq U,\ \mathcal{A} \neq \emptyset \end{aligned} \tag{2}$$

where × represents a Cartesian product.

It is noteworthy that the criteria in C can be a simple one or a complex one. The latter is the combination of a number of joint criteria depending on multiple factors.

Definition 3. *Decision making* is a process of decision selection from available alternatives against the chosen criteria for a given decision goal.

According to Definition 2, the *number of possible decisions, n*, can be determined by the sizes of $\mathcal{A}$ and C, for example:

$$n = \#\mathcal{A} \bullet \#C \tag{3}$$

where # is the cardinal calculus on sets, and $\mathcal{A} \cap C = \emptyset$.

According to Eq.3, in case $\#\mathcal{A} = 0$ and/or $\#C = 0$, no decision may be derived.

The previous definitions provide a generic and fundamental mathematical model of decision making, which reveal that the factors determining a decision are the alternatives $\mathcal{A}$ and criteria C for a given decision making goal. A unified theory on fundamental and cognitive decision making can be developed based on the axiomatic and recursive cognitive process elicited from the most fundamental decision-making categories as shown in Table 1.

Strategies and Criteria of Decision Making

According to Definition 2, the outcomes of a decision making process are determined by the decision-making strategies selected by decision makers when a set of alternative decisions has been identified. It is obvious that different decision making strategies require different decision selection criteria. There is a great variation of decision-making strategies developed in traditional decision and game theories, as well as cognitive science, system science, management science, and economics.

The taxonomy of strategies and corresponding criteria for decision making can be classified into four categories known as *intuitive*, *empirical*, *heuristic*, and *rational* as shown in Table 1. It is noteworthy in Table 1 that the existing decision theories provide a set of criteria (C) for evaluating alternative choices for a given problem.

As summarized in Table 1, the first two categories of decision-making, *intuitive* and *empirical*, are in line with human intuitive cognitive psychology and there is no specific rational model for explaining those decision criteria. The rational

Table 1. Taxonomy of strategies and criteria for decision-making

No.	Category	Strategy	Criterion (*C*)
1	**Intuitive**		
1.1		Arbitrary	Based on the most easy or familiar choice
1.2		Preference	Based on propensity, hobby, tendency, expectation
1.3		Common senses	Based on axioms and judgment
2	**Empirical**		
2.1		Trial and error	Based on exhaustive trial
2.2		Experiment	Based on experiment results
2.3		Experience	Based on existing knowledge
2.4		Consultant	Based on professional consultation
2.5		Estimation	Based on rough evaluation
3	**Heuristic**		
3.1		Principles	Based on scientific theories
3.2		Ethics	Based on philosophical judgment and belief
3.3		Representative	Based on common rules of thumb
3.4		Availability	Based on limited information or local maximum
3.5		Anchoring	Based on presumption or bias and their justification
4	**Rational**		
4.1	Static		
4.1.1		Minimum cost	Based on minimizing energy, time, money
4.1.2		Maximum benefit	Based on maximizing gain of usability, functionality, reliability, quality, dependability
4.1.3		Maximum utility	Based on cost-benefit ratio
4.1.3.1		- Certainty	Based on maximum probability, statistic data
4.1.3.2		- Risks	Based on minimum loss or regret
		- Uncertainty	
4.1.3.3		- Pessimist	Based on maximin
4.1.3.4		- Optimist	Based on maximax
4.1.3.5		- Regretist	Based on minimax of regrets
4.2	Dynamic		
4.2.1		Interactive events	Based on automata
4.2.2		Games	Based on conflict
4.2.2.1		- Zero sum	Based on $\sum$ (gain + loss) = 0
4.2.2.2		- Non zero sum	Based on $\sum$ (gain + loss) $\neq$ 0
4.2.3		Decision grids	Based on a series of choices in a decision grid

decision-making strategies can be described by two subcategories: the *static* and *dynamic* strategies and criteria. The *heuristic* decision-making strategies are frequently used by human beings as a decision maker. Details of the heuristic decision-making strategies may be referred to cognitive psychology and AI (Hastie, 2001; Matlin, 1998; Payne et al., 1998; Wang, 2007a).

It is interesting to observe that the most simple decision making theory can be classified into the intuitive category such as arbitrary and preference choices based on personal propensity, hobby, tendency, expectation, and/or common senses. That is, a naïve may still be able to make important and perhaps wise decisions every day, even every few seconds. Therefore, the elicitation of the most fundamental and core process of decision making shared in human cognitive processes is yet to be sought in the following sections. Recursive applications of the core process of decision making will be helpful to solve complicated decision problems in the real world.

The Framework of Rational Decision Making

According to Table 1, rational and complex decision making strategies can be classified into the static and dynamic categories. Most existing decision-making strategies are static because the changes of environments of decision makers are independent of the decision makers' activities. Also, different decision strategies may be selected in the same situation or environment based on the decision makers' values and attitudes towards risk and their prediction on future outcomes. When the environment of a decision maker is interactive with his or her decisions or the environment changes according to the decision makers' activities and the decision strategies and rules are predetermined, this category of decision making needs are classified into the category of dynamic decisions such as games and decision grids (Matlin, 1998; Payne et al., 1998; Pinel, 1997; Wang, 2005a,b).

Definition 4. The *dynamic strategies and criteria* of decision-making are those that all alternatives and criteria are dependent on both the environment and the effect of the historical decisions made by the decision maker.

Classic dynamic decision making methods are decision trees (Edwards et al., 2001). A new theory of decision grid is developed in Wang (2005a,b) for serial decision making. Decision making under interactive events and competition is modeled by games (Matlin, 1998; Payne et al., 1998; von Neumann & Morgenstern, 1980; Wang, 2005a). Wang (2005a) presents a formal model of games, which rigorously describes the architecture or layout of games and their dynamic behaviors.

An overview of the classification of decisions and related rational strategies is provided in Figure 1. It can be seen that games are used to deal with the most complicated decision problems, which are dynamic, interactive, and under uncontrollable competitions. Further discussion on game theories and its formal models may be referred to von Neumann et al. (1980), Berger (1990), and Wang (2005a,b). Decision models may also be classified among others point of views such as structures, constraints, degrees of uncertainty, clearness and scopes of objectives, difficulties of information processing, degrees of complexity, utilities and beliefs, ease of formalization, time constraints, and uniqueness or novelty.

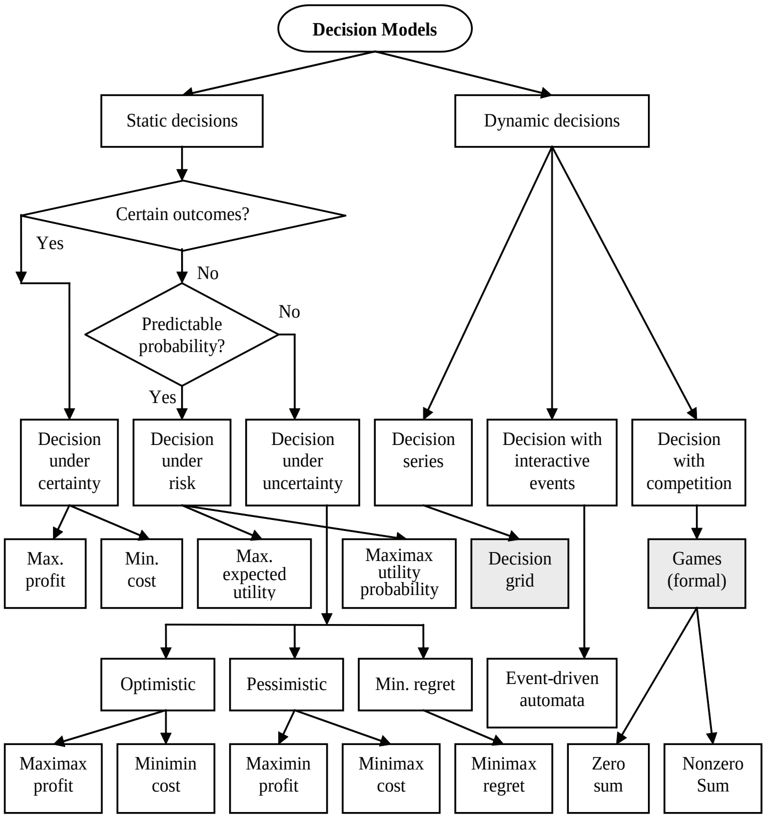
Typical Theories of Decision Making

Decision making is the process of constructing the choice criteria (or functions) and strategies and use them to select a decision from a set of possible alternatives. In this view, existing decision theories are about how a choice function may be created for finding a good decision. Different decision theories provide different choice functions. The following are examples from some of the typical decision paradigms as shown in Table 1.

(a) The Game Theory

In game theory (Osborne et al., 1994), a decision problem can be modeled as a triple, for example:

Figure 1. A framework of decisions and strategies



$$d = (\Omega, C, \mathcal{A}) \qquad (4)$$

where Ω is a set of possible states of the nature, C is a set of consequences, and $\mathcal{A}$ is a set of actions, $\mathcal{A} \subset C^{\Omega}$.

If an action $a \in \mathcal{A}$ is chosen, and the prevailing state is $\omega \in \Omega$, then a certain consequence $\alpha(\omega) \in C$ can be obtained. Assuming a probability estimation and a utility function be defined for a given action a as $p(a)$: $\mathsf{A} \rightarrow \Re$ and u: $C \rightarrow \Re$, respectively, a choice function based on the utility theory can be expressed as follows:

$$d = \{\ a\ |\sum_{\Omega} u[a(\omega)]p(a) = max\ (\sum_{\Omega} u[x(\omega)]p(x)) \wedge x \in \mathcal{A})\} \qquad (5)$$

(b) The Bayesian Theory

In Bayesian theory (Wald, 1950; Berger, 1990) the choice function is called a decision rule. A loss function, L, is adopted to evaluate the consequence of an action as follows:

$$L: \Omega \times \mathcal{A} \rightarrow \Re \qquad (6)$$

where Ω is a set of all possible states of nature, $\mathcal{A}$ is a set of actions, and $\Omega \times \mathcal{A}$ denotes a Cartesian product of choice.

Using the loss function for determining possible risks, a choice function for decision making can be derived as follows:

$$d = \{\ a\ |p[L(\omega,\alpha)] = \min_{x \in \mathrm{A}}(p[L(\omega,x)])\} \qquad (7)$$

where $p[L(\omega,\alpha)]$ is the expected probability of loss for action x on $\omega \in \Omega$.

Despite different representations in the utility theory and Bayesian theory, both of them provide alternative decision making criteria from different angles where loss in the latter is equivalent to the negative utility in the former. Therefore, it may be perceived that a decision maker who uses the utility theory is seeking optimistic decisions; and a decision maker who uses the loss or risk-based theory is seeking pessimistic or conservative decisions.

THE COGNITIVE PROCESS OF DECISION MAKING

The LRMB model has revealed that there are 37 interacting cognitive processes in the brain (Wang et al., 2004). Relationships between the decision-making process and other major ones in LRMB are shown in Figure 2. Figure 2 indicates that, according to UML semantics, the decision-making process inherits the *problem-solving* process. In other end, it functions by aggregations of or supported by the layer 6 processes *comprehension*, *qualification*, and *quantification*, as well as the layer 5 processes of *search*, *representation*, and *memorization*. Formal descriptions of these related cognitive processes in LRMB may be referred to in Wang (2003b), Wang et al., (2003), and Wang et al. (2003, 2004).

In contrary to the traditional *container* metaphor, the human memory mechanism can be described by a *relational* metaphor, which perceives that memory and knowledge are represented by the connections between neurons in the brain, rather than the neurons themselves as information containers. Therefore, the cognitive model of human memory, particularly the long-term memory (LTM) can be described by two fundamental artifacts (Wang et al., 2003): (a) *Objects*: The abstraction of external entities and internal concepts. There are also sub-objects known as *attributes*, which are used to denote detailed properties and characteristics of an object. (b) *Relations*: Connections and relationships between object-object, object–attributes, and attribute-attribute.

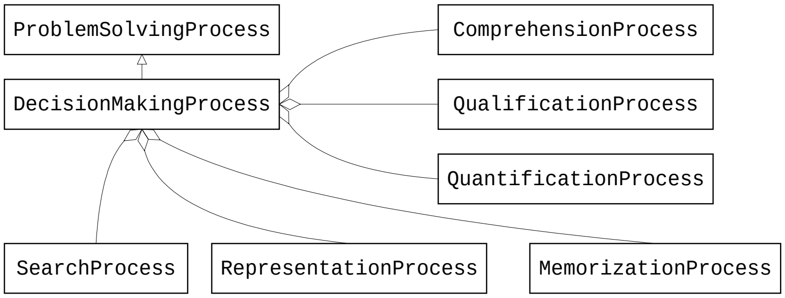
Based on the previous discussion, an object-attribute-relation (OAR) model of memory can be described as a triple (Wang & Wang, 2004; Wang et al., 2003), for example:

$$OAR = (O, A, R) \quad (8)$$

where O is a given object identified by an abstract name, A is a set of attributes for characterizing the object, and R is a set of relations between the object and other objects or attributes of them.

On the basis of the LRMB and OAR models developed in cognitive informatics (Wang, 2003a, 2007b), the cognitive process of decision making may be informally described by the following courses:

Figure 2. Relationships between decision-making process and other processes in LRMB

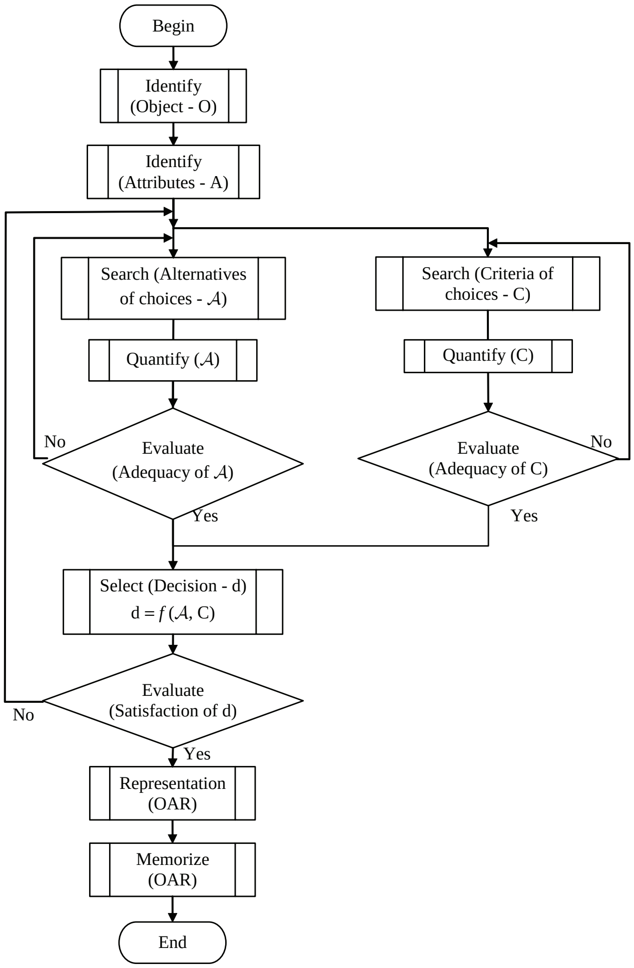


1. To comprehend the decision making problem and to identify the decision goal in terms of Object (O) and its attributes (A).
2. To search in the abstract layer of LTM (Squire, Knowlton, & Musen et al. 1993; Wang & Wang, 2004) for alternative solutions ($\mathcal{A}$) and criteria for useful decision strategies (C).
3. To quantify $\mathcal{A}$ and C and determine if the search should be go on.
4. To build a set of decisions by using $\mathcal{A}$ and C as obtained in previous searches.
5. To select the preferred decision(s) on the basis of satisfaction of decision makers.
6. To represent the decision(s) in a new sub-OAR model.
7. To memorize the sub-OAR model in LTM.

A detailed cognitive process model of decision making is shown in Figure 3 where a double-ended rectangle block represents a function call that involve a predefined process as provided in the LRMB model.

The first step in the cognitive process of decision making is to understand the given decision-making problem. According to the cognitive process of comprehension (Wang et al., 2003), the object (goal) of decision will be identified and an initial OAR model will be created. The object, its attributes, and known relations are retrieved and represented in the OAR model. Then, alternatives

Figure 3. The cognitive process of decision making



and strategies are searched, which result in two sets of $\mathcal{A}$ and C, respectively. The results of search will be quantified in order to form a decision as given in Eq. 2, for example: $d = f: \mathcal{A} \times C \rightarrow \mathcal{A}$, where $\mathcal{A} \subseteq U$ and $\mathcal{A} \neq \emptyset$.

When the decision d is derived, the previous OAR model will be updated with d and related information. Then, the decision maker may consider whether the decision is satisfied according to the current states of nature and personal judgment. If yes, the OAR model for the decision is memorized in the LTM. Otherwise, the decision-making process has to be repeated until a satisfied decision is found, or the decision maker chooses to quit without a final decision. During the decision making process, both the mind state of the decision maker and the global OAR model in the brain change from time to time. Although the state of nature will not be changed in a short period during decision making, the perception towards it may be changed with the effect of the updated OAR model.

As described in the LRMB model (Wang et al., 2004), the process of decision making is a higher-layer cognitive process defined at Layer 6. The decision making process interacts with other processes underneath this layer such as search, representation, and memorization, as well as the processes at the same layer such as comprehension, qualification, quantification, and problem solving. Relationships between the decision-making process and other related processes have been described in Figure 1 and in Wang and Wang (2004) and Wang et al. (2004).

FORMAL DESCRIPTION OF THE COGNITIVE DECISION MAKING PROCESS

On the basis of the cognitive model of decision making as described in Figure 3, a rigorous cognitive process can be specified by using RTPA (Wang, 2002; Wang, 2003b). RTPA is designed for describing the architectures, static and dynamic behaviors of software systems (Wang, 2002), as well as human cognitive behaviors and sequences of actions (Wang, 2003b; Wang et al., 2003).

The formal model of the cognitive process of decision making in RTPA is presented in Figure 4. According to LRMB and the OAR model of internal knowledge representation in the brain, the result of a decision in the mind of the decision maker is a new sub-OAR model, or an updated version of the global OAR model of knowledge in the human brain.

As shown in Figure 4, a decision-making process (DMP) is started by defining the goal of decision in terms of the object attributes. Then, an exhaustive search of the alternative decisions ($\mathcal{A}$) and useful criteria (C) are carried out in parallel. The searches are conducted in both the brain of a decision maker internally, and through external resources based on the knowledge, experiences, and goal expectation. The results of searches are quantitatively evaluated until the searching for both $\mathcal{A}$ and C are satisfied. If nonempty sets are obtained for both $\mathcal{A}$ and C, the n decisions in d have already existed as determinable by Eqs. 2 and 3.

It is noteworthy that learning results, experiences, and skills of the decision maker may dramatically reduce the exhaustive search process in DMP based on known heuristic strategies.

When one or more suitable decisions are selected from the set of d by decision makers via evaluating the satisfaction levels, satisfied decisions will be represented in a sub-OAR model, which will be added to the entire knowledge of the decision maker in LTM.

SOLVING COMPLEX PLANNING PROBLEMS BY DECISION SUPPORT SYSTEMS

The decision-making models and the formal description of the cognitive decision-making process

as presented in the second through fourth sections, can be used to address the solution of wicked planning problems in software engineering. Wicked planning problems are not only difficult to solve but also difficult to be explicitly formulated. The notion of a wicked planning problem was introduced by Rittel and Webber (1984), where several characteristics were given to classify a problem as wicked. One of them states that there is no definite formulation of the problem. Another one states that wicked problems have no stopping rule. So, in these cases, does it make sense to look into a more systematic approach at all or shouldn't we just rely on human intuition and personnel experience to figure out a decision?

A systematic approach for solving the wicked planning problem of software release planning was given in Ngo-The and Ruhe (2006). Release planning is known to be cognitively and computationally difficult (Ruhe & Ngo-The 2004).

Different kinds of uncertainties make it hard to be formulated and solved because real-world release planning problems may involve several hundred factors potentially affecting the decisions for the next release. Thus, a good release plan in decision-making is characterized as:

- It provides a maximum utility value from offering a best possible blend of features in the right sequence of releases.
- It is feasible to the existing hard constrains that have to be fulfilled.
- It satisfies some additional soft constraints sufficiently well. These soft constraints, for example, can be related to stakeholder satisfaction, consideration of the risk of implementing the suggested releases, balancing of resources or other aspects which are either hard to formalize or not known in advance.

It seems that uncertain software engineering decision problems are difficult to be explicitly modeled and completely formalized, since the constraints of organizations, people, technology, functionality, time, budget, and resources. Therefore, all spectrum of decision strategies as identified in Table 1 and Figure 1 need to be examined. This is a typical case where the idea of decision support arises when human decisions have to be made in complex, uncertain, and/or dynamic environments. Carlsson and Turban (2002) point out that the acceptance of theses systems is primarily limited by human related factors: (1) cognitive constraints, (2) understanding the support of such a model, (3) difficulty in handling large amounts of information and knowledge, and (4) frustration caused by complicated theories.

The solution approach presented in Ngo-The et al. (2006) address the inherent cognitive and computational complexity by (1) an evolutionary problem solving method combining rigorous solution methods to solve the actual formalization of the problem combined with the interactive involvement of the human experts in this process; (2) offering a portfolio of diversified and qualified solution at all iterations of the solution process; and (3) using the multi-criteria decision aid method ELECTRE (Roy, 1991) to assist the project manager in the selection of the final solution from the set of qualified solutions. Further research is ongoing to integrate these results with the framework of the decision-making models and the improved understanding of the cognitive process of decision-making as developed in this article.

CONCLUSION

Decision-making is one of the basic cognitive processes of human behaviors by which a preferred option or a course of actions is chosen from among a set of alternatives based on certain criteria. The interest in the study of decision-making has been widely shared in various disciplines because it is a fundamental process of the brain.

This article has developed an axiomatic and rigorous model for the cognitive decision-making process, which explains the nature and course in human and machine-based decision-making on the basis of recent research results in cognitive informatics. A rigorous description of the decision process in real-time process algebra (RTPA) has been presented. Various decision-making theories have been comparatively analyzed and a unified decision-making model has been obtained, which shows that existing theories and techniques on decision-making are well fit in the formally described decision process.

One of the interesting findings of this work is that the most fundamental decision that is recurrently used in any complex decision system and everyday life is a Cartesian product of a set of alternatives and a set of selection criteria. The larger both the sets, the more ideal the decisions generated. Another interesting finding of this work is that, although the cognitive complexities of new decision problems are always extremely high, they become dramatically simpler when a rational or formal solution is figured out. Therefore, the reducing of cognitive complexities of decision problems by heuristic feedbacks of known solutions in each of the categories of decision strategies will be further studied in intelligent decision support systems. According to case studies related to this work, the models and cognitive processes of decision-making provide in this article can be applied in a wide range of decision-support and expert systems.

Pearl Pu
Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland

ABSTRACT

Consumer decision support systems (CDSSs) help online users make purchasing decisions in e-commerce Web sites. To more effectively compare the usefulness of the various functionalities and interface features of such systems, we have developed a simulation environment for decision tasks of any scale and structure. Furthermore, we have identified three criteria in an evaluation framework for assessing the quality of such CDSSs: users' cognitive effort, preference expression effort, and decision accuracy. A set of experiments carried out in such simulation environments showed that most CDSSs employed in current e-commerce Web sites are suboptimal. On the other hand, a hybrid decision strategy based on four existing ones was found to be more effective. The interface improvements based on the new strategy correspond to some of the advanced tools already developed in the research field. This result is therefore consistent with our earlier work on evaluating CDSSs with real users. That is, some advanced tools do produce more accurate decisions while requiring a comparable amount of user effort. However, the simulation environment will enable us to efficiently compare more advanced tools among themselves, and indicate further opportunities for functionality and interface improvements.

INTRODUCTION

With the rising prosperity of the World Wide Web (WWW), consumers are dealing with an increasingly large amount of product and service information that is far beyond any individual's cognitive effort to process. In early e-commerce practice, online intermediaries were created. With the help of these virtual storefronts, users were able to find product information on a single Web site that gathers product information from thousands of merchants and service suppliers. Examples include shopping.yahoo.com, froogle.com, shopping. com, cars.com, pricegrabber.com, and so forth. However, due to the increasing popularity of electronic commerce, the amount of online retailers proliferated. As a result, there are now easily millions (or 16-20 categories) of brand-name products available on a single online intermediary Web site. Finding something is once again difficult, even with the help of various commercially available search tools.[1] Recently, much attention in e-commerce research has focused on designing and developing more advanced search and product recommender tools (Burke, Hammond, & Young, 1997; Pu & Faltings, 2000; Reilly, McCarthy, McGinty, & Smyth, 2004; Shearin & Lieberman, 2001; Shimazu, 2001; Stolze, 1999). However, they have been not employed in large scales in practicing e-commerce Web sites. Pu and Kumar (2004) gave some reasons as to why this is the case and when such advanced tools are expected to be adopted. This work was based on empirical studies of how users interact with product search tools, providing a good direction as to how to establish the true benefits of these advanced tools. However, insights gained from this work are limited. This is mainly due to the lack of a *large* amount of *real* users for the needed user studies and the high cost of user studies, even if real users were found. Each of the experiments reported in Pu and Kumar (2004) and Pu and Chen (2005) took more than 3 months of work, including the design and preparation of the study, the pilot study, and the empirical study itself. After the work was finished, it remains unclear whether a small amount of users recruited in an academic institution can forecast the behavior of the actual user population, which is highly diverse and complex.

Our main objective in this research is to use a simulation environment to evaluate various search tools in terms of interaction behaviors: what users' effort would be to use these tools and what kind of benefits they are likely to receive from these tools. We base our work on some earlier work (Payne, Bettman, & Johnson, 1993) in terms of the design of the simulation environment. However, we have added important elements to adapt such environments to online e-commerce and consumer decision support scenarios. With this simulation environment, we hope to more accurately forecast the acceptance of research tools in the real world, and curtail the evaluation of each tool's performance from months of user study to hours of simulation and a week of fine tuning the simulation results against a small but diverse amount of real users. This should allow us to evaluate more tools and, more importantly, discover design opportunities of new tools.

Our initial work of measuring the performance of various decision support strategies in e-commerce environments was reported in a conference paper (Zhang & Pu, 2005). The current article is an extended version of the conference paper. Besides adding significantly more details on the work already reported, there are a number of important and new contributions:

- In the conference paper, we only reported the performance evaluation results of various decision strategies such as the lexicographical (LEX) strategy, the elimination-by-aspects (EBA) strategy, and so forth; in this paper, we consider the evaluation of a consumer decision support system as an integral unit compromising decision strategies, user interfaces, and the underlying product catalog;
- In the extended effort-accuracy framework described in the conference paper, we only used a classical definition of decision accuracy; here we propose two new definitions of decision accuracy that correspond more precisely with a user's choice behavior in

e-commerce situations rather than the classical choice problem in decision literature;

- Based on the new definitions, we were able to draw more conclusions from the simulation results: not only can we establish that hybrid decision approaches can reduce user's effort while achieving a high level of decision accuracy, but we can also see some opportunities for improving consumer decision support systems by designing better interfaces and decision approaches, courtesy of the simulation environment.

This paper is organized as follows: the second section reviews some related research work; the third section defines the consumer decision support system (CDSS) and clarifies its relationship with our earlier published concepts on multi-attribute decision problem (MADP) and various decision strategies; the fourth section describes in detail the simulation environment for the performance evaluation of CDSSs; the fifth section describes the extended effort-accuracy framework consisting of three performance criteria: cognitive effort, elicitation effort, and decision accuracy; the sixth section reports the performance evaluation of various CDSSs with respect to a set of simulated MADPs and user preferences; the seventh section discusses the main research results obtained, followed by the conclusion section.

RELATED WORK

In traditional environments where no computer aid is involved, behavioral decision theory provides adequate knowledge describing people's choice behavior, and presents typical approaches of solving decision problems. For example, Payne et al. (1993) established a well-known effort-accuracy framework that described how people adapted their decision strategies by trading off accuracy and cognitive effort to the demands of the tasks they faced. The simulation experiments carried out in that work were able to give a good analysis of various decision strategies that people employ, and the decision accuracy they would expect to get in return.

In the online electronic environment where the support of computer systems is pervasive, we are interested in analyzing users' choice behaviors when tools are integrated into their information processing environments. That is, we are interested in analyzing when given a computer tool with its system logic, how much effort a user has to expend and how much decision accuracy he or she is to obtain from that tool. On one hand, though the decision maker's cognitive effort is still required, it can be significantly decreased by having computer programs carry out most of the calculation work automatically; on the other hand, the decision makers must expend some effort to explicitly state their preferences to the computer according to the requirements of the underlying decision support approach employed in that system. We would like to call this extra user effort (in addition to the cognitive effort) preference elicitation effort. We believe that elicitation effort plays an important role in the new effort-accuracy model of users' behavior in online choice environments.

Many other researchers have carried out simulation experiments in evaluating the performance of their systems or approaches. Payne et al. (1993) introduced a simulation experiment to measure the performance of various decision strategies in off-line situations. Recently, Boutilier (Boutilier, Patrascu, Poupart, & Schuurmans, 2005) carried out their experiments by simulating a number of randomly generated synthetic problems, as well as user responses to evaluate the performance of various query strategies for eliciting bounds of the parameters of utility functions. In Reilly et al. (2005), various users' queries were generated artificially from a set of off-line data to analyze the recommendation performance of the incremental critiquing approach. These related works generally suggest that simulating the interaction between users and the system is a promising methodology for performance evaluation. In our work, we go further in this direction and propose the general simulation environment that can be adopted to evaluate the performance of various CDSSs systematically within the extended effort-accuracy framework. To the best of our knowledge, our simulation work is the first attempt in systematically evaluating the performance of various CDSSs with simulation methodology.

CONSUMER DECISION SUPPORT SYSTEM

In a scenario of buying a product (such as a digital camera), the objective of consumers is to choose the product that most closely satisfies their needs and preferences (decision result), and furthermore, they are not likely to regret the products that they have bought (how accurate their decision is). They usually face a large amount of product alternatives (or options) and need a decision support system in order to process the entire product catalog without having to examine all items exhaustively. Therefore, a consumer decision support system consists of three components: (1) the product catalog that is accessible to consumers via an interface; (2) the underlying decision support approach that helps a consumer to choose and determine the product most satisfying his or her preferences; (3) the user interface with which a consumer interacts in order to state his or her preferences. We will now introduce these three components respectively.

The product catalog or more precisely an electronic product catalog (EPC) (Palmer, 1997; Torrens, 2002) provides a list of products, each one represented by a number of attributes. The process of determining the most preferred product from the EPC can be formally described as solving a multi-attribute decision problem[2] $\Psi = \langle \mathbf{X}, \mathbf{D}, \mathbf{O}, \mathbf{P} \rangle$, where $\mathbf{x}=\{x_1, ..., x_n\}$ is a finite set of attributes the product catalog has, $\mathbf{D}=D_1 \times ... \times D_n$ indicates the space of all possible products in the catalog (each $D_i (1 \leq i \leq n)$ is a set of possible domain values for attribute X_i), $\mathbf{O}=\{O_1,...,O_m\}$ is a finite set of available products (also called alternatives or outcomes) that the EPC offers, and $\mathbf{P}=\{P_1,...,P_t\}$ denotes a set of preferences that the decision maker may have. Each preference P_i may be identified in any form as required by the decision methods. The solution of a MADP is an alternative O most satisfying the decision maker's preferences.

In traditional decision making environments, consumers usually adopt various decision strategies such as EBA or LEX to obtain decision results (Payne et al., 1993). In a computer assisted scenario, the distribution of work is quite different. It is the CDSS that will perform these decision strategies to help the consumer to make decisions. The consumer is only required to input his or her preferences as required by the specific decision strategy; and then the solution can be chosen for the consumer automatically. When a decision strategy is adopted in the consumer decision support system, we also say it is a decision support approach for that system. In this paper, we focus on the following decision strategies and study the performance of CDSSs based on these decision strategies.

1. The weighted additive (WADD) strategy. It is a normative approach based on multi-attribute utility theory (MAUT) (Keeney & Raiffa, 1993). In our simulation experiment, we use it as the baseline strategy.
2. Some basic heuristic strategies. They are the equal weight (EQW) strategy, the elimination-by-aspects strategy, the majority-of-confirming dimensions (MCD) strategy, the satisficing (SAT) strategy, the lexicographic (LEX) strategy and the frequency of good and bad features (FRQ) strategy. Their detailed definitions can be found in Payne et al. (1993) and Zhang and Pu (2005).

3. Hybrid decision strategies. Besides the basic heuristic strategies, people may also use a combination of several of them to make a decision to try to get a more precise decision result. These kinds of strategies are called hybrid decision strategies. As a concrete example of hybrid decision strategies, The C4 strategy (Zhang & Pu, 2005), which is a combination of four basic heuristic strategies: EBA, MCD, LEX, and FRQ, is also studied in this paper.

In a CDSS, the user-interface component is used to obtain the consumers' preferences. However, such preferences are largely determined by the underlying decision support approach that has been adopted in the system. For example, the popular ranked list interface is in fact an interface implementing the lexicographical strategy. Also, if we adopt the weight additive strategy in a consumer decision support system, the user interface will be designed in the manner of asking the user to input corresponding weight and middle values for each attribute. In our current work, we assume the existence of a very simple user interface. Thus, we regard the underlying decision support approach as the main factor of the consumer decision support system.

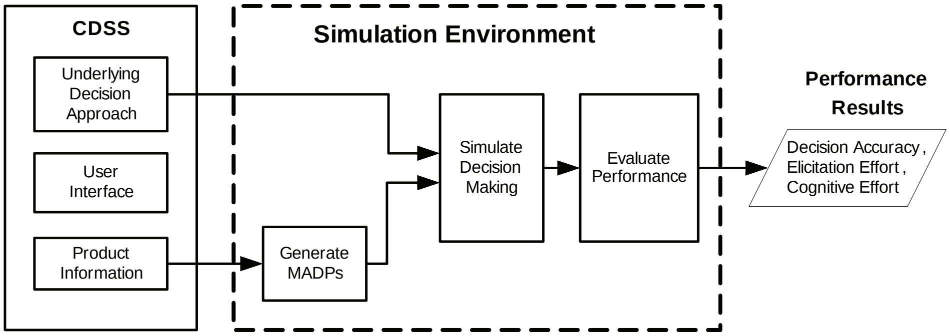
SIMULATION ENVIRONMENT FOR PERFORMANCE EVALUATION

Our simulation environment is concerned with the evaluation of how users interact with consumer decision support systems (CDSSs), how decision results are produced, and the quality of these decision results.

The consumer first interacts with the system by inputting his or her preferences through the user interface. With the help of decision support, the system generates a set of recommendations to the consumer. This interactive process can be executed multiple times until the consumer is satisfied with the recommended results (i.e., a product to purchase) or gives up due to loosing patience.

As shown in Figure 1, for a given CDSS, we evaluate its performance in a simulated environment by the following procedure: (1) we generate a set of MADPs using Monte Carlo method to simulate the presence of an electronic catalog up to any scale and structure characteristics; (2) we generate a set of consumer preferences also with the Monte Carlo method, taking into account user diversity and scale; (3) we carry out the simulation of the underlying decision approach of the CDSS to solve these MADPs; (4) we obtain associated decision results for the given CDSS (which product has been chosen given

Figure 1. An architecture of the simulation environment for performance evaluation of a given consumer decision support system



the consumer's preferences); and finally, (5) we evaluate the performance of these decision results in terms of cognitive effort, preference elicitation effort, and decision accuracy under the extended accuracy-effort framework (detailed discussion of this framework in the next section).

The simulation environment can be used in many ways to provide different performance measures of a given CDSS. For instance, if both the detail product information of CDSS and the consumer's preferences are unknown, we can simulate both the alternatives and the consumer's preferences, and the simulation results would be the performance of the CDSS independently of users and the set of alternatives; if the detail product information of the CDSS is provided, we then only need to simulate the consumer's preferences, and the alternatives of the MADPs can be copied from the CDSS instead of being randomly generated. The simulation results would be the performance of the CDSS under the specified product set.

As a concrete example to demonstrate the usage of such a simulation environment, we will show a procedure in evaluating the performance of various CDSSs in terms of the scale of the MADPs, which is determined by two factors: the number of attributes *n* and the number of alternatives *m*. Since we are trying to study the performance of different CDSSs (currently built on heuristic decision strategies) in different scales of MADPs, we assume that users and alternatives are both unknown and they are simulated to give results independently of the user and the system. More specifically, we classify the decision problems into 20 categories according to the scales of *n* (the number of attributes) and *m* (the number of alternatives): *n* has five values (5, 10, 15, 20, and 25), and *m* has four (10, 100, 1,000, and 10,000). To make the performance evaluation result more accurate, each time we randomly generate 500 different MADPs in the same scale and use their average performance as the final result. The detail simulation result will be reported in the experimental result section.

THE EXTENDED EFFORT-ACCURACY FRAMEWORK

The performance of the system can be evaluated by various criteria such as the degree of a user's satisfaction with the recommended item, the amount of time a user spends to reach a decision, and the decision errors that the consumer may have committed. Without real users' participation, the satisfaction of a consumer with a CDSS is hard to measure. However, the other two criteria can be measured.

The amount of time a user spends to reach a decision is equivalent to the amount of time he or she uses to express preferences and process the list of recommended items in order to reach a decision. The classical effort-accuracy framework mainly investigated the relationship of decision accuracy and cognitive effort of processing information by different decision strategies in the off-line situation. In the online decision support situation, however, the effort of eliciting preferences must be considered as well.

Furthermore, most products carry a fair amount of financial and emotional risks. Thus, the accuracy of users' choices is extremely important. That is, there is a posterior process where users evaluate the search tools in terms of whether the products they have found via the search tool are really what they want and whether they had enough decision support. This is what we mean by decision accuracy.

We therefore propose an extended effort-accuracy framework by explicitly measuring three factors of a given consumer decision support system: cognitive effort, elicitation effort, and decision accuracy. In the remainder of this section, we first recall the measurement of cognitive effort in the classical framework, we give various definitions of accuracy, and then we detail the method of measuring elicitation effort. Finally, the cognitive and elicitation effort of these decision strategies are analyzed in section 5.4, in an online situation.

Measuring Cognitive Effort

Based upon the work of Newell and Simon (1972), a decision approach can be seen as a sequence of elementary information processes (EIPs), such as reading the values of two alternatives on an attribute, comparing them, and so forth. Assuming that each EIP takes equal cognitive effort,[3] the decision maker's cognitive effort is then measured in terms of the total number of EIPs. Conformed with the classical framework, a set of EIPs for the decision strategies is defined as (1) READ: read an alternative's value on an attribute into short-term memory (STM), (2) COMPARE: compare two alternatives on an attribute, (3) ADD: add the values of two attributes in STM, (4) DIFFERENCE: calculate the size of the difference of two alternatives for an attribute, (5) PRODUCT: weight one value by another, (6) ELIMINATE: eliminate an alternative from consideration, (7) MOVE: move to next element of the external environment, and (8) CHOOSE: choose the preferred alternative and end the process.

Measuring Decision Accuracy

Accuracy and effort form an important performance measure for the evaluation of consumer decision support systems. On one hand, consumers expect to get highly accurate decisions. On the other hand, they may not be inclined (or able) to expend a high level of cognitive and elicitation effort to reach a decision. Three important factors influence the decision accuracy of a consumer decision support systems: the underlying decision approach used; the number of interactions required from the end user (if a longer interaction is required, a user may give up before he finds the best option); the number of options displayed to the end user in each interaction cycle (a single item is likely to miss the target choice compared to a list of items; however, a longer list of items requires more cognitive effort to process information). In our current framework, we investigate the combined result of these three factors (i.e., decision approach as well interface design components) of a given consumer decision support system.

In the following sections, we start with classical definitions of decision accuracy, analyze their features and describe their weaknesses for the online environments, and then we propose two definitions, which we have developed, that are likely to be more adequate for measuring decision accuracy in e-commerce environments. To eliminate the effect of a specific set of alternatives on the decision accuracy results, in the following definitions we assume that there is a set of N different MADPs to be solved by a given consumer decision support system that implements a particular decision strategy S. The accuracy will be measured in average among all those MADPs.

Accuracy Measured by Selection of Nondominated Alternatives

This definition comes from Grether and Wilde (1983). After adapting it to decision making with the help of a computer system, this definition says that a solution given by CDSS is correct if and only if it is non-dominated by other alternatives. So the decision accuracy can be measured by the numbers of solutions which are *Pareto optimal* (i.e., not dominated by other alternatives, see also Viappiani, Faltings, Schickel-Zuber, & Pu, 2005). We use O_S^i to represent the optimal solution given by the CDSS with strategy S when solving $MADP_i (1 \le i \le N)$. The accuracy of selection of nondominated alternatives $Acc_{NDA}(S)$ is defined as the following:

$$Acc_{NDA}(S) = \frac{N - \sum_{i=1}^{N} \text{Dominated}(O_S^i)}{N}, \quad (1)$$

where

$$\text{Dominated}(O_S^i) = \begin{cases} 1 & \text{if } O_S^i \text{ is dominated in } MADP_i \ (1 \le i \le N) \\ 0 & else \end{cases}$$

According to this definition, it is easy to see that a system employing the WADD strategy has 100% accuracy because all the solutions given by WADD are *Pareto optimal*. Also, this definition of accuracy measurement is effective only when the system contains some dominated alternatives, otherwise the accuracy of the system is always 100%.

This definition of accuracy can distinguish the errors caused by choosing dominated alternatives of the decision problems. However, measuring decision accuracy using this method is limited in e-commerce environments. In an efficient market, it is unlikely that the consumer products or business deals are dominated or dominating. That is, it is unlikely an apartment would be both spacious and less expensive compared to other available ones. We believe that although this definition is useful, it is not helpful to distinguish various CDSSs in terms of how good they are for supporting users to select the best choice (not just the nondominated ones).

Accuracy Measured by Utility Values

This definition of measuring accuracy was used in the classical effort-accuracy framework (Payne et al., 1993). Since no risk or uncertainty is involved in the MADPs, the expected value of an alternative is equivalent to the utility value of each alternative. The utility value of each alternative is assumed to be in the weight additive form. Formally, this accuracy definition can be represented as:

$$Acc_{UV}(S) = \frac{\sum_{i=1}^{N} \frac{V(O_S^i)}{V(O_{WADD}^i)}}{N}, \qquad (2)$$

where $V(O_S^i)$ is the value function given by the WADD strategy in $MADP_i$. In this definition, a system employing the WADD strategy is also 100% accurate because it always gives out the solution with the maximal utility value.

One advantage of this measure of accuracy is that it can indicate not only that an error has occurred, but also the severity of the error of the decision making. For instance, a system achieving 90% accuracy indicates that an average consumer is expected to choose an item that is 10% less valuable from the best-possible option. While this definition is useful for choosing a set of courses to take for achieving a particular career objective, it is not most suitable in e-commerce environments. Imagine that someone has chosen and purchased a digital camera. Two months later, she discovers that the camera that her colleague has bought was really the one she wanted. She did not see the desired camera, not because the online store did not have it, but because it was difficult to find and compare items on the particular e-commerce Web site. Even though the camera that she bought satisfied some of her needs, she is still likely to feel a great sense of regret, if not outright disappointment. Her likelihood of returning to that Web site is in question. Given that bad choices can cause great emotional burdens (Luce, Payne, & Bettman, 1999), we have developed the following definition of decision accuracy.

Accuracy Measured by Selection of Target Choice

In our earlier work(Pu & Chen, 2005), we defined decision accuracy as measured by the percentage of users who have chosen the right option using a particular decision support system. We call that option the target choice. In empirical studies with real users, we first asked users to choose a product with the consumer decision support system, and then we revealed the entire database to them in order to determine the target choice.

If the product recommended by the consumer decision support system was consistent with the target choice, we said that the user had made an accurate decision.

In simulation environment, we take the WADD strategy as the baseline. That is, we assume the solution given by WADD is the user's final most-preferred choice. For another given strategy *S*, if the solution O_S^i is the same as the one determined by WADD, then we count it as one *hit* (this definition is called the *hit ratio*). The accuracy is measured statistically by the ratio of hit numbers to the total number of decision problems:

$$Acc_{HR}(S) = \frac{\sum_{i=1}^{N} Hit(O_S^i)}{N}, \qquad (3)$$

where

$$Hit(O_S^i) = \begin{cases} 1 & \text{if } O_S^i = O_{WADD}^i \text{ in } MADP_i \\ 0 & \text{else} \end{cases}$$

This measure of decision accuracy is ideally consistent with the consumers' attitude towards the decision results. However, by this definition, it is assumed that the consumer decision support system only recommends one product to the consumer each time. In reality, the system may show a list of possible products to the consumer, and the order of the product list is also important to the consumer: the products displayed at the top of the list are more likely to be selected by the consumer. Therefore, we have developed the following definition to take into account that a list of products is displayed, rather than a single product.

Accuracy Measured by Selection of Target Choice Among K-best Items

Here we propose measuring the accuracy of the system according to the ranking orders of the K-best products it displays. This is an extension of the previous definition of accuracy. For a given $MADP_i$, instead of using strategy *S* to choose a single optimal solution, we can use it to generate a list of solutions with ranking order $L_S^i = \{O_{S,1}^i, O_{S,2}^i, \ldots, O_{S,K}^i\}$, where $O_{S,1}^i$ is the most-preferred solution according to the strategy S, and $O_{S,2}^i$ is the second-preferred solution, and so on. The first *K-best* solutions consist of the solution list. If the user's final choice (which is assumed to be given by the WADD strategy O_{WADD}^i) is in the list, we assign a *rank value* to the list according to the position of O_{WADD}^i in the list. Formally, we define this accuracy of choosing K-best items as:

$$Acc_{HR\_in\_Kbest}(S) = \frac{\sum_{i=1}^{N} RankValue(L_S^i)}{N}, \qquad (4)$$

where

$$RankValue(L_S^i) = \begin{cases} 1 - \frac{k-1}{K} & \text{if } O_{S,k}^i = O_{WADD}^i \text{ in } MADP_i \quad (1 \le k \le K, 1 \le n \le N) \\ 0 & else \end{cases}$$

According to this definition, the WADD strategy still achieves 100% accuracy and is used as the baseline. A special case of this accuracy definition is that when *K=1*, it degenerates to the previous definition of *hit ratio.* In the simulation experimental results that we will show shortly, we have set *K* to 5.

In practice, it is required to eliminate the effect of random decision, and we expect that the strategy of *random choice* (selecting an alternative randomly from the alternative set, denoted as *RAND* strategy) could only produce *zero* accuracy. By doing so, we define the *relative accuracy* of the consumer decision support system with strategy *S* according to different definitions as:

$$RA_Z(S) = \frac{Acc_Z(S) - Acc_Z(RAND)}{1 - Acc_Z(RAND)}, \qquad (5)$$

where

Z= NDA, UV, HR, or HR_in_Kbest.

For example, $RA_{HR}(LEX)$ denotes the relative accuracy of the *LEX* strategy under the accuracy measure definitions of *hit ratio.*

From the previous definitions, we can see that each definition represents one aspect of the accuracy of the decision strategies. We think that the definitions of *hit ratio* and *K-best items* are more suitable to measure the accuracy of various consumer decision support systems, particularly in e-commerce environments. In the sixth section, we will study the performance of various decision strategies with these accuracy measurement definitions.

Measuring Elicitation Effort

In computer-aided decision environments, a considerable amount of decision effort goes into preference elicitation since people need to "tell" their preferences explicitly to the computer system. So far, no formal method has been given to measure the preference elicitation effort. An elicitation process can be decomposed into a series of basic interactions between the user and the computer, such as selecting an option from a list, filling in a blank, answering a question, and so forth. We call these basic interaction actions elementary elicitation processes (EEPs). In our analysis, we define the set of EEPs as follows: (1) SELECT: select an item from a menu or a dropdown list, (2) FILLIN: fill in a value to an edit box, (3) ANSWER: answer a basic question, (4) CLICK: click a button to execute an action.[4]

It is obvious that different EEPs require different elicitation effort (for instance, the EEP of one CLICK would be much easier than an EEP of FILLIN a weight value for a given attribute). For the sake of simplification, we currently assume that each EEP requires an equal amount of effort from the user. Therefore, given a specific decision approach, elicitation effort is measured by the total amount of EEPs it may require.

This elicitation effort is a new factor for the online environment. The main difference between cognitive effort and elicitation effort lies in the fact that cognitive effort is a description of the mental activities in processing information, while the elicitation effort is about the interaction effort between the decision maker and the computer system through predesigned user interfaces. Even though the decision makers already have clear preferences in their mind, they must still state their preferences in a way that the computer can "understand." With the help of computer systems, the decision maker is able to reduce the cognitive effort by compensating with a certain degree of elicitation effort.

Let us consider a simple decision problem with three attributes and four alternatives. When computer support is not provided, the cognitive effort of solving this problem by the WADD strategy will be 24 READS, 8 ADDS, 12 PRODUCTS, 3 COMPARES, and 1 CHOOSE. The total number of EIPs is therefore 48.[5]

However, with the aid of a computer system, the decision maker could get the same result by spending two units of elicitation effort (FILLIN the weight value of first two attributes) and one unit of cognitive effort (CHOOSE the final result).

Analysis of Cognitive and Elicitation Effort

With the support of computer systems, the cognitive effort for WADD, as well as the basic heuristic strategies, is quite low. The decision maker inputs his or her preferences, and the decision support system executes that strategy and shows the proposed product. Then the decision maker chooses this product and the decision process is ended. Thus, the cognitive effort is equal to one EIP: CHOOSE the final alternative and exit the process. For the *C4* strategy, the cognitive effort of solving an MADP with *n* attributes and *m* alternatives is equal to that of solving a problem with *n* attributes and *4* alternatives in the traditional situation, the cognitive effort of which has been studied in (Payne et al., 1993).

According to their definitions, various decision strategies require that preferences with different parameters be elicited. For example, in the WADD strategy, the component value function and the weight for each attribute must be obtained, while for the EBA strategy, the importance order and cutoff value for each attribute are required. The required parameters for each strategy are shown in Table 1.

For each parameter in the aforementioned strategies, a certain amount of elicitation effort is required. This elicitation effort may vary with different implementations of the user interface. For example, to elicit the weight value of an attribute, the user can just FILLIN the value to an edit box, or the user can ANSWER several questions to approximate the weight value. In our analysis and the following simulation experiments, we follow the *at least* rule: the elicitation effort is determined by the least number of EEP(s). In the above example, the elicitation effort for obtaining a weight value is measured as 1 EEP.

SIMULATION RESULTS

In this section, we report our experimental results of the performance of various consumer decision support systems under the simulation environment that was introduced earlier. To simplify the experiments, we only evaluate those CDSSs built on the decision strategies listed in Table 1. Without loss of generality, we will also use the term *decision strategy* to represent the CDSS built on that decision strategy.

Table 1. Elicitation effort analysis of decision strategies

Strategy	**Parameters required to be elicited**
WADD	Weights, component value functions
EQW	Component value functions
EBA	Importance order, cutoff values
MCD	*None*
SAT	Cutoff values
LEX	Importance order
FRQ	Cutoff values for good and bad features
C4	Cutoff values, importance order

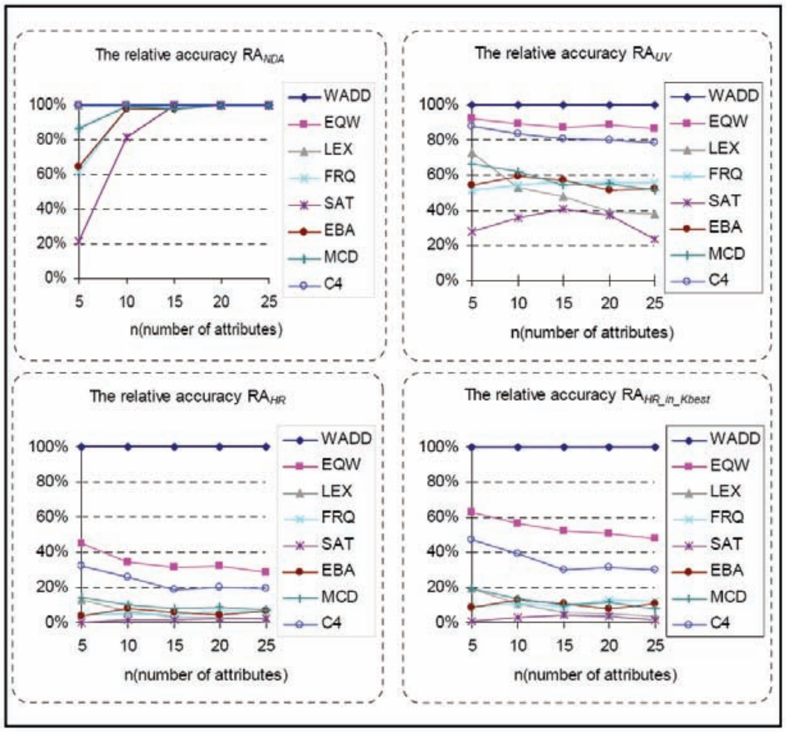
For each CDSS, we first simulate a large variety of MADPs, and then run the corresponding decision strategy on the computer to generate the decision results. Then the elicitation effort and decision accuracy are calculated according to the extended effort-accuracy framework. For each MADP, its domain values for a given attribute are determined randomly: the lower bound of each attribute is set to 0, and the upper bound is determined randomly from the range of 2 to 100. Formally speaking, for each attribute X_i, we define $D_i = [0,z_i]$ where $z_i \in [2,100]$.

As shown in Table 1, each decision strategy (except MCD) requires the elicitation of some specific parameters such as attribute weights or cutoff values to represent the user's preferences. To simulate the component value functions required by the WADD strategy, we assume that the component value function for each attribute is approximated by three midvalue points, which are randomly generated.[6] Thus, each component value function requires three units of EEPs. Other required parameters, such as the weight and cutoff value (each requires one unit of EEP) for each attribute are also simulated by the random generation process. The order of importance is determined by the weight order of the attributes for consistency.

In our simulation experiments, the WADD strategy is appointed as the baseline strategy, and the relative accuracy of a strategy is calculated according to equation (5). The elicitation effort is measured in terms of the total number of EEPs required by the specific strategy, and the cognitive effort is measured by the required units of EIPs. Since the relationship between accuracy and cognitive effort has already been studied and analyzed by Payne et al. (1993), in this section, we only focus on the performance of each strategy in terms of decision accuracy and elicitation effort.

Figure 2 shows the changes in *relative accuracy* with four different accuracy measure definitions for the listed decision strategies as *the number of attributes* increases in the case that each MADP has 1,000 alternatives. In all cases, the WADD is the baseline strategy; thus it achieves 100% accuracy. When measured by the selection of nondominated alternatives (RA_{NDA}), the relative accuracy of each heuristic strategy increases as the number of alternatives increases. This is mainly because the alternatives are more likely to be *Pareto optimal* when more attributes are involved. Furthermore, the RA_{NDA} of all strategies could achieve 100% accuracy when the attributes number is 20 or 25. This shows that the RA_{NDA} is not able to distinguish the decision errors occurred with the heuristic strategies in the simulated environment. When the accuracy is measured under the definitions of $\mathrm{RA}_{\mathrm{UV}}$, $\mathrm{RA}_{\mathrm{HR}}$ and $\mathrm{RA}_{\mathrm{HR\_in\_Kbest}}$, the EQW strategy achieves the highest accuracy besides the baseline WADD strategy, and the SAT strategy has the lowest relative accuracy. The four basic heuristic strategies EBA, MCD, LEX, and FRQ are in the middle-level range. The LEX strategy, which has been widely adopted in many consumer decision support systems, is the least accurate strategy among the EBA, FRQ, and MCD strategies when there are over 10 attributes. When the accuracy is measured by $\mathrm{RA}_{\mathrm{UV}}$, the EQW strategy could gain over 90% relative accuracy, while it could only achieve less than 50% relative accuracy when measured by $\mathrm{RA}_{\mathrm{HR}}$. This comparison generally suggests that most of the decision results given by EQW strategy may be very close to a user's target choice (which is determined by the

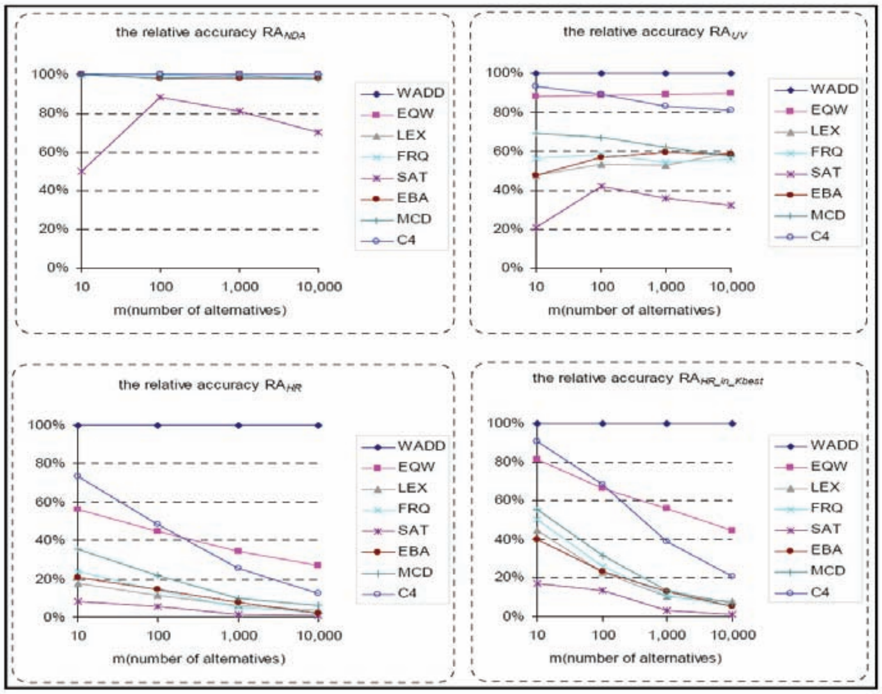
Figure 2. The relative accuracy of various decision strategies when solving MADPs with different number of attributes, where m*(number of alternatives)* = 1,000



WADD strategy), but are not identical. Also, in all cases, the accuracy measured by $RA_{HR\_in\_Kbest}$ (where *K=5* in the experiment) is always higher than that measured by $\mathrm{RA}_{\mathrm{HR}}$ (which is a special case of $RA_{HR\_in\_Kbest}$ when *K=1*). This shows that under this definition, the possibility of containing the final target choice in a K-item list is higher when K is larger. Of particular interest is that the proposed *C4* strategy, which is a combination of the four basic strategies, could achieve a much higher accuracy than any of them alone. For instance, when there are 10 attributes and 1,000 alternatives in the MADPs, the relative accuracy of *C4* strategy could exceed the average accuracy of the four basic strategies by over 27% when the definition of $RA_{HR\_in\_Kbest}$ is adopted.

Figure 3 shows the relationship between *relative accuracy* and *the number of alternatives* (or the number of available products in a catalog) for the listed decision strategies. When the accuracy is measured by the selection of nondominated alternatives (RA_{NDA}), all strategies except SAT could gain nearly 100% of relative accuracy without a significant difference. This generally shows that the RA_{NDA} is not a good definition of accuracy measurement in the simulated environment. When the accuracy is measured by the utility values (RA_{UV}), the accuracy of the heuristic strategies remains stable as the number of alternatives increases. With the definitions of *hit ratio* (RA_{HR}) and *hit ratio in K-best items* ($\mathrm{RA}_{HR\_in\_Kbest}$), however, the heuristic strategies strongly descend into a lower range of accuracies as the size of a catalog increases. This corresponds to the fact that consumers have increasing difficulties finding the best product as the number of alternatives in the catalog increases. The *C4* strategy, though its accuracy decreases when the number of alternatives increases, could still maintain a considerably higher relative accuracy than that of the EBA, MCD, LEX, and FRQ strategies when using the accuracy definition of RA_{HR} and $RA_{HR\_in\_Kbest}$.

Figure 3. The relative accuracy of various decision strategies when solving MADPs with a different number of alternatives, where n*(number of attributes)* = 10



The effect of the number of attributes on elicitation effort for each strategy is shown in Figure 4. As we can see, the elicitation effort of the heuristic strategies increases much slower than that of the WADD strategy as the number of attributes increases. For instance, when the number of attributes is *20*, the elicitation effort of the FRQ strategy is only about *25%* of that of WADD strategy. The FRQ and SAT strategies require the same level of elicitation effort, since both of them require the decision maker to input a cutoff value for each attribute. Except the MCD strategy, which requires no elicitation effort in the simulation environment, the LEX strategy is the one that requires the least elicitation effort in all cases among the listed strategies. The combined C4 strategy, which could share preferences among its four underlying basic strategies, requires only a slightly higher elicitation effort than the EBA strategy.

Figure 5 shows the relationship between *elicitation effort* and *the number of alternatives* for each strategy. As the number of alternatives increases exponentially, the level of elicitation effort for WADD, EQW, MCD, SAT, and FRQ strategies remains unchanged. This shows that the elicitation effort of these strategies is unrelated to the number of alternatives that a decision problem may have. For the LEX, EBA, and *C4* strategies, the elicitation effort increases slowly as the number of alternatives increases. As a whole, Figure 5 shows that the elicitation effort of the studied decision strategies is quite robust to the number of alternatives that a decision problem has.

A combined study from Figure 2 to Figure 5 can lead to some interesting conclusions. For each category of MADPs, some decision strategies, such as WADD and EQW, could gain relatively high-decision accuracy with proportionally high-elicitation effort. Other decision strategies, especially *C4*, MCD, EBA, FRQ, and LEX, could achieve a reasonable level of accuracy with much lower elicitation effort compared to the baseline WADD strategy. Figure 6 illustrates the relationship between elicitation effort and $RA_{HR\_in\_Kbest}$ for various strategies when solving different scales of decision problems. For the MADPs with 5 attributes and 100 alternatives, the MCD strategy could achieve around *35%* relative accuracy without any elicitation effort. The *C4* strategy, in particular, could achieve over *70%* relative ac-

Figure 4. The elicitation effort of various decision strategies when solving MADPs with a different number of attributes, where m*(number of alternatives)* = 1,000

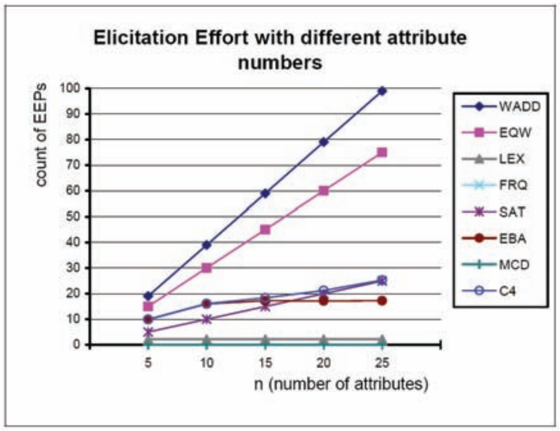


Figure 5. The elicitation effort of various decision strategies when solving MADPs with a different number of alternatives, where n*(number of attributes)* = 10

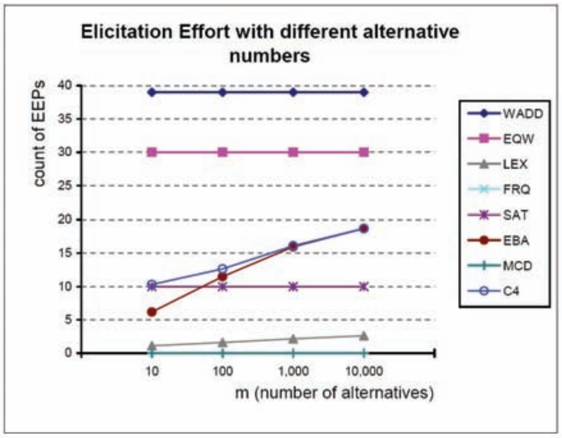


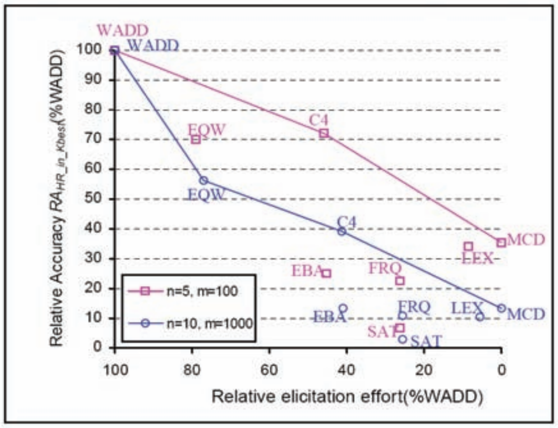
curacy while only requiring about 45% elicitation effort compared to the WADD strategy.

For all the decision strategies we have studied here, we say that a decision strategy *S* is *dominated* if and only if there is another strategy *S'* that has higher relative accuracy and lower cognitive and elicitation effort than *S* in the decision problem. Figure 6 shows that when the MADPs have 10 attributes and 1,000 alternatives, the WADD, EQW, *C4*, and MCD are nondominated approaches. However, for a smaller scale of MADPs (5 attributes and 100 alternatives), only the WADD, *C4*, and MCD strategies have the possibility of being the optimal strategy. This figure also shows that if the user's goal is to make decisions as accurately as possible, WADD is the best strategy among the listed strategies; while if the decision maker's goal is to have reasonable accuracy with a certain elicitation effort, then the *C4* strategy may be the best option.

DISCUSSION

The simulation results suggest that the tradeoff between decision accuracy and elicitation effort is the most important design consideration for inventing high-performance CDSSs. That is, while advanced tools are desirable, we must not ignore the effort that users are required to make when stating their preferences.

Figure 6. Elicitation effort/relative accuracy trade-offs of various decision strategies



To show how this framework can provide insights to improve user interfaces for the existing CDSSs, we have demonstrated the evaluation of the simplest decision strategies: WADD, EQW, LEX, EBA, FRQ, MCD, and SAT (Payne et al., 1993). The performance of these strategies was measured quantitatively in the proposed simulation environment within the extended effort-accuracy framework. Since the underlying decision strategy determines how a user interacts with a CDSS system (preference elicitation and result processing), the performance data allowed us to discover better decision strategies and eliminate suboptimal ones. In this sense, our work provides a new design method for developing user interfaces for consumer decision support systems.

For example, LEX is the underlying decision strategy used in the ranked list interface that many e-commerce Web sites employ (Pu & Kumar, 2004). However, our simulation results show that LEX produces relatively low-decision accuracy, especially as products become more complex. On the other hand, a hybrid decision strategy, *C4*, based on any combinations of LEX, EBA, MCD, and FRQ was found to be more effective. Combining LEX and EBA together, for example, we can derive an interface that looks like SmartClient. EBA (elimination by aspect) corresponds to eliciting constraints from users, and this feature was implemented as a constraint problem-solving engine in SmartClient (Torrens, Faltings, & Pu, 2002). After users have eliminated the product space by preference constraints, they can use the LEX strategy (ranked list) to further examine the remaining items. Even though this hybrid strategy does not include any interface features to perform trade-off navigation, the simulation results are still consistent with our earlier empirical work on evaluating CDSSs with real users (Pu & Chen, 2005; Pu & Kumar, 2004). That is, advanced tools such as SmartClient can achieve a higher accuracy while requiring users to expend slightly extra cognitive and elicitation effort than the basic strategies it contains.

The strongest implication of the simulation results is that we will be able to efficiently evaluate more-advanced tools and compare them in terms of effort and accuracy. Our plan for the future therefore includes evaluating SmartClient (Pu & Faltings, 2000) and its trade-off feature, FindMe (Burke et al., 1997), Dynamic Critiquing (Reilly et al., 2004), and Scoring Trees (Stolze, 2000), and comparing their strengths and weaknesses. We will also perform more simulations using different scales of K with the accuracy definition of $RA_{HR\_in\_Kbest}$. Because K is the size of the result set displayed in each user interaction cycle, we hope to gain more understanding on the display strategy used for CDSSs.

Finally, we do emphasize that the simulation results need to be interpreted with some caution. First of all, the elicitation effort is measured by approximation. As mentioned earlier, we assumed that each EEP requires an equal amount of effort from the users. Currently, it is unknown whether this approximation would affect the simulation results largely. In addition, when measuring the decision accuracy, the WADD strategy is chosen as the baseline, assuming that it contains no error. However, this is not the case in reality. Moreover, as the MADPs in the simulation experiments are generated randomly, there is a potential gap between the simulated MADPs and the product catalog in real applications. We are currently addressing these limitations, and fine-tune some of the assumptions with real user behaviors.

CONCLUSION

The acceptance of an e-commerce site by consumers strongly depends on the quality of the tools it provides to help consumers reach a decision that makes them confident enough to purchase. Evaluation of these consumer decision support tools on real users has made it difficult to compare their characteristics in a controlled environment, thus slowing down the optimization process of the interface design of such tools. In this paper, we described a simulation environment to evaluate the performance of CDSSs more efficiently. In this environment, we can simulate the underlying decision support approach of the system based on the consumers' preferences and the product catalog information that the system may have. The decision results can then be evaluated quantitatively in terms of decision accuracy, elicitation effort, and cognitive effort described by the extended effort-accuracy framework. More importantly, we were able to discover new decision strategies that led to interface improvements of existing CDSSs. Even though this is the first step, we hope to be able to evaluate and design new user interfaces for high performance CDSSs, and forecast users' acceptance of a new interface based on benefits such as effort and accuracy.

ENDNOTES

[1] Search tools and consumer decision support systems are two terms used interchangeably throughout this article although the latter is considered to be more advanced in terms of its implementation and interface features.

[2] It is also known as multicriteria decision making (MCDM) problem (Keeney & Raiffa, 1993). Our definition emphasizes on the term *attribute*, which is an objective aspect of products, not related to the decision maker's preferences.

[3] Though this assumption is obviously imprecise, more studies by assigning different weighting of effort for the various EIPs show that the key relationships between the decision strategy and the decision environments were largely unchanged. See page 137 of Payne et al. (1993).

[4] We assume that the actions are in their basic forms only. For example, the FILLIN operation is not allowed to elicit more than one value or even an expression. Otherwise a usability issue will arise.

[5] The detail analysis is given at pages 80–81 of Payne et al. (1993). This example assumes the values of all attributes are numeric and consistent with the decision maker's preferences.

[6] The procedure of assessing component value functions with midvalue points is introduced in page 120 of Keeney and Raiffa (1993).

Nonparametric Decision Support Systems in Medical Diagnosis:

Modeling Pulmonary Embolism

ABSTRACT

Patients face a multitude of diseases, trauma, and related medical problems that are difficult to diagnose and have large treatment and diagnostic direct costs, including pulmonary embolism (PE), which has mortality rates as high as 10%. Advanced decision-making tools, such as nonparametric neural networks (NN), may improve diagnostic capabilities for these problematic medical conditions. The research develops a backpropagation trained neural network diagnostic model to predict the occurrence of PE. Laboratory database values for 292 patients who were determined to be at risk for PE, with almost 15% suffering a confirmed PE, were collected and used to evaluate various NN models' performances. Results indicate that using NN diagnostic models enables the leveraging of knowledge gained from standard clinical laboratory tests, specifically the d-dimer assay and reactive glucose, significantly improving overall positive predictive value, compared to using either test in isolation, and also increasing negative predictive performance.

INTRODUCTION

Medical and surgical patients today face a variety of conditions that are both difficult and costly to diagnose and to treat. With ever skyrocketing medical costs (Benko, 2004), the use of information technology is seen as a much-needed means to help control and potentially to reduce medical direct costs (Intille, 2004). Deep vein thrombosis (DVT) and pulmonary embolism (PE) are medical conditions that are particularly difficult to diagnose in the acute setting (Mountain, 2003). Frequent usage of costly clinical laboratory tests to screen patients for further treatment is commonplace. All too commonly, hospitals provide treatment to patients without PE as a preventative measure (Mountain, 2003). Furthermore, patient mortality, morbidity, and both direct and indirect costs for delayed diagnosis of these conditions also may be substantial. Recent studies show that 40% to 80% of patients that die from PE are undiagnosed as having a potential PE (Mesquita et al., 1999; Morpurgo, Schmid, & Mandelli, 1998).

DVT may occur as the result of patient genetic and environmental factors or as a side effect of lower extremity immobility (e.g., following surgery). When a blood clot in the veins of a lower extremity breaks away, it may travel to the lungs and lodge in the pulmonary arterial circulation causing PE. If the clot is large enough, it may wedge itself into the large pulmonary arteries, leading to an acute medical emergency with a significant mortality rate. Approximately 2 million people annually experience DVT, with approximately 600,000 developing PE and approximately 10% of those PE episodes resulting in mortality (Labarere et al., 2004, Mesquita et al., 1999). Documented occurrence of DVT in postoperative surgical populations ranges from 10% (Hardwick & Colwell, 2004) to 28% (Blattler, Martinez, & Blattler, 2004).

Direct costs associated with DVT and PE come from the expensive diagnostic and even more expensive treatment protocols. It may be possible to lower these direct costs, especially when additional testing or treatment may be ruled out due to available knowledge. Nonparametric neural network (NN) systems enable the economic examination (Walczak, 2001) and nonlinear combination of various readily available clinical laboratory tests. Laboratory tests typically performed on surgical patients (e.g., blood chemistry) form the foundation for analysis and diagnostic model development.

One such test is the D-dimer assay that measures patient plasma for the concentration of one molecular product released from blood clots. When blood vessels are injured or when the movement of blood is too slow through veins of lower extremities, blood may begin to clot by initiating a series of steps in which fibrin molecules are cross-linked by thrombin to form a structure that entraps platelets and other coagulation molecules — a blood clot. As healing begins to occur, plasmin begins to break down the clot and releases, among other things, D-dimer molecules. D-dimers are actually small fragments of cross-linked fibrin and provide the basis for assessing blood-clotting activity. Patients with DVT and PE frequently have elevated levels of D-dimer in their plasma. Consequently, many hospitals now employ the D-dimer assay as a first test in the diagnostic pathway for these conditions. Usage of the results of a D-dimer assay effectively reduces the direct costs of DVT by reducing the requirement for downstream testing and treatment, specifically Doppler ultrasound tests (Wells et al., 2003). The use of nonparametric models enables the analysis of laboratory tests without regard to the population distribution, which may be a problematic factor when combining more than one laboratory test for the diagnostic prediction. Additionally, NNs provide nonlinear modeling capabilities that may be beneficial in combining pathology tests.

The research reported in this article will examine the efficacy of using NN models to predict the likelihood of a PE in surgical patient populations. A corollary research question is whether less invasive and less costly diagnostic methods are both available and reliable in predicting PE. The benefit of the reported research is twofold. First, the reported research examines new combinations of laboratory tests in order to determine if a combined model may be more reliable than currently used single variable medical models. Second, the research evaluates the viability of utilizing an NN model to predict PE (and potentially DVT). The NN provides improved positive predictive performance of the combined laboratory test model over the more traditional stepwise logistic regression models that currently are employed in medical modeling (León, 1994; Tran, VanOnselen, Wensink, & Cuesta, 1994; Walczak & Scharf, 2000). The cost effectiveness of utilizing the described neural network pathology tool is determined by examining the direct costs to patients, where direct costs represent the costs of diagnostic workups and the costs of any goods, services, and other resources utilized in any subsequent intervention (Patwardhan et al., 2005; Wildner, 2003). Implementing the described NN-based PE predictive model is capable of reducing patient evaluation direct costs by well over $1,200 per patient suspected of having a potentially life-threatening PE as well as reducing medical risks associated with some of the more advanced diagnostic methods.

The organization of the remainder of this article follows. The next section gives background on some of the issues associated with diagnosing and treating PE and DVT as well as examining the utilization of NN systems in medicine and issues surrounding the design of NN systems. The methodology section describes the patient population and development of the neural network models for predicting PE occurrence. The next section performs an analysis of the NN system's performance and consequent savings in direct costs. The last section concludes with a summary of the research findings and directions for future research.

BACKGROUND AND LITERATURE REVIEW

Diagnostic Difficulties of PE

Various tests exist for attempting to detect the presence of DVT or PE and commonly are administered to patients viewed as being at risk, based on medical history as well as patient signs and symptoms. For example, leg pain or swelling may indicate a patient with DVT; however, such symptoms are far from specific. Venography (x-ray with injected intravenous radioactive contrast dye) of the legs, Doppler ultrasound scans, plethysmography (measuring differential blood pressure between arms and legs), and the D-dimer assay blood test are some of the tests that may be employed in the evaluation of DVT (see http://www.nlm.nih.gov/medlineplus/ ency/article/000156.htm). Venography is the gold standard for diagnosing DVT, which commonly is treated with anticoagulant therapy such as intravenous heparin, requiring hospitalization, or injected low molecular weight heparin combined with oral warfarin medication, which may be continued for six months.

Patients with a sudden onset of chest pain or tachycardia or rapid shallow breathing may have PE, but these are also general signs of a wide variety of medical conditions (Mesquita et al., 1999; Mobley et al., 2005). PEs often are evaluated first using ventilation perfusion scanning (cost is $300 to $500 and involves the injection of radioactive tagged material) and chest x-rays that may be followed by pulmonary angiography (see http://www.nlm.nih.gov/medlineplus/ency/article/000132.htm). If the diagnosis of PE is made, the patient requires emergency treatment, typically thrombolytic therapy in order to dissolve the clot, and hospitalization.

While the pulmonary angiogram is considered the gold standard for determining PE presence (Evander et al., 2003; Mountain, 2003), it has a direct cost between $800 and $1,200 and involves injecting radio contrast die through a catheter that has been threaded into major coronary blood vessels with associated morbidity and mortality risks. If use of the D-dimer assay can determine better the likelihood or absence of PE, then a significant reduction in risks to the patient and costs ensues. The D-dimer assay has a direct cost of less than $7. Another factor that encourages the use of the D-dimer and other blood tests is the timeliness of the test, which averages approximately 30 minutes total time, including acquisition of the sample, transportation, analysis, and delivery of results. Improved detection of PE and early management will decrease the mortality and morbidity associated with PE (Stein, Kayali, et al., 2004).

Currently, the D-dimer assay has strong negative predictive reliability that excludes DVT or PE patients who are exceedingly unlikely to benefit from further invasive testing (e.g., angiography) or very few false negatives. Unfortunately, the test does not appear to have reliable positive predictability (Stein, Hull, et al., 2004), leaving the diagnostic role of the D-dimer uncertain. A potential cause of the lack of positive predictability is that, due to the potential life-threatening outcome of PE, the screening threshold for the D-dimer result is set very low (e.g., 400 or 450) in order to avoid false negative tests. As a result, many patients who do not have PE must undergo a pulmonary angiogram or other expensive testing procedures to determine if PE exists. Additionally, no standard for the D-dimer result threshold has been established, allowing for a wide range of cutoff values between hospitals (Stein, Hull, et al., 2004) and subsequent variation, though usually high, of patient population percentages undergoing unnecessary treatment.

Neural Networks in Medicine

The issues related to the use of D-dimer assay results — lack of standardized cutoff value, lack of positive predictive capability, and other influencing factors—pose a modeling problem. NNs provide strong modeling capabilities when population dynamics of the independent variables are unknown or nonlinear (Smith, 1993; Walczak & Cerpa, 2002), as would happen when using multiple laboratory test results to perform a diagnosis.

Before examining the factors that affect NN development (in the next section), a brief review of NN applications in medical domains is provided in this section. Neural networks or artificial neural networks applied to solve or provide decision support for a variety of medical domain problems started nearly two decades ago (Leese, 1986).

Many physicians are reluctant to utilize artificial intelligence technologies, including NN, especially neural networks that attempt to perform diagnosis or treatment in other than a decision support role (Baxt, 1995; Baxt & Skora, 1996; Hassoun, Wang, & Spitzer, 1994; Hu, Chau, Sheng, & Tam, 1999; Kleinmuntz, 1992; Walczak, 2003). The reluctance of physicians to adopt neural networks has led to the usage of neural networks as primarily image processing and laboratory test analysis tools. Table 1 provides a brief overview of historic and more recent neural network applications in medicine. A full review of all neural network applications in medicine is beyond the scope of this article,[1] and as such, Table 1 only provides a representative sample of research over the past decade.

Although representative and not comprehensive, Table 1 indicates that NN applications in medical domains tend to be used either in imaging or in laboratory settings (Walczak & Scharf, 2000), with diagnostic neural networks occurring rarely. Of interest from Table 1 for the research presented in this article are the three PE-related NN applications. Each of these NN research applications (Evander et al., 2003; Fisher, Scott, & Palmer, 1996; Serpen, Iyer, Elsamaloty, & Parsai, 2003) examines the improvement in identification or validation of PE from chest x-ray images or pulmonary angiogram data. Thus, each of these

Table 1. Types of neural network applications in medicine

Classification	NN applications research
Imaging (detect indicators in images)	Breast disease (Khuwaja & Abu-Rezq 2004, Papadopoulos et al. 2005), Coronary artery disease (Baxt 1991, Baxt & Skora 1996, Dorffner & Porenta 1994, Lapuerta et al. 1995, Scott et al. 2004), Electromyography (Hassoun 1994), Lung disease (Lin et al. 2005, Suzuki et al. 2004), Pulmonary embolism (Evander et al. 2003, Fisher et al. 1996, Serpen et al. 2003), Tomography (Bruyndonckx et al. 2004, Tourassi & Floyd 1995)
Laboratory (produce test results)	Breast disease (Mattfeldt et al. 2004), EEG (Güler et al. 2005b, Nowack et al., 2002, Walczak & Nowack 2001), General blood test pathology (Liparini et al. 2005) Head injury (Erol et al. 2005), Heart disease (Andrisevic et al. 2005, Haraldsson et al. 2004, Mobley et al. 2005), Hematology (Zini 2005), Lung disease (Güler et al. 2005a, Folland et al. 2004),
Resource Planning	Blood transfusions (Covin et al. 2003, Pereira 2004, Ruggeri et al. 2000, Walczak 2005, Walczak & Scharf 2000), Pharmacology (Gaweda et al. 2005, Polak et al. 2004)
Diagnostic	Breast cancer (Übeyli 2005)
Other	Medical cost estimation (Crawford et al. 2005, Goss & Vozikis 2002, Polak et al. 2004), Medical data mining (Petrovsky & Brusic 2004) Patient Outcomes Assessment (Buchman et al. 1994, Frye et al. 1996, Izenberg et al. 1997, Orunesu et al. 2004, Walczak et al. 2003, Yeong et al. 2005)

existing methods still requires the usage of and incurrence of the direct costs associated with these more costly diagnostic methods.

While NNs previously performed image analysis in order to confirm a diagnosis of PE, the use of NNs to predict a PE from standard low direct-cost blood tests is a novel application of this nonparametric modeling paradigm. The next section examines factors impacting the development of NN models, with an emphasis on the medical domain application of predicting PE.

Neural Network Design Issues

Patient treatment information necessarily must be of high quality (Silverman, 1998), since the consequences of prediction error can lead to increased morbidity and even mortality. NNs have been shown to outperform various statistical modeling methods in medical domains with respect to the accuracy of results (Baxt & Skora, 1996; Buchman, Kubos, Seidler, & Siegforth, 1994; Dybowski & Gant, 1995; Lapuerta, Azen, & LaBree, 1995; León, 1994; Stair & Howell, 1995; Walczak, 2005; Walczak & Scharf, 2000; White, 1992). NN design can be problematic and should account for the following influencing design factors (Walczak & Cerpa, 1999, 2002): training algorithm selection, input variable selection, and hidden layer architecture.

Various NN training algorithms exist; however, Alpsan, Towsey, Ozdamar, Ah, & Ghista (1995) have claimed that the backpropagation training algorithm produces classification and prediction models that generalize (on out of sample data) as well as or better than most other NN training algorithms, at least for their specific medical domain problem. Backpropagation-trained NN, in particular have been proven to be robust models of arbitrary complex equations (Hornik, 1991; Hornik, Stinchcombe, & White, 1989; White, 1990). Backpropagation-trained NNs are used commonly to provide solutions to business and engineering problems and also are the most common NN type for medical domain applications, which facilitates cross-research comparison of methodologies (Alpsan et al., 1995; Baxt, 1995; Cherkassky & Lari-Najafi, 1992; Dorffner & Porenta, 1994; Dybowski & Gant, 1995; Montague & Morris, 1994; Rodvold, McLeod, Brandt, Snow, & Murphy, 2001).

A reason for selecting another training algorithm besides backpropagation, such as the radial basis function, is to overcome problems with very noisy input data in the training sets (Barnard & Wessels, 1992; Carpenter, Grossberg, & Reynolds, 1995). Since the proposed NN prediction model utilizes the results of laboratory tests, many that already are controlled by computers and robotics, the resultant error rate in the input data is minimal and should not require a training algorithm that may not generalize well in order to alleviate error-prone data problems. Generally considered the best and most robust training method for NN classification and prediction models, backpropagation works well when low noise input data exist (Walczak & Cerpa, 2002). The backpropagation algorithm has been discussed widely in literature, and readers should see Fu (1994), Hertz, Krogh, and Palmer (1991), Jain, Mao, and Mohiuddin (1996), and Rodvold et al. (2001) for further details on the function of the backpropagation NN training methodology.

A critical step in the design of any NN model and especially in medical applications is the selection of high-quality predictive input (independent) variables that are not highly correlated with each other (Pakath & Zaveri, 1995; Smith, 1993; Tahai, Walczak, & Rigsby, 1998; Walczak & Cerpa, 1999). Domain expert physicians identify all available data that are related to the PE diagnosis problem.

The final influencing factor from the previous in developing NN models is the determination of the hidden node architecture (Smith, 1993; Walczak & Cerpa, 1999). The quantity of hidden nodes has a direct effect on generalization performance (Hung, Hu, Shanker, & Patuwo, 1996) with both too few and too many hidden nodes decreasing performance. The number of hidden layers also affects the smoothness and closeness of fit of the solution surface (Barnard & Wessels, 1992). A common heuristic method to determine the optimal number of hidden nodes is to start with a small quantity of hidden nodes (commonly one-fourth to one-half of the quantity of input nodes) and increment the hidden node quantity by one, until generalization performance begins to deteriorate. This method will safeguard against underfitting and overfitting the model (Walczak & Cerpa, 1999).

The research reported next will evaluate the efficacy of utilizing an NN methodology for developing a diagnostic model of PE that utilizes tests with a lower direct cost.

METHODOLOGY: A NEURAL NETWORK DIAGNOSTIC MODEL FOR PE BASED ON THE D-DIMER

As stated previously, the evaluation mechanisms for determining if a patient has a PE and requires treatment currently have high direct costs (e.g., ventilation perfusion scan that costs from $300 to $500, and pulmonary angiogram that costs from $800 to $1,200). In addition to other demographic and medical risk factors, the purpose of this research is to determine if less costly evaluation mechanisms for PE are available, especially using the D-dimer assay results, which have a direct cost of less than $7 and is used commonly to negatively screen out patients for PE (Stein, Hull, et al., 2004).

Research Population Description

The patient population in this research was 292 surgical patients admitted to a large Midwest teaching hospital during a nine-and-a-half-month period. All patients during the period of the study diagnosed by physicians as being at risk either for

DVT or for PE were included in the study with no exclusions. Database records maintained by the hospital clinical laboratory as well as clinical information provided from radiology and chart records provide the data used in the NN input vector (independent variables). Patient records used in this study only come from patients clinically identified as being at risk for a DVT or possible PE by attending physicians based on signs (e.g., swelling in legs or irregular breathing) and symptoms (e.g., report of pain in legs for DVT or chest for PE). Just over 15% of this patient population, 44 out of 292, suffered a confirmed PE, which is consistent with other findings on the rate of DVT occurrence in surgical populations and consequent occurrence of PE (Hardwick & Colwell, 2004; Blattler et al., 2004). A pulmonary angiogram confirmed or negated the presence of PE.

The at-risk population of surgical patients for DVT and a possible PE has some basic statistical measures that are displayed in Table 2. From Table 2, it can be seen that the D-dimer results alone are not significantly different between patients with PE and patients without PE, although the PE patients have a much larger average D-dimer result and also a wider distribution. High D-dimer values may result from a variety of causes in addition to DVT or PE, which further confuses the application of the D-dimer for diagnosing PE.

NN Design of a PE Diagnosis Model

The focus of this study is on the use of the D-dimer assay results in possible combination with other values to improve the overall positive predictive performance to reduce false positives, which leads to unnecessary PE evaluation direct costs. As discussed in the "Neural Network Design Issues" section, the small error associated with laboratory tests and the reported robustness of the backpropagation training algorithm implied selection of backpropagation as the training algorithm for implementing the NN-based PE diagnosis model. Radial basis function (RBF) neural networks and stepwise logistic regression (LR) models also were implemented simultaneously in order to produce multiple models for comparison and to evaluate if a backpropagation-trained neural network would produce the optimal model. Using the model selection perspective (Swanson & White, 1995), comparison of each of the independent model types yielded the backpropagation NN model as the optimal model. The backpropagation models, with regard to overall accuracy (the sum of true positives and true negatives divided by all cases) outperformed both of the other model types ($p <$ .01 against the RBF-trained NN and $p < 0.10$ for the LR models).

Domain expert physicians identified blood test results with minimal direct costs that would be available for suspected DVT and PE patients prior to the performance of an angiogram. Since the research question of trying to determine if one or more of these test results could improve the PE diagnosis accuracy, a correlation matrix of all blood chemistry and other blood test results is performed to determine those variables that appear to be correlated with a positive diagnosis of PE. The variables include D-dimer, reactive glucose (Glu-R), blood urea nitrogen, serum creatinine,

Table 2. Typical d-dimer surgical population values

	D-dimer minimum	**D-dimer maximum**	**D-dimer μ (average)**	**D-Dimer σ (std dev)**	**Age μ** **Age σ**	**Gender**
Patients w/ confirmed PE	145	35450	4218.7	5862.75	48.45 22.38	47.5 % male
Patients w/o PE	124	22375	1782.63	1264.16	53 16.64	38.34 % male

serum sodium, serum potassium, serum chloride, serum carbon dioxide level, serum calcium, white blood cell count, red blood cell count, hemoglobin, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, red cell distribution width, and platelet count. Other values, including mean platelet volume, absolute neutrophil count (and percent), absolute lymphocyte count (and percent), absolute monocyte count (and percent), absolute eosinophil count (and percent), and absolute basophile count (and percent), were considered for use but eliminated due to missing data for many of the patients (i.e., the tests had not been ordered by their attending physician). The predictive correlation of different blood test results measured by a Pearson's correlation matrix indicated that the D-dimer had the highest correlation with a validated PE for those test results included in the matrix and that randomized glucose (Glu-R) and CO_2 also both had significant ($p < 0.05$) predictive correlations with the PE-dependent variable. The age and sex of the patient also are included as independent variables to determine if these may be predictive when combined with blood test results.[2] Different backpropagation-trained NN models use various combinations of these five variables: age, sex, D-dimer, Glu-R, and CO_2 as the input vector of independent variables, producing 23 different sets of input variables and corresponding diagnosis models.

NN models for each of the 23 different input vectors start with a single hidden processing node. Both one- and two-hidden-layer architectures are evaluated, since the complexity of the diagnosis solution surface is unknown (Fu, 1994). When a second hidden layer is implemented, it also is started with a single hidden processing node. The quantity of processing nodes in each layer is incremented independently of the other layer and by a quantity of one. Reinitialization of each new larger model produces random interconnection weights before training occurs. Hidden node expansion stops, once the generalization performance begins to deteriorate and the model with the best generalization performance is kept.

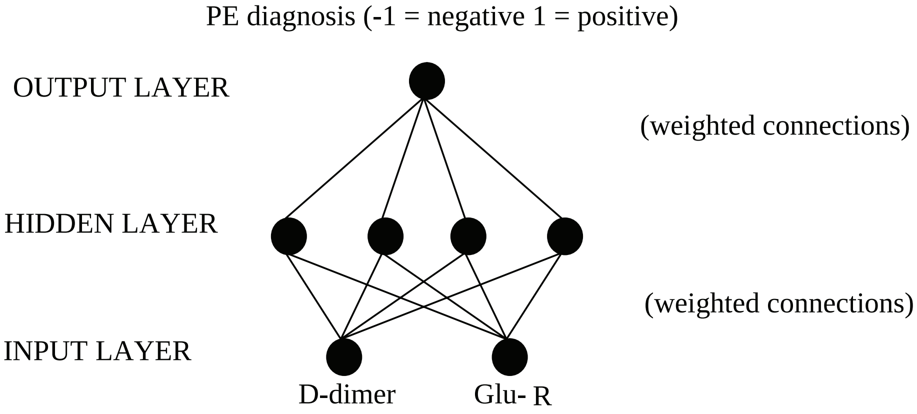
Training of each NN model uses one sample of data, and then validation uses a separate holdout sample. Due to the relatively small size of the population data, we use an eightfold cross validation technique in order to increase the quantity of holdout samples analyzed in the results to the full population of 292. The majority of the NNs evaluated performed similarly to just using the D-dimer result alone, meaning they had very good specificity (identifying positive PE cases) but very poor sensitivity (identifying negative PE cases). The finding that the sex-independent variable did not influence the performance of the various neural supports the findings of Stein et al. (2003b), who found that sex was not a factor in the diagnosis of PE.

The best performing NN model utilized both the D-Dimer and the GLU-R result for each patient. The name of the NN PE diagnosis model is PEDimeNet, since it utilizes the D-dimer laboratory test in combination with another test in order to maximize positive PE-predictive performance. The hidden node architecture for this backpropagation-trained NN is two input nodes representing the D-dimer and Glu-R results, four hidden nodes, and one output node, as shown in Figure 1. This NN is the one discussed in the next section.

RESULTS AND DISCUSSION

Backpropagation-trained NNs provide a real number output between -1 and 1 (though some NN shell tools allow this range to be extended) and not a true or false result for predicting the occurrence of a PE in a patient. These real-number output values require interpretation in order to determine the optimal cutoff point for partitioning the solution space into the two desired groups: probable PE and unlikely PE. An ROC (Receiver Operating Characteristic) curve analysis is performed commonly

Figure 1. PEDimeNet NN architecture



by those involved in medical diagnostics in order to determine the optimal threshold cutoff value for maximizing positive predictive performance on the generalization sample (Kamierczak, 1999; Obuschowsk, Lieber, & Wians, 2004), and this technique is used with the NN training sample output values in order to determine the optimal real number threshold value for performing the classifications. A similar and independent ROC curve analysis for the RBF and LR models reported in the previous section determines each model's cutoff value. The area under the ROC curve for the training data was 0.79. Once the ROC threshold value is determined, it is then applied universally to all out-of-sample output values produced by the NN in order to determine the NN's PE diagnosis for the corresponding patient.

Table 3 displays the prediction results of the resulting NN model. Similar to increasing the D-dimer cutoff value to include more of the patient population in the group that undergoes further evaluation via an angiogram or other PE verification method, a tradeoff exists between the positive predictive accuracy and the negative predictive accuracy using the NN model. Lowering the PE cutoff point causes the positive predictive accuracy to increase and creates a corresponding decrease in the negative predictive accuracy. Due to the possible outcome of mortality for PE patients, a positive predictive performance of 90% sensitivity is desired, as specified by the domain expert physicians (where the TP rate in Table 3 is the sensitivity, and the TN rate is the specificity). The overall diagnosis accuracy ([TP+TN]/Total) performance of the PEDimeNet NN model is 62.33% with almost 91% of all PE patients identified as well as nearly 57% of patients that do not have a PE and, therefore, do not require any additional testing for PE with subsequent reduction in direct costs.

Recall that traditional usage of the D-dimer with a relatively low threshold value produces a

Table 3. NN diagnostic prediction results for PE

	NN positive PE	NN negative PE
Actual PE (positive)	TP = 40 (90.91%)	FN = 4 (9.09%)
No PE (negative)	FP = 107 (43.15%)	TN = 141 (56.85%)

(TP = True Positive, FN = False Negative, FP = False Positive, and TN = True Negative)

false negative (FN) rate very close to 0%. As a result, a negative PE result usually means that the patient truly will not have a PE. The false positive rate for the standard D-dimer test is very high, which leads to increased medical costs through unnecessary costly procedures for follow-up evaluation (e.g., pulmonary angiogram).

For the test population used in the research reported in this article, a simulation of adjusting the D-dimer cutoff value to produce a false negative rate identical to the proposed NN model produced a false positive rate of 91.53% (227 patients that require unnecessary evaluation tests), meaning that only 21 of 248 patients did not have further costly PE evaluation procedures recommended. Whereas, the PEDimeNet NN was able to save additional laboratory testing for 141 patients, as opposed to just 21 when using the traditional D-dimer only diagnosis. Therefore, an NN model of PE that utilizes both D-dimer and Glu-R test results provides a high-quality positive predictor. The NN PE prediction model exceeds using a non-NN D-dimer-based evaluation mechanism with respect to true negatives (patients without PE) by well over 600%, resulting in significant cost savings for the patients. Direct cost savings would be approximately $96,000 to $144,000 for the nine-and-a-half-month period of the research study, which translates to a $121,000 to $182,000 direct-cost annualized savings.

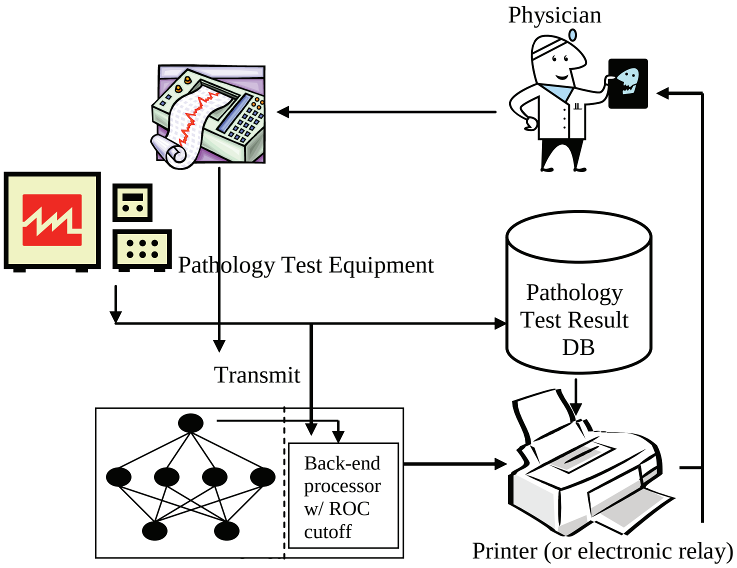
A limitation of the reported research is that the NN diagnosis model only models the population at a single hospital. While this hospital is one of the larger providers in a major metropolitan area and, as such, has a demographically diverse population, differences in the correspondence between the D-dimer and Glu-R values with an actual PE may exist in different geographic populations (Stein, Kayali, et al., 2004). As such, the methodology described would require each hospital to independently train their own NN model and to establish their own ROC cutoff threshold value for interpreting the generalization (out-of-sample) diagnosis values of the NN.

Utilizing the proposed NN system would require only very minor workflow changes in the emergency department and clinical laboratory of the studied hospital and would integrate similarly at most hospitals that follow similar diagnostic methodologies. Medical user acceptance of new decision support technology is highly dependent on two factors: (1) that the decision support technology not be perceived as attempting to make diagnosis (Baxt, 1995; Baxt & Skora, 1996; Walczak & Scharf, 2000) and (2) that the new information technologies not disrupt normal workflows (Kirkley & Stein, 2004; Walczak, 2003). Physicians receive laboratory results at most hospitals either electronically or on paper after encoding and storing the results in a pathology database. The PEDimeNet NN-based decision support system would be positioned architecturally in the pathology departments' IT framework, as displayed in Figure 2. This integration of the PEDimeNet NN diagnostic tool then would appear seamless to physicians, integrating with their existing workflow simply by adding the analysis to the pathology report already received by the physician.

The PEDimeNet PE diagnosis decision support tool is composed of the PEDimeNET NN, an interface that allows the entry of D-dimer and Glu-R laboratory test results (which may be handled electronically through an EDI interface or performed manually at a keyboard), a backend program that contains the ROC curve analysis-based decision cutoff value (which also may be read from a database to allow for movement in the cutoff value over time, perhaps due to new pathology equipment sensitivity) and produces the go/no-go diagnostic recommendation for probable PE in a patient. Future enhancements would include a database or agent-oriented Web browser to recommend additional tests, if necessary, and treatment protocols.

The following scenario presents an illustration of the functioning of the proposed PEDimeNet system within a hospital setting. A physician

Figure 2. PEDimeNet relative to other pathology IT systems



would request a diagnostic workup, including a patient blood draw. The clinical laboratory receives the patient's blood sample. Laboratory tests are completed using the existing laboratory equipment. The results are delivered to the physician either electronically (with EDI requiring a small hardware modification to interface with the existing pathology instrumentation) or on paper (after entering the results into the laboratory database with a simultaneous transmission to the PEDimeNet). A software interface to the database or other peripheral devices (in C# or Java) encodes the received value into the format required by the NN. The PEDimeNet diagnostic decision support system then would interpret the NN's results, based on a cutoff value established by applying the ROC curve analysis determined threshold. The backend analysis of the NN output provides a report of the interpreted NN prediction in either electronic or printed format for the attending physician, who then would determine if any further evaluation was required. Other than the step in the lab necessary to transmit the results to the PEDimeNet decision support system, the automated process is similar to standard decision-making processes for evaluating the need to screen for a PE. From the physician's perspective, there is no change in workflow from the traditional receipt of the original noninterpreted D-dimer assay results.

CONCLUSION

The research presented in this article demonstrates the efficacy of utilizing NNs for predicting the occurrence of PE in patients presenting to the emergency department and those at risk of PE following surgery. The reported results were able to match the very low false negative rate of a more traditional test that relied on the D-dimer alone. Although the usage of a D-dimer screening test is questioned in cases of PE (Stein, Hull, et al., 2004), it has proved reliable for evaluating the presence of DVT (Wells et al., 2003), a leading cause of PE. Furthermore, over a 600% increase in true negative predictions with a corresponding decrease in associated medical risks to patients and decreased medical costs of hundreds of thousands of dollars per hospital per year demonstrates the benefits of using a nonlinear and nonparametric modeling technique such as the backpropagation train NN.

Another benefit derived from this research is the identification of the superior positive predictive performance for PE when using the combination of the D-dimer result value in combination with the Glu-R result value. The D-dimer individually was not able to distinguish reliably between positive PE cases and negative ones, creating a high corresponding false positive assessment rate so that only a very small number of actual PEs would be misdiagnosed. The utilization of an NN as the statistical analysis component of the PEDimeNet NN decision support system enabled the rapid combination of input values in nonlinear ways without regard to population distribution characteristics. A potential drawback of using NNs as a model determination mechanism in order to evaluate the contribution of various independent variables is the need to determine the ideal architecture. While the current research utilized a brute force incremental process to analyze both single- and two-hidden-layer networks, new neural network shell tools are able to automate some or all of the NN node architecture optimization process.

While the research reported in this article focused on the prediction of PE, the relationship between PE and DVT and previous research has indicated a strong positive correlation between the D-dimer assay results and accurate DVT diagnosis (Wells et al., 2003), which indicates that a similar NN model would be able to accurately predict DVT. This would permit the operation of two side-by-side (or possibly one) NNs in the PEDimeNet decision support system in order to evaluate both PE and DVT simultaneously, which is a topic of future research.

In addition to the specific research benefits just described, generalizing the research method and results provides implications for both researchers and practitioners. Future research efforts will benefit by realizing that nonparametric modeling techniques in general and neural networks specifically are a viable method for analyzing complex and potentially ill-defined (unknown population and error distributions) problems. Researchers should embrace the most advanced modeling techniques available, especially since neural networks repeatedly have demonstrated increased performance over more traditional parametric statistical methods. The data set for the presented NN PE diagnosis application is relatively error-free. Researchers should note that designing optimal neural network models has many implementation factors, and careful attention in selecting input variables, selecting the training algorithm, and determining the hidden-layer and hidden-node architecture will help to produce the optimal NN model (Smith, 1993; Walczak & Cerpa, 1999, 2002).

An implication for practice is to challenge existing protocols and heuristics. The addition of a low direct-cost variable to the PE diagnosis model significantly increases the accuracy and reduces direct costs. Other medical diagnostic and assessment problems may derive benefit from examining new sets of variables. The NN modeling method provides an inexpensive and reliable way to rapidly assess the impact of adding new variables or removing existing decision variables (Walczak, 2001). Previous research (Walczak et al., 2003) demonstrates this by showing that a commonly used variable for determining acute pancreatitis patient outcomes, RANSON score, detracts from the predictive performance of other readily available variables.

The research reported in this article demonstrates the impact of NN diagnosis models through the reduction of direct costs. Future research is needed to realize the overall benefit gained from NN diagnosis models by examining the impact on indirect costs, such as reduced patient healing times and overall quality of care received.

ENDNOTES

[1] A database inquiry on EBSCO using the terms *neural network* AND (medicine OR medical) produced 997 articles. A similar query on PubMed, the NIH article database, produced 6,120 articles.

[2] The occurrence of PE between blacks and whites has been found to be comparable (Stein et al., 2003a) and, as such, is not included in the variables considered for the NN input vector. Additionally, this variable is subjective, being either self-reported by patients or reported as an observation by the admitting nurse in the studied hospital and, as such, may have a higher than acceptable error rate for use in a backpropagation-trained NN.

ABSTRACT

Clinical Decision Support Systems (CDSS) are typically constructed from expert knowledge and are often reliant on inputs that are difficult to obtain and on tacit knowledge that only experienced clinicians possess. Research described in this article uses empirical results from a clinical trial of a CDSS with a decision model based on expert knowledge to show that there are differences in how clinician groups of the same specialty, but different level of expertise, elicit necessary CDSS input variables and use said variables in their clinical decisions. This article reports that novice clinicians have difficulty eliciting CDSS input variables that require physical examination, yet they still use these incorrectly elicited variables in making their clinical decisions. Implications for the design of CDSS are discussed. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

Clinical decision-making is a complex process frequently complicated by a variety of uncertainties. It is dependent on accurate information, that according to proponents of evidence based medicine (EBM) and decision making should include the integration of clinical expertise with the best available clinical evidence generated by high quality research (Sackett, Rosenberg, Gray, Haynes & Richardson, 1996). EBM is gaining support and momentum and has been called the prevailing clinical decision making paradigm for medicine (Haynes, 2002). A need to follow EBM guidelines has resulted in a situation where clinicians are dependent on massive amounts of information and knowledge to make decisions that are in the best interest of the patient. These information and knowledge sources include electronic medical records, clinical practices guidelines, academic and practitioner journals among others. Increasingly, information technology (IT) solutions are being considered as crucial decision support mechanism to ensure that clinicians have access to appropriate knowledge sources while making clinical decisions. One particular class of IT solutions that the medical community is showing increased interest in is Clinical Decision Support Systems (CDSS).

According to a well accepted definition, a CDSS is "any program designed to help healthcare professionals make clinical decisions" (Musen, Shahar & Shortcliffe, 2001). This definition includes several categories of IT solutions, including:

- *Systems for information management* that provide general data and knowledge for a variety of healthcare workers, including medical information retrieval systems for managing and extracting medical knowledge, and electronic patient record systems (EPRS: Shortcliffe, 1993) for managing patient data.
- *Systems for focusing attention* that are normally present in the intensive care units and are used to remind clinicians about actions that might require attention.
- *Systems for providing patient-specific recommendations* that assess or advise using patient-specific clinical data. These include systems ranging from direct implementation of clinical practice guidelines (Seroussi, Bouaud & Antoine, 2001) to advanced techniques of artificial intelligence (Hanson & Marshall, 2001).

CDSS from the first two categories have been relatively well accepted and used in clinical practice for more than three decades (Anderson, 1997). Increasing interest in systems from the third category is driven by a move towards EBM (deDombal, Leaper & Staniland, 1972), and the efforts to improve patient outcomes (Hunt, Haynes, Hanna & Smith, 1998). Patient-specific recommendation systems usually help clinicians make two types of decisions – diagnostic (what is the underlying health condition of the patient) and management (what is the treatment plan for the patient). Although it is rather artificial to separate the diagnostic process from the management one, many clinicians believe that it is for the management process that they would most often seek support (Musen et al., 2001).

Almost all patient-specific CDSS decision models reflect encoded clinician expertise and are reliant on accurate input to produce appropriate output that is in the best interest of the patient. The implication is that clinicians using such systems have to provide values for input variables to the CDSS that may be correctly elicited only with an appropriate level of expertise. That is, only experienced clinicians will be able to provide such information in a reliable and comprehensive manner, while inexperienced clinicians may be forced to gather information and make assessments for activities that they may lack the clinical acumen to do accurately. Thus, the resulting 'treatment plan' output provided by the CDSS may be inappropriate for the patient under question due to the poor quality of the inputs provided by the clinician.

The purpose of this article is to challenge a common perception that a CDSS designed for a specific and well-defined clinical domain, and for users from the same domain, can satisfy the needs of clinicians who may have varying degrees of domain experience. Research described in this article uses empirical results from a clinical trial of a CDSS to show that there are differences in how the clinician groups of the same specialty, but different level of expertise, elicit necessary CDSS input variables and use said variables in their clinical decisions. By establishing differences between the quality and use of CDSS input variables by clinicians of differing expertise we can then offer prescriptive guidance on improvements to CDSS design that ultimately should assist in providing better care to patients.

This article is organized as follows. First, relevant background literature on expert and novice clinical decision-making is reviewed and used to formulate two research hypotheses. This is followed by a brief description of the MET-AP CDSS along with an explanation of the clinical input variables that are required by the system. Next, descriptions of the experimental design is provided, along with the analytical methodology that was used. This is followed by a discussion of the results and implications for CDSS design.

BACKGROUND AND RESEARCH HYPOTHESES

Patient-specific CDSS are deployed in different settings and used by different classes of users. Decision models implemented in patient-specific CDSS are normally based on expert clinician knowledge, either discovered from past data, elicited from medical books or practice guidelines, or elicited directly from clinicians using a variety of knowledge acquisition strategies such as repertory grids or think aloud protocols. While techniques for obtaining expert knowledge vary, resulting patient-specific CDSS decision models almost always reflect clinician expertise. Sometimes, these models reflect 'best practice' by representing knowledge that has been culled from valid scientific research (for example, the encoding of a clinical practice guideline into a decision model that has been generated from systematic observations of research results). Other times, these decision models need to become part of the scientific research base from which clinicians can draw on to improve patient outcomes.

Clinicians, especially in a teaching hospital, can be considered either novice or expert, based on their medical experience and associated knowledge. Differences between these two categories of decision makers have been widely documented in the decision making and medical literature. It has been stated that in complex domains such as medicine, it typically takes 10 years of training before one can be considered an expert (Prietula & Simon, 1989). Over time, experts develop a capability to systematize information and to form complex networks of knowledge that is stored in long term memory (Arocha, Wang & Patel, 2005; Prietula & Simon, 1989). Novices lack such complex knowledge networks, and, thus, when faced with new informational cues they need to produce more hypothesis than experts (Kushniruk, 2001), are unable to filter out irrelevant cues (Patel, Arocha & Kaufman, 1994; Patel & Groen, 1991), and resultantly take a longer time in making their decisions.

In order to improve these generally weaker information gathering and decision making skills (Johnson & Carpenter, 1986; Mangione et al., 1995), medical graduates and specialty residents undergo practical training during their residency, where they learn how to assess and diagnose patients under the supervision of experienced physicians. Research has shown that residents often have deficiencies in their physical examination skills, yet they place great clinical importance on the physical examination and desire to have greater educational attention put on those skills (Mangione et al., 1995). Through self-recognizing weak skills that are widely considered critical to making important decisions, novice clinicians compensate by placing more emphasis on scientific evidence, as opposed to experts who rely on clinical experience (Patel, Groen & Patel, 1997; Patel et al., 1994). This observation was confirmed in a prospective cohort trial of a handheld CDSS for antibiotic prescribing in critical care (Sintchenko, Iredell, Gilbert & Coiera, 2005). The system offered four types of support functions: patient reports, local antibiotic guidelines, antibiotic susceptibility data and a clinical score calculator. During the trial it was observed that senior physicians used antibiotic susceptibility data more often then other support functions, while it was the least frequently used by junior physicians. The junior physician tended to use the remaining functions with local antibiotic guidelines being most frequently accessed.

Empirical studies have shown that clinicians with different levels of expertise exhibit differences in their ability to elicit information from physical examinations (Pines, Uscher Pines, Hall, Hunter, Srinivasan & Ghaemmaghami, 2005; Yen, Karpas, Pinkerton & Gorelick, 2005). In comparing abdominal examinations of Emergency Department (ED) pediatric patients undertaken by residents and attending physicians, it was found that all parts of the examination had less than moderate agreement (Yen et al., 2005). Similar results were found in studying abdominal examinations of adult patients by residents and attending physicians (Pines et al., 2005). Additional studies of residents have confirmed that they are deficient in performing physical examinations (Mangione, Burdick & Peitzman, 1995). Performing physical examinations accurately, among other clinical tasks, requires tacit knowledge that is "expressed in actions rather than conscious thoughts" (Goldman, 1990). While none of these studies involved the use of a patient-specific CDSS, the implications are that there are distinct differences between the abilities of novice and expert clinicians, and these differences may affect the novice clinicians' ability to provide accurate inputs into the expert generated CDSS decision models. The inexperienced clinicians may lack the clinical acumen necessary to make accurate elicitations and could potentially enter incorrect inputs. Such a situation may not only diminish the usefulness of the CDSS and the validity of the advice generated by the system, but also might lead to the rejection of the system by a broad group of clinicians.

The study reported here is based on a clinical trial of the Mobile Emergency Triage (MET-AP) CDSS that was developed for supporting triage decisions of pediatric abdominal pain in the ED. While the trial was originally designed to assess the CDSS's performance in terms of accuracy of the suggested decisions (Farion, Michalowski, Slowinski, Wilk & Rubin, 2004), our focus is on the CDSS decision model's input variables and the resulting decisions made by the clinicians. The decision model embedded in MET is based upon 13 input variables. We show how different clinician user groups (staff physicians (experts) and residents (novices)) used the system and made clinical decisions based on the required CDSS input variables. We also evaluate differences between these two groups and draw more general conclusions for supporting clinical decision-making with IT. Our research addresses a call for a better understanding of real decision makers making ill structured decisions in a naturalistic setting as mediated by technology (Kushniruk, 2001).

Research described here is structured around two research hypotheses. The first hypothesis builds on the results reported earlier on the differences in clinician elicitation capabilities is:

H1: *Residents will not accurately elicit all values of decision making variables required by a CDSS model built from expert knowledge*

It is our contention that because residents have limited clinical experience and associated tacit knowledge, they will not be able to accurately elicit values of all of the input variables for a CDSS decision model derived from expert knowledge.

The overall goal of the research described in this article is to challenge the idea that a single CDSS is able to appropriately support clinicians of varying experience and associated expertise. To accomplish this goal we need a comprehensive assessment of both the elicitation of input variables and whether said variables are predictive of the actual decision making of clinicians of varying expertise. So while assessment of the accuracy of elicitation of CDSS input variables is critical, we are also interested in whether novice clinicians use different input variables in their clinical decisions than do staff physicians. More specifically we are concerned with whether residents rely on input variables that are relatively easy to elicit properly and that are not normally associated with clinical experience, or whether they incorporate variables that are more difficult to elicit, and traditionally require experience, into their decision making models.

Thus, our second research hypothesis is:

H2: *Residents and physicians will use different decision model input variables in making their clinical decisions*

Because of the clinical expertise required for certain model inputs to be correctly elicited, we expect that residents and physicians will use different input variables in their decision making models. Further, we expect that these differences will be moderated by the ‘type of input variable’, with variables requiring tacit knowledge and clinical experience to be less important in residents decision making models. This would be consistent with classical decision making where it is stated that decision makers will use the best information available and if there is uncertainty, the decision makers will act in a way to reduce uncertainty if possible (Simon, 1957).

CDSS: MET-AP

The MET-AP CDSS was designed and developed to support ED clinicians in making triage decisions about children with abdominal pain (Michalowski, Slowinski, Wilk, Farion, Pike & Rubin, 2005). It facilitates early patient management by ED clinicians who need to make decisions about the clinical management of patients based on initial clinical history and assessment. In this sense MET-AP is not a diagnostic CDSS because it does not provide clinicians with a differential diagnosis but rather with broad management categories (i.e. discharge from the ED, keep for further observation, or request specialist consult). The MET-AP system architecture consists of a server that interfaces with the hospital’s electronic patient record system using the HL7 protocol (Quinn, 1999) and clients that reside on mobile devices such as a Personal Digital Assistant (PDA). The client facilitates the collection of clinical data (CDSS input variables) at the point of care and is used during patient examination by the physician.

The system provides a user interface composed of a series of screens to collect 11 out of 13 CDSS input variables required by the pediatric abdominal pain triaging model. These include variables related to physical findings as well as patient history. The remaining two variables, gender and age, are extracted automatically from the electronic patient record system. All variables are detailed in Table 1 and were identified using retrospective chart analysis. The triage decision making model was created using knowledge discovery techniques based on rough set theory (Pawlak, 1991; Slowinski, 1995) and implemented as a rule-based model.

Based on the values of the input variables the MET-AP’s triage model generates suggested triage decision which can be one of the following three outcomes:

Table 1. Abdominal pain triaging attributes

Attribute Name & Description	Possible Values
Age	0-5, >5 years
Localized guarding: localized muscle sustained contraction noted when palpating the abdomen	Absent, Present
Duration of pain	<=24 hrs, 1-7 and >7 days
Shifting of pain	Absent, Present
Site of maximal pain	Right lower quadrant (RLQ), lower abdomen, other
Type of maximal pain	continuous, other
Previous visits in the ED for abdominal pain during the last 48 hours (irrespective of site)	yes, no
Rebound tenderness: pain felt at site of maximal tenderness, produced by altering intra-abdominal pressure	absent, present
Gender	male, female
Temperature	<37, 37-39, > 39 Cel
Site of maximal tenderness	RLQ, lower abdomen, other
Vomiting	yes, no
WBC (white blood cells)	<=4000, 4000-12000, >=12000

- *Discharge*: patient can be discharged home as his/her pain is caused by a non-serious problem,
- *Observation/Investigation*: further in-hospital evaluation (either in the ED or hospital ward) is required to better evaluate the cause of the pain,
- *Consult*: surgical consult is required due to suspicion of acute appendicitis (most common surgical emergency in children with abdominal pain).

Values of all numerical input variables (WBC, temperature, duration of pain) were collected by physicians entering direct numerical values using either a virtual keyboard or a handwriting recognition system. Entered values were then discretized for the rule based decision models according to discretization norms developed with physician experts. Values of all input variables that involved a specific location within the abdomen (site of maximal pain, site of maximal tenderness) were collected by physicians tapping on an abdomen pictogram on the mobile device. Other input variables were collected via standard user interfaces for mobile devices. For example, figure 1 shows the MET-AP screen for 'type of maximal pain'. All screens were designed and developed with participation from multiple physicians. This ensured that the resulting user interface mimicked clinicians' natural data collection procedures as closely as possible.

METHODS

This research on staff physician and resident decision making was part of a larger clinical trial that was designed to evaluate MET-AP decision accuracy in comparison with clinicians' triage predictions. Results of that clinical trial can be found in Farion, Michalowski, Rubin, Wilk, Correll and Gaboury (2008).

Sample and Data Collection

A convenience sample of 574 eligible children with acute abdominal pain, aged 1 to 16 years, were enrolled with consent between July 2, 2003 and February 29, 2004 in the ED of the Children's Hospital of Eastern Ontario, Ontario, Canada. Under some conditions, convenience samples are not representative of the population under study (in this case, children with acute abdominal pain). While there were a variety of factors that effected enrolment of patients, including how busy the ED was and the attending clinician's level of comfort with technology, because of the long enrolment period (8 months), the number of clinicians involved (150), and the number of patients seen (574), it is likely that the patient sample is reasonably representative of the population under study.

A typical MET-AP usage scenario for clinicians participating in the study is presented in figure 2. After logging in to the MET-AP system, the attending resident or staff physician would enroll a patient and collect and record their medical history into the system. The attending clinician would then typically collect physical findings from the patient through physical examination and verbal interaction and enter the relevant input variables into the MET-AP system via the user interface. Participating clinicians were instructed to only record data for those input variables they felt were relevant to the patient's presentation. After reflecting on the findings the attending clinician, blinded to the CDSS recommendation, entered his/her prediction of which triage category the patient was most likely to fit (i.e., discharge, observation/investigation, or consult). Where possible, a clinician with a different level of expertise (i.e., resident or staff physician) from the attending clinician was asked to complete an independent interrater assessment within one hour of the original assessment using the MET-AP system as described above.

Forty staff physicians and one hundred and ten residents enrolled patients. This type of prospective evaluation of CDSS is rare, as all physicians were asked to use the MET-AP, not just those few associated with the development team. The physicians had varying degrees of experience with handheld computers before entering the trial and all of them participated in in-depth training sessions after which they were able to easily use the CDSS. Two hundred and twenty two of the patients were seen by both a resident and a staff physician.

Analysis

The analysis starts by addressing H1 to establish whether residents are accurate at eliciting the input variables required by MET-AP. Once that is established, H2 is addressed to compare which MET-AP input variables predict the triage decision in the resident and staff physician decision making models. In this study, the more experienced staff physicians' inputs represent the benchmark to which residents' values are compared. This approach is widely used in the literature to evaluate performance of less experienced clinicians and can take the form of comparing novices to experts performing the same task (Nodine, Kundel, Mello-Thoms, Weinstein, Orel, Sullivan & Conant, 1999; Sklar, Hauswald & Johnson, 1991), or having expert clinicians evaluating the performance of novice clinicians (Burdick et al., 1996; Steinbach, 2002; Wray & Friedland, 1983). As a measure of proper elicitation, we use a level of agreement beyond chance between values for CDSS input variables provided by staff physicians and residents. Statistically, this is measured using the Cohen's Kappa statistic (Cohen, 1960) which was calculated for each of input variables across the two groups of clinicians who have seen the same patient.

Addressing H2 involves the use of logistic regression to determine which CDSS input variables are significant in predicting the clinicians' triage decision. In this analysis, the CDSS input variables are independent variables, and the triage decision made by staff physicians and residents is the dependent variable. It should be clear that the dependent variable is the clinician's actual triage decision, not the decision provided by the CDSS. Logistic regression was chosen given that the dependent variable was categorical. In conducting this analysis we collapsed the original three possible values for the dependent variable (the clinician's triage decision) into two distinct values. This was done by combining 'observation/investigation' and 'discharge' into one category. 'Consult' remained a distinct category. This isolated the significance of the input variables associated with the 'consult' value of the dependent variable. This situation serves as a proxy for a critical triage decision typical of a diagnosis of acute appendicitis.

The regression analysis was conducted separately for data derived from patients who were seen by residents, and patients who were seen by staff physicians so we could investigate and compare decision making models across clinician type. Typical model building strategies suggest doing extensive univariant analyss for each potential independent variable to determine which variables should be added to the model (Hosmer & Lemeshow, 2000). However, epidemiological researchers suggest including all clinically and intuitively relevant variables into the initial model regardless of their significance. Because the input variables included in the MET-AP were derived from a retrospective chart study and were validated with ED physicians, all of them were included in the analysis. Before running the regression, we studied the contingency tables for all independent variables against the dependent variable to ensure that no zero cells existed. This basic logistic regression requirement was met successfully for both resident and staff physician data.

Design Effect

Because this study involved a prospective trial in the ED, it was unrealistic to obtain random sampling of patients, residents and staff physicians. In situations like this, the cluster sampling of a population may suffer from a sampling bias. In order to determine if this is the case, design effects (DEFF) are calculated. This measure assumes that the respondents in the same cluster are likely to be similar to one another and thus each respondent from a cluster typically contributes less new information than would a randomized respondent. The DEFF is calculated as a ratio of the variance under the sampling method employed to the variance computed using simple random sampling (Skinner, Holt & Smith, 1989):

DEFF = 1 + δ (n-1), where:

- δ is the intercluster correlation for the statistic in question
- n is the average size of the cluster

The sample used in our study is not independent because there were multiple staff physicians and multiple residents, each of whom saw more than one patient. A cluster was formed by grouping together the multiple patients seen by a given staff physician and the multiple patients seen by a single resident. Because information on the performance of individual clinicians was not permitted by the Research Ethics Board, the association between staff physician/resident to individual patients is unavailable, and thus it is impossible to calculate δ and subsequently DEFF. To alleviate the concern around clustering, we calculated a 'critical DEFF' defined as the DEFF that would adjust the statistic in question to the point where it was no longer significant at value of 0.05. This approach has been used successfully in previous research (Thomas & Cyr, 2002). The critical DEFF was calculated as:

$$\text{Critical DEFF} = \frac{\hat{W}}{c^2}$$

Where $\hat{W}$ is the calculated Wald Statistic for the CDSS input variable in question, and c^2 is the critical chi square value for n-1 degrees of freedom. While values of DEFF can vary depending on the study design and individual variable in question, research suggests that a well-designed study should result in values of DEFF between 1 and 3 (Shackman, 2001). While it is impossible to accurately estimate the DEFF for this study, we would expect its value to be very low. For the physicians clustering, we would not expect the likelihood that a randomly selected staff physician from the overall population would provide input variable values much different from those currently elicited. While we expect there would be higher variance for the residents (because of less expertise), the cluster size for the resident population in the study is small (because of the large number of residents participating) which might contribute to a lower value of DEFF.

RESULTS

H1: *Accuracy of Collected Inputs*

Kappa measures and associated interpretation information (Posner, Sampson, Caplan, Ward & Cheney, 1990) of agreement between staff physicians and residents for CDSS input variables are presented in table 2. It should be noted that all of the input variables were assessed using discretized values. While some of the input variables are naturally scalar data (for example, temperature), the discretizations adopted were generated by a panel of experts and reflect critical threshold as used by clinicians in daily practice. As expected, input variables which are objective and easily measured or assessed (vomiting, temperature) have high levels of agreement indicating that residents are able to accurately elicit this information. However, all other input variables had only fair or moderate levels of agreement. Except for 'previous visit', the elicitation of these input variables are more difficult and subjective than the previous mentioned input variables. 'Previous visit' is defined as a "previous visit to the ED for abdominal pain during the last 48 hours (irrespective of site)". We suspect that the low value of the Kappa statistic may be attributed to the fact that some of the patient/parent(s) interpreted the first examination (conducted by staff physician/

Table 2. Values of Kappa statistic: resident vs. staff physician

Attribute	Kappa	Agreement Quality[1]
Localized guarding	0.31	Fair
Rebound tenderness	0.45	Moderate
Previous visit	0.48	Moderate
Type of pain	0.48	Moderate
Site of pain	0.51	Moderate
Shifting of pain	0.52	Moderate
Site of tenderness	0.57	Moderate
Duration of Pain	0.83	Very Good
Vomiting	0.89	Very Good
Temperature	0.95	Very Good

resident) as a previous visit when they were asked the same question by the second observer.

The values of Kappa statistic indicate that residents are less accurate eliciting input variable values that require experience and clinical acumen, as opposed to straight application of 'textbook knowledge'. Of the input variables that had fair to moderate levels of agreement, the ones with the lowest values of Kappa (localized guarding and rebound tenderness) are more dependent on experience in conducting physical examination than the remaining attributes (type of pain, site of pain, shifting of pain, site of tenderness) and are typically considered the most difficult to accurately elicit. The elicitation of these physical examination input variables can be obstructed due to the child's sensitivity to being touched, his/her fear, and other factors that may cause muscle contraction leading to misinterpretation. The examination for rebound tenderness is painful for patients when it is present, so repeated examinations to confirm this finding is discouraged. Thus, experience in carrying out examinations is likely to increase the reliability of eliciting values for physical examination input variables. Residents may not have enough experience to distinguish the subtle difference between a patient with true guarding and one that is just uncomfortable with the physical examination (Mangione et al., 1995). At the same time it is important to recognize that according to clinical knowledge, the combination of the presence of localized guarding and rebound tenderness is a 'strong indicator' for surgical consult due to possible appendicitis. In the case of MET-AP input variables, those that are the most difficult for residents to elicit provide the most insight into the patient's state. In summary, those attributes that required physical examination, and thus clinical acumen and experience, to accurately elicit their values for CDSS inputs were done poorly by residents.

The remaining input variables having moderate level of agreement (type of pain, site of pain, shifting of pain, and site of tenderness) are reliant on the ability of the physician to 'touch and ask' to elicit accurate values from the patient. The capability to elicit an accurate response through the dynamic interplay between clinician and patient is affected by level of expertise, with less experienced physicians having weaker information gathering skills (Johnson & Carpenter, 1986; Mangione et al., 1995).

Based on these results H1 is supported. The results add further evidence to the literature that residents do not have sufficient clinical expertise required to reliably elicit information that is dependent on the physical examination. In the next step of our research we wanted to determine differences between MET-AP input variables used by residents and staff physicians in making their triage decisions. Because of the clinical experience required for certain input variables to be correctly elicited, we expect that residents and physicians will use different input variables in their mental decision making models.

H2: *Critical Decision Making Variables*

The results for residents and staff physicians are shown in Tables 3 and 4 respectively. The values of Nagelkerke's R^2 is 0.568 and 0.699 for the resident and staff physician models indicating that the CDSS input variables provide a better fit for staff physician mental model than for the resident model.

The design effects are reflected in critical DEFF values that are shown in Tables 3 and 4 to the immediate right of the calculated p-values. For example, for the 'localized guarding' input variable for the resident analysis, a critical DEFF value of 3.508 is the minimal value required to categorize 'localized guarding' as insignificant. Based on the critical DEFF values for the physician analysis, we would expect one of the 'significant

variables' to become insignificant if simple random sampling was used. Specifically, vomiting (with a critical DEFF of 1.217) will most likely become insignificant. The critical DEFF values for the input variables that are significant for the residents' model are all high enough to expect that these input variables would remain significant if randomized sampling was used. Because of the difficulties associated with calculating values of DEFF and a need to resort to using critical DEFF instead, the results presented here should be interpreted with caution. While this could be viewed as a limitation it should be noted that prospective trial data of CDSS use in a naturalistic setting is rare and efforts should be taken to use the data in a responsible academic fashion.

Localized guarding and rebound tenderness are highly significant in the residents' mental model for making the consult decision. This is not surprising considering the importance of these input variables in determining acute appendicitis. When taken in concert with the Kappa statistic for the same input variables we have a situation where residents rely on input variables that they have trouble eliciting correctly while making a decision to ask for a surgical consult. There are several plausible diverging explanations for this result dependent upon whether residents are cognizant of their (in)ability to properly elicit certain input variables.

Residents may be aware of their deficiencies in eliciting certain input variables, but that awareness is counter balanced or overridden by an accepted clinical guideline that is reliant on aforementioned variables. While this seems counter-intuitive, it is not entirely inconsistent with previous research where residents have been shown to be deficient at performing physical examinations, yet they acknowledge both their own deficiencies and the importance of being able to properly and reliably do physical examinations (Mangione et al., 1995). Our results indicate that the perceived importance of localized guarding and rebound tenderness by the residents outweighs their perception of the degree of difficulty in eliciting the input variable values and the degree of reliability in collecting this information, and thus they use these input variables when making a consult triage decision.

Alternatively, residents may incorrectly feel confident in their ability to elicit all input variables required by the CDSS decision model. In this case we would expect the residents to consider and apply the variables as specified in their training and education into decision making activities. Previous studies have shown that residents cannot accurately estimate their performance and that they have a tendency to overestimate their performance (Parker, Alford & Passmore, 2004). It has also been shown that while residents and physicians both overestimate the accuracy of their clinical diagnoses, residents overestimate more often than physicians (Friedman, Gatti, Franz, Miller & Elstein, 2005). More research is required to investigate perceptions of accuracy of CDSS input variables and resulting clinical decisions.

Overall, staff physicians have more significant variables that predict their triage decision making than do residents. Specifically, site of pain, type of pain, localized guarding and rebound tenderness are significant predictors for physicians. Alternatively, significant predictive variables in the residents' model are site of tenderness, localized guarding and rebound tenderness. H2 is thus supported. These results are consistent with the literature on strategic experts, which states that experts have complex structures that assist in the recognition and interpretation of environmental signals and events (Lyles & Schwenk, 1992) and that these structures are more complex and contain more links among elements than the cognitive structures of less experienced strategists (Day & Lord, 1992; Lurigio & Carrol, 1985; McKeithen, Reitman, Rueter & Hirtle, 1981).

LIMITATIONS, CONCLUSION AND IMPLICATIONS FOR CDSS DESIGN

There are several limitations associated with this study that are worth mentioning. First, a convenience sample of patients was used which can limit the generalizability of the results as there is no guarantee that enrolled patients were representative of the overall population of interest (children with abdominal pain). An additional limitation was the time lag between the assessments made by the clinicians of differing expertise on the same patient (< 1 hour). It is possible in some cases that the patient's condition could change during the time between assessments. There was nothing to indicate that this effect was occurring during the data collection process. As mentioned previously, the sample used in our study is not independent because there were multiple staff physicians and multiple residents, each of whom saw more than one patient. Without the knowledge of which physician and which resident saw which patients, we were unable to apply more advanced statistical techniques such as hierarchical linear modeling to determine the decision making models of the different clinician groups. However, we did attempt to alleviate the above problem by calculating critical DEFF values and applying said values to refine the final logistic regression models. A final limitation relates to the enrollment of patients by the attending clinicians. Those clinicians who were less comfortable with the MET-AP technology could be less likely to enroll patients into the trial.

The quality of any patient specific CDSS is reliant on the quality of the underlying decision model(s). These models have to reflect clinical expertise associated with expert decision makers (staff physicians in our situation). Models associated with such expertise will usually require inputs that are difficult to assess and interpret by novice users. Broadly speaking, customizing CDSS technology for users of different expertise has been proposed by several researchers (Kushniruk, 2001; Patel, Arocha, Diermeier, How & Mottur-Pilson, 2001), but to our knowledge this research is one of the first that provides empirical evidence gathered through the prospective evaluation of a CDSS, that such an approach is required. In typical CDSS designs, residents and physicians would be treated as a single user group, and thus would be interacting and accessing the same interface and underlying decision models.

In evaluating the use of a CDSS for ED triage of patients with abdominal pain, we found that staff physicians and residents elicited several of the CDSS input variables differently while examining the same patients. Specifically, for CDSS input variables involving physical examination typically in concert with verbal elicitation, calculated Kappa values were low indicating that the values recorded by the residents were different than those recorded by staff physicians. Considering that we use staff physicians' values as the benchmark (in accordance with expert vs novice literature), we interpret this discrepancy as indicative of the difficulties the residents had with correctly eliciting values of such input variables. When individual mental decision making models (operationalized as significant CDSS input variables for predicting triage decisions) were examined it was found that the staff physicians and residents models were similar, albeit the staff physicians' model had one more significant variable. The importance of the input variables that required physical examination was underlined by their presence in both staff physicians' and residents' mental models, even though the residents were not eliciting this information accurately. In order to take into account differences in clinical experience and to ensure appropriate support is available to these different user groups, we propose that the CDSS designers should (a) differentiate between information values provided by the data coming from expert and novice assessments, and (b) implement logical attribute monitoring that warns users when a single attribute value or a combination of attribute values is outside of expected ranges or patterns.

To design and implement aids that consider the information value of the inputs, the input variables used in CDSS models must be categorized. Required input variables could be logically categorized based on how difficult they are to elicit and to what extent they are reliant on tacit, explicit, or declarative knowledge. Subsequently, each input variable could be indicated as 'low confidence' or 'high confidence'. While this is a broad categorization, it reflects the ability of different physician user groups to accurately elicit different values of the input variables. While the categorization of the variables is encoded into the system, it can remain relatively transparent to the user (i.e., there would be nothing that would explicitly label a variable as being 'low confidence'). According to the proposed categorization, a typical novice physician would have elicitation difficulty with 'low confidence' input variables. Therefore, the user interface for the 'low confidence' attributes should provide extensive explanations and guidelines to assist the process of collection. Some progress has been made in providing explanations and guidelines for CDSS input elicitation. AI/RHEUM (Kingsland, Lindberg & Sharp, 1983) is an expert-based system for diagnosing rheumatic diseases and was created to provide knowledge elicited from rheumatology experts to physicians with no training in rheumatology. To support physicians in providing accurate input information, AI/RHEUM included an extensive repository of 180 definitions of items from the finding list (Porter, Kingsland, Lindberg, Shah, Benge, Hazelwood, Kay, Homma, Akizuki, Takano & Sharp, 1988). A more recent version of the system this information was augmented with multimedia presentations including videos and pictures and a function to search for referenced articles directly on Medline (Athreya, Cheh & Kingsland, 1998).

Provision for recording imprecise or uncertain information (e.g., selecting several values instead of a single one, entering some 'confidence' factor associated with a value, or having a discrete option for 'uncertain') should be provided. Additional factors related to the process of eliciting values for 'low confidence' input variables should be considered by expanding the clinical value set with conditional information such as 'recorded with difficulty', or 'child crying and fidgeting'. This will allow a dynamic confidence factor to be calculated. Moreover, to help with 'learning by analogy', at any time, and at the users discretion, similar patient cases could be retrieved based on values of individual input variables or on a more complete clinical model. This approach is consistent with knowledge transfer literature that states that while tacit knowledge cannot necessarily be made explicit, it can be transferred through repeated exposure to similar situations and cases (Nickols, 2000). 'High confidence' input variables would not require such additional assistance and could be elicited in the usual manner. Finally, following accepted principles of interaction design, the additional input support functionality for low confidence attributes discussed above should be automatically turned on for less experienced clinicians, while more experienced clinicians could bypass the additional support if desired (Shneiderman, 1998).

In clinical decision making, values of selected attributes often form a certain pattern that is indicative of an underlying health condition. For example, as stated earlier, for pediatric abdominal pain, pain and tenderness located in the right lower quadrant in concert with presence of guarding are indicative of possible acute appendicitis. It is possible to use information about such patterns to develop context sensitive monitoring for values of both individual input variables and their combinations. If values entered by a clinician significantly deviate from the dynamically adjusting thresholds, either assessed individually or within clinical patterns, a CDSS would issue specific warning alerting the clinician to this situation. While this will provide additional support for novice clinicians, it will also help minimize the potential error between user and technology which has recently been identified as an important source of clinical error (Kohn, Corrigan & Donaldson, 2000). The derivation of the thresholds of the input variables should be generated dynamically based on an abstraction of the patient profile and subsequent heuristic matching against a set of likely profiles developed on a basis of past cases. The case base could provide the core knowledge repository on which to derive the threshold values that can be obtained in a manner similar to case-based reasoning in artificial intelligence. Machine learning algorithms and induction techniques could also be adopted to derive threshold values, rules, and patterns that new patient profile information can be compared to. These approaches assume a sufficiently large case database to ensure realistic variances are reflected in establishing the threshold values.

Many decision models implemented into CDSS encapsulate knowledge that relies on evaluating attributes that require experience and significant clinical acumen. Results of the research reported here indicate that residents have not completely mastered this knowledge and thus encounter difficulties with providing the required input to the CDSS. This creates uncertainty about the quality of the recommendations produced by the CDSS. It is clear that customized decision support, taking into account the level of clinical expertise and background of a given physician, is required to ensure that the accuracy of the CDSS is maximized. Such expanded support is as important for the acceptance of a CDSS by physicians as the quality of the underlying decision model and user interface.

ACKNOWLEDGMENT

This research has been funded by grants from NSERC-CIHR and Physicians Services Incorporated. The authors would like to thank Roland Thomas for assistance with the statistical analyses reported in this article.

INTRODUCTION

The widespread availability of new computational methods and tools for data analysis and predictive modelling requires medical informatics researchers and practitioners to systematically select the most appropriate strategy to cope with clinical prediction problems. In particular, data mining techniques offer methodological and technical solutions to deal with the analysis of medical data and construction of decision support systems. Furthermore, fuzzy modelling deals with the ambiguity inherent in all medical problems. These methods can be used to design and develop clinical decision support systems (CDSSs), which, after evaluated from the experts, can be integrated into clinical environments.

Cardiovascular diseases (CVDs) are the leading cause of death in many countries worldwide. According to the World Health Organization, CVDs are the cause of death of 16.6 million people around the globe each year. The multifaceted nature of these diseases, combined with a wide variety of treatments and outcomes, and complex relationships with other diseases, for example, diabetes, have made diagnosis and optimal treatment of cardiovascular diseases a problem for all but experienced cardiologists.

This article addresses the decision support regarding cardiovascular diseases, using computer-based methods, focusing on the coronary artery disease (CAD) diagnosis and on the prediction of clinical restenosis in patients undergoing angioplasty. Methods reported in the literature are reviewed with respect to (i) the medical information that are employing in order to reach the diagnosis and (ii) the data analysis techniques used for the creation of the CDSSs. In what concerns medical information, easily and noninvasively-obtained data present several advantages compared to other types of data, while data analysis techniques that are characterized by transparency regarding their decisions are more suitable for medical decision making. A recently developed approach that complies with the above requirements is presented. The approach is based on data mining and fuzzy modelling. Using this approach, one CDSS has been developed for each of the two cardiovascular problems mentioned above. These CDSSs are extensively evaluated and comments about the discovered knowledge are provided by medical experts. The later is of great importance in designing and evaluating CDSSs, since it allows them to be integrated into real clinical environments.

BACKGROUND

Data Mining is the process of discovering patterns and correlations from large amounts of data, using artificial intelligence, statistical, and mathematical techniques (Tan, Steinbach, & Kumar, 2005). Fuzzy logic is the extension of the classical crisp (binary) logic into a multivariate form. Fuzzy logic is closer to the human logic, thus being able to deal with real world noisy and imprecise data (Wang, 1986). CDSSs are computerized tools developed to assist physicians through the process of decision making. A known approach for the development of CDSSs is the use of experts' knowledge combined with an inference engine. However, recent advances in designing CDSSs employ automated knowledge extraction from data, using data mining techniques, while fuzzy logic provides several advantages in designing inference engines, compared to the classical crisp logic. The combination of data mining and fuzzy modelling provides a powerful tool for fully automated creation of CDSSs, experiencing several advantages: (i) transparency in decision making, (ii) addressing the ambiguity inherent in clinical data, and (iii) ability to interpret all decisions in a medical manner. All the above are of great importance for physicians, when performing decision making.

Coronary artery disease (CAD) is the development of atherosclerotic plaques in coronary arteries, resulting in coronary luminal narrowing and subsequently occlusion, and thus leading to myocardial infarction or sudden cardiac death. Coronary angiography (CA) is considered to be the "gold standard" method for the diagnosis of CAD and it is widely used. However, CA is an invasive and costly procedure that needs high level technical experience and technology and cannot be used for screening of large populations or close follow-up of treatment (Escolar, Weigold, Fuisz, & Weissman, 2006). Computer aided methodologies for CAD diagnosis have also been proposed in the literature; in this case the data obtained by some of the above mentioned methods or other sources (i.e., laboratory examinations, demographic, and/or history data, etc.) are evaluated by a computer-based application, leading to a CAD diagnosis. These methodologies can be divided into various categories, based on the type of data they use for subject characterization. Several methods are based on heart sounds associated with coronary occlusions (Akay & Welkowitz, 1993). Also, methods which employ the resting or exercise electrocardiogram (ECG) of the patient, extracting features from it, like the R wave (Szildgyi, Szildgyi, & David, 1997), the QT interval (Ng, Wong, Mora, Passariello, & Almeida, 1998), the T wave amplitude (Sabry-Rizk et al., 1999), the heart rate variability (Tkacz & Kostka, 2000), and the ST segment (Lewenstein, 2001) have been proposed. Furthermore, there are methods using medical images, such as SPECT (Haddad, Adlassnig, & Porenta, 1997), and methods based on arterio-scillography (Pouladian, Golpayegani, Tehrani-Fard, & Bubvay-Nejad, 2005). There exist also methods that employ demographic, history, and laboratory data (Frossyniotis et al., 2001; Mobley, Schechter, Moore, McKee, & Eichner, 2005; Tsipouras et al., 2006) and methods that combine more than one type of data (Kukar, Kononenko, Groselj, Kralj, & Fettich, 1999; Scott, Aziz, Yasuda, & Gewirtz, 2004).

The evolution and widespread adoption of percutaneous transluminal coronary angioplasty (PTCA) represents a major advance in the management of acute coronary syndromes, resulting in a significant reduction in early and late mortality compared to pharmacologic reperfusion therapy. Coronary artery restenosis remains a major limitation of PTCA and is usually defined as $\geq 50\%$ stenosis in the treated segment at follow up, or at least 50% loss of the original gain in the minimal luminal diameter. Many clinical, angiographic, and procedural features have been studied as predictors for restenosis but it has proven difficult to stratify patients with regard to the risk of restenosis. Knowledge of risk factors for restenosis may help to refine indications of PTCA, reduce the frequency of restenosis, and select optimal candidates for a PTCA procedure. Despite lowering the restenosis rate with the implantation of coronary stents, it occurs in approximately 12-60% of the patients within 6 months after intervention depending mainly on the patients' and procedural characteristics. Computer aided methodologies for the prediction of clinical restenosis have also been proposed in the literature. These can be divided into two categories, regarding the data they use for the analysis: methods that employ only CAD risk factors such as demographic, history, and clinical data (Budde, 1999; Tsipouras et al., 2006) and methods that combine CAD risk factors with angiographic features (Maier, Mini, Antoni, Wischnewski, & Meier, 2001; Resnic, Popma, Ohno-Machado, 2000).

CDDSS FOR CARDIOVASCULAR DISEASES

A recently developed method for automated CDSSs creation is based on data mining and fuzzy modeling (Tsipouras et al., 2006). Specifically, in order to create the CDSS, a three stage methodology is used: (i) creation of a rule-based classifier using data mining techniques, (ii) development of a fuzzy logic model, and (iii) optimisation of the fuzzy logic model's parameters. Briefly, in the first stage, a set of crisp rules is generated. This is performed by inducing a decision tree from a training dataset and then transforming the tree into a set of rules. In the second stage, the crisp set of rules is transformed to a fuzzy set of rules, using a membership function instead of the crisp ones and S and T norms instead of the binary AND and OR operators. Finally, in the third stage, all thresholds and parameters involved in the fuzzy model are optimized with respect to a training dataset. The fuzzy model with the optimized parameters comprises the final CDSS. To apply the above methodology in a specific domain, an annotated dataset is required. The quality of this dataset is very important for developing an effective CDSS. This methodology has been used in order to create CDSSs for CAD diagnosis and prediction of clinical restenosis in patients undergoing angioplasty.

Application to CAD Diagnosis

The dataset used for CAD diagnosis included 199 subjects suspected of having CAD and who underwent coronary angiography for the first time. Patients with known CAD were excluded from the study. Of the subjects, 89 had normal angiograms and in the remaining 110 subjects the presence of CAD was confirmed by two experts. In order to characterise each subject, 19 features (shown in Table 1) were used. Two demographic features were recorded: the age and sex of the patient. From the subject's history data, the family history of CAD, smoking history, history of diabetes mellitus, and measurements of hypertension or hyperlipidaemia were used. The incorporated laboratory investigations were creatinine, glu-

18	Carotid femoral pulse wave velocity (PWVcf)	m/sec
19	Augmentation Index (AIx)	%

cose, total cholesterol, high density lipoprotein, and triglycerides. In addition, Carotid-Femoral Pulse Wave Velocity and Augmentation index were also used as non-invasive indices of arterial stiffness (Van Bortel et al., 2002; Woodman & Watts, 2003). In order to confirm the presence or absence of CAD, coronary angiography was performed by the Judkins technique. All coronary angiograms were visually assessed by two experienced cardiologists to reach consensus agreement. Significant CAD was defined as at least one stenosis of 50% or greater diameter in at least one coronary artery vessel. The absence of CAD was defined as completely smooth epicardial coronary arteries.

In Figure 1 an indicative set of rules is presented. These rules are extracted using data mining and (before fuzzification) were commented by the experts. According to the experts, gender is the most important feature in the produced set of rules. However, this is partially driven from the dataset since 64% of our male population (98/152) was diagnosed with CAD as compared with 25% (12/47) in the female population. Smoking has also been proven to be an important marker for CAD prediction in women; 77% of non smoking women did not suffer from CAD (33/42). In the male population, low HR (i.e., <=49 beats per minute) was found to be an important predictor of CAD; this might be explained by the use of β-blockers (antianginal medications that lower HR) in subjects with very high clinical suspicion of CAD. Also, it appears that elderly males (i.e., age>69 years) with symptoms and signs of CAD have high probability to be diagnosed with CAD, since CAD was found in 92% (24/26) of our elderly male population. In males aged less than 69 years, family history of CAD appears to be a relatively important diagnostic feature for CAD (76% of those with positive family history had CAD, i.e., 26/34). However, some of the derived rules cannot be fully explained based on standard medical knowledge, mainly due to the data-driven nature of the proposed method, which can also discover non important and spurious rules.

```

In Table 2, several computer aided diagnosis methodologies for CAD are presented. Some of the noninvasive methods, such as computerized tomography or magnetic resonance imaging, suffer from similar problems as CA, that is, being costly and requiring specialized technology and expertise, while they are not widely available (Escolar et al., 2006). Most of the computer based methods are based on the analysis of data obtained by examinations, such as stress ECHO and SPECT, which are also expensive, not widely available, and suffer from technical limitations (Merz, 2005). Exercise stress testing is inexpensive and widely available, but cannot be applied to all patients and has low sensitivity and specificity in the diagnosis of CAD. The populations and the parameters collected and analyzed differ among studies; in some of the studies, only male subjects (Lewenstein, 2001; Mobley et al., 2005) or subjects with previous myocardial infarction (MI) or coronary artery bypass grafting (CABG) (Kukar et al., 1999), were included. It should be mentioned that most of the methods reported in Table 2 are based on neural networks (Akay & Welkowitz, 1993, Frossyniotis et al., 2001; Kukar et al., 1999; Mobley et al., 2005; Scott et al., 2004). These methods are not able to provide clear interpretation for their decisions.

Application to Prediction of Clinical Restenosis in Patient Undergoing Angioplasty

The dataset used for prediction of clinical restenosis in patients undergoing angioplasty consisted of 1,000 subjects that underwent angioplasty. In order to characterise the subjects, the 15 features shown in Table 3 were used. Family history, hypertension, diabetes mellitus, current smoking, and hyperlipidemia were defined as for the CAD CDSS. Clinical presentation of CAD was classified as unstable angina, stable angina, or acute myocardial infarction. The vessels treated with angioplasty were the right coronary artery, left

main stem, left anterior descending artery, left circumflex artery, and bypass grafts. The patients underwent either angioplasty with balloon alone or balloon followed by stenting with a noncoated metal stent. All patients were followed up for at least 12 months. The composite end point of the study was clinical restenosis manifested as cardiac death, a new non fatal myocardial infarction or a new revascularisation attempt of the stented vessel in less than 6 months after the initial angioplasty procedure.

In Figure 2, some indicative rules are presented. The experts agree that the most important feature in the production of rules for the prediction of clinical restenosis is the number of diseased coronary vessels since 15.4% (i.e., 87/565) of the multivessel cases presented with restenosis in less than 6 months after the percutaneous coronary intervention (PCI) procedure in contrast to only 7.9% (i.e., 29/365) of the single vessel patients. Patients who underwent the angioplasty in a stable condition (i.e., stable angina) had probably a favourable prognosis (only 8.3% of patients with stable angina presented with restenosis in less than 6 months compared to 13.5% of those with unstable coronary syndromes), except perhaps for older (i.e., > 65 years old) or diabetic people. On the other hand, unstable coronary syndromes (i.e., unstable angina and myocardial infarction) are related to worse prognosis in terms of clinical restenosis even in younger ages (i.e., 55 years old) or patients without many severe cardiovascular risk factors. History of a previous PCI procedure and especially history of coronary aortic bypass surgery (occurrence of restenosis in 19.4% of patients with previous CABG compared to 12.2% without CABG history) are associated with increased risk of restenosis after coronary angioplasty. However, some of the derived rules could not be explained based on current medical knowledge on various interactions among the features used in our models.

In Table 4, a comparison of several computer-aided methodologies for the prediction of clinical

restenosis is presented. Different datasets were used in each method; therefore a direct comparison is not feasible. Some approaches (Budde, 1999; Tsipouras et al., 2006) are based on noninvasively acquired data, while others employ also data obtained from angiographies (Maier et al., 2001; Resnic et al., 2000), thus being invasive approaches. Data analysis is performed mainly using rule based systems (Budde, 1999, Maier et al., 2001, Tsipouras et al., 2006) or artificial neural networks (Resnic et al., 2000).

FUTURE TRENDS

Researchers have spent great efforts in the design and development of CDSSs for several domains in medicine and health care. Most of the CDSSs try to reduce the effort and time of the experts when performing diagnosis. However, a plethora of systems has been presented for staging, treatment, dose adjustment, and follow-up. An important requirement of this type of system is the transparency regarding the automated decisions and the interpretation they provide. Moreover, experts rely more on systems that their automated decisions coincides with established medical knowledge. Integration of knowledge provided by the experts and knowledge generated using data mining methods, for the creation of more sophisticated CDSSs, is the trend of the future. Established medical knowledge combined with data mining models is the key to increase the effectiveness of these systems and provide advanced tools for computer based clinical medicine.

CONCLUSION

CVDs are among the most life threatening diseases worldwide. A vast amount of patients suffering from CVDs are examined, hospitalized, and treaded every day; this has a major impact in national health care systems. The importance of CVDs has lead to the development of a large number of computer-based CDSSs that mainly focus in diagnosis, treatment, or follow-up. An important requirement of a CDSS is its ability to provide transparency regarding the generated decisions, thus providing a clear insight of their inner process for decision making; this is essential for physicians in order to incorporate such systems in their clinical practice. Another important requisite is an extensive evaluation of a CDSS by medical experts, in order to comment on the functionality of the system and fully exploit its potential. Furthermore, the employment of easily obtained and noninvasive features for decision support is considered an advantage since it facilitates the straightforward application of the system. Most of the CDSSs proposed in the literature do not meet these requirements, thus complicating their application in clinical practice. The CDSSs presented in this article fulfill these issues, making them suitable to be used in clinical practice.

KEY TERMS

Artificial Neural Network: An interconnected group of artificial neurons that uses a mathematical or computational model for information processing based on a connectionist approach to computation.

Clinical Decision Support Systems (CDSS): Computer based methods that aim to assist clinicians in decision making. The core of CDSSs is an inference engine that can generate case specific advice based on medical data.

Clinical Restenosis: Death presumably from cardiac causes, myocardial infarction not attributable to another coronary artery than the target vessel, and target vessel revascularization either by repeat PTCA or CABG.

Coronary Artery Disease: The narrowing of the coronary arteries, sufficiently to prevent adequate blood supply to the heart muscle. It is usually caused by atherosclerosis and may progress to the damage of heart muscle.

Data Mining: The process of extracting previously unknown and potentially useful knowledge, hidden in large volumes of data.

Fuzzy Logic: A way of reasoning that can cope with uncertain or partial information.

Inference Engine: The part of a decision support system that performs the reasoning function.

Analysis and Intuition in Strategic Decision Making:

The Case of California

Zita Zoltay Paprika
Corvinus University of Budapest, Hungary

INTRODUCTION

"The primary wisdom is intuition."
Ralph Waldo Emerson, American philosopher

Many management scholars believe that the process used to make strategic decisions affects the quality of those decisions. However, several authors have observed a lack of research on the strategic decision-making process. Empirical tests of factors that have been hypothesized to affect the way strategic decisions are made are notably absent (Fredrickson, 1985). This article reports the results of a study that attempts to assess the effects of decision-making circumstances, focusing mainly on the approaches applied and the managerial skills and capabilities the decision makers built on during concrete strategic decision-making procedures. The study was conducted in California between September 2005 and June 2006 and it was sponsored by a Fulbright research scholarship grant.

Strategic decisions are those that affect the direction of the firm. These major decisions concern areas such as new products and markets, product or service development, acquisitions and mergers, subsidiaries and affiliates, joint ventures, strategic alliances, finding a site for a new investment, reorganisation, and other important matters. Strategic decision making is usually conducted by the firm's top management, led by the CEO (chief executive officer) or president of the company. That is why in this research 20 top-level managers were targeted: 12 were CEOs, presidents, vice presidents, or chief financial officers (I will call them executives) while 8 were founders and majority owners of their own enterprises (they will be called entrepreneurs). Sixteen respondents were male, four were female. The average respondent has been working for 28.7 years in general, for 13.8 years for the actual company, and for 8.4 years in the current position. Sixty percent of the respondents have a graduate business degree, 60%

have an undergraduate degree, seven of them have an MBA or a PhD, and two out of these seven have both an MBA and a PhD. One respondent is working on his PhD right now.

The interviews took 2½ hours on the average, varying from 2 hours up to 5 hours. During the interviews, a preliminary structured list of questions was followed. With each respondent we investigated the circumstances of four different strategic-decision cases from his or her practice. The participants could choose the cases on their own. Using this technique, a database of 80 strategic decisions could be built.

BACKGROUND

Kathleen M. Eisenhardt (1998), professor of strategy and organisation at Stanford University, found that top managers at more effective firms were able to make quick and high-quality decisions that were highly supported throughout the firm. Her studies identified four areas in which effective decision makers outperformed counterparts at less effective firms:

- Building collective intuition
- Stimulating conflict
- Maintaining a pace or schedule for decision making
- Defusing political behaviour

In my research, I focused on the role of intuition in strategic decision making. As Ashley F. Fields (2000) stated, intuition is one of the more mysterious concepts associated with the study of human capital. Classical theoreticians, from Carl Jung (1934) to Chester Barnard (1938) and Abraham Maslow (1954) have commented on the existence and value of intuition in organisational settings. Carl Jung said, "Intuition does not denote something contrary to reason, but something outside of the province of reason." It is real but it is not in our heads, and our heads cannot control it. Harold Leavitt (1975) viewed intuition as a valuable weapon to be used against the heavily analytical practices, which gave rise to his derisive term "analysis paralysis." Fascination with the subject of intuition remains alive and well in recent years too.

Intuition is usually defined as knowing or sensing something without the use of rational processes. Alternatively, it has been described as a perception of reality not known to consciousness, in which the intuition knows, but does not know how it knows. Westcott (1968) redefined intuition as a rational process, stating that it is a process in which an individual reaches a conclusion on the basis of less explicit information than is ordinarily required to reach that decision. Weston Agor (1997) argued that intuition is a built-in capacity that some of us have and some do not. In my research, I basically relied on the definition given by Martha Sinclair and Neal Ashkanasy (2000). According to these authors, intuition is a non-sequential information processing mode, which comprises both cognitive and affective elements and results in direct knowing without any use of conscious reasoning. Practically, it is an unconscious process of making decisions on the basis of experience and accumulated judgment.

Isenberg (1984), who studied managers in Fortune 500 firms, found that they combine both rational and intuitive methods in decision making. Parikh (1994) studied more than 1,300 managers and found that intuition is cross-national. Catford's (1987) study of 57 business professionals demonstrated that intuition was used commonly as a business tool. These and many other researchers have demonstrated that intuition is used regularly in the conduct of business (Fields, 2000).

Interestingly, more than half of today's intuition books are authored by females. Psychologists debate whether the intuition gap is truly intrinsic to gender. Whatever the reason, Western tradition has historically viewed rational thinking as masculine and intuition as feminine. Women's way of thinking gives greater latitude to subjective knowledge. Some personality tests show that nearly 6 in 10 men score as "thinkers" (claiming to make decisions objectively, using logic) while 3 in 4 women score as "feelers" (claiming to make decisions subjectively, based on what they feel is right; Meyers, 2002).

In recent years instinct appears ascendant. Decision makers have good reasons to prefer instinct. In a study, executives said they use their intuition as much as their analytical skills, but credited 80% of their success to instinct (Buchanan & O'Connell, 2006). Mintzberg and Westley (2001) explain that strategic thinking calls for creativity and synthesis, and this is better served by intuition than analysis. Buchanan and O'Connell cited some famous statements related to intuition:

"Pragmatists act on evidence. Heroes act on guts."

"Intuition is one of the X-factors separating the men from the boys."

One feature common to all the authors cited above is an inability to articulate a coherent, consistent, and verifiable theory of what underlies the intuitive phenomenon. These researchers unanimously declare that something really exists, but they cannot agree on just what exists or why it works as it does (Fields, 2000). Recent advances in cognitive science and artificial intelligence suggest that there is nothing mystical or magical about intuitive processes, and that they are not paranormal or irrational. Rather, intuitive processes evolve from long experience and learning and consist of the mass of facts, patterns, concepts, abstractions, and generally what we call formal knowledge or beliefs, which are impressed in our minds (Isenberg, 1984; Simon, 1987). Intuition is not the opposite of rationality, nor is it a random process of guessing, as we very often think. It is a sophisticated form of reasoning based on chunking that an expert hones over years of job-specific experience. Consequently, intuition does not come easily; it requires years of experience in problem solving and is founded upon a solid and complete grasp of the details of the business. However, in some cases, it compresses experience and learning into seconds, as it was shown in some cases during my interviews.

RATIONAL/INTUITIVE ORIENTATION

The lack of field studies in strategic decision-making processes called for a research study to examine concrete real-life cases and to analyze the following:

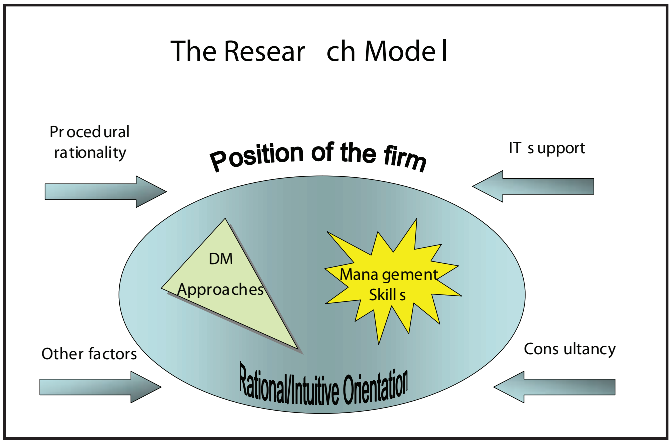
- How top-level managers really make strategic decisions.
- How entrepreneurs and executives differ, if at all, in their approach to strategic decision-making processes when they combine rational thinking with their intuition
- Similarities and differences, if any, in management skills between entrepreneurs and executives

The logic of the research model can be described as seen in Figure 1.

Rational/intuitive orientation is a concept that has yet to make a significant impact on mainstream decision-making research. Consequently, no well-established indicators of rational/intuitive orientation exist. Based on understanding the concept, however, two optional indicators (decision-making approaches and management skills) were identified in this study.

In the literature of decision theory, several models of organisational decision making can be found. These differ from each other in the sense that they use other prerequisites of decision makers and also refer to the organisational connections of decision makers. On the basis of the above dimensions, four different models and decision-making mechanisms were identified (analytical, political, bounded rationality, and intuitive). Eleven man-

Figure 1. The research model



agement skills were investigated and rated as to whether they support analytical or intuitive thinking. In this article, we will focus on the core of the above-mentioned research model, namely on rational/intuitive orientation.

The main hypotheses of the research can be summarized as follows:

H1: Intuition plays a key role in strategic decision making since strategic problems are ill structured and hence cannot be programmed. Decision makers at the top level combine analytical and intuitive approaches, but more heavily rely on their intuition.

H2: Intuitive decision making is more favoured by independent decision makers (entrepreneurs) who have extended control over their firms and are more often in the final decision maker's position. When they put the dot on the i, they are almost always intuitive.

H3: The level of management skills is high. The creative/intuitive skills are even more developed in the sample.

Herbert Simon (1982) was the first to distinguish between the two extreme types of decisions. He called recurring, routine-like, or ready-made ones programmed decisions, while those being unique and unstructured with long-term impacts were called nonprogrammed decisions. Programmed and nonprogrammed decisions naturally set the two extreme poles of one continuum, and the appearance of interim cases is much more probable. In the course of company operations, it happens very rarely that a decision situation clearly corresponds to the terminology of the programmed or nonprogrammed decisions. On the other hand, most managers develop some kind of practice for the handling of nonprogrammed decision situations that can be successfully applied if a ready-made solution can be fitted to an actual situation. Certain nonprogrammed decisions may become programmed in the course of time in a company's practice. It is rather meaningful that programmed and nonprogrammed decisions are sometimes referred to as well structured and ill structured as well.

A central part of this survey consisted of the examination of 20 plus 60 real strategic decisions. At the beginning of the interview, every respondent could mention a big case that was mainly ill structured. When I asked the respondents to quote three more decision cases, they mainly mentioned semistructured problems that could be positioned somewhere between the well-structured and ill-structured extremes. These cases were not as big as the previous 20 decision situations, but they still had long-term consequences and strategic importance. Practically, each participant could mention four cases, one big case and three semi-structured cases. This is how the database of the survey was built up based on the cases of the 20 contributors.

In the interest of comparability, the semistructured decision cases were classified into categories that are borrowed from the "Bradford Studies" (Hichson, Butler, Cray, Mallory, & Wilson, 1986). According to this, I distinguished the following types of decisions:

- Investment
- Reorganisation
- Acquisition
- Fundraising
- Marketing
- Service or product development
- Production
- Finding a site for investment
- Human resource management
- Quality management
- Other decisions

Decisions related to service or product development (10), investment (9), reorganisation (9), marketing (8), and finding a site for investment (7) were the most frequently mentioned cases. However, I also found at least a single case for each other category.

The respondents mixed the analytical and intuitive problem-solving approaches when they made these decisions. As they argued, they found it very difficult to use only the rational approach for these semiprogrammed decisions, therefore intuitive decision making was very often valuable and also applied. However, it was also typical that decision makers made their decisions and later developed rational-sounding reasons for the decision after the fact. It seemed that for some reason they like to be seen as rational. However, some of them were very proud of relying on their instinct in solving particular cases. Demonstrating the concept of bounded rationality, the respondents recognized that at least in part their decisions were based on intuition or a gut feeling. This was most typical in marketing cases, where the respondents needed more experience and judgment than sequential logic or explicit reasons to make those decisions. As they explained it, they made these decisions based upon what they believed to be right rather than upon what they could document with hard data. In the other categories, especially in cases of service or product development, investment, acquisition, and finding a site, they did not find it appropriate to apply this kind of logic.

When the respondents were given an extra opportunity to rethink their earlier answers concerning the analytical and intuitive approaches in their cases, they changed their minds only slightly. If they could repeat the same decisions, which will of course never happen, they would rely more on analysis in marketing decisions too, but in service and product development interestingly would give more room for intuition.

Clearly, there were major perceived differences between entrepreneurs' and executives' answers in terms of how their decisions were made. One of the main differences is that executives tend to exhibit more characteristics of analytical decision making than entrepreneurs do. Executives more heavily rely on the analytical approach. However, it is interesting to note that entrepreneurs are more careful in cases of investment decisions, where they insist on preliminary analytical investigation. A logical explanation could be that they risk their own money when investing and are therefore more careful about it.

The quality of the decision-making activity and the company's success is considerably influenced by the fact of who makes the decisions, what skills and capabilities they have, what their managerial style is, and also what techniques and methods they use in the course of decision making. Consequently, it is not only the applied decision-making approach and the managerial style that leave their mark on decision making, but equally important is the level of professional abilities, education, and experience the managers have.

What characteristics or individual skills must management have to be successful? The survey embraced the general abilities of management. What is more, in the in-depth interviews I encouraged respondents to make some self-evaluations. I asked them to define their strengths and weaknesses according to the investigated characteristics and skills by evaluating themselves on a five-point Likert scale. However, the first task was to rank the skills according to their importance. Considering the opinions of all respondents (N=20), the "image of the ideal manager" fulfilling all expectations of management appeared in decreasing order:

- Excellent communication skills
- Sense for business
- Problem-solving skills
- Practice-minded behaviour
- Ability to represent ideas
- Risk-taking nature
- Expertise
- Organising skills
- Executive skills
- Analytical skills
- Use of PC and computers

Some interesting features are revealed from this ranking. Naturally, the top and the bottom of the list are worth attention, since the skills there outline a manager image frequently mentioned during the interviews. The major task of a manager is to communicate inside and outside of the company (as they stated they do most of the marketing) while the use of computers at top level is not a must since they can get all necessary IT support whenever they need. The other skills could be divided into two subgroups. As one of the respondents stated, the skills that are more important, which you cannot buy, happen to be in the upper part of the list, while those that are available through different channels, for example, consultancy, like organising skills, analytical skills, or IT knowledge, are in the second half of the list.

If we compare these results to the actual self-assessments, we can see interesting evidence of cognitive dissonance. The respondents ranked less important their weaknesses and more important their strengths. They were far beyond the average performers (if we define this category on a five-point scale with the middle position indicated by 3) on all criteria except one, the use of computers, but as we saw earlier, they did not feel that fact was a disadvantage. They are very good communicators, which I can confirm based on my personal experiences. They quite heavily rely on their accumulated knowledge, experiences, and expertise, and are equipped with the necessary problem-solving skills. They named as a real strength their sense for business. We cannot forget that two fifths of them are the founders and majority owners of their enterprises in the sample. Two of them started totally new businesses when they recognized new business opportunities. They left behind their emerging and safe careers and chose unknown and challenging new fields. Both of them are very successful in their new businesses.

We know that some skills and capabilities support more the intuitive way of problem solving than the others. My research method also involved interviewing a dozen university professors in an effort to link the management skills involved in this research with the analytical or intuitive way of problem solving. A quick survey was designed and the professors were asked to evaluate the above-mentioned skills by indicating whether these skills supported analytical or intuitive thinking strongly. They could mark only one answer for each skill. All of the respondents had strong management background since they were teaching either in the field of organisational behaviour or decision sciences.

The skills were split into two groups depending on their role supporting intuitive or analytical problem solving. According to the opinion of the university professors with management background, intuitive thinking and problem solving are best supported by the following skills: a willingness to take risks, a sense for business, the ability to represent ideas, practice-minded behaviour, and excellent communication skills. On the other hand, different skills take precedence when problems require analytical solutions. The skills that most support this approach were determined to be analytical skills, computer skills, organising skills, professional expertise, and problem-solving skills. Not surprisingly, executive skills are somewhere between these two groups of skills since effective leadership requires a combination of analytical and intuitive approaches.

Subsequently, I revised this distinction at two points. Most of the authors (Csikszentmihalyi, 1996; Klein, 2004; Sinclair & Ashkanasy, 2005) agree that intuition is nothing else than experience put into practice. This demystified definition of intuition shows how one can become expert in one's profession through one's cumulative experience or knowledge. Klein argues that intuition is a developed sense helping to put experience into recognizable patterns for future use. As it is well known, good communication skills often go with good analytical skills since both are the functions of the left hemisphere of the brain (Browning, 2005).

Putting this split into practice, the chart of the managers shows a rather balanced picture of their analytical and intuitive skills. Problem-solving skills lead the rank of the analytical skills while business sense is the most important strength among the intuitive skills. Among the 80 analyzed decision cases, I found much that confirms the importance of business sense as the path toward success. The weaknesses are compensated by the high level of strengths. Lack of computer knowledge or organising skills does not seem to be a big problem because top-level managers can easily find someone to do these jobs.

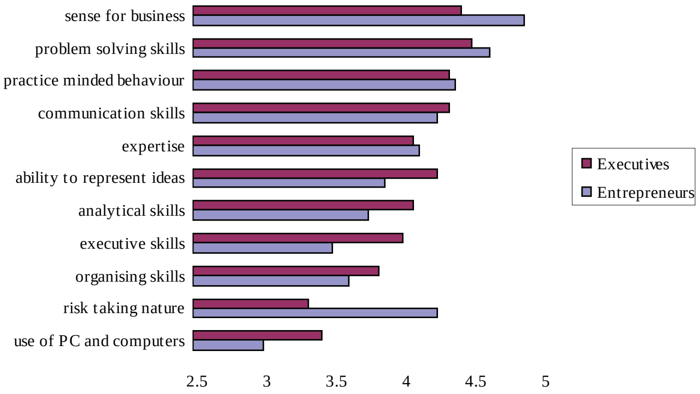
The largest gap could be recognized in the ability to represent ideas. Entrepreneurs do not have to sell their decisions because they are typically the final decision makers; consequently for them this skill is not a must. Their priorities are instead risk-taking nature, problem-solving skills, a sense for business, and communication skills. Executives consider the ability to represent ideas far more important than the entrepreneurs. Analytical and organising skills are ranked a little bit higher by them too.

Differences between groups that exceed 10% are considered to be very significant in survey research. There were relatively large differences in this research between the two responding groups according to the capabilities and skills based on their self-assessments (Figure 2). Entrepreneurs have better business sense and they are ready to take far more risks. They evaluated their problem-solving skills slightly higher than the executives. Executives' strengths are in the ability to represent ideas, analytical skills, and executive skills. The more balanced picture emerged when we compare practice-minded behaviour, communication skills, and expertise.

FUTURE TRENDS

When analyzing these findings, it must be remembered that these results were based on self-assessments. Rarely are self-assessments and independent (objective) assessments congruent. However, we do not have any techniques to measure the level of the different management skills and capabilities or decision-making approaches objectively yet. We feel that there might be a lack of agreement between the self-assessments and an imaginative objective assessment of these parameters. We call this gap "the coefficient of self–delusion." This coefficient can be positive (when the objective rating is higher than the self-assessment) or it can be negative (when the objective ratings are lower than the self-assessments). The

Figure 2. Differences in management skills of executives and entrepreneurs



positive coefficient of self-delusion occurs with people who either are genuinely humble or may be trying to avoid overinflating their self-ratings for a variety of reasons, for example, because of their cultural background. The negative coefficient of self-delusion usually occurs with people who are not conscious of the impact of their behaviours on others or they have an inflated sense of self. In either case, it is important to investigate why the assessment gap exists and reflect upon ways that it can be narrowed, perhaps even closed, which is a big research challenge.

There is a big debate at the present time whether the analytical or the intuitive way of thinking is more powerful in the business arena. Thomas Davenport (2006) argued that some companies have built their very businesses on their ability to collect, analyze, and act on data. Every company can learn from what these firms do. The popular "head vs. formula" controversy that is based mostly on laboratory studies in the past established the superiority of the rational-analytical approach over the soft judgmental or intuitive approach. The extension of this approach to strategic decision making is problematic, however. This is because strategic decisions are characterized by incomplete knowledge. Consequently, it may be impossible to identify quantitative equations among variables and find numeric values for parameters and initial states. That is why people still use their heads instead of formulas in strategic cases (Khatri & Alvin, 2000). As a conclusion of the very intensive debate, there is now an agreement that intuition is not an irrational process. It is based on a deep understanding of the situation. It is a complex phenomenon that draws from the store of knowledge in our subconscious and is rooted in past experience. It is quick, but not necessarily biased as presumed in previous research on rational decision making (Khatri & Alvin).

CONCLUSION

In everyday language, we tend to use the word intuitive with some connotation of irrational. This is probably due to Bergson (1911) who attached great importance to intuition but interpreted it as a mystic force that by definition could not be subject to rational means of inquiry (Wierzbicki, 1997). However, almost a hundred years of research in various fields of science now leads to a reversal of this interpretation. In the management literature of our days, we can read that intuition is not arbitrary or irrational because it is based on years of practice and hands-on experience, often stored in the subconscious. Managers started to accept that new interpretation and they believe that their intuition is part of their business knowledge. Decision support systems might help to strengthen this perception by providing user-friendly tools to obtain and sort the necessary knowledge for successful decisions. It will probably take time until this view is widely recognized.

This study showed that executives in a corporate setting tend to view decision making differently than entrepreneurs. Since they are typically given a fixed amount of budgeted resources to work with, they tend to define a problem in terms of what can be done with the resources on hand. Entrepreneurs, on the other hand, will likely pose the problem in terms of an objective. They usually state, “This is what I want to get done,” and then start to worry about finding the resources to accomplish that objective. As a result, entrepreneurial decision makers feel less constrained by the lack of resources. They are famous for making “seat-of-the-pants” decisions, which means they make quick decisions based on a good feeling or intuition. This kind of challenge requires different skills from the entrepreneurs than from the executives.

There was another interesting finding when I compared the decision-making practices of the executives and the entrepreneurs. Both groups relied quite heavily on analysis in the preparation phase of the decision-making process, which gave room for decision support applications. However, executives were ready to follow the decision support systems’ recommendations in the moment of choice while entrepreneurs preferred to follow their intuition. As a conclusion, we can state that entrepreneurs’ support must focus mainly on the preparation phase, and decisions should be made by them vs. support systems.

KEY TERMS

Analytical Skills: The skills that most support the analytical approach in problem solving are determined as follows: analytical skills, computer skills, organising skills, professional expertise, problem-solving skills, and communication skills.

Intuition 1: Intuition is usually defined as knowing or sensing something without the use of rational processes.

Intuition 2: Intuition has been described as a perception of reality not known to consciousness, in which the intuition knows, but does not know how it knows.

Intuition 3: Intuition is a rational process in which an individual reaches a conclusion on the basis of less explicit information than is ordinarily required to reach that decision.

Intuition 4: Intuition is a nonsequential information processing mode, which comprises both cognitive and affective elements and results in direct knowing without any use of conscious reasoning.

Intuitive Skills: Intuitive thinking and problem solving are best supported by the following skills: the willingness to take risks, a sense for business, the ability to represent ideas, and practice-minded behaviour and expertise.

Nonprogrammed or Ill-Structured Decisions: Unique and unstructured decisions with long-term impacts are nonprogrammed decisions. Programmed and nonprogrammed decisions naturally set the two extreme poles of one continuum and the appearance of interim cases is much more probable. In the course of company operations, it happens very rarely that a decision situation clearly corresponds to the terminology of the programmed or nonprogrammed decisions. On the other hand, most managers develop some kind of practice for the handling of nonprogrammed-decision situations that can be successfully applied if a ready-made solution can be fitted to an actual situation. Certain nonprogrammed decisions may become programmed in the course of time in a company's practice. It is rather meaningful that programmed and nonprogrammed decisions are sometimes referred to as well-structured and ill-structured decisions as well.

Programmed or Well-Structured Decisions: Herbert Simon was the first to distinguish between the two extreme types of decisions. He called recurring, routine-like, or ready-made ones programmed decisions.

Strategic Decisions: Strategic decisions are those that affect the direction of the firm. These major decisions concern areas such as new products and markets, product or service developments, acquisitions and mergers, subsidiaries and affiliates, joint ventures, strategic alliances, finding a site for a new investment, reorganisation, and other important matters. Strategic decision making is usually conducted by the firm's top management, led by the CEO or president of the company.

Section V

Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of strategic information systems around the world. Chapters included in this section analyze organizational knowledge management, e-collaboration, and group decision support systems. The inquiries and methods presented in this section offer insight into the implications of strategic information systems at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1

Group Decision Support Systems

John Wang
Montclair State University, USA

James Yao
Montclair State University, USA

INTRODUCTION

Group decision support systems (GDSSs) which aim at increasing some of the benefits of collaboration and reducing the inherent losses are interactive information technology-based environments that support concerted and coordinated group efforts toward completion of joint tasks (Dennis, George, Jessup, Nunamaker, & Vogel, 1998). The term *group support systems* (GSSs) was coined at the start of the 1990's to replace the term GDSS. The reason for this is that the role of collaborative computing was expanded to more than just supporting decision making (Patrick & Garrick, 2006). For the avoidance of any ambiguities, the latter term shall be used in the discussion throughout this paper.

If we trace back, GDSSs are specialized model-oriented *decision support systems* (DSSs) or management decision systems that were born in the late 1960s. By the late 1970s, a number of researchers and companies had developed interactive information systems that used data and models to help managers analyze semi-structured problems. From those early days, it was recognized that DSSs could be designed to support decision makers at any level in an organization. DSSs could support operations, financial management, and strategic decision making.

BACKGROUND

In the early 1980s, academic researchers developed a new category of software to support group decision making. Execucom Systems developed *Mindsight*, the University of Arizona developed *GroupSystems*, and researchers at the University of Minnesota developed the *SAMM system (Power, 2003).* These are all examples of early GDSSs. The increased need for GDSSs arises from the fact that decision making is often a group phenomenon, and therefore computer support for communication and the integration of multiple inputs in DSSs is required. The desire to use GDSSs therefore comes from the need of technological support for groups.

GDSSs are designed to remedy the dysfunctional properties of *decision*-making *groups*. These systems are becoming popular in aiding *decision* making in many organizational settings by combining the computer, communication, and *decision* technologies to improve the *decision*-making process. These systems use a key tool to improve the quality of *decisions made by a group*. This key tool is the anonymity of members of a *decision*-making *group*. The purpose of GDSSs is to maximize the benefits of group work, while minimizing the dysfunctions of group work. This maximization and minimization can be made possible by GDSSs mainly by two factors: anonymity and parallelism.

MAIN FOCUS

Strengths and Weaknesses of GDSSs

GDSSs provide a lot of support for communication, deliberation, and information flow especially for group activities that may be distributed geographically and temporarily. Group work has numerous benefits and advantages. First, groups are better at understanding problems and catching errors than individuals. Second, a group has more information than any one member which when combined can create new knowledge. Third, working in a group stimulates creativity and synergy. Finally, groups balance out the risk-tolerant and risk-averse. GDSSs offer many benefits. First, GDSSs support parallel information processing, parallel computer discussion, and generation of ideas. Second, they promote anonymity, which allows shy people to contribute and helps prevent aggressive individuals from driving the meeting. Finally, these systems help keep the group on track and show the big picture. The two keywords here are parallelism and anonymity (Turban, Aronson, & Liang, 2005).

Some of the potential dysfunctions of group work are not automatically eliminated by GDSSs. First, as mentioned earlier, groupthink is where people begin to think alike and not tolerate new ideas. We can also include inappropriate influences, and free-riding. Second are the lack of coordination, excess time consumption, poor quality solutions, and nonproductive time. Third are the duplication of efforts, and high cost of meetings, including travel. Finally, information overload, concentration blocking, and group misrepresentation add to the potential dysfunctions of group work. Process dysfunctions are caused by structural characteristics of the group setting that could hinder a group from reaching its full potential. Process dysfunctions hinder productivity because of unequal participation or unequal air time; this happens in a setting where only one person can take control of the floor. This sort of dysfunction can be countered by the use of computerized exchanges because people may enter their comments and thoughts simultaneously. Power (2003) states that simultaneous expression of ideas may be beneficial for the quantity of ideas generated because of the computer's capacity for concurrency. Finally, process dysfunctions are usually caused by limitations in the structure and form of meetings.

Social dysfunctions, as Power (2003) describes, can hinder group productivity through undesirable social processes that occur in the group. For example, a group may limit the quality and quantity of input from any of its members by social processes such as evaluation apprehension, conformity pressures, free riding, social loafing, cognitive inertia, socializing, and domination due to status imbalance, groupthink, and incomplete analysis. These problems arise from processes present in all groups and are rooted in the ways in which group members change their behavior to adapt to the group. Finally, the prevalent analysis of group decision making is that social influences within the group lead the rational individual astray.

The view of GDSSs portrayed by Power (2003) is that they are text-based tools made with the purpose of remedying some problems of *decision* making in co-present *groups*. These *systems* claim to remove the social obstacles that prevent individuals from attaining their full potential in the *group*. Anonymity is central to achieving this full potential of individuals in a group.

Recent GDSSs Research Findings

Decision-making in an organization today has become more the work of some form of group. Whether this group is a board, team, or a unit, important issues can be at stake. It is fair to ask, given the possible problems that occur in a group setting: Would the group setting have a negative effect on the quality of decisions that have to be made by the group? Current research in this area suggests that GDSSs, if implemented and used correctly, can improve the quality of group decision making significantly by minimizing the negative effects of group decision making and by maximizing the benefits of group collaboration and decision making. Having come a long way since their inception, current and previous research efforts have made significant findings on the effects of the numerous criteria that affect the decision-making process in a group setting while using GDSSs. The results show that while the Internet has made it easier and less costly to use GDSSs than ever before, the social effects of group decision making can have a significant effect on the quality of decisions made in a group setting using GDSSs. By manipulating things such as visual cues, group versus individual-based incentives, anonymity, group size, feedback, leadership role, communication mode, type of tool used, social presence, face-to-face versus distant, shift work or non-shift work, the fit between facilitation style and agenda structure, and finally, a relationship versus a task focus, it is possible to significantly impact the quality off decisions made by a group using GDSSs.

According to Barkhi, Jacob, and Pirkul (2004), GDSSs are divided into two groups: distributed GDSS (DGDSS) and face-to-face GDSS (FGDSS). DGDSS groups consist of members who use a GDSS at the same time but at different places. On the other hand, FGDSS groups consist of members who use a GDSS at the same time and same place. The authors studied and compared the decision process and outcomes of groups that use FGDSS to those that use DGDSS. The results indicate communication mode, and incentive structure can influence the effects of each other. Therefore, the appropriate design of incentive structures may be important to the success of virtual organizations.

The *Web-based multi-criteria group support system* (MCGSS) according to Zahir and Dobing (2002) is designed so that users can enter their preferences in an easily understood and user-friendly interface through a Web browser. They state that easy-to-learn and user-friendly interfaces are essential if GDSSs are to become more commonly used in organizational decision making and that MCGSS uses a new visual mode of preference entry. The relative importance of any two objects is expressed through a pair of side-by-side bars drawn in a graphical window. The ratio of the heights of two bars represents the user's relative preference for the two objects. Bar heights can be adjusted dynamically by dragging the mouse or utilizing some other device. Their article presents the design of a Web-based MCGSS that can be used by a group of geographically dispersed decision makers. This system takes advantage of Internet technology and enables a novel procedure to aggregate intensities of preferences.

In line with Kim (2006), the role of leadership facilitates group processes by adding structure to group interaction. The effects of leadership on group performance in GDSSs settings still remains one of the least studied areas of GDSSs research. An analysis of comments by group leaders show that they are more efficient when making comments on group objectives and interaction structure, but this is only true in the early stages of group interaction. In the later stages, it is of increasing importance that group leaders make comments that encourage interaction and maintain cohesion between members of the group. Dennis and Wixom (2001/2002) presented a meta-analysis investigating five moderators. These moderators are as follows: tool, the type of group, task, the size of the group, and facilitation. The authors studied their effects on GDSSs. Results of the study draw multiple conclusions. First, process satisfaction is less for decision-making tasks than it is for the idea-generation tasks. Second, the GDSSs tool itself influences decision quality. Finally, the authors conclude that group size is an important moderator when it comes to measuring satisfaction with the process and decision time.

Rutkowski, Fairchild, and Rijsman (2004) demonstrated experimentally that in the context of dyadic conflict, patterns of interpersonal communication, supported by a particular GDSS technology, affect the quality of decision making. The authors find that GDSSs are efficient tools that support inter-group communication and relations. The authors also delve further into this topic and discuss the implications of their research on the study of intercultural negotiation and conflict resolution. Groups are becoming increasingly important in organizations, and that they use electronic groupware to facilitate communication and workflow. Barkhi (2005) compared the performance and information exchange truthfulness of groups under these various experimental conditions. The author utilizes a game theory perspective to study the behavior of members in these groups. The results indicate that communication channel and incentive structure mitigate strategies that lead to decision choices and information exchange truthfulness among members in a group.

GDSSs can improve communication and learning as demonstrated by Bandy and Young (2002). Their study examined the impact of two collaborative technologies and a priming agent upon communication complexity and learning style in a group decision-making context. Findings revealed that communication complexity was significantly greater in groups using a GDSS compared to groups using a simple chat system, suggesting that characteristics of the GDSS served to structure discourse among group members. Burke (2001) examined how GDSS learning environments (face-to-face vs. distant) and task difficulty level (simple vs. difficult) influenced participation levels and social presence among accounting students working collaboratively on an accounting task.

Hostager, Lester, Ready, and Bergmann (2003) examined the effects of agenda structure and facilitator style on participant satisfaction and output quality in meetings employing GDSSs. This study indicates that GDSSs facilitators should try to find a fit between their facilitation style and the agenda structure, while not forgetting to adopt either a relationship or a task focus and ensuring that they are consistent with their choice. A GDSS is designed as an analysis tool to support the decision processes of a group. Inherent in the design is the developer's desire to make the basic meeting process better either by increasing process gains or reducing process losses. Further, it is suggested by Martz and Sheperd (2003) that one way that GDSSs attack these losses is by providing immediate feedback.

GDSSs in the Real World

There are options for setting up GDSSs technologies. One of them is in a special-purpose decision room, another is at a multiple-use facility, and the third is a Web-based groupware with clients running wherever the group members are.

Facilitating Meetings

One example of the use of GDSSs is the system developed by a group of researchers from the University of Arizona to facilitate the organization of meetings. A typical meeting room consisted of a microcomputer for each participant, as well as a large projector for the display of either individuals' work or the combined results off the group efforts. A typical meeting consisted of a three-tier process consisting of electronic brainstorming, idea generation, as well as voting. Under the electronic brainstorming phase, all group members typed at separate terminals using electronic brainstorming software, and recorded their ideas regarding questions posed for the day. Even though these sessions were anonymous, everyone could see the abundance of ideas. Additionally, an issue analyzer assisted the group in identifying and consolidating key ideas generated from the idea generation. Finally, a voting tool provided various methods for prioritizing key terms. Here, even though voting is anonymous, the results are readily displayed for all to view. This GDSS by Nunamaker, Briggs, Mittleman, Vogel, and Balthazard (1996/1997) was used at an IBM site. It was found that process structure helps focus the group on key issues and discourages irrelevant digressions and unproductive behaviors.

Web-Based GDSSs

A Web-based GDSS is a GDSS built with Web technologies so that the users access with Eeb browsers through Internet connections (Chen et al., 2005). In addition, Web-based GDSSs applications that are developed by companies may be deployed on company intranets to support internal business processes or can be integrated into public corporate Web sites to enhance services to trading partners (Power & Kaparti, 2002).

Most Web-based GDSSs are currently individual DSS systems (Bharati & Chaudhury, 2004). On the contrary, Web-based *GDSSs* provide a broader approach to solving complex problems that are less structured. As noted earlier, there are a few Web-based GDSSs and one of them, *GroupSystems*, is a local area network-based client-server that exists for online collaboration (Chen et al., 2005). Several commercially available Web-based GDSS products also contain decision-making tools. One such product is *FacilitatePro 9.0*, which provides support to the group decision-making process with tools that facilitate brainstorming, idea generation, organization, prioritization, and consensus development (Facilitate.com, 2006).

Distance Learning

Several courseware packages facilitate distance learning. They range from such tools like *Blackboard*, through *Microsoft NetMeeting*, to *PlaceWare Virtual Classroom*. Distance learning can be an effective learning tool, and many corporations have taken advantage of it mostly through Web-based streaming and other private company intranets. Distance learning therefore acts as a strong collaborative and knowledge management tool and is accessible every hour of the day.

GSS for Political Events

The multi-faceted use of GDSS is reflected in the dynamism inherent in organizational structures. For instance, political risk associated with corporations' decisions to expand internationally could be alleviated using GDSS. This is because the key to analyzing political events is obtaining good information about these events. GDSS thus provides higher reliability in accessing this needed information, through anonymity, simultaneity, and documentation features that are lacking in face-to-face interactions. Among other advantages, anonymity offers participants a greater degree of freedom in expressing their thoughts, and presents them with a greater sense of confidence to be more critical. Blanning &

Reinig (2005) suggest a two-characteristic framework depending on whether analysis of the event under consideration is static or dynamic, as well as whether the analysis is one-dimensional or multi-dimensional.

FUTURE TRENDS

GDSSs are transforming into GSSs and the same ideology used for enhancing group meetings is being used in other areas as well. The idea is not just to increase the effectiveness of decision making, but to incorporate the current improvements in communication technology to redefine collaboration. Anonymity is also becoming more and more widespread in this new Internet culture; its effects on collaboration are very interesting as shown. The findings presented in this paper uncover the social effects that might affect group work. These findings can also be applied to other fields in which collaboration is experiencing growth as in education and social networking. By combing the Internet, emerging technologies, and the findings in social behavior as they relate to group work, with the exploding growth currently being experienced in communication, the results and the rate of introduction of new ways of collaborating will be absolutely amazing.

CONCLUSION

GDSSs, if implemented and used correctly, can improve the quality of group decision making significantly by minimizing the negative effects of group decision making and by maximizing the benefits of group collaboration and decision making. GDSSs have come a long way since their inception. Current and previous research efforts have made significant findings on the effects of the numerous criteria that affect the decision-making process in a group setting while using GDSSs. The results show that while the Internet has made it easier and less costly to use GDSSs than ever before, the social effects of group decision making can have a significant effect on the quality of decisions made in a group setting using GDSSs. By manipulating things such as visual cues, group versus individual-based incentives, anonymity, group size, feedback, leadership role, communication mode, type of tool used, social presence, face-to-face versus distant, shift work or non-shift work, the fit between facilitation style and agenda structure, and finally, a relationship versus a task focus, it is possible to significantly improve the quality of decisions made by a group using GDSSs.

KEY TERMS

Distributed Group Decision Support Systems (DGDSS): Groups consisting of members who use a GDSS at the same time but at different places.

Face-to-Face Group Decision Support Systems (FGDSS): Groups consisting of members who use a GDSS at the same time and same place.

Group Decision Support System (GDSS): Can also be referred to as a GSS or an electronic meeting system. A GDSS is characterized by being used by a group of people at the same time to support decision making

Group Polarization: The tendency of people to become more alike or extreme in their thinking following group discussion. It is also the phenomenon that is generally considered decision bias.

Group Support Systems (GSS): Any combination of hardware and software that enhances group work. GSS is a generic term that includes all forms of collaborative computing.

Multi-Criteria Group Support Systems (MCGSS): GSS designed so that users can enter their preferences in an easily understood and user-friendly interface through a Web browser.

Social Presence: The degree to which people establish warm and personal connection with each other in a communication setting. Changes in the level of social presence can affect group communication.

Time/Place Framework: A framework for classifying IT communication support technologies. The matrix consists of four possibilities: same time/same place systems, same time/different place systems, different time/different place systems, and different time/same place systems.

Chapter 5.2

Cooperative Decision Support Systems

Pascale Zaraté
Université de Toulouse – INPT – IRIT, France

INTRODUCTION

The subject of our research aims to support in the most suitable way the collaborative decision-making process. Several scientific approaches deal with collaborative decision-making: decision analysis (Carlsson & Turban, 2002; Doyle & Thomason, 1999; Keeney & Raiffa, 1976) developing different analytical tools for optimal decision-making; in management sciences the observation of decision-making styles activity (Nuut, 2005; Fong, Wyer, & Robert 2003); decision-making as a group work (Esser, 1998; Matta & Corby, 1997); studies concerning different types of decisions focalised on number of actors: individual (Keeney & Raiffa, 1976), group (Shim, Warkentin, Courtney, Power, Sharda, & Carlsson, 2002), cooperative (Zaraté, 2005), and collaborative (Karacapilidis & Papadias, 2001). For the collaborative decision-making field, the situation is clear. In most of research studies, the concept of collaborative decision-making is used as a synonym for cooperative decision-making. Hence, the collaborative decision-making process is considered to be distributed and asynchronous (Chim, Anumba, & Carillo, 2004; Cil, Alpturk, & Yazgan, 2005). However, we can stand out several works, having different research approaches, considering collaborative decision-making process as multi-actor decision-making process, where actors have different goals. Considering (Panzarasa, Jennings, & Norman, 2002) the collaborative decision-making process is seen as “a group of logically decentralised agents that cooperate to achieve objectives that are typically beyond the capacities of an individual agent. In short, the collaborative decision-making has generally been viewed and modelled as a kind of distributed reasoning and search, whereby a collection of agents collaboratively go throughout the search space of the problem in order to find a solution." The main interrogation of this article is to study the best way to support collaborative decision-making process.

BACKGROUND

Many studies are based upon the work of Simon (Simon, 1977). Le Moigne (1990) develops the canonical model of decision-resolution process based upon the Simon's definition of the process. The working hypothesis adopted in this study is that "the decision can be represented as a work of symbolic computation," as Simon's model. The decision-making process, considered as a cognitive process of problem solving, is constituted of four main phases: intelligence, conception, selection, and review.

We notice that there have been changes influencing decision-making process (Teulier-Bourgine & Zaraté, 2001). Decision-making in organisation is becoming more and more multi-actor and complex. We could cite the work of Gorry and Scott Morton (1971) stating that the more one organisation is complex, the less are the chances that the decision will be taken by one single actor. Therefore, participants of one decision-making process have to integrate multiples points of view that are not necessarily in harmony. Due to the rapidly changing environment, every actor involved in a decision-making process has to augment his or her own vigilance and information research. Therefore, based upon the work of Simon, we propose a revisited decision-making process. The intelligence phase is becoming more complex and more active because of the environment to be taken into account. These changes have also influenced the decision-making progress. The actors have a prominent role of research of pertinence. Before these changes, the decision-makers have to search for efficient information in order to not forget important information; they must very rapidly sort out information that is very numerous. The conception step is also more frequent because every time the context is changing, every time the decision-maker must redesign a new solution.

The step of choice seems to stay the same because the very rapid sorting out process does not imply an alternatives generation and a systematic comparison among them and finally the choice of one of them.

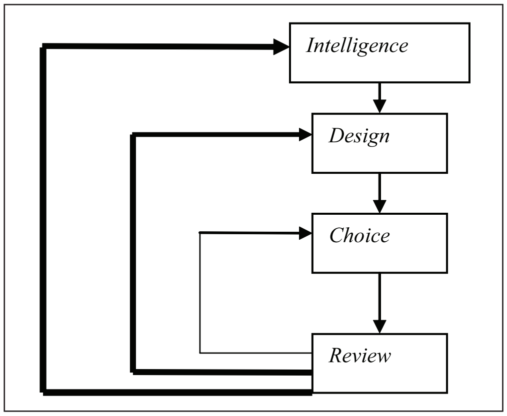
The review process is then modified. As shown in Figure 1, the two first steps are visited more often than the third one. Several iterations are necessary for decision-makers before the choice by itself.

Summarising, the revisited cognitive decision making process is composed by four steps: intelligence, design, choice, and review and the two forts steps are visited very often, the decision makers must sort out the information in a very efficient may.

This process being modified, the need of new kind of decision support systems is obvious.

We present a study developing different situations of collaborative decision-making process and give an overview of different support adequate in each case. We develop a matrix of collective decision-making process taking into account two criteria: time and space.

Figure 1. The revisited decision-making process of Simon (1977)



Our purpose is to define what a collective decision making process is.

Authors consider collaborative decision-making process as a multi-agent socio-cognitive process. Thus, they incorporate beliefs, goals, desires, intentions, and preferences in what they call mental modeling. Panzarasa, Jennings et al. (2002) formalise a model giving the insight in: a) the agent's mental states and processes and b) a range of social behaviours that lead them to solicit and take part in decision-making process.

The authors also adopt a prescriptive approach in order to give a set of possible actions in every step of collaborative decision-making. The model is developed using social mental shaping, the process by which the mere social nature of agents may impact upon their mental states and motivate their behaviour. Their collaborative decision-making model consists of four phases:

1. The practical starting-point
2. Group ideas generation
3. Social practical reasoning
4. Negotiation.

This developed model, as the authors state, "aims at developing the theoretical foundation of collaborative decision-making by using a formal language." The authors do not propose a concrete help for decision makers in this process. Moreover, they consider the collaborative decision-making process in an idealised world and not to be iterative. The process is socially oriented and "captures underpinning motivations and social processes of each stage."

In order to clarify this collective decision making process, we intend to propose a typology of it according to the different situations. Decision makers could work:

- In one hand at different places or not, and
- In another hand at different times or not.

We then can find different types of collective decision making process (see Figure 2).

Collective decision making situations and the corresponding supports are defined as follows:

1. Face to face decision making: different decision makers are implied in the decisional process and meet them around a table. This is a very classical situation and it could be supported by every kind of group decision support systems (GDSSs) as well as GDSSs rooms.
2. Distributed synchronous decision making: different decision makers are implied in the decisional process and are not located in the same room but work together at the same time. This kind of situation is enough known and common in organizations and it could be supported by every kind of electronic meeting systems (EMS), videoconferences, telephone meetings, and so forth.
3. Asynchronous decision making: different decision makers are implied in the decisional process and they come in a specific room to make decisions but not at the same time. The specific room could play a role of memory for the whole process and also a

Figure 2. Collective decision making situations

	Same time	Different times
Same place	Face to face decision making	Asynchronous decision making
Different places	Distributed synchronous decision making	Distributed asynchronous decision making

virtual meeting point. This kind of situation is well known in the CSCW field and some real cases correspond to it, but for decision making it have no intrinsic meaning for a physical point of view, we cannot imagine decision made in organisation in this way: it is the reason why this case has a grey bottom in Figure 2.

4. Distributed asynchronous decision making: different decision makers are implied in the decisional process and they do not necessarily work together at the same time and in the same place; each of them give a contribution to the whole decisional process. This is a new kind of situation and decision-makers must cooperate. For this purpose cooperative decision support systems must be designed.

Summarising, for us a collective decision making process is defined as a decision making process in which several decision makers are involved that could happen in three kinds of situations: face to face, distributed synchronous, and distributed asynchronous situations.

COOPERATIVE DECISION SUPPORT SYSTEMS

Several systems have been designed for this purpose. One of them is designed by Karacapidilis and Papadias (2001) and is called the Hermes. Therefore, they develop the Hermes system as a "generic active system that efficiently captures users' rationale, stimulates knowledge elicitation, and argumentation on the issues under consideration, while it constantly (and automatically) checks for inconsistencies among users preferences and considers the whole set of argumentation items asserted to update the discourse status." In this argumentation process, Karacapilidis and Papadias (2001) present the argumentation basic elements: issues, alternatives, positions, and constraints representing preference relations.

The field of cooperative decision-making processes is mostly addressing distributed and asynchronous situation. When addressing likewise defined cooperative decision-making processes, we can state several research approaches, mostly support oriented:

- Multi-agent support systems and
- Cooperative decision support systems.

Multi-agent systems are systems constituted of different information processes that are realised at the time, that is, of different living agents, using the common resources and communicating between them.

In his work Bui and Lee (1999) defines a software agent as "a program that performs a specific task on behalf of a user, independently or with little guidance. An intelligent agent performs, reactively and/or pro-actively, interactive tasks tailored to a user's needs without humans or other agents telling it what to do." Researches in the field of multi-agent systems supporting decision-making processes can be illustrated by several studies:

- Bui and Lee (1999) propose a framework for building decision support systems using agent technology. They propose taxonomy of agents' characteristics that can be used to help identify agent necessary to support different decision tasks. The authors propose a life-cycle for cooperative decision support building.
- Pinson, Louca, and Moraitis (1997) develop a general framework for building distributed decision support systems (DSDSS). The application is developed for strategic planning where "users intervene as human agents in the solution formation, and strategic knowledge and domain knowledge are distributed in different agents who communicate through various blackboards and message passing."

- Vahidov and Fazlollahi (2004) use agent technology for developing pluralistic multi-agent DSS. They develop a framework where agents are organised in groups according to the phases of the problem-solving.

As pointed out in the previous section and also by many other authors (Gachet & Haettenschwiler, 2001), the decision-making environment has changed. In order to support decision-making, the tools have to be able to support decisions in a dynamic environment that is rapidly changing and often distributed. Therefore, distributed decision support systems are defined by Gachet and Haettenschwiler (2001) as "a collection of services that are organised in a dynamic, self-managed, and self-healing federation of hard and software entities working cooperatively for supporting the solutions of semi-structured problems involving the contributions of several actors, for improved decision-making." This definition is based on several assertions:

1. A distributed DSS is not necessarily data intensive.
2. In a distributed DSS, two data units, which are not semantically related can always be physically stored in different storage devices.
3. A distributed DSS takes advantage of decentralized architectures.
4. A distributed DSS can survive on an unreliable network.
5. A distributed DSS enhances mobility.
6. A distributed DSS does not replace face-to-face meetings, it promotes and enhances them.

Other author defines collaborative decision support system (CDSS) as follows: "Collaborative decision support systems (CDSSs) are interactive computer-based systems, which facilitate the solution of ill-structured problems by a set of decision makers working together as a team." (Kreamer & King, 1998)

We find this definition very large and find it necessary to define the following architecture for these systems. Therefore, we propose a cooperative decision support framework. This framework is composed by several packages:

1. An interpersonal communication management system.
2. A task management system.
3. A knowledge management tool.
4. A dynamical man/machine interactions management tool.

This framework is described in Figure 3.

The interpersonal communication management tool is able, as in every kind of CSCW tool, to help users and decision-makers to very easily interact among themselves.

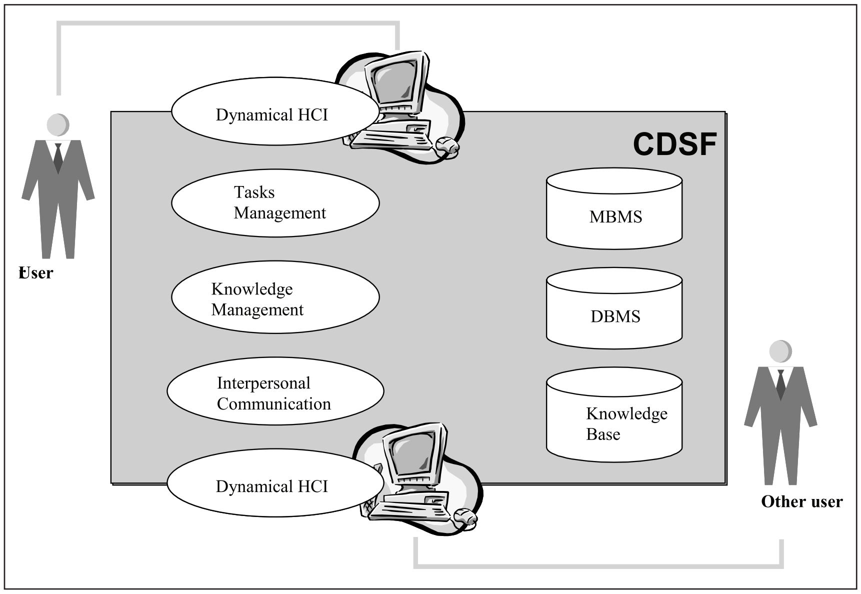
The dynamical man/machine interactions management tool guides the users in their processes of solving problems in order to solve the misunderstanding problems.

The knowledge management tool storages the previous decision made by the group or by other groups. The system proposes solutions or part of solutions to the group in very similar situations. In the case of a different situation, the system must be able to propose the solution the most appropriated and the users could accept it or not. This tool is based on a knowledge management tool and based reasoning tools.

Based on the DSSs' architecture defined by Sprague and Carlson (1982), the system includes also a data base management system, a model base management system. Nevertheless, this system is based on the development of knowledge based system and more particularly cooperative knowledge based system. Thus, the proposed system includes a knowledge base.

This tool is based on cooperative knowledge based system architecture. This cooperative knowledge based architecture is based on libraries of models: users' models, domain models (or problems models), and contextual models. The

Figure 3. Cooperative decision support framework architecture



calculation of the proposed solutions is based on several techniques: planning tools (Camilleri, 2000), linear programming (Dargam, Gachet, Zaraté, & Barnhart, 2004). The main usage principle of this kind of tool is based on the interaction between the system and the users. The system proposes a solution to the group, the group takes in charge some tasks and then the system recalculates a new solution and proposes the new one to the group and so forth. The problem or the decision to make is solved step by step, each actor (system and users) solving parts of the problem.

The part of the system for which the development is deeper is the task management system. This tool has for objective to propose solutions or part of solutions to users. It calculates the scheduling of tasks and sub-tasks and each role that is assigned to each task. It also proposes an assignment of tasks to users or to the system itself.

FUTURE TRENDS

The cooperative decision support system is a proposal of architecture rather than a complete software package. The fundamental principle of this proposal is to support the users in an integrated approach. The main contribution of this kind of tool is the possibility given to the user to solve a part of the problem. The system must be able to dynamically react, that is, taking into account the users' answers, it must recalculate and propose a new assignment of the tasks to solve, to the different users. This is possible thanks to the interactive planning of decisions to make or tasks to realise. Nevertheless, the human confrontation stays essential for decision-making. This confrontation is possible through a solid argumentation among the decision-makers. Thus, we underline the fact that the use of this kind of tool will be efficient only if it is going with a methodology of the cooperative decision-making process management.

CONCLUSION

We have shown that the collaborative decision-making is a complex process. In order to support it, several kinds of tools are necessary depending of the king of collective situations. New kinds of systems are necessary: cooperative decision support systems. These systems are generally defined by several authors as frameworks integrating several tools. The main point of these frameworks is that the system must be able to support dynamically, decision-makers by proposing an "intelligent" assignment of tasks among the involved actors: decision-makers and software seen as agents.

KEY TERMS

Collective Decision-Making Process: Collective decision making process is defined as a decision making process in which several decision makers are involved that could happen in three kinds of situations: face to face, distributed synchronous, and distributed asynchronous situations.

Cooperative Decision Support Systems: Is seen as a framework in which several packages are necessary for supporting in an efficient way, decision makers involved in cooperative decision making process. This framework is composed by: an interpersonal communication management system, a task management system, a knowledge management tool, and a dynamical man/machine interactions management tool.

Revisited Cognitive Decision-Making Process: Is composed by four steps: intelligence, design, choice, and review and the two forts steps are visited very often, the decision makers must sort out the information in a very efficient way.

Chapter 5.3

Supporting Distributed Groups with Group Support Systems:

A Study of the Effect of Group Leaders and Communication Modes on Group Performance

Youngjin Kim
Fordham University, USA

ABSTRACT

The leadership role facilitates group process by structuring group interaction. How leadership affects group performance in GSS settings remains one of the least investigated areas of GSS research. In this study, the presence of a group leader is found to make a significant difference in objective decision quality and satisfaction with the decision process. At the same time, perceived decision quality and consensus are not significantly different in groups with a leader and those without one. A content analysis of comments by group leaders shows that group leaders are effective when making comments on clear group objectives and interaction structure in the early stages of group interaction. In the later stages, however, it becomes more important for group leaders to offer comments encouraging interaction and maintaining group cohesion.

INTRODUCTION

Group support systems (GSS) are information technology-based environments to support group activities that may be distributed geographically and temporally (Dennis, George, Jessup, Nunamaker, & Vogel, 1988). The objective of GSS is to increase the effectiveness and efficiency of group interaction by facilitating the interactive sharing of information among group members (Nunamaker, Dennis, Valacich, Vogel, & George, 1991). These objectives are accomplished by augmenting the group's information-processing capability, increasing participation, and improving communication by structuring the interaction with technology (Ho & Raman, 1991). In this respect, there are clear parallels between GSS studies and structured group interaction techniques, such as the nominal group technique and the Delphi method (Turoff, Hiltz, Baghat, & Rana, 1993), in which leadership and structured communication have been found to exert a significant influence on group outcomes. In fact, GSS research has a strong tradition of studying the effects of structuring group communication (Fjermestad & Hiltz, 1998-1999). Investigation into the impact of leadership on group performance, however, is seldom part of GSS studies (Briggs, Nunamaker, & Sprague, 1997-1998; Parent & Gallupe, 2001). Out of about 230 published papers on GSS, only 6% investigated the effect of leadership in GSS environments (Fjermestad & Hiltz, 1999).

Another little-explored area is the effect of distributed group support systems (DGSS) on dispersed groups, where all group members are geographically and/or temporally dispersed and interact asynchronously through computer-mediated communication systems (CMCS) (Turoff et al., 1993). Although there has been considerable research on communication behavior in face-to-face groups with GSS, there have been few efforts to verify the generalizability of face-to-face communication behaviors in distributed group settings or to investigate factors of computer-mediated communication that uniquely affect the performance of distributed groups (Fjermestad, 2004).

Synthesizing previous studies, Bordia (1997) reports several behavioral differences between groups with CMCS and those with face-to-face communication. The main reason for these differences is that in computer-mediated communication, the lack of social presences (Short, Williams, & Christie, 1976) affects the perception and interpretation of the meaning of the messages exchanged (Rice, 1984), making exchange of information among dispersed group members difficult (Hightower & Sayeed, 1996). This implies that communication support for distributed groups is necessary to overcome the potential problems with limited bandwidth and lack of social presences in CMCS (Hiltz & Johnson, 1990). In addition, the support for asynchronous communication with CMCS should include ways to support larger decision groups, improve the participation of uncooperative subgroups, and deal with critical mass activity phenomena (Turoff et al., 1993). To this end, this study was designed to look into the effects of leadership and communication structuring on group performance in asynchronously interacting distributed groups with CMCS. In the following sections, the literature on leadership and GSS is briefly reviewed, research design and methodology are explained, and research findings are discussed.

LEADERSHIP AND GROUP SUPPORT SYSTEMS

Leadership, by its very nature, is the process of directing and coordinating group interaction (Jago, 1982). According to path-goal theory (House, 1971), a leader affects group performance by clarifying the path to the group's goals, reducing obstacles that prevent the group from reaching these goals, and trying to increase the group's satisfaction as it works toward achieving its goals. In doing so, a leader may define objectives, maintain goal direction, provide the means for goal attainment, provide and maintain group structure, facilitate group action and interaction, maintain group cohesiveness and member satisfaction, and facilitate group task performance (Roby, 1961; Schutz, 1961). Leaders also establish and maintain the link between satisfaction and group performance by employing different leadership styles whose effectiveness can be moderated by the nature of the task, which may account for variance in group performance of more than 50% (Hirokawa & Poole, 1986).

The study of leadership in GSS research also sees leadership as the process of directing and coordinating group interaction. In this research, leadership is considered to be another layer of the group interaction structure (George, Easton, Nunamaker, & Northcraft, 1990; Hiltz, Johnson, & Turoff, 1991) that uses GSS tools to dictate who can say what and when. But the effect of leadership in GSS still remains largely unexplored (Ho & Raman, 1991; Briggs et al., 1997-1998; Parent & Gallupe, 2001), particularly in DGSS settings. In fact, leadership effects have been investigated in just under 10% of the GSS studies (Fjemestad & Hiltz, 1998-1999). One reason is the lack of GSS software tools to support leadership functions. Since GSS research depends on software tools, as Turoff, et al. (1993) argue, there should be more efforts to develop GSS software tools to support the roles of leaders in GSS-supported groups. However, it is difficult to develop software tools that may replace/support the leadership role without understanding the behavior of leaders in GSS settings.

The majority of GSS leadership studies argue that leadership alone rarely affects group outcomes, although it may do so in group performance in interaction with other variables. This is probably the case, because the effect of a group leader is offset by the GSS tools used, where leadership itself is another GSS tool for interaction facilitation (Hiltz et al., 1991; Briggs et al., 1997-1998). This means that leadership alone does not have a significant impact on group performance. Rather, leadership in GSS settings is a moderating variable that affects group outcomes in conjunction with other variables such as anonymity (George et al., 1990; Sosik, Avolio & Kahai, 1997), communication channel (Barkhi, Jacob, Pipino, & Pirkul, 1998), and other GSS tools used (Ho & Raman, 1991; Lim, Raman, & Wei, 1994). Therefore, caution should be exercised when adopting leadership as a complement to GSS tools in GSS-supported groups. When care is not taken, it could negatively affect group performance by creating too restrictive of an interaction structure (Kim, Hiltz, & Turoff, 2002). One case study, in fact, does report the failure of the use of GSS when the leadership style collides with the GSS arrangement (Parent & Gallupe, 2001). A few other studies demonstrate the mediating effect of leadership in a GSS environment. Hiltz, et al. (1991) find that when statistical feedback is given by the system, groups without leaders perform better, while groups with leaders are less able to reach consensus. Ho and Raman (1991) corroborate that a leader in GSS settings may be effective only when a group needs to establish an interaction structure, because this structure is already available as a GSS tool. George, et al. (1990) observe that anonymous groups with leaders are significantly more satisfied with the decision process. Equal participation and consensus are more likely to be achieved, since leaders are highly influential and dominant over group members and their interaction (Ho & Raman, 1991; Lim et al., 1994).

What do these findings mean to asynchronously interacting groups through CMCS? Can these findings be extended to distributed groups in order to improve their performance? The answer may be no. All these findings are context-specific, not replicated in other studies, and found mostly with face-to-face groups. Still, the way leaders work in CMC settings remains unstudied (George & Sleeth, 2000). To date, Kim, et al. (2002) is the only GSS leadership study with fully distributed groups with CMCS. Although Hiltz, et al. (1991) and Barkhi, et al. (1998) investigated the leadership effect with distributed groups, the group distribution was limited to groups meeting at the same time but in different places. In this regard, a study was designed, as in Figure 1, to investigate how leadership would affect the performance of distributed groups in conjunction with communication modes.

HYPOTHESES DEVELOPMENT

Decision Quality

GSS research has shown clearly that the communication mode has a positive impact on a group's decision quality. The impact of leadership in previous GSS studies, however, is inconsistent. The

Figure 1. Research design

impact either was not measured (Ho & Raman, 1991; Lim et al., 1994), tested insignificant (George et al., 1990), or reported significant (Hiltz et al., 1991; Tan, Wei, & Lee-Partridge, 1999). In GSS research, because most tasks chosen for studies are preference tasks, decision quality generally is measured using either the perceptions of a panel of experts or the responses to a questionnaire. Perceived decision quality, however, rarely measures decision quality itself. Tan, et al. (1999) assert that perceived decision quality measures decision confidence, which is the degree to which group members are sure that they have arrived at an appropriate group decision. The nature of the experimental task in this study, however, allows objective decision quality as well as perceived decision quality to be measured.

Objective Decision Quality

H1a: Groups with a leader will make better decisions than groups without a leader.

H1b. Parallel communication groups will make better decisions than sequential communication groups.

Perceived Decision Quality

H2a: Groups with a leader will perceive that their decisions are better than groups without a leader.

H2b. Parallel communication groups will perceive that their decisions are better than sequential communication groups.

Consensus

Consensus refers to the degree of support among group members in synthesizing divergent and mutually conflicting ideas during interaction. The level of consensus indicates what happens during group interaction. Consensus also measures the degree of the acceptance of a decision and the commitment to it (Dess & Orieger, 1987; McGrath, 1984) and the level of effective completion of preferred tasks (Tan et al., 1999). Thus, when implementing a decision is more important than reaching a correct decision, consensus as the measure of the acceptance of a decision should take precedence over objective decision quality (Dickson, Lee-Partridge, & Robinson, 1993).

Leadership in GSS settings generally shows no significant impact on consensus. Ho and Raman (1991) indicate that a leader in an unsupported or unstructured group has more influence on consensus, but the leader's effectiveness may be canceled out when another process structuring mechanism is present (Hiltz et al., 1991). These findings suggest that leadership may be more important when a group needs to establish a structure for interaction. Hiltz, et al. (1991) also found that asynchronously interacting groups through CMCS tend to be more task-oriented and, therefore, generate a lower level of consensus than face-to-face communication groups. This suggests that the influence of leadership on consensus in dispersed groups should be significant, because asynchronous interaction through CMCS requires more structure in order to coordinate its activities (Turoff et al., 1993).

With regard to the communication mode, the sequential communication mode is likely to show a higher level of consensus, because it provides a more focused interaction than the parallel communication mode. In interacting through CMCS, where social presences already are missing, groups interacting in the parallel communication mode, by allowing discussion on all topics, may have difficulty maintaining group cohesion (Turoff et al., 1993), which easily could lead to a low level of consensus.

H3a: Groups with a leader will show a higher level of consensus than groups without a group leader.
H3b: Sequential communication groups will show a higher level of consensus than parallel communication groups.

Participation

One or a small number of individuals generally dominate a discussion when there is unsupported group interaction. This may lead to lower decision quality and less effective group performance (Hiltz et al., 1991; Tan et al., 1999). GSS generally can ensure equal participation (Fjermestad, 2004). This is because GSSs diminish the potential for dominance by an informal leader by filtering out certain interpersonal cues and regulating the frequency and duration of speaking, which is linked empirically to the emergence of an informal leader (Culnan & Markus, 1987). Therefore, group leadership in GSS is likely to have a positive influence on equal participation. At the same time, participation is expected to be less equal with the parallel communication mode, because when group members are allowed to discuss any of the topics when they see them, individuals may speak with greater frequency and for longer periods of time.

H4a. Participation will be more equal in groups with a leader than in groups without a leader.
H4b. Participation will be more equal in sequential communication groups than in parallel communication groups.

Satisfaction with the Decision Process

Satisfaction refers to morale, loyalty, or any other manifestation of individual contentment with group outcomes and processes. It is important to measure the level of satisfaction, because it clearly is related to group consensus, productivity, general performance, and effectiveness. Satisfaction also includes attitudinal changes, either positive or negative, toward GSS and the willingness of members to work again.

Findings on satisfaction with the decision process in GSS-supported groups are mixed. Some research results report higher satisfaction with the decision processes in GSS-supported groups (Easton, George, Nunamaker, & Pendergast, 1990). In other studies, however, either no difference or lower satisfaction is found in GSS-supported groups (Chidambaram & Jones, 1993). Findings on the impact of a group leader on satisfaction with the decision process also are inconsistent. While George, et al. (1990) find no impact, Hiltz, et al. (1991) and Tan, et al. (1999) observe that satisfaction with the decision process is significantly higher in groups with leaders.

H5a: Satisfaction with the decision process will be higher in groups with a leader than in groups without a leader.
H5b. Satisfaction with the decision process will be higher in parallel communication groups than in sequential communication groups.

RESEARCH METHODOLOGY: CONTROLLED EXPERIMENT WITH 2 X 2 FACTORIAL DESIGN

Operationalization of Independent Variables

A group leader selected by group members during a training session is given the flexibility to change any interaction rules or structure, as necessary. In groups with a group leader, these rules and structure thus are not adhered to strictly during the experiment. Groups without a leader, however, are asked simply to adhere to the given interaction rules and structure; they do not have flexibility to modify them.

Communication structuring is arranged in two different modes: parallel and sequential. Generally, research on the impact of communication structuring compares the parallel communication mode through CMCS in GSS-supported groups and the sequential communication mode of turn-taking in face-to-face groups. What is different in this study is the control of human parallel processing (Gray, 1988). With human parallel processing, all group members contribute at the same time in an effort to eliminate communication inefficiencies, such as airtime fragmentation or production blocking (Nunamaker et al., 1991) of sequential face-to-face communication. In both the parallel and sequential communication modes in this study, human parallel processing always is allowed, because all communication takes place through CMCS. The difference between the parallel and sequential communication mode, as operationalized for the experiment, is the difference in the number of discussion items open for group discussion at a time. In the parallel communication mode, all discussion items are open concurrently to the group from the very beginning, until the experiment is completed. All group members concurrently discuss any topic at any time in any order throughout the experiment. In the sequential communication, when the experiment begins, groups are informed of all of the topics to discuss during the experiment. However, groups discuss one topic at a time sequentially. Once a group moves to the next discussion topic, it may not revisit previously discussed topics. This step-by-step communication leaves no freedom to deviate from a system-defined linear interaction procedure.

Experimental Task

The task developed for the study is the Investment Club Task (Kim et al., 2002). In performing this task, participants attempt to maximize their portfolio value by agreeing to invest in at least one but no more than three stocks out of 15 candidate stocks to be held for at least six months. Basic information about each stock is provided, and group members are free to gather additional information from any source. The task in a GSS experiment study is usually one of McGrath's Circumplex Task Types (McGrath, 1984). The problem with this task classification is its insistence upon the mutually exclusive categorization of tasks based on performance processes (Rana et al., 1997). The investment club task, however, has characteristics of both Intellective and decision-making task types (McGrath, 1984). It has the characteristics of a decision-making task, because when a decision is made at the end of the experiment, there is no way to have objective knowledge of the decision quality. On the other hand, after the decision horizon is reached (at least six months after the experiment), objective decision quality can be evaluated by measuring actual changes in stock prices.

Subjects

There were 212 subjects in 47 groups in this experiment. The subjects were recruited from universities in the New York area. All subjects were enrolled in undergraduate or graduate-level MIS classes. During the recruiting session, the subjects filled out preexperiment questionnaires; were assigned to groups of five; and were scheduled for a one-hour, face-to-face training session. After the training session, groups were assigned randomly to experimental conditions. In a few groups, however, the experiment was conducted with three or four subjects due to dropouts during the training session. The subjects' backgrounds are summarized in Table 1.

Nunamaker, Briggs, Mittleman, Vogel, and Balthazard (1996-1997) argue that established groups of managers perform far better than the student subjects used in most GSS experiment studies. An advantage of using student groups, however, is the accessibility to a larger pool of subjects with little variances in their ages, education, or business experience that would enhance the statistical power in testing hypotheses. The use of student subjects can be justified, because when training is given to ad hoc groups before an experiment, ad hoc groups seem to perform as well as established groups (Mennecke, Hoffer, & Wayne, 1992).

Technology and Training

Electronic Information Exchange System 2 (EIES 2) was used for this experiment and modified to add experiment-specific procedures and rules. EIES 2 is one of the major GSS research tools (Fjermestad & Hiltz, 1998-1999) and is used frequently in conducting asynchronous experiments for DGSS research. It is similar to many group communication support systems now available for use through the Internet. To minimize the problems associated with student subjects, a week-long asynchronous online training session with EIES 2 was given to all subjects, beginning with a one-hour, face-to-face session. All the subjects in a training group were assigned to the same experimental group. During training, all subjects were introduced to the system's features and experimental formats. Each group then selected a group leader, who would serve as the group leader if the group were assigned to the with-a-group-leader condition in the experiment.

Administration of the Experimental Procedure

The experiment continued for two weeks. The experimental procedures were constructed by arranging discussion items, and the details are summarized in Table 2. There was no face-to-face session during the experiment. Each group member had to respond to each topic before seeing the responses of others or joining the discussion on the topic. All interactions took place asynchronously through EIES 2.

MS/MBA	68%	No	57%
Ph.D.	2%		

FINDINGS AND DISCUSSION

Statistical Measures

Except for the objective decision quality, all other dependent variables were measured by composite variables of multiple questionnaire items. A composite variable was used to test a hypothesis only when Cronbach's Coefficient Alpha was higher than 0.8. Because of the unequal number of subjects and groups for each experimental condition, the General Linear Model procedure was used instead of ANOVA for hypothesis testing. Whenever an interaction effect was significant, Fisher's Least Significant Difference Test (LSD) was used for pair-wise comparison of means among all experimental conditions. The results of the statistical analysis are summarized in Table

Discussion

Objective decision quality was measured twice by comparing the dollar values of portfolios in six months and one year after the experiment, and perceived decision quality at the end of the experiment with the questionnaire. Although it did not play any significant role in perceived decision quality, the presence of a group leader significantly improves the objective decision quality after six months and after one year. The leadership variable was expected to have an impact on group performance in interaction with another variable (George et al., 1990; Hiltz et al., 1991; Ho & Raman, 1991)—communication mode in this study. However, there was no interaction effect with the communication mode on objective decision quality.

Although it made no significant difference in objective decision quality, the communication mode had a significant impact on perceived decision quality. Parallel communication groups felt that they made significantly better decisions than sequential communication mode groups (F=5.26 and p=0.0268). This finding can be explained by the preference for procedural order construct (Putnam, 1979), which states that individuals enter groups with a predisposition for particular work habits, ranging from tightly organized procedures to loosely structured ones. In making a decision in a group, all group members have implicit cognitive maps for structuring group activity that interacts with the group's contingency factors that influence group performance. These cognitive maps are relatively inflexible, regardless of their previous success or failure. Satisfaction with the decision process may have resulted from the fact that in the parallel communication mode, group members were able to rearrange the sequence of topics in a way that was compatible with their cognitive maps. Hence, they gave a high rating to perceived decision quality, which is correlated highly with satisfaction with the decision process. Indeed, perceived decision quality was found to correlate highly with satisfaction with the decision process ($\rho=0.7718$). On the other hand, group members with the sequential communication mode might have had a conflict with a GSS-enforced decision procedure, if it was not their preference. This preference for procedural order also was confirmed in the study of how group members appropriate and react to GSS technology and structured heuristics (Wheeler & Mennecke, 1992).

Another finding on decision quality is the relationship between objective and perceived decision quality. Although objective and perceived decision qualities were not expected to be

Group Leader: W: *With a Leader*, O: *Without a Leader*
^{M}: *Marginally Significant*

different (Gopal, Bostrom, & Chin, 1992-1993), Pearson's Correlation Coefficient Rho between perceived and objective decision qualities was –0.0604. This simply indicates no correlation between them. The significance of this finding is that perceived decision quality cannot be used as a surrogate measure for objective decision quality in all situations. It must be used with caution. Any study that measures only perceived decision quality must make clear why objective decision quality cannot be measured. It also should state how perceived decision quality can be used as a surrogate measure for objective decision quality. Otherwise, the findings of studies will be misleading. Failure to distinguish clearly between perceived and objective decision quality may have contributed to inconsistent findings on decision quality in previous GSS research.

With regard to satisfaction with the decision process, there are significant differences in the communication mode and the presence of a group leader. Parallel communication mode groups reported a higher level of satisfaction with decision process than sequential communication groups, while groups with a leader reported a higher level of satisfaction with decision process than groups without a leader. Further analysis with Fisher's LSD indicates that sequential communication groups with a leader report a higher level of satisfaction with the decision process than sequential communication groups without a leader.

One important finding in satisfaction measure is that parallel communication groups generally indicate a higher level of satisfaction than sequential communication groups. The results of satisfaction with the decision process are particularly interesting. Because of novelty effect (Watson, DeSanctis, & Poole, 1988), parallel communication groups were expected to show a lower level of satisfaction with the decision process. These groups, however, reported higher satisfaction than sequential communication groups with more commonly used face-to-face interaction. It appears that as the use of multiple topics and multiple-participant CMCS such as e-mail or instant messengers becomes pervasive, sequential communication no longer may be the preferred mode of communication, thereby dissipating the novelty effect. This opens up a new avenue for the use of GSS in different settings where it may be used as a knowledge management tool or organizational memory and not be limited to task-oriented groups or decision-making groups.

The equality of participation was measured objectively, by counting the number of groups in which an informal leader emerged, and subjectively with a questionnaire. The emergence of an informal leader was used as a surrogate measure for equal participation because it is linked to participation rate (Mullen, Sales, & Drisekll, 1987), and the rule of 50% or more comments than the group's average was used to determine the emergence of an informal leader (Hiltz, Johnson, & Turoff, 1982). The communication mode made no significant difference in either case. However, the number of groups where informal leaders emerged was significantly lower in groups with a leader than in groups without a leader. Ho and Raman (1991) and Lim et al. (1994) argue that the emergence of informal leaders is low in groups with a formal leader who tends to dominate the group process. This may impede a group member from accumulating idiosyncrasy credits that eventually can confer leadership status (Hollander, 1974). For the subjective measure of equal participation, neither the communication mode nor the presence of a group leader made any difference. All groups felt that participation was equal. This finding is in line with previous findings that CMCS increases the level of equal participation by reducing or eliminating the social influence of communication (Steiner, 1972).

The simple presence of a leader, however, did not make much difference. What was more important was whether leaders properly performed their leadership roles. To investigate the group leaders' performances, the contents of the group leaders' comments were analyzed to determine

Table 5. Average number of comments by group leader by content

Condition	Content Category				N. Items	N. CMT.	T.CMT	Percent
	DFN	*SRT*	*FCT*	*MTN*				
Sequential	1.3	3.8	6.1	2.3	11.6	10.8	25.3	41.7%
Parallel	3.3	5.2	6.3	3.2	13.6	12.3	24.8	51.1%

Content Category:
DFN: the number of comments on defining objectives
SRT: the number of comments on providing structure
FCT: the number of comments on facilitating interaction
MTN: the number of comments on maintaining the group
N.Items: the sum of the number of DFN, SRT, FCT, and MTN
N.NMT: the number of comments where content category appeared
T.CMT: the total number of comments generated by a group leader
Percent: the percentage of N.HMT over T.CMT

whether they were task-related or leadership-related, as summarized in Table 5. In doing so, all leadership-related comments were classified as being in one of the content categories based on previous studies of leadership functions (Roby, 1961; Schutz, 1961): defining objectives, providing interaction structures, facilitating interaction, or maintaining group cohesion.

Of these, the category *providing interaction structure* shows the greatest difference in terms of the average number of comments between group leaders in parallel communication groups (5.2 comments) and those in sequential communication groups (3.8 comments). It appears that for groups interacting through CMCS, there is a need to provide a certain number of interaction requirements. In parallel communication groups, group leaders were effective in dealing with what could have been chaotic interaction due to the lack of social presences and concurrent discussion. They did so by providing more interaction structure, such as initiating further discussion on some topics or summarizing and pointing out explicit differences in the underlying assumptions of group members. Indeed, Ho, and Raman (1991) found that leadership in GSS settings appears more effective when there is a need to bring structure into group interaction. In sequential communication groups, where the interaction structure of what to discuss and when was known throughout the experiment, additional leader-initiated interaction requirements might have created too restrictive of an interaction structure, which negatively affects group performance (Kim et al., 2002).

The timing of each content category is also worth mentioning. In both sequential and parallel communication groups, group leaders tended to generate more comments on defining group objectives and providing interaction structure in the early stages of the experiment. The frequency of these comments diminished toward the middle of the experiment. On the other hand, group leaders started making comments on facilitating interaction and on maintaining a group shortly before the middle of the experiment and continued through the later stages of the experiment. It seems that in asynchronous interaction through CMCS, the role of a group leader in the early stages is to make clear the decision strategy by which group interaction is coordinated. As all group members come to understand the interaction requirements of the decision strategy, however, the role of a group leader tends to change to that of a facilitator. This facilitation encourages uncooperative members to improve their participation in order to increase group cohesiveness and to deal with the critical mass activity phenomenon associated with negative feedback, if the participation rate is too low (Turoff et al., 1993).

LIMITATION AND FUTURE RESEARCH

One limitation of the study was the training of groups before the experiment. The task given to all the training groups was the selection of a group leader to serve as a leader in the experiment. The selected leader was announced to groups in *with-a-leader* conditions at the beginning of the experiment. In groups in *without-a-leader* conditions, the selected leader was never announced. However, it is suspected that by selecting a group leader during the training session, the subjects in without-a-leader conditions may have participated in the experiment, subconsciously feeling the presence of a group leader. A different training task could have prevented this feeling in groups in without-a-leader conditions. Fortunately, however, not many of the leaders selected in training sessions emerged as informal leaders in groups in without-a-leader conditions.

This study can be extended further to examine the impact of different leadership styles in GSS settings. Leadership is a very complex construct for which a stronger theoretical basis is needed to develop software support for leadership and facilitation roles in DGSS and GSS, in general. Leadership might not be affected by GSS; however, the use of GSS may be affected by a leader, particularly by leadership style (Parent & Gallupe, 2001). For example, one study found that while interaction-oriented transformational leadership positively has amplified the effect of GSS anonymity on group potency and effectiveness, outcome-oriented transactional leadership did not (Sosik et al., 1997). Unfortunately, in this study, leadership styles were not controlled. Groups in the same experimental condition could have had different interaction environments because of the different leadership styles used by group leaders. In a future study with the group leader variable, it may be necessary to control different leadership styles rather than simply to adopt the with-and-without-a-group-leader conditions.

Chapter 5.4

Supporting Structured Group Decision Making Through System-Directed User Guidance:

An Experimental Study

Harold J. Lagroue III
University of Louisiana - Lafayette, USA

ABSTRACT

This article addresses an area which holds considerable promise for enhancing the effective utilization of advanced information technologies: the feasibility of using system-directed multi-modal user support for facilitating users of advanced information technologies. An application for automating the information technology facilitation process is used to compare group decision-making effectiveness of human-facilitated groups with groups using virtual facilitation in an experiment employing auditors, accountants, and IT security professionals as participants. The results of the experiment are presented and possible avenues for future research studies are suggested.

INTRODUCTION

Intelligent information technologies have demonstrated considerable potential in helping users more effectively utilize advanced IT applications. Indeed, their widespread use as components of help functions in software applications has made the appropriation process for such software considerably less taxing. On a more complex level, expert systems and other “advice-giving intelligent systems” have proven to be effective in such diverse fields as medicine and finance. Their potential as “explanation facilities” for assisting users in meaningful ways is well documented (Berry & Broadbent 1987; Shortliffe, 1976).

Several researchers have argued that intelligent systems may be the most significant technical contribution to the effective utilization of information technology (Crowston & Malone 1988, Johansen 1988). In the context of group decision making, a number of researchers have claimed that expert systems may hold the potential of transforming group decision support systems (GDSS) from merely "passive agents" that process and present group decision-making information, into "active agents" that enhance group interaction (Aiken, Liu Sheng, & Vogel, 1991, Ellis et al. 1988, Liu Sheng et al. 1989). Aiken, Liu Sheng and Vogel (1991) have asserted that the goal of integrating expert systems with group decision support systems should be in designing systems that facilitate simplified and enhanced group decision-making.

A number of research studies have demonstrated that system-directed user guidance holds the potential of replacing human facilitation for supporting group decision making. Limayem and DeSanctis (2000) found that automated facilitation could result in higher levels of understanding and improved perceptions of the group decision making process. In a follow-up study, Limayem (2003) compared human facilitation with automated facilitation and found that the latter was as effective as human facilitation in improving faithfulness of appropriation.

Wong and Aiken (2003) likewise demonstrated that automated facilitation could be as effective as expert facilitators—and better than novice-human facilitators—for idea generation and ranking tasks. However, their study did not consider the effect of using automated facilitation for providing structured decision-making support, or for affecting satisfaction levels of participants. Likewise, Ho and Antunes (1999) examined the effectiveness of an automated tool for meeting planning, but their results were inconclusive. Chalidabhongse et al. (2002) similarly studied the effects of an intelligent facilitation agent and found that their automated system resulted in greater group participation, more ideas generated, and less group distraction. However, the effects of automated facilitation on intellective tasks were not considered.

Still other studies have proposed integrating expert systems with group support systems but have not empirically tested the effectiveness of such systems. Aiken, Liu Sheng and Vogel (1991) examined potential synergies between intelligent systems and GSS and described a system which would effectively integrate the two technologies, but they did not empirically evaluate their system. Lopez et al. (2002) proposed the possibility of embedding facilitation features in group support systems, but likewise, no empirical study was conducted. Recently, Briggs, DeVreede and Nunamaker (2003) introduced their "thinkLets" concept designed to help systemize the GSS facilitation process, but did not empirically test it.

Because qualified facilitators are not always available or affordable, the need for automated systems that are capable of effectively replicating the human facilitator function is apparent. Moreover, by systemizing the facilitation process and ensuring its consistent replication, the benefits from advanced information technology use can be more predictable (Briggs et al. 2003).

This research addresses an area which holds considerable promise for enhancing the effective utilization of advanced information technologies: the feasibility of using system-directed guidance for facilitating users of advanced information technologies. An application for automating the information technology facilitation process is used to compare decision-making effectiveness of human-facilitated groups with groups using system-directed facilitation in an experiment employing auditors, accountants, and IT security professionals as participants. Comparisons of the two methods of facilitation are made on the basis of brainstorming effectiveness and user satisfaction.

DECISIONAL GUIDANCE

Directly related to the idea of system-directed facilitation is the concept of decisional guidance, or how decision support systems "enlighten or sway users as they structure and execute their decision-making processes" (Silver 1991). As such, decisional guidance can be thought of as one way in which the technology appropriation process is expedited to fully exploit a decision support system's functional capabilities: "Just as a DSS (decision support system) supports the judgments required enroute to making decisions, decisional guidance can support the judgments required in the course of operating the DSS" (Silver 1991, p.106).

The concept of decisional guidance for computer-based decision support was first advanced by Silver (1991) in his explanation of *when and why* decisional guidance should be provided, *how* system designers can build decisional guidance into DSS, and what the *effects* of providing it are. Limayem (1992) defined guidance in a GSS context as "the enrichment of decision models with cues that direct decision makers toward successful structuring and execution of model components." As such, guidance can inform groups as to what to do next (forward guidance), help groups resolve problems from prior activities (backward guidance), or in the case of preventive guidance, prevent disruptions that obstruct progress in group decision-making (Limayem 1992).

Silver asserts that decisional guidance should be provided when users need to make *discretionary judgments*, which is dependent upon how much discretion the system allows its user. Likewise, the decision to provide decisional guidance is primarily based on a desire to create a DSS that is more supportive and that assists users in exercising their judgment as they interact with the decision support system. Thus, the need for decisional guidance is dependent upon both the complexity of the DSS system, as well as the users' perceptions of the decision-making task.

The decision to provide user guidance, however, must be weighed against the possibility of overloading users with information, or in fact making the system more complex with an excessive amount of guidance mechanisms. Moreover, the guidance system should avoid directing users to a specific decision, but should instead attempt to influence how users reach a decision (Silver, 1991, pp. 108-109)

DSS design features can be structured to either directly influence how decisions should be made (directed change) or to provide users with a number of alternative capabilities from which to choose in their decision-making activities (non-directed change). A number of design strategies exist for doing so, ranging from highly restrictive DSS, to minimally restrictive DSS. In his earlier study on directed and non-directed change, Silver (1991) presents a broad set of objectives for determining the appropriate level of system restrictiveness.

While Silver established the primary framework for assessing the effectiveness of decisional guidance, he did not empirically examine the efficacy of providing it. Parikh, Fazlollahi, and Verma (2001) conducted an empirical evaluation of the effectiveness of various forms of decisional guidance in four areas: decision quality, user satisfaction, user learning, and decision-making efficiency. The study found that deliberate decisional guidance was more effective in all four areas. Suggestive guidance was found to be more effective in improving decision quality as well as user satisfaction, while informative guidance was determined to be more effective in improving user learning.

EXPERT SYSTEMS

Broadly related to the concept of decisional guidance is the functionality of expert systems, in that each is designed to guide IT users in some fashion. However, while decisional guidance relates to how systems "enlighten or sway" users as they utilize decision support systems (Silver, 1991), expert systems are designed to simulate human experts within a specific domain. As such, expert systems are artificial intelligence tools that support decision making by using a knowledge base and inference techniques. While decisional guidance can provide procedures explaining how to solve problems and why a certain solution is recommended in order to assist groups in their decision-making processes, expert systems attempt to replicate a human adviser (e.g., a group facilitator) and, if effective, can potentially replace them.

Turban and Watson (1986) examined various issues relating to integrating decision support systems and expert systems (ES), and presented two frameworks for integrating DSS and expert systems: ES integration into DSS components; and ES as an additional component of a decision support system. Among the benefits resulting from combining expert systems and decision support systems, are the following, as summarized by Turban and Watson:

- Assistance in selecting decision models
- Providing judgmental elements to models
- Providing heuristics
- Providing explanations
- Providing terms familiar to user
- Acting as a tutor
- Providing intelligent advice
- Adding explanation capabilities
- Expanding computerization of the decision-making process (Turban and Watson. p.124)

By replicating the manager-consultant-computer process, as advocated by Goul and Tonge (1987), an integrated DSS/ES can be designed to query users to determine the general category of a problem, the exact nature of a problem, and finally, suggest an appropriate model for solving the problem. By using expert systems as "consultants" to determine what to do in specific problem-solving situations, the complexity of using GDSS for group decision-making activities can be significantly reduced. Similar applications of integrating DSS and expert systems can include the provision of explanation capabilities to the DSS that allow users to follow the reasoning behind specific recommendations. By using terms that are familiar to the user as well as by providing tutoring to users, such integrated systems can significantly reduce the cognitive load placed on users of GDSS.

Also related to the concept of decisional guidance and expert systems is the concept of cognitive feedback, or feedback about an individual or collective decision-making process which is "provided interactively as an integral part of the individual and group processes" (Sengupta & Te'eni, 1993). In their study investigating cognitive feedback for improving control and convergence in computer supported group decision-making, cognitive feedback was found to increase cognitive control, resulting in uniformly high levels of cognitive control over time. Additionally, cognitive feedback was found to result in increased levels and degrees of collective control for group decision making. As hypothesized, groups receiving cognitive feedback were found to formulate group decision rules more frequently than groups not receiving cognitive feedback.

Dhaliwal and Benbasat (1996) proposed a model based on cognitive learning theories explaining the reasons and theoretical basis for providing system explanations for facilitating user learning, and a two-part framework and for examining the use of knowledge-based system (KBS) explanations.

Hayes and Reddy (1983) assert that explanations are needed for three principal reasons: explanations *clarify* particular intentions; explanations are intended to *teach*; and explanations are used to *convince*. Although clarifying, teaching and convincing can indeed increase the understanding of information systems users receiving the explanations, the question of whether such explanations actually result in better decision-making remains unclear (Dhaliwal & Benbasat, 1996, p.345).

Dhaliwal and Benbasat contend that only *task information* is effective in promoting learning, and, as such, it forms the "coherent theoretical basis" for the various types of explanations that KBS should provide, including the "explanations provision model" they propose. Moreover, the authors contend that three possible *explanation provision strategies* exist for designing knowledge-based systems: feedforward only, feedback only, or both feedforward and feedback.

Dhaliwal and Benbasat used MYCIN, one of the earliest expert systems developed in the early 1970s at Stanford University, to illustrate the use of feedforward and feedback explanations. For example, "why" explanations in MYCIN were feedforward and presented information explaining why a particular question was being asked of a user. "How" explanations provided information regarding the basis on which a specific conclusion was reached. Although no strategic explanations were provided by MYCIN, later versions (NEOMYCIN) provided such explanations using a combination of feedforward and feedback (Dhaliwal & Benbasat, 1996, p.352).

The automated facilitation application used in the present research provides various feedforward and feedback explanations designed to explain *why* a group decision-making procedure and/or GSS tool is being used and *how* the previous decision-making activity has influenced the current activity and/or GSS tool. As predicted in the system-directed facilitation model presented in the following, the provision of such explanations should lead to improved user understanding of the decision-making process, resulting in improved user satisfaction, in comparison to groups not receiving such explanations.

As discussed more fully later, the system-directed facilitation application provides explanations to participants who lack significant knowledge regarding the GSS system and the group decision-making processes employed in the experiment. Likewise, by virtue of their audio-based delivery, provision of the explanations is designed to require minimum cognitive effort to assess and assimilate.

FACILITATION

Also broadly related to the concept of decisional guidance is what Dickson, Partridge, and Robinson (1993) originally termed facilitative support, or "the manner in which GDSS users are supported in their utilization of group decision support systems." While decisional guidance is primarily related to how inanimate decision support systems (DSS) advise users as they execute the decision-making processes, facilitative support, and the more general term "facilitation," generally refers to the use of "facilitators" whose function is to direct group members regarding which GDSS features to use, as well as when to use them (Dickson et al., p.173).

Keltner (1990) proposed that the facilitator function is to ensure that all group members are able to fully participate in the decision-making process, and that the process is not dominated by a minority of group members. Ackermann (1990) asserted that external facilitators could help support cognitive processing by providing the group a structure in which to operate. As such, he believed that facilitators could enable the group to match specific modeling techniques to assigned group tasks more easily. Eden, Jones, and Sims (1983) believed that external facilitators could be used to improve a group's cognitive judgment by encouraging discussion of differences in group members' perspectives, reviewing the objectives of a particular task, and identifying inconsistencies among group members' perspectives. Kayser (1990) proposed that facilitators could help the group "free itself from internal obstacles or difficulties so that they more efficiently the effectively pursue the achievement of its desired outcomes (p.12-13).

In an early study of group facilitation, George, Dennis, and Nunamaker (1992) compared facilitated and non-facilitated groups using electronic meeting systems and found no significant differences between the groups in terms of alternatives generated, decision quality, satisfaction levels, or ability to reach consensus.

Anson, Bostrom and Wynne (1995) investigated the effects of human facilitation on group performance, group cohesion, and group interaction processes in group decision-making situations. Their study found that facilitated groups achieved improvements in group performance, interaction processes and group cohesion levels. Moreover, facilitation combined with GSS utilization, were found to enhance the effectiveness of group cohesion and group decision making processes. As such, facilitation was deemed critical in improving GSS effectiveness, especially for first-time users, and in situations where less restrictive GSS tools are used. Moreover, the quality of facilitation is believed to be a significant factor in improving group decision-making outcomes. Indeed, facilitators lacking proper skills may have minimal effects on improving outcomes.

Griffith et al. (1998) describe the facilitator's role as one of "improving a group's communication and information flow…to enhance the manner in which a group makes decisions without making those decisions *for* the group" (p.20). Nunamaker et al. (1997) list four functions normally provided by GSS meeting facilitators:

1. Providing technical support by initiating and terminating specific software tools and functions and guiding the group through the technical aspects necessary to work on the task.
2. Chairing the meeting, maintaining the agenda, and assessing the need for agenda changes.
3. Working with the group to highlight the principal meeting objectives and developing an agenda to accomplish them
4. Providing organizational continuity by setting ground rules for interaction, enforcing protocols and norms, maintaining the group memory repository, and acting as champion/sponsor (p.192-193).

The system-directed facilitation application used in the present study is designed to provide these four facilitator functions in providing GSS fit and appropriation support. As described more fully in the following section, the application is envisioned to provide technical support by offering a simplified tool selection interface, maintaining the agenda, highlighting principal meeting objectives, setting initial ground rules for interaction, and enforcing protocols through both audio and visual messaging.

As previously noted, Limayem and DeSanctis and others (Briggs, De Vreede & Nunamaker, 2003; Chalidabhongse et al. 2002; Ho & Antunes 1999; Lopez et al., 2002; Nunamaker & Zhao 2002; Wong & Aiken 2003) have expanded the concept of facilitation to include the use of "automated facilitation mechanisms" and "intelligent facilitation agents." Indeed, the terms "decisional guidance" and "automated facilitation" are sometimes used interchangeably to describe such software-directed group support and intervention mechanisms (e.g., Limayem, 2003; Limayem & DeSanctis, 2000).

In a survey of 45 experienced GSS facilitators, Bostrom et al. (1996) found that planning and designing a meeting agenda was significantly more important than all other facilitator functions. Other significant contributions of facilitators included matching GSS tools to the assigned task, adapting the meeting agenda is needed, clarifying meeting goals and agenda items; remaining focused on the outcome; and creating an open environment for anticipation. Traditional facilitator functions relating to managing group dynamics, such as building rapport and managing conflict were found to be significantly less important facilitator functions. The system-directed facilitation application used in the present study focuses primarily on planning and directing the meeting agenda, derived principally from Wheeler and Valacich's (1996) multiple activity group decision making heuristic.

In his definitive work on facilitators and their role in developing group effectiveness, Schwarz (1994) describes how facilitators can help improve the way that groups identify and solve problems and make better decisions by improving the manner in which group members work together. As he explains, facilitators can assume one of two roles. In basic facilitation, the facilitator guides the group in reaching an effective decision using the appropriate group process. In developmental facilitation, the facilitator teaches group members how to carry out specific processes for future problem-solving:

Schwarz's approach to facilitation is based on three values: "valid information, free and informed choice, and internal commitment to those choices" (1994, p.8). As opposed to changing group members' behaviors, he argues that the role of facilitators is to provide information to enable group members to decide *whether* to change their behavior, and if they choose to do so, to help them learn *how* to change (p.8). Schwarz asserts that for groups to become more effective, facilitators need to understand which factors contribute to group effectiveness, which factors detract from it, and how such factors can interact, in impacting group effectiveness, using a model built largely on the work of Hackman (1987) and Sundstrom, DeMeuse and Futrell (1990).

While Schwarz does not directly address the role the facilitator in the context of group support systems, his intimate knowledge of the group facilitation process, including his considerable experience in facilitating a number of diverse groups, offers valuable insights into the successful integration of group facilitation theory and practice.

Because the manner in which group members are facilitated during their utilization of a GDSS will have a "profound effect" on the outcome of GDSS use (Dickson et al., p.174) the most effective mode of providing GSS support is of critical importance. Specifically, the need for GDSS facilitation arises from two problems that must be addressed for groups using a GDSS system for the first time, namely:

1. GDSS users must "overcome the mystique" of using a new and unknown technology,
2. "A sound problem-solving process" used by the group in its GDSS interaction, including the application of the GDSS technology, must be provided (Dickson et al., p. 174).

As discussed in the following section, the automated virtual facilitation application was designed to provide task facilitative support, focusing primarily on which GSS tools to use, in addition to when and how to use them. The research framework is designed to evaluate the effectiveness of groups having such facilitation, in comparison to groups having operational facilitative support (chauffer-driven support) only.

Such "chauffer-driven" support is similar in nature to what Maier (1952) described as *free discussion* techniques, in which a leader poses a problem, then conducts the group discussion "in a permissive manner without making value judgments, but merely helps the group reach agreement on a solution" (p. 320). In comparison, the *developmental* technique for group discussion involves a leader who "breaks the problem into parts so that each part of the problem is discussed separately before the final decision is made" (Dickson, et al, p. 180). Maier found that the "developmental" approach was more effective than the "free" discussion approach in improving decision quality. In contrast, DeSanctis, D'Onofrio, Sambamurthy, and Poole (1989) found that restrictiveness did not lead to improved group consensus, and that excessive restrictiveness may indeed result in groups losing their "sense of ownership and control over the technology," resulting in lower levels of consensus.

As more fully described in the following section, the virtual facilitation application attempts to maintain the meeting agenda without being overly restrictive by requiring all group members to proceed to the next step in the multi-step decision-making process, thus granting each group member a veto power on proceeding to the next step in order to foster a more democratic decision-making process and one which helps ensure greater equality of participation.

METHODOLOGY

The present study examines the effectiveness of system-directed facilitation for supporting structured group decision making through an experiment involving internal auditors, information systems auditors, CPAs, and IT security professionals as participants. Specifically, system-facilitated teams using group decision support systems are compared to human-facilitated teams using GDSS in four areas of decision-making effectiveness: number of problems identified, number of solutions recommended, satisfaction with the decision-making process, and satisfaction with the decision-making outcome).

The number of problems identified and solutions recommended (Hypotheses 1 and 2) was determined by the number of such items submitted by each group for problem identification and solution recommendations. Scores for satisfaction with the meeting process and meeting outcome were calculated by adding the individual item Likert scores in the Briggs et al., (2003) post-session questionnaire, contained in Appendix A.

To distribute unique information among team members, a hidden-profile task was used. Hidden-profile tasks are believed to more accurately simulate real world situations in which relevant information for completing a task is known only by specific group members. In addition, a hidden-profile task does not state the specific problem for the group to solve, as is common with many tasks used in experimental research (Wheeler & Valacich, 1996, p.438).

A hidden-profile task requires all group members to participate and share information in order for the group to identify the pertinent problems and to develop a feasible solution. In a manner similar to the "School of Business Policy Task" used by Wheeler and Mennecke (1992), group members in the current study were required to identify as many IT security-related problems as possible, and to formulate as many recommendations as possible to address those problems. Different information is provided in each of the three case study roles, requiring effective information sharing among team members to successfully complete the assigned tasks.

Participants

Participants in the current study consisted of accountants, auditors, and IT security professionals in government, industry, and public practice, including CPAs, CIAs (certified internal auditors) and CISAs (certified information systems auditors). Participants received eight hours of continuing professional education (CPE) credit for attending a free day-long seminar entitled "Using COBIT for Complying with the Sarbanes-Oxley Section 404 Provisions" which was designed to cover many of the same IT security issues and information systems control objectives that were pertinent to developing appropriate recommendations for the assigned hidden profile task described in the previous section.

Procedures

In order to balance each set of teams on the basis of information systems audit expertise, participants were assigned to treatment groups based upon their level of previous IS audit experience, as reported during the registration period prior to the seminars. Participants were then randomly assigned to one of the three auditor roles of the hypothetical three-person audit team employed to investigate IT security issues.

Treatment group assignment was based upon the day the seminar was conducted (the first day

Table 1. Summary of participants by occupation

Occupation	Percentage of Total Participants
Certified Public Accountants	28%
Certified Internal Auditors/Internal Auditors	48%
IT Security Personnel	12%
Corporate Accountants and Controllers	12%

Table 2. Summary of treatment group participants by group size

Treatment Group	Total Participants
Human-Facilitated Groups	23
System-Facilitated Groups	22
Total Participants	47

of the seminars tested GSS-supported groups and the subsequent day tested unsupported groups). After participants were assigned to groups and then randomly assigned to one of the three auditor roles, each day's participants were read an identical series of introductory remarks, and were then read a series of instructions specifically tailored to each treatment group. They were then each given a specific version of the IT policy case based upon their audit team role

Human facilitated groups were instructed to complete their assigned group decision-making tasks using a prescribed agenda adapted from a group decision-making heuristic by Schwarz (1994) and consisting of problem identification, problem rating, problem drafting, solution brainstorming, solution rating, and solution drafting. Participants were also presented the normal introductory information regarding the GSS software that is typically given to participants before beginning their use of the GSS application.

System-facilitated groups were instructed on the required procedures before beginning the experiment. Participants were informed as to how the automated virtual facilitation application is used (see AVFA section), including the process of clicking an agenda item's hyperlink to hear that agenda item's instructions and subsequently completing the assigned tasks that were explained in the pre-recorded instructions. AVFA-supported groups were also informed that they would not be allowed to ask researchers or other groups for assistance, and that any problems that might occur would need to be resolved within their own group, or by using the user FAQs, or the leader FAQ's that were accessible through the AVFA software's homepage. Participants who had been assigned the "audit partner" role were designated as the team leader for each group. As such, they were required to perform the GSS management tasks that are normally carried out by the GroupSystems facilitator or "chauffer" (e.g., initiating GSS tool usage, transferring brainstorming results to the voting tool).

Automated Virtual Facilitation Application

The automated virtual facilitation application (AVFA) is a multi-modal application for prescribing GSS tools to ensure proper task-technology fit, and providing appropriation support for more effectively utilizing the underlying GSS technology. The AVFA application is used in the present research to investigate the effectiveness of virtual facilitation in comparison to conventional facilitation and unsupported group decision-making to determine whether virtual facilitation can be as effective as conventional facilitation in the areas of appropriation, efficiency, and effectiveness.

As previously discussed, the AVFA application is based primarily on operationalizing a multiple-activity group decision-making heuristic, similar to the one utilized by Wheeler and Valacich in their 1996 study. Indeed, the research design described in this chapter is to a large degree adapted from that study, including the incorporation of a hidden-profile task similar to the *School of Business Policy Task* (Wheeler & Mennecke, 1992) utilized in that study. Specifically, the automated facilitation application is intended to guide subjects in faithfully following the structured group decision-making heuristic, the sequence of which provides the basic structure of the AVFA software application. As recommended by the authors, a key extension of the present study is to test an *automated* version of a multiple activity group decision-making heuristic:

The AVFA application was designed to recommend GSS tools for the sequenced activities of the six-step heuristic by operationalizing the GSS fit profiles advocated by Zigurs and Buckland (1999) and Dennis and Valacich (1999). The multi-activity group decision-making heuristic used by Wheeler and Valacich (1996) and the problem-solving model presented by Schwarz (1994) incorporate findings from the behavioral literature regarding how heuristic structures can assist groups in overcoming common obstacles to effective decision-making, including separating divergent (idea generation) and convergent (choice) phases of group activity, and writing-out an agreed upon problem statement before working on a solution (Wheeler & Valacich, 1996, p.438). Specifically, the problem-solving model used in the present research incorporates the following two major goals and six sequenced activities:

Hypotheses

As previously noted, the present research was designed to assess the effectiveness of virtual facilitation for supporting structured group decision-making, As illustrated in Figure 1, the

Table 3. Two-step, multiple-activity group decision-making heuristic: Adapted from Schwarz (1994) and Wheeler and Valacich (1996)

Major Goals	Sequenced Activities
(1) Problem identification	Problem statement brainstorming (EB) Problem statement rating (Vote) Problem statement drafting
(2) Solution recommendation	Solution brainstorming (EB) Solution rating (Vote) Solution drafting
GSS Tool Abbreviations: EB = Electronic Brainstorming Tool, Vote = Voting Tool,	

virtual facilitation model posits that the assigned task characteristics will dictate established task-technology fit profiles (Dennis & Valacich, 1999; Zigurs & Buckland, 1999) and appropriate group problem-solving models (Briggs et al., 2003). These, in turn, will dictate appropriate GSS tools and group decision-making procedures ("meeting agendas") to be employed in completing assigned group decision-making tasks. Through this process, virtual facilitation is posited to result in efficiency levels, appropriation measures, and decision-making performance metrics that are equal to those achieved through conventional (human) facilitation.

Specifically, the current study posits the following:

H1: *System-facilitated groups will be at least as effective as human-facilitated groups in identifying problems.*

H2: *System-facilitated groups will be at least as effective as human-facilitated groups in recommending solutions.*

H3: *Satisfaction with the meeting process for system-facilitated groups will be at least equal to that of human-facilitated groups.*

H4: *Satisfaction with the meeting outcome for system-facilitated groups will be at least equal to that of human-facilitated groups.*

RESULTS

Hypothesis 1 posited that system-facilitated groups would be at least as effective as human-facilitated groups in identifying problems presented in the case study. As indicated in Table 4, while human-facilitated groups identified more problems and than system-facilitated groups, the difference was not found to be significant. Accordingly, the failure to reject the null hypothesis that system facilitated groups are less effective than human-facilitated groups resulted in the conclusion that system facilitated groups are at least as effective as human facilitated groups in this measure of brainstorming effectiveness.

Likewise, while human-facilitated groups recommended an average of 9.4 solutions per group, system-facilitated groups recommended an average 8.9 solutions, as indicated in Table 5. Accordingly, Hypotheses 2 (system-facilitated groups will recommend at least as many solutions as unsupported groups) was supported by

Figure 1. System-directed facilitation model

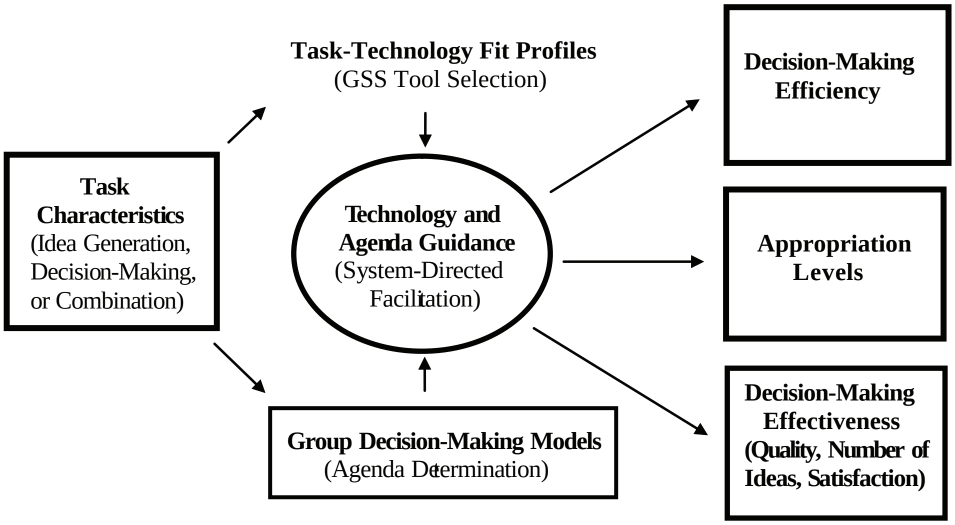

Table 4. Average number of problems identified by treatment group

Treatment Group	Mean Number of Problems Identified	Standard Deviation	Sig. (1-tailed) Human-Facilitated Groups vs. System-Facilitated Groups
Human-Facilitated Groups	15.0	5.95	.063
System-Facilitated Groups	10.6	3.01	

Table 5. Average number of solutions recommended by treatment groups

Treatment Group	Mean Number of Solutions Recommended	Standard Deviation	Sig. (1-tailed) Human-Facilitated Groups vs. System-Facilitated Groups
Human-Facilitated Groups	9.4	3.70	.390
System-Facilitated Groups	8.9	1.58	

the findings for this measure of brainstorming effectiveness.

Hypotheses 3 and 4 relate to participants' satisfaction with the meeting's process and outcome, positing that system-facilitated groups will be at least as satisfied as human-facilitated groups. Scores for satisfaction with the meeting's process were calculated by adding the individual item Likert scores in the Briggs et al. post-session questionnaire, as shown in Appendix A.

System-facilitated participants were found to be slightly more satisfied with the meeting's process than human-facilitated participants, as indicated in Table 6. Accordingly, Hypothesis 3 (satisfaction with the meeting process for system-facilitated groups will be at least equal to that of human-facilitated groups) was supported by the data.

Satisfaction with the meeting's outcome was posited in Hypothesis 4. As indicated in Table 7, system-facilitated participants were found to be slightly more satisfied with the meeting's outcome than were human-facilitated participants Accordingly, Hypothesis 4 (satisfaction with the meeting outcome for system-facilitated groups will be at least equal to that of human-facilitated groups) was supported by the data.

DISCUSSION AND CONCLUSION

This research addresses the feasibility of using system-directed guidance for facilitating users of advanced information technologies in an experiment involving CPAs, internal auditors, and IT security personnel as participants in a simu-

Table 6. Satisfaction with meeting process

Treatment Group	Mean Satisfaction with Meeting Process Score	Standard Deviation	Sig. (1-tailed) Human-Facilitated Groups vs. System-Facilitated Groups
Human-Facilitated Groups	23.6	6.75	.211
System-Facilitated Groups	25.3	3.82	

Table 7. Satisfaction with meeting outcome

Treatment Group	Mean Satisfaction with Meeting Outcome Score	Standard Deviation	Sig. (1-tailed) Human-Facilitated Groups vs. System-Facilitated Groups
Human-Facilitated Groups	24.3	6.63	.414
System-Facilitated Groups	24.7	7.36	

lated information systems audit. Contrary to the study's hypotheses, system-facilitated teams were found to be less effective than human-facilitated groups in completing their assigned tasks. Likewise, satisfaction levels for system-facilitated teams were found to be only slightly higher for system-facilitated teams in comparison to human-facilitated teams.

A significant portion of the lower than expected effectiveness levels of system-facilitated groups can likely be attributed to the complexity of the GDSS application that was used in the experiment and the fairly steep learning curve required to effectively utilize the GDSS software. In a separate post-experiment survey, a significant number of participants commented on various difficulties that were encountered in utilizing the GDSS software.

Moreover, by simplifying the user interface and improving the overall user friendliness of the GDSS application used by audit team members, it is quite likely that audit team performance levels could be significantly improved. Accordingly, future research efforts should focus on utilizing GSS systems such as Microsoft's Live Meeting application which are believed to be significantly easier to utilize and which do not have many of the complexities that participants noted in their evaluations of the GDSS application utilized in the experiment.

APPENDIX A

Post-Session Questionnaire[*]

Dependent Variable: Satisfaction with Meeting Process (PROSATIS):

PROSATIS1: I feel satisfied with the way in which today's meeting was conducted.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

PROSATIS2: I feel good about today's meeting process.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

PROSATIS3: I liked the way the meeting progressed today.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

PROSATIS4: I feel satisfied with the procedures used in today's meeting.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5

___ I would quite agree 6
___ I would strongly agree 7

PROSATIS5: I feel satisfied about the way we carried out the activities in today's meeting.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

Minimum PROSATIS Score = 5
Maximum PROSATIS Score = 35

Dependent Variable: Satisfaction with Meeting Outcome (OUTSATIS):

OUTSATIS1: I liked the outcome of today's meeting.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

OUTSATIS2: I feel satisfied with the things we achieved in today's meeting.

___ I would strongly disagree 1
___ I would quite disagree 2
___ I would slightly disagree 3
___ I would neither agree nor disagree 4
___ I would slightly agree 5
___ I would quite agree 6
___ I would strongly agree 7

OUTSATIS3: When the meeting was finally over, I felt satisfied with the results.

___ I would strongly disagree	1
___ I would quite disagree	2
___ I would slightly disagree	3
___ I would neither agree nor disagree	4
___ I would slightly agree	5
___ I would quite agree	6
___ I would strongly agree	7

OUTSATIS4: Our accomplishments today give me a feeling of satisfaction.

___ I would strongly disagree	1
___ I would quite disagree	2
___ I would slightly disagree	3
___ I would neither agree nor disagree	4
___ I would slightly agree	5
___ I would quite agree	6
___ I would strongly agree	7

OUTSATIS5: I am happy with the results of today's meeting.

___ I would strongly disagree	1
___ I would quite disagree	2
___ I would slightly disagree	3
___ I would neither agree nor disagree	4
___ I would slightly agree	5
___ I would quite agree	6
___ I would strongly agree	7

Minimum OUTSATIS Score = 5
Maximum OUTSATIS Score = 35

How Well Do E-Commerce Web Sites Support Compensatory and Non-Compensatory Decision Strategies?

An Exploratory Study

Naveen Gudigantala

Donald R. Jones
Texas Tech University, USA

ABSTRACT

The burgeoning growth of online retailing is forcing businesses to provide better support for consumer decision making on e-commerce Web sites. Consequently, researchers in information systems and marketing have been focusing on investigating the effectiveness of Web-based decision support systems (WebDSS) in providing accurate and satisfying choices for customers. We consider WebDSS implementation based on compensatory, non-compensatory decision strategies and synthesize the existing literature. The results of synthesis show that compensatory WebDSS perform better than non-compensatory WebDSS in terms of decision quality, satisfaction, effort, and confidence. We then investigate the level of Web site support provided for consumers' execution of compensatory and non-compensatory strategies. We examined 375 U.S.-based company Web sites and found that though moderate levels of support exists for consumers to implement non-compensatory choice strategies, virtually no support exists for executing multi-attribute-based compensatory choice strategies.

INTRODUCTION

The advent of the World Wide Web and search engines caused a revolution in the way people search for information. The Internet is now used by 73% of all American adults as of 2006 (Pew Internet and American Life, 2006). In addition, the rapid growth of e-commerce has resulted in digital marketplaces offering a wide variety of product alternatives, elaborate product related information, and great convenience for visitors. Consequently, ever-greater numbers of individuals are interacting with online environments to search for product related information and to buy products and services (Xiao & Benbasat, 2007). In fact, searching for product or service related information was the second most popular activity on the Internet in 2003 after e-mail or instant messaging (U.S. Department of Commerce, 2004). Concurrently, online sales are expected to reach $331 billion by 2010, according to a report by Forrester research.[1] The Web retailers with their retailer innovations and Web site improvements are expected to account for 13% of total retail sales in 2010, up from 7% in 2004. These statistics suggest that e-commerce is growing at a rapid pace, and individuals are increasingly using digital market places at every phase of their decision making process from search to choice.

Nonetheless, access to abundant information on the Web can be a blessing and a curse at the same time (Hauble & Murray, 2003). It is a blessing in that consumers now have access to a huge amount of information from several sources, and a curse because human beings are limited in their information processing capabilities (Simon, 1955). Therefore, many Web retailers are incorporating WebDSS to assist consumers with their decision-making process (Grenci & Todd, 2002). WebDSS capture individual user preferences for products either explicitly or implicitly and provide recommendations based on such preferences (Xiao & Benbasat, 2007). WebDSS have the potential to ease consumers' information overload and to reduce search complexity in addition to improving their decision quality (Haubl & Trifts, 2000).

The research in the area of consumer decision support on e-commerce Web sites is rapidly becoming interdisciplinary. Researchers from computer science, library sciences, social psychology, marketing, management, and information systems are beginning to make important contributions to this area of research. Consequently, the decision technology implemented on e-commerce Web sites is known with different names although they all refer to the same tool to be used by the consumers. Examples include intelligent agents, electronic product recommendation agents, recommendation systems, and WebDSS. In their extensive review of electronic recommendation agents, Xiao and Benbasat (2007) categorized recommendation agents (RAs) into three types. The first type of RAs includes content-filtering, collaborative-filtering, and hybrid agents. The second type includes feature-based and need-based RAs. Finally, the third type of RAs includes compensatory and non-compensatory-based systems.

The present article considers only compensatory and non-compensatory WebDSS and investigates the level of consumer support provided on commercial Web sites to execute compensatory or non-compensatory strategies. We present a synthesis of literature concerning the effectiveness of implementing compensatory versus non-compensatory DSS, and then examine whether or not such findings have made their way into the design of commercial Web sites. We believe that understanding the reality of the extent to which e-commerce Web sites support compensatory and non-compensatory strategies is important for several reasons. From a practical standpoint, if we find that relatively a smaller fraction of Web sites provide compensatory-based support despite a well supported finding that such support is normatively better, then that would highlight an opportunity for the Web retailers to increase the support levels to their customers. From a theoretical standpoint, such finding would raise further questions concerning the factors affecting the implementation of non-compensatory and compensatory WebDSS.

The rest of the article is organized as follows. We first present backgrounds concerning WebDSS types and research concerning the effectiveness of compensatory versus non-compensatory DSS. We then describe the methodology used for the study and present the results. We conclude with a discussion on managerial implications, directions for future research, and conclusion.

BACKGROUND: TYPES OF WEBDSS

One of the common implementations of WebDSS use filtering-based methods. Content-filtering WebDSS consider users' most desired attributes and provides recommendations accordingly. Some of the commercial implementations of content filtering WebDSS include Active Buyers Guide and MySimon (Xiao & Benbasat, 2007). Collaborative-filtering WebDSS use the suggestions provided by like-minded consumers to provide recommendations (Ansari, Essegaier, & Kohli, 2000). Amazon, CD Now provides collaborative filtering WebDSS on their Web sites.

On the other hand, WebDSS can also be implemented using decision strategies. Research investigating the decision strategies used by individual decision makers has a long history. Much of the knowledge acquired from the research domain of traditional DSSs is now guiding the research that examines the effectiveness of WebDSS implementing using different decision strategies. The scope of our study is limited to studying the commercial implementation of compensatory and non-compensatory WebDSS, and the following section provides an in-depth treatment of the related concepts.

Decision strategies refer to the rules employed by individuals to arrive at decisions (Hogarth 1987, p. 72). The decision strategies can be classified into compensatory and non-compensatory decision strategies. These strategies are discussed using an example of renting an apartment (see Table 1).

Non-Compensatory WebDSS

A non-compensatory WebDSS implements one of the many non-compensatory decision strategies. The use of a non-compensatory strategy avoids confronting the conflicts inherent in the choice situation and does not allow the decision maker to trade off a low value on one attribute against a high value on another attribute (Hogarth, 1987). In the apartment rental example, if a university student decides that covered parking represents the most important attribute, alternatives A, B, and C are immediately eliminated. Irrespective of the attractiveness of alternatives A, B, and C, the use of one attribute to make the decision results in their elimination.

Table 1. Four apartment alternatives

Alternatives	**Attributes**				
	Rent ($)	A/C	Covered Parking	Washer and Dryer	Dish Washer
A	350	Yes	No	No	No
B	400	Yes	No	Yes	No
C	450	Yes	No	Yes	Yes
D	500	Yes	Yes	Yes	Yes

There are many examples of non-compensatory strategies. The *conjunctive* strategy sets cut off points for certain attributes, and the alternatives that do not meet all of these thresholds are eliminated. The use of the *disjunctive* strategy allows an alternative to remain under consideration so long as either of two attributes has a value that meets its specified cutoff. Executing an *elimination-by-aspects* strategy (EBA) requires selecting an attribute at every stage and eliminating the alternatives that do not include such aspect. The process continues until a winner is selected. The *satisficing* strategy compares each attribute value with a predetermined cut-off level and the alternative that fails to meet the cut-off level is rejected (Hogarth, 1987).

Computer support for non-compensatory strategies focuses on allowing the consumer to have some control over viewing and manipulating features of interest. For example, a Web site could allow the consumer to specify the value of an attribute (e.g., enter text for searching a Web site or choosing from a list of criteria) to help select a set of products for further investigation. Even more support is given when the consumer can sort products based on the value of an attribute (as in sorting by price, weight, or category). Nonetheless, many Web sites do not give even this level of support, forcing the user to "drill down" in each product to find its features and their values.

In general, the use of non-compensatory WebDSS results in presentation of options that meet the predetermined thresholds set by the decision maker. However, the use of non-compensatory WebDSS by decision makers may not always yield the recommendations suggested by normative decision-making models. First, non-compensatory WebDSS do not consider a consumer's preference function for multiple attributes. Second, at times, the use of non-compensatory WebDSS may result in the elimination of some alternatives based on criterion set on one attribute, though such options may be very attractive on the other attributes.

Compensatory WebDSS

A compensatory WebDSS implements one of the many compensatory decision strategies on a Web site. The use of a compensatory strategy mandates confronting the conflicts inherent in the choice situation and allows the decision maker to trade off a low value on one attribute against a high value on another attribute (Hogarth, 1987). Using the example presented in Table 1, if a university student decides to rent an apartment, the use of a compensatory strategy would facilitate balancing the lack of some apartment features of alternative A against high value (low rent) of another apartment feature.

Compensatory strategies enable desirable values of one attribute of a product or service to *compensate* for undesirable values of another. Compensatory strategies require computations or judgmental assessments that combine multiple variables for each product being considered. An example of a compensatory strategy is a *weighted-additive* strategy in which a weight (relative importance) is assigned to each attribute and multiplied by its value. These products are summed to provide a score for each product. Then the product with the highest score is selected. Variations of the weighted-additive strategy use judgmental assessment of these trade-offs rather than an actual calculation. Compensatory strategies are more accurate than non-compensatory strategies when potential trade-offs exist between variables, such as when the consumer would say, "I would rather have a convertible, but not if I have to pay too much extra to get it." Unfortunately, compensatory strategies are so difficult that they are rarely used except for small sets of products or if some sort of computer-based assistance is provided (Johnson & Payne, 1985; Todd & Benbasat, 1994).

Computer support for compensatory strategies would also make it easier for consumers to see several attributes for several products at a time, such as when a Web site displays an array of rows of products with columns for various attributes. Such an array makes it easier for the consumer to identify and assess the trade-offs inherent in compensatory strategies. Some Web sites provide the display of such an array. Support for compensatory strategies could also enable the selection of products based on multiple criteria. Still further support would be to assist the consumer in evaluating trade-offs by providing some sort of scoring computation of the values of various attributes. Such a *model* would best serve the consumer if the consumer were allowed to say which attributes were important and how much weight to give each attribute. Finally the consumer would need a way to easily find out which products or services obtained the highest scores, such as having the system sort or select products based on scores provided by the model.

Partial support for compensatory strategies can come from allowing the consumer to see external ratings of products (such as *Consumer Reports*). External ratings have the advantages of being an overall assessment of multiple criteria (i.e., they are *compensatory*) and of being objective. They have the disadvantage that they are based on someone else's assumption about the relative importance of various criteria. They do not capture the consumer's own preferences.

Edwards and Fasolo (2001) note that "the idea of a procedure for making important decisions that does not depend heavily on human inputs seems unlikely as well as unattractive. Selection, training, and elicitation of responses from the person…become crucial" (p. 588). Compensatory WebDSS are specifically designed to implement such an idea. As opposed to a non-compensatory WebDSS, compensatory WebDSS need to draw on the processing capacity and storage abilities of the computers to implement the normative algorithms such as multi-attribute utility theory, Bayesian nets, and subjective expected utility theory that are otherwise very difficult for the unaided decision maker to implement (Larrick, 2004). Compensatory WebDSS execute algorithms in the background and also perform consistency checks on user provided weights making the decision tools more appealing to end users (Larrick, 2004).

Research Comparing the Effectiveness of Compensatory Versus Non-Compensatory WebDSS

How effective are compensatory WebDSS compared to non-compensatory WebDSS? We address this question in this section based on empirical results from five studies that compared compensatory and non-compensatory WebDSS. The results are summarized in Table 3. The compensatory WebDSS used in these studies elicit weights from users on attributes and present alternatives with final scores based on expected values. The non-compensatory WebDSS used were based on any of the conjunctive, disjunctive, EBA, or satisficing strategies. The explanations of the variables used to compare the two types of WebDSS are provided in Table 2.

Satisfaction

Previous research suggests that users experience more satisfaction with the use of compensatory WebDSS compared to that of non-compensatory WebDSS (Fasolo, McClelland, & Lange, 2005; Olson & Widing, 2002; Pereira 2001; Song, Jones, & Gudigantala, 2007). Widing and Talarzyk (1993) found that no such differences exist between the two formats. However they used only one item to measure satisfaction. The result by Fasolo et al. (2005) concerning the effectiveness of compensatory WebDSS is noteworthy because their research study employed an alternative set with negative inter-attribute correlations. Inter-attribute correlation is obtained by calculating the average correlation among the all the pair of attributes. With positive inter-attribute correlations (friendly environment), the alternative that is favorable on one attribute tends to be favorable on

Table 2.Variables used for comparing the effectiveness of compensatory and non-compensatory WebDSS

Variable	Explanation
Satisfaction	The user's satisfaction with the WebDSS in supporting the decision making process
Decision Quality/ Accuracy	Preference matching: The extent to which the choice selected by the user matches her stated preferences Product switching: Once a purchase decision is made, will the user change his mind and switch to another choice given a chance?
Effort	The amount of cognitive resources exerted by the user in processing the information to arrive at the choice
Confidence	The degree to which a user has confidence in WebDSS's recommendations
Decision Time	The time taken to arrive at the final choice

Table 3. Studies that compared the effectiveness of compensatory and non-compensatory WebDSS

	Fasolo et al. (2005)	Song et al. (2007)	Olson and widing (2002)	Periera (2001)	Widing and Talarzyk (1993)
Satisfaction	Compensatory WebDSS are better	Compensatory WebDSS are better	Compensatory WebDSS are better	Compensatory WebDSS are better	No Difference
Decision Quality/ Accuracy	Compensatory WebDSS are better	Compensatory WebDSS are better	Compensatory WebDSS are better	Compensatory WebDSS are better	Compensatory WebDSS are better
Effort	Compensatory WebDSS are better	Compensatory WebDSS are better		Compensatory WebDSS are better	
Confidence				Compensatory WebDSS are better	
Decision Time			No Difference		Non-Compensatory WebDSS took more time

others. With negative inter-attribute correlations (unfriendly environment), the more attractive level of one attribute is associated with less attractive level on the other. Alternatives characterized by negative inter-attribute correlations such as those between cost and quality, are common and lower consumer confidence and satisfaction (Fasolo et al., 2005). Therefore, consumers require more support when dealing with alternatives with negative inter-attribute correlations. Hence, existing evidence overwhelmingly supports the notion that compensatory WebDSS contribute to better satisfaction ratings compared to those of non-compensatory WebDSS.

Decision Quality

Decision quality has been measured in various ways in literature. Preference matching measures the extent to which the choice selected by the user matches his/her stated preferences (Pereira, 2001) whereas product switching measures the extent to which the user is likely to change his/her mind and switch to alternative choice given that he/she already made a purchase decision (Widing & Talarzyk, 1993). The existing evidence strongly suggests that compensatory WebDSS provide better decision quality to users compared to non-compensatory WebDSS (Fasolo et al., 2005; Olson

& Widing, 2002; Pereira 2001; Song et al., 2007; Widing & Talarzyk, 1993).

Effort

The existing evidence supports the idea that non-compensatory WebDSS requires more effort from users than that of compensatory WebDSS (Fasolo et al., 2005; Pereira, 2001; Song et al., 2007).

Confidence

Research by Pereira (2001) found out that users felt more confident when making choices with compensatory WebDSS as opposed to a non-compensatory WebDSS.

Decision Time

While research by Widing and Talarzyk (1993) suggests that non-compensatory DSS took more time to arrive at a choice, Olson and Widing (2002) found that no such differences exist. Therefore, the existing evidence is inconclusive whether the use of compensatory WebDSS saves time.

Therefore, overwhelming evidence supports the notion that compensatory WebDSS are better than non-compensatory WebDSS on important variables such as satisfaction, decision quality, effort, and confidence. In addition, even in the absence of decision tools implementing compensatory decision strategies, Web sites that facilitate the comparison of alternatives contribute to an increased use of compensatory strategies by users (Jedetski, Adelman, & Yeo, 2002). However, research also suggests that non-compensatory WebDSS support consumer decision making better than Web sites that just provide products by alphabetical order (Widing & Talarzyk, 1993). When technology makes compensatory strategies easier, consumers are more likely to use them (Todd & Benbasat, 1994). Moreover, consumers are more likely to use ratings based on their own weightings of the features, rather than someone else's preferences (Jones & Brown, 2003). Hence, based on the empirical results that non-compensatory WebDSS are better than Web sites providing alphabetical order of products, and compensatory WebDSS are better than non-compensatory WebDSS, we set out to investigate how well the commercial Web sites provide support to compensatory and non-compensatory strategies.

METHODOLOGY

Research on evaluation of Web-based information systems in the context of e-commerce has been ongoing. Previous work has examined e-commerce Web sites based on concordance analysis (Jinling & Guoping, 2005) and the factors that influence Web-based information systems success (Garrity, Glassberg, Kim, Sanders, & Shin, 2005). Garrity et al. (2005) found that decision support satisfaction plays an important role in Web-based information system success. Given this finding and the evidence that compensatory and non-compensatory WebDSS provide varying levels of decision support satisfaction (with compensatory WebDSS providing more satisfaction), we set out to evaluate retail Web sites based on three criteria:

1. Does the Web site have useful features commonly found on competitors' Web sites?
2. How much support does the Web site give to consumers' non-compensatory decision strategies?
3. How much support does the Web site give to compensatory strategies in a way that captures consumers' own preferences and weightings of product features?

Selection of Data Source

In identifying business firms used in this study (as opposed to personal or very small operations), we used the Business and Company Center database.[2] This is one of the most comprehensive

Web-based business databases available today that offers extensive information on hundreds of thousands of companies worldwide. We focused on retail and service industry based on four-digit industry codes. The scope of our analysis is restricted to the U.S.-based companies. The database contains approximately 2,600 U.S. companies out of approximately 7,600 worldwide companies. We selected about 25% of the U.S. companies by selecting every fourth company from the database consisting of 2,600 companies.

Questionnaire Preparation and Pilot Testing

The first part of the data collection procedure involved preparation of the questionnaire to be used by the researcher evaluating a Web site. The questionnaire elicited information concerning different kinds of decision support provided by Web retailers. The questionnaire was intended to capture information concerning the support provided to help users locate, evaluate, and compare products. In addition, information concerning the provision of a multi-attribute model that would elicit user preferences as well as the provision of others ratings' about products was captured. The information concerning the communication of privacy policy was also captured. The questionnaire is included in Appendix A. In a nutshell, the questionnaire was intended to capture Web site support for executing non-compensatory strategies, compensatory strategies, product related information, and security and privacy based information.

A pilot study was conducted to refine the questionnaire and to examine the agreement about the information collected. The three authors individually visited 30 Web sites and gathered data. The authors found 90% agreement on the data collected. Based on discussions about the sources of the few disagreements, further revisions were made to the questionnaire to remove ambiguities in the questions.

Data Collection

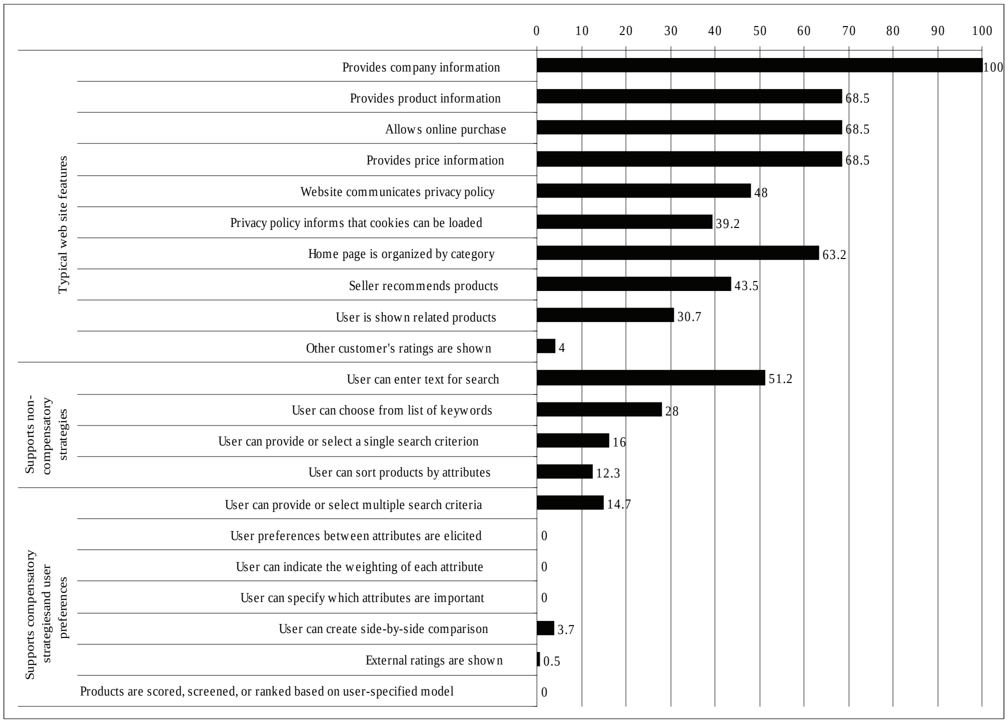
We selected about 25% of the 2,600 U.S. companies, and one of the authors visited 610 Web sites to collect data.[3] In order to reduce the possible bias in the sample, we avoided any duplication, such as companies listed in multiple SIC industries. In addition, the URLs of many companies are out of date, and some URLs represented replications of those that were already considered for the study. Finally, the data set consisted of complete observations for 375 business firms operating on the Web. Out of the 375 Web sites, 310 were retail Web sites and 65 were service Web sites. The retail industry contained Web sites on merchandize stores; apparel and accessory stores; furniture; household appliances; electronics; and so forth, where as the service industry consisted of Web sites on hotels and motels; rooming and boarding houses; sporting and recreational camps; RV parks; software services; and so forth. The collected data provided rich description of the typical features, their level of support for consumers' non-compensatory strategies, and their level of support for consumers' compensatory strategies and preferences.

To give further assurance of accuracy and validity of data collection, a second author randomly gathered data about some companies in the sample to compare to the other author's data collection. There was almost perfect agreement between the two authors.

Results

Our overall findings are displayed graphically in Figure 1. Typical Web site features are shown first. Of our sample of 375 Web sites, all give general company information and about two-thirds (68.5%) support online purchasing of products or services. Most of the Web sites that support online purchases display the privacy policy and inform that cookies can be loaded to the consumer's computer. Most of the Web sites that support online

Figure 1. The percentage of web-retailers' web sites investigated (375 total) having various web site features, including features that would support consumers' decision strategies and preferences



purchases also enable consumers to find specific categories, which facilitates consumers' search. About half of the Web sites recommend products in some way, about a third show related products. Only 4% of the Web sites surveyed show other customers' ratings.

In the middle of Figure 1, the results are shown for features that would be helpful to consumers desiring to execute non-compensatory strategies. Most of the Web sites that supported selling had at least one feature that would enable the consumer to find products based on a certain criterion, such as entering text for a search, choosing from a list of keywords, or providing a single search criterion. Nonetheless, only 12.3% of the Web sites enable the sorting of products based on an attribute value.

At the bottom of Figure 1, the results are shown for features that would be helpful to consumers desiring to execute compensatory strategies. When we considered the support for compensatory strategies that incorporated consumer preferences, we found almost no support. Just 14.7% of the Web sites supported searches based on multiple criteria. Only 3.7% displayed side-by-side comparison. Only .5% showed external ratings of products or services. NONE of the Web sites assisted the consumers by allowing the users to give weights of attributes or specify which weights are important. NONE of the Web sites provided for scoring based on user-specified models.

To gain further insight into the breakdown of the Web sites in our sample, we subdivided our sample two ways: retail versus service, and sales volume above or below average. These results are shown in Table 4. Inspection of these breakdowns reveals several patterns. First, the typical Web site features are provided more often for retail products than for services.

Service industry Web sites are more prone to just give company information and not try to sell directly on the Web site. On the other hand,

Table 4. Survey of WebDSS attributes

Attributes	All (N=375)	Industry		Sales Volume	
		Retail (N=310)	Service (N=65)	Above (N=188)	Below (N=187)
Typical Web Site Features					
Provides company information	100.0 (%)	100.0(%)	100.0(%)	100.0(%)	100.0(%)
Provides product information	68.5	72.3	50.8	69.7	67.4
Allows online purchase	68.5	72.3	50.8	69.7	67.4
Provides price information	68.5	72.3	50.8	69.7	67.4
Website communicates privacy policy	48.0	51.7	29.2	59.6	36.4
Privacy policy informs that cookies can be loaded	39.2	42.6	23.1	53.7	24.6
Home page is organized by category	63.2	66.1	49.2	63.8	62.6
Seller recommends products	43.5	47.7	23.1	50.0	36.9
User is shown related products	30.7	36.8	1.5	39.9	21.4
Other customers' ratings are shown	4.0	4.8	0.0	7.4	0.5
Web Site Features Supportive of Non-Compensatory Decision Strategies					
User can enter text for search	51.2	60.0	9.2	51.6	50.8
User can choose from list of keywords	28.0	25.5	40.0	30.9	25.1
User can provide or select a single search criterion	19.2	15.2	38.5	20.7	17.6
User can sort products by attributes	12.3	13.5	6.2	16.0	8.6
Web Site Features Supportive of Compensatory Decision Strategies or User Preferences					
User can provide or select a multiple search criterion	14.7	10.0	36.9	13.8	15.5
User preferences between attributes are elicited	0.0	0.0	0.0	0.0	0.0
User can indicate the weighting to each attribute	0.0	0.0	0.0	0.0	0.0
User can specify which attributes are important	0.0	0.0	0.0	0.0	0.0
User can create side-by-side comparison	3.7	4.5	0.0	5.3	2.1
External ratings are shown	0.5	0.6	0.0	0.5	0.5
Products are scored, screened, and ranked based on user specified model	0.0	0.0	0.0	0.0	0.0

company size did not appear to affect the extent of online selling, perhaps because there are few financial or technological barriers to a small business that wants to begin selling on the Internet. The larger companies appear to attempt to market their products somewhat more by recommending products, showing related products, and showing other customer ratings.

Retailers of products more frequently allowed users to enter text for a search, while service companies more frequently allowed a choice of keywords or provision of a single search criterion. Since these features are merely different ways of achieving the same objective, we do not see sellers of products or services as dominating in supporting ways of specifying criteria. For the few Web sites that supported sorting of products by attributes, this feature was more frequently provided by retailers of products than by service firms. The sort feature was also more frequently provided by large firms than small firms.

For compensatory strategies, the main result is that Web sites gave little support at all. For some reason service firms gave more support in searching multiple criteria than sellers of products. Of the few Web sites showing side-by-side comparisons, all were retailers of products (rather than services) and most were large companies. External ratings were all of products rather than services. This may be due to a lack of available external ratings of services.

MANAGERIAL IMPLICATIONS

The main finding of our investigation of e-commerce Web sites is a complete absence of support for consumers' compensatory strategies based on their own preferences. Given the results of academic research that compensatory WebDSS provide better decision quality, satisfaction, and confidence to consumer, and reduce effort, an opportunity is waiting for managers to start looking for ways to implement such tools.

The purpose of a DSS is to help a customer pick the best possible choice in all situations. The use of non-compensatory DSS is not associated with better decision quality (Fasolo et al., 2005). However, managers have to make sure that compensatory WebDSS are easy to use. Most of the compensatory WebDSS implemented in research experiments typically have two screens. In the real world, as the number of screens used to capture consumer preferences increases, the longer it takes for customers to make a decision. Such design may discourage users. Therefore, to the extent that compensatory WebDSS are easy to use, they are likely to be used by consumers.

The execution of compensatory strategies requires users to submit weights to attributes and then the DSS recommends products with highest expected values. But, how does a user know what algorithm is being used to come up with the results? Therefore, it is recommended that managers provide information concerning how the final scores (expected values) are calculated from the user supplied weights.

It is also possible that the lack of expertise and developmental costs may influence managers not to implement compensatory WebDSS. We believe that the extent to which the benefits of implementing such WebDSS outweigh the costs implies that it would be a worthwhile proposition for managers to consider developing compensatory based decision support tools.

Directions for Future Research

While our study results showed absence of support for executing compensatory strategies in e-commerce Web sites based on consumer preferences, with some additional research, we were surprised to find some third party Web sites providing such support. Examples of such third party sites include My product advisor (http://www.myproductadvisor.com), Select smart (http://www.selectsmart.com), and Yahoo! shopping smart sort computer and electronic recommendations (http://shopping.yahoo.com/smartsort). Future research could investigate two research questions. First, what are the factors that inhibit e-commerce Web sites from providing support for compensatory-based strategies based on consumer preferences? Second, what are the implications for e-commerce Web sites with third party Web sites providing such support when consumers expect such support from the Web retailers themselves?

A second area of research could look into the issues surrounding consumers' adoption of decision technology implemented to support individuals' decision-making processes. Research shows that less than 10% of home users visit shopbots (Montgomery, Hosanagar, Krishnan, & Clay, 2004). Therefore, future research could look into various factors that would improve the consumer adoption of decision technology. Furthermore, additional research is needed to understand how individual differences in decision makers affect adoption and usage of decision technology on e-commerce Web sites.

The present survey considers only compensatory and non-compensatory based systems, and the results suggest that an important gap exists between theory and practice. Future studies could conduct similar kinds of studies to investigate how well e-commerce Web sites provide support concerning content, collaborative, and hybrid WebDSS as well as the feature- and need-based WebDSS. It is our hope that as with our study, important insights could be brought out by conducting studies that investigate the extent of Web site support concerning other types of WebDSS.

Compensatory decision tools that are implemented in the experiments may face challenges when extended to the real world. For example, most of the compensatory WebDSS designed in experiments contain all the attribute values for a given alternative set. However, in the real world, attributes values may be missing for some alternatives, and therefore computing expected values for such alternatives could be problematic. Therefore, future research could look at the effects of missing information on consumer choices in online decision support environments.

Future research could also look at measuring the monetary benefit to an organization implementing a Web-based decision support tool on its Web site. The existing research so far has focused on decision outcome variables such as satisfaction, decision quality, effort, and so forth. Of interest to managers could be whether improved WebDSS tools augment the user's willingness to purchase.

CONCLUSION

Research conducted by decision scientists over the last few decades has examined the normative way of decision making (how decisions must be made) and identified several decision strategies individuals use to make a decision. These decision strategies are compensatory and non-compensatory in nature. After the advent of the Internet and the subsequent growth of the e-commerce market, most Web sites are implementing Web-based decision support tools to help consumer make their choices. One category of Web-based decision tools uses decision strategies to provide consumer support. In this study, we focus on Web site support for executing consumers' compensatory and non-compensatory strategies.

The study makes two contributions. By synthesizing the existing literature concerning the effectiveness of implementing compensatory versus non-compensatory WebDSS, we found that a majority of the evidence favors implementing compensatory WebDSS. If compensatory WebDSS are so effective, one would expect to observe e-commerce Web sites increasing the level of support for executing consumers' compensatory strategies. Based on a study of 375 U.S. company Web sites, we found that very little support exists for features that support compensatory strategies (such as side-by-side comparison of alternatives) and no support exists for executing compensatory strategies based on consumer preferences.

We also note several limitations of our study. As far as we are aware, there is no study that explored how well Web sites provide support for compensatory and non-compensatory based strategies. Though it is problematic to generalize the findings of U.S.-based companies to companies worldwide, a future study could look into how well such strategies are supported in Web sites worldwide. Secondly, choosing 25% of U.S.-based companies is purely arbitrary. However, we believe that the results of our study are representative of the current situation on e-commerce Web sites. For example, Fasolo et al. (2005) state that "although we have no precise data to support it, we are under the impression that real World Wide Web compensatory sites are having rougher and shorter lives than non-compensatory sites….We have anecdotal evidence that transparency and length might be a reason for the lack of success of compensatory ones" (p. 341).

The results of this study open up an opportunity for managers to start providing more support for compensatory-based decision strategies, and at the same time begs the question of the lack of popularity of such tools. A number of potential reasons have been presented and a host of research questions have been raised. It is our hope this attempt fuels further research in improving the design of WebDSS and finding factors that affect the adoption of WebDSS, ultimately contributing to the benefit of both the Web sites and users.

[3] The questionnaire captures general details, support for user to locate a product, evaluate individual products, support in terms of others ratings, support to compare products, support for multi-attribute models, and information about cookies. The only place where the researcher's perceptions could bias the results is the section on support provided to user to select a specific product. This part is not used in the analysis. The rest of the variables are binary in nature. For example, a Web site can provide a keyword-based search or not. Similarly, a Webs ite can let the users pick important attributes or not, weight the attributes or not. Therefore, we believe that what is needed from a data collector is general observation skills and since perceptions are not recorded, we believe that use of one of the authors to collect data is reasonable.

APPENDIX A.

URL: _________________________________ SIC Code: _________________
Preparer __________
Name of Business ____
Date__________
Types of Products Offered ____

Circle all that apply:

shows company info, shows product info, shows prices, allows online purchase

Support that Helps User Locate a Product:

Y N Home page is organized by category to assist with product search
Y N User can enter text for search
Y N User can choose from list of keywords for search
Y N User can provide or select a single search criterion (e.g., homes with 3 bedrooms, < $200,000)
Y N User can provide or select multiple search criteria
Y N User is shown related products

Support that Helps User Evaluate Individual Products:

BA A AA Products are described in detail (Below average, average, above average)
BA A AA Products are shown in high quality pictures
Special features (pictures): ____

Support that Provides User with Others' Ratings of a Specific Product:

Y N Other customers' ratings or comments are shown for products
Y N External ratings (e.g. Consumer Reports ratings) are shown for products
Source: ____
Y N Seller recommends some products (e.g., "best value")
Verbiage: ____

Support that Helps User Compare Products:

Y N User can sort products by an attribute: ____
Y N User can create side-by-side comparison of products on a single web page

Support that Creates Multi-Attribute Model of Elicited User Preferences:

Y N User can specify which attributes are important and system picks products for user to review
Explain: ____
Y N User preferences between attributes are elicted by system (e.g., providing user with pairs of product attributes and asking user which is more important).
Y N User can indicate how much weight should be given to each attribute.

Y N Products are scored, screened, or ranked (indicate which) based on multi-attribute model of user preferences

Explain: ____

System Informs of Cookies in Privacy Policy:

Y N Website communicates a privacy policy

Y N Privacy policy informs that cookies might be loaded onto user's computer

Other Type of Support:

Please describe in detail any other type of decision support provided for the consumer

Chapter 5.6

E-Collaboration Using Group Decision Support Systems in Virtual Meetings

Jamie S. Switzer
Colorado State University, USA

Jackie L. Hartman
Colorado State University, USA

INTRODUCTION

When e-collaborating, there is often a need to bring everyone involved together for a meeting. With potential meeting participants often widely dispersed geographically, the meeting could be conducted virtually by utilizing technology known as groupware. Procedures for conducting successful face-to-face meetings have been in place for many years. However, with the rise in the number of computer-mediated virtual meetings being held amongst e-collaborators, there are additional considerations to take into account when conducting virtual meetings using groupware. This article discusses the use of a particular type of groupware (GDSS) in virtual meetings conducted by participants collaborating in an electronic environment.

GROUPWARE

Groupware is defined as any technology that improves group productivity (Briggs & Nunamaker, 1994). It is a generic term for specialized computer aids designed for use by collaborative work groups (Johansen, 1988).

Types of Groupware

The term *groupware* can in actuality stand for many different things. Briggs and Nunamaker (1994, p. 61) have identified several names and concepts defined as equivalent to groupware: group decision support systems, electronic conferencing, team databases, computer supported cooperation, video teleconferencing, shared drawing, workflow automation, information filtering, coordination support, collaboration support, electronic meeting systems, and team scheduling and project management.

Regardless of what it is called, groupware supports e-collaboration (Kock & McQueen, 1997), communication, and coordination (Orlikowski & Hofman, 2003) and allows people to work together to perform the following types of functions in an electronic environment (Liff, 1998):

- Management support, including meeting facilitation
- Document sharing and management
- Group calendaring and scheduling
- Project management
- Information sharing and threaded discussion forums
- Real-time interactions, including audio and video conferencing and whiteboard collaboration
- Knowledge management, which allows organizations to create a corporate memory

Group Decision Support Systems

One category of groupware increasing in popularity is group decision support systems (GDSS). GDSS encourage such activities as group idea generation, voting, brainstorming, decision making, and consensus reaching (Holtham, 1994) by removing common communication barriers. Huber defines GDSS as "a set of software, hardware, and language components and procedures that support a group of people engaged in a decision-related meeting" (1984, p. 195). DeSanctis and Gallupe offer a similar definition, calling it "an interactive, computer-based system that facilitates the solution of unstructured problems by a set of decision makers working together as a group" (1985, p. 379). Pollock and Kanachowski (1993) define GDSS as a system where group members use computers interactively to support the group's decision-making capacity.

Studies have shown that technology is essential to the success of e-collaborations (see Cai, 2005). According to Poole and Holmes (1995), the strength of GDSS comes from its ability to enhance communication and information exchange, complex information processing tasks, and coordination and organization of group collaborations. GDSS facilitate e-collaboration by combining the use of computer technology (both hardware and software), video, audio, and telecommunication systems (Barnes & Greller, 1994).

There are different levels of GDSS involved in e-collaboration (DeSanctis & Gallupe, 1987). At its most basic, GDSS provide features that facilitate common communication behaviors such as voting and electronic message exchange. The next level of GDSS provide a means to model decisions and group decision techniques to reduce the uncertainty that can occur in the decision making process. At its highest level, GDSS are tools to manage group communication patterns in e-collaboration and can include expert advice in the selection and arrangement of procedures to be followed during a virtual meeting.

CONDUCTING VIRTUAL MEETINGS USING GDSS

The primary purposes of meetings are to exchange work-related information, to make decisions, or to accomplish tasks. Guidelines for conducting successful face-to-face meetings have been in place for many years. For each face-to-face meeting, four stages of meeting protocol should be adhered to:

1. Determine the need for a meeting
2. Prepare for the meeting
3. Conduct the meeting
4. Follow-up after the meeting

Even when proper procedures are followed, there are several problems that can arise in traditional face-to-face meetings. Issues not related to the relevant task can sidetrack the group. Dominant personalities can monopolize the group's time and attention. The free flow of creative thought may be discouraged by ideas being attacked or the fear of retribution. There can be premature closure of the meeting to avoid conflict. The record of the meeting can be subjective, incomplete, or lost.

Compounding traditional face-to-face meeting complexities is the rise in the number of virtual meetings, which necessitate additional considerations. As with face-to-face meetings, organizers of virtual meetings should also follow the four stages of meeting protocol mentioned previously. But because of the very nature of the virtual meeting, there are additional considerations that need to be taken into account to conduct effective virtual meetings using GDSS. By utilizing e-collaboration technologies such as GDSS, interference with collaborative activities can be reduced and problems inherent in traditional meetings eliminated (DeSanctis, 1993).

To determine if a meeting is warranted is particularly important in a virtual environment. With e-collaborators scattered around the world in several different time zones, conducting meetings virtually presents a challenge that goes beyond the issues associated with face-to-face meetings. With participants thousands of miles apart geographically, scheduling the virtual meeting can be a difficult task. The use of an e-collaboration technology such as GDSS to conduct electronically mediated meetings is very effective in reaching those geographically dispersed team members (Munter & Netzley, 2002).

Technological considerations are the most crucial part of preparing for the virtual meeting. Determining the most appropriate technology to conduct the virtual meeting depends on the meeting agenda as well as organizational resources. Consider if the information to be delivered or the task to be achieved could best be accomplished via GDSS. The technology should serve the meeting, not dominate it (Duarte & Snyder, 1998). Nunamaker, Briggs, Mittleman, Vogel, and Balthazard (1996) argue that technology cannot make up for poor planning or ill-conceived meetings, and could even make the situation worse.

The technology must be in good working order, and a back-up plan must be in place in the (very likely) event the technology will fail. All of the people at the virtual meeting need to be trained and experienced in the technology, otherwise they will not participate. Additionally, a trained GDSS facilitator must be present at the virtual meeting to ensure its success. According to Munkvold, "the use of a facilitator is an absolute necessity for running an effective, co-located electronic meeting" (2003, p. 18).

Distributing the agenda in a timely fashion is also an important part of preparing for the virtual meeting. Besides the agenda, any additional materials must also be distributed to the e-collaborators before the scheduled meeting. If the virtual meeting is held to discuss a particular report, for instance, a person at a remote site would be at a definite disadvantage if the report was not sent in time for the virtual meeting.

When conducting a virtual meeting, facilitators need to be extremely aware of the fact that words or phrases can quite easily be misinterpreted. Some GDSS are text based only and therefore do not allow e-collaborators to view nonverbal cues. The lack of nonverbal cues such as body language and facial gestures can make communication more difficult in virtual meetings, thus accentuating language, culture, and style differences (Henry & Hartzler, 1998). To avoid creating tension among the e-collaborators, everyone must make certain the communication is clear and precise with no chance for a misunderstanding.

It is easy for people to "fade into the background" during virtual meetings, particularly those facilitated by GDSS. If the virtual meeting participants can't see each other, some people may never contribute to the discussion. In a computer-mediated meeting environment, it could simply be that the e-collaborator's typing skills are poor, and keeping up with the "discussion" is too difficult. Regardless of the reason, virtual meeting facilitators must make certain that everyone is participating and has equal opportunity to share thoughts and ideas. Virtual meeting participants should also identify themselves each time they contribute to the discussion.

When the virtual meeting ends, the communication and e-collaboration do not (Hoefling, 2001). GDSS meetings tend to generate quite a bit of information (Arkesteijn, DeRooij, & VanEekhout, 2004). It is critical to follow up after virtual meetings to make sure everyone understood the results of the meeting and knows what action to take. GDSS allows e-collaborations to be recorded electronically, thereby facilitating follow-up activities from the virtual meeting. The use of GDSS can also be very valuable in collecting a myriad of data for further consideration by the e-collaborators.

Using GDSS and other types of groupware "symbolizes new ways of integrating information technology with innovations in management and group process to produce more effective forms of collaboration" (Creighton & Adams, 1998, p. 13), including virtual meetings. But while groupware tools are very effective in many e-collaboration circumstances, there are potential downfalls (Burnett, 1994; Creighton & Adams, 1998; Johansen, 1988).

The technical problems are the most obvious, since technology is vulnerable to failure. The technology may fail during the virtual meeting, effectively ending the session without completing the agenda; computers do crash. The software may not function properly. If the technology is not working, the meeting cannot be held and valuable time and energy is lost.

The other concerns are social in nature. Using GDSS to facilitate virtual meetings may result in the over-control of the e-collaborators by focusing too much on the technology and process. People may not be computer literate. Creativity may be stifled because the meeting is too structured around the groupware requirements. Meeting participants may also lose a sense of community and personal touch.

MIXED RESULTS IN THE USE OF GDSS

Results of years of research on e-collaborating using GDSS are proving to be inconclusive, with studies supporting both positive effects on collaboration using GDSS and negative effects from the use of the tool (see Limayem, Banerjee, & Ma, in press). Jessup, Connolly, and Galegher (1990) also cite numerous studies that obtained mixed results in examining the effectiveness of GDSS.

Despite the fact that decades of research have yielded inconsistent findings, overall results "suggest that the use of a GDSS improves decision quality, depth of analysis, (and) equality of participation" (Fjermestdad, 2004). The use of GDSS tends to produce more positive effects compared to face-to-face methods, particularly with respect to the type of task the participants in the virtual meeting are engaged in (Fjermestdad & Hilz, 1998/99).

TRENDS IN CONDUCTING VIRTUAL MEETINGS USING GDSS

New technologies supporting e-collaboration are being developed and evaluated in virtual meeting contexts. "Smart meeting rooms" take GDSS technologies to a much higher level and allow for augmented reality meeting support and virtual reality generation of meetings, both in real time or off-line (Nijholt, Akker, & Heylen, 2006). Meeting participants in these "smart" or "virtual" meeting rooms will conduct all the virtual meeting activities currently facilitated by GDSS (brainstorming, discussing, voting, etc.), only with virtual reality representations of themselves, instead of e-collaborating in a strictly textual environment.

CONCLUSION

GDSS assist in focusing the efforts of e-collaborators toward the task or problem at hand. They enable productivity in virtual meetings through technology-facilitated collaboration and avoid information overload. Inputs can be anonymous, so many ideas can be quickly generated to solve problems or identify opportunities. GDSS facilitate distilling those ideas to the very best ones, clarify exactly what is intended, organizing the ideas, and evaluating and prioritizing them. It can help e-collaborators build consensus and produce deliverables that result in specific actions.

Using GDSS to facilitate a virtual meeting ensures the overall quality of effort put into the process is increased, as is the probability of reaching consensus. It guarantees no single person dominates the procedure. The e-collaborators can easily stay on task and not get distracted. An objective, precise documentation of the entire meeting is generated. Virtual meetings can also be much more efficient using GDSS.

The use of GDSS is intended, among other things, to promote e-collaboration by providing the opportunity to generate a wealth of ideas from virtual meeting participants since they can input their thoughts using the computer without interrupting another person (Olson & Olson, 2003). Using GDSS in a technology-mediated collaborative meeting environment can greatly increase efficiency. As Lococo and Yen observe, “Efficient sharing of ideas can be transformed into shared understanding and into shared priorities” (1998, p. 91). Smith (2001) argues that by improving how meetings are conducted, communication, morale and productivity will also improve.

GDSS can be very powerful tools for conducting effective virtual meetings. Used properly, as previously discussed, e-collaboration technologies such as GDSS have tremendous potential to successfully facilitate virtual meetings. While “the same technology will not provide the same results with each group and in each setting” (Boiney, 1998, p. 343), e-collaborating using GDSS has many benefits.

Duarte and Snyder (1999) emphasize the importance of understanding the issues regarding e-collaboration by making five points regarding virtual meetings:

1. Facilitating a virtual meeting includes managing the agenda, the participants, and the technology
2. Select the technology that is appropriate for the outcome of the meeting. Match the use of technology to specific agenda items
3. Leverage the agenda and the use of technology to maximize participant recall, the opportunity for participants to contribute, motivation of the participants, and to reduce social pressure on the participants
4. Make use of social protocols and best practices for using the selected technology
5. Make certain that logistics cover issues such as compatibility of technology training in using new systems as well as backup plans

For virtual meetings to be effective when they are conducted via GDSS, traditional meeting procedures need to be adjusted and redefined to take into consideration the special circumstances involved in using technology that facilitates e-collaboration. As Grenier and Metes (1995) observe, “This meeting’s not over, it’s just gone to another medium.”

Chapter 5.7

Open Content Distribution Management in Virtual Organizations

Amir Hassan
Lappeenranta University of Technology, Finland

Herkko Hietanen
Lappeenranta University of Technology, Finland

INTRODUCTION

Future scenarios of **organization**s envision companies that are organized around a central **knowledge** base in the form of a **network**. It is assumed that each company contributes its own expertise and intellectual capital to the network's knowledge base. This article discusses the use of **open content** distribution management systems (OCDMSs) in knowledge-intensive fields, such as content production and software development, in order to ensure seamless and open collaboration between the firms in the organization.

OCDMSs offer participants several advantages. For instance, such systems can be seen as a way of enhancing the competitiveness of small and micro-sized knowledge-based firms by ensuring that each firm receives fair compensation for the content it develops. OCDMSs are revolutionary in the sense that they allow participants to contribute content to a common resource pool and add all the required **metadata** to the content. A common information pool where information is shared with well-defined rules lowers transaction costs between participating organizations. This article looks at one open content distribution management system that was developed in a university-industry research project and is being further developed by a company that is a spin-off company from the project.

BACKGROUND

Virtual Organizations

Developments in information technology as well as new organizational concepts have led to the emergence of new types of organizations. Miles, Miles, and Snow (2004), Miles and Snow (1995), and Miles, Snow, and Miles (2000) have discussed network organizations that rely on collaboration between independent units. The term virtual organization has become ever more commonplace in organizational literature. Walters (2004) discusses the business model of the virtual or holonic organization and refers to McHugh, Merli, and Wheeler (1995) in listing the following properties of a virtual organization.

- The organization consists of businesses of equal standing; that is, there is no hierarchy between the individual businesses in a virtual organization.
- Information can be accessed and exchanged freely throughout the organization and across its boundaries; that is, the organization is open.
- The organization is evolutionary and is involved in constant interaction with its environment.

One interesting form of virtual organizing is the virtual web, defined by Franke (1999) as "the base of virtual corporations" (p. 211). According to Franke, a virtual web belongs to the typology of dynamic networks, as defined by Miles and Snow (1986), which has the following characteristics.

1. **Vertical Disaggregation:** Different organizations in the network perform separate functions that have been performed by functional units in a traditional organization.
2. **Brokers:** Brokers bring together the necessary functions available in the organization and play a leading role in building business units and subcontracting for needed services. Brokers can operate at different levels of a dynamic network and, thereby, have varying degrees of responsibility.
3. **Market Mechanisms:** These hold the network together and regulate its functioning. Competition is promoted amongst the members of the network and also with external companies, and this regulates the internal prices of the services available in the network.
4. **Full-Disclosure Information Systems:** Companies wishing to become a part of the network, even for a fixed-term project, are expected to connect their information systems to the network's continuously updated information system via broadband access in return for a general payment structure for the value they add to the network. The purpose of this, according to Miles and Snow (1986), is to facilitate the rapid and mutual assessment of contributions and to speed up the trust-building process.

According to Franke (1999), virtual corporations are involved in temporary partnerships established by brokers in a virtual web in order to bring together the necessary combination of skills and resources. In order for a virtual web to successfully generate virtual corporations, the web must offer an environment that encourages the member companies to participate in virtual corporations without compromising confidentiality and intellectual property rights, while, at the same time, preserving the dynamic and flexible properties of the virtual corporation.

Virtual Communities

Lee, Vodel, and Limayem (2003) have analysed various definitions of virtual communities and have identified four elements that they found common to most definitions. First, a virtual community should exist in cyberspace; that is, the members of a virtual community use computer-mediated spaces in order to interact. Second, the activities of a virtual community are supported by computer-based technologies, such as e-mail, message boards, and chat. Third, the main focus and content of virtual communities are participant driven, and the content of such communities is formed through the communication between the members of the community. The fourth and final element that Lee et al. found to be common to all virtual community definitions was the formation of a sustained relationship as a result of the interaction between the members of the community. Koh and Kim (2003-2004, 2004) have also observed cyberspace to be a usual feature for identifying virtual communities. However, they also found the interaction of many virtual communities to take place off line as well as online, especially in the case of communities that have originated off line. Koh and Kim's definition of a virtual community is "a group of people with common interests or goals, interacting for knowledge (or information) sharing predominantly in cyberspace" (p. 157). Etzioni and Etzioni (1999) point out the discrepancies in the definitions given for computer-mediated communities (CMCs) by different authors; some authors may refer to tightly knit communities while others to groups of acquaintances. The authors have found communities to have two common features: networks of relationships that may overlap rather than single links between the members, and a common set of values and norms to which the members of the community adhere and are committed and a common shared history.

One of the most productive virtual organization models is the free and **open source** software (later FOSS) movement (see DiBona, Ockman, & Stone, 1999). It uses licenses that allow the use and modification of FOSS program components. Open-source licenses grant rights that are otherwise exclusive to the copyright holder. FOSS licensing enables the flexible but controlled use of software resources. FOSS is a multibillion-dollar business that has shown how less restrictive content sharing can lead to considerable benefits for the whole software industry and society at large.

The uncontrolled sharing of information goods leads to exploitation that does not benefit content providers or society in the long run. According to Kwok, Yang, Tam, and Wong (2004), digital and peer-to-peer (P2P) technologies have made it easier to produce and distribute illegal copies of copyrighted material. Thus, a virtual web that is supported by a common broadband information system, to which all the participants are linked, poses risks in terms of content and copyright management. Digital rights management (DRM) is one of the concepts for managing the rights of information products. Benkler (2002) points out how computers have changed copyrights into "privately created and enforced exclusion—created by contracts and enforced by technology" (p. 81). In most cases, DRM systems limit access to information through the use of technical protection measures. This does not serve the purposes of virtual organizations. While DRM might be an overly restrictive tool, some control is needed. This can be obtained by using digital rights expression (DRE).

DIGITAL RIGHTS EXPRESSION

In the digital environment, it is possible to attach a license to a work. Most new music, image, and text formats have a field reserved for metadata. The attaching of metadata that describes the copyright status of a work is called digital rights expression. DRE uses semantic web methods to let users know of the permission that they have. Unlike DRM systems, DRE does not use technical means to restrict users from violating these terms.

One of the most commonly used ways of expressing digital rights is W3C's (World Wide Web Consortium's) resource description framework (RDF). It provides a foundation for the processing and exchange of machine-understandable information on the Web. RDF can be used for cataloguing (to describe content that is in a digital format on a Web page, in a digital library, or on a P2P network), for resource discovery (for example, to let a search engine search for works that have certain licenses), and by intelligent software agents (to facilitate knowledge sharing and exchange) in content rating. The W3C glossary (http://www.w3.org/2003/glossary/) defines metadata as “Data about data on the Web, including but not limited to authorship, classification, endorsement, policy, distribution terms, IPR, and so on.” Most file formats support metadata. Metadata can be easily attached and read from Mp3, PDF (portable document format), mpeg4, and HTML (hypertext markup language) formats. Machine-understandable metadata can be used to efficiently define rights in the information management system of a virtual organization. Metadata can hold pricing and author information as well as licensing terms.

Open content can be briefly defined as being creative works that are in a format that explicitly allows their copying and distribution. Open content must also have a license that allows copying and distribution, or must belong to the public domain. By automating the licensing procedure, transaction costs can be further lowered. While the licenses are expensive to write, they can be used over and over again with minor modifications. These modifications can be made automatically through the use of a licensing engine. In this way, licensing can be fixed to an organization’s work flow. Creative Commons (http://www.creativecommons.org), a nonprofit organization, has produced a set of open content licenses and a Web interface that allow content producers to tailor copyright licenses that suit their needs. They also provide licenses in RDF format. More than 4 million works have been licensed with Creative Commons licenses.

Open content files carrying legal metadata serve virtual organizations by lowering transaction costs. Members of an organization do not have to search for the holders of the rights and negotiate license agreements, and they have the content at their disposal. Open but controlled sharing also has a positive impact on marketing (Nadel, 2004). Benkler (2002) notes how organizations should adapt different information policies and levels of exclusivity depending on their business models. Open content systems benefit creative networks that depend on cooperation.

For the rights holder, the system enables easy licensing, a distribution channel, and the possibility for price discrimination. The price can be set dynamically for different projects. For example, the Magnatune record company (http://www.magnatune.com) uses dynamic pricing for their records that are available online. Magnatune music is available for free for noncommercial use, but commercial licenses must be bought from the Magnatune Web site. The price is preset and is fixed by the licensee, who has to enter the details of the commercial activity. Magnatune’s system calculates the prices of licenses, which depend on the size of the budget and the rights to be licensed. The system also generates a license that is valid after the license payment has been made.

AN EXAMPLE OF AN OPEN CONTENT INFORMATION SYSTEM

Virtual organizations and communities that have grown on the Internet and out of networks of content-production companies need systems for managing content contributed by their members for common use. This article discusses one such system, the Digital Content Distribution Management System (DiMaS). DiMaS is a prototype of a system designed for use within a community of content producers and was developed in cooperation with the Digital Economy Core (DE Core) and Mobile Content Communities (MC^2) research projects at the Helsinki Institute of Information Technology (HIIT).3 The following description is based on two papers by Reti and Sarvas (2004a, 2004b) that outline the functions of the system.

DiMaS enables multimedia producers to publish their works along with content metadata. The content-import user interface is the front end of the system and contains the user registration, user-information database, log-in, user manual, and content-import functionalities. At the point of registration, the user must accept the system's rules of conduct. After registration, the content provider can upload content to a server. Users enter content-related metadata using a chain of Web forms that appear in a particular succession and between which the user can move freely backward and forward. During the upload procedure, the content provider can add metadata, preview files, and feedback questions for the primary content payload. Once entered, the content file, metadata, and preview image are stored in the system until the user publishes them using a specific control button in the user interface.

The structure of the DiMaS system is shown in Figure 1.

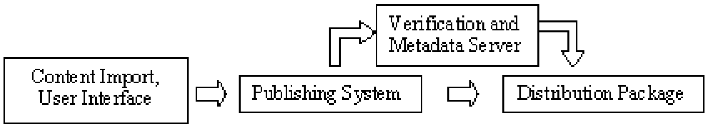
After being uploaded, the content is forwarded to the publishing system. The publishing system forms a distribution package using the inserted content file, preview file, user interface, and metadata. The publishing system can be in a closed or open environment. Publishing can be performed in uncontrolled peer-to-peer networks, such as Gnutella or KaZaa. DiMaS also enables content encryption. In this way, the content can be distributed on public P2P networks and stored on uncontrolled servers. If the content is access controlled, it is not open content.

When consumers, or other end users, find content that they want, they can download and open it, for instance, on their PDAs (personal digital assistants). When opening the content, a user application that resembles a DVD (digital videodisc) menu appears and the system can update the content metadata, for example, the description of the content stored on the metadata server. This makes it possible for the content provider to change the pricing or licensing terms after the content has been uploaded and even after it has been distributed to end users. This feature can be used to set the price of the product according to the product's life cycle. Novel works may carry a higher price tag than vintage material. The system can also notify the user when a new version of a work is available. Users can browse through the copyright license or contract in the price section of the application. The only technology required by the end user in order to run the distribution package is the Java Standard Edition Runtime Environment (http://java.sun.com).

In open content mode, an entire virtual organization can browse the content freely. The metadata inform users on how the content can be modified or exported out of the virtual organization for commercial use. DiMaS also has a feedback option. The system can collect user feedback after content browsing and store this information along with the metadata. Feedback enables content rating, which helps to distinguish premium content from large information masses.

DiMaS is an MIT-licensed open-source product and can be customised to meet the needs of specific content-production communities. The goal of DiMaS is to be executable without specific client software and independent of the type of content to be distributed. The DiMaS prototype supports Windows Media Player files and, as mentioned above, requires that the user have the Java Standard Edition Runtime Environment installed on his or her system. As yet, DiMaS has not been used in any real-life organizations since it is still in the prototype stage.

Figure 1. The structure of DiMaS



CONCLUSION AND FUTURE TRENDS

This article has discussed the problems related to the management of digital rights in virtual communities and the meaning of open content systems. It also presents the prototype of one system for content distribution: DiMaS. DiMaS allows content producers to attach metadata to their works, share works on a publishing platform, and modify the metadata attached to content after the content has been published. DiMaS enables version handling as well as the dynamic pricing of copyright licenses. Because the system packs the metadata into a distribution package, it does not have to rely on any proprietary file format. This also means that the system can be used to distribute all kinds of content without introducing new file formats or players.

Semantic webs and metadata will be a part of knowledge management in future organizations. The management of the vast knowledge bases of networks will require systems that can handle different types of files and can hold all various types of information. Already, file sharing and P2P technologies have made it important for organizations to have in place tools for the management of content with different rights, and there is a clear market for technologies that allow different users different levels of access to common content pools.

KEY TERMS

Digital Rights Expression (DRE): The attachment of metadata to a work in order to describe the copyright status of that work

Digital Rights Management (DRM): The limitation of the access of users to information in a repository through the use of technical protection measures.

Metadata: Metadata are data about data. In information repositories, metadata are used for labeling the content of such repositories with appropriate descriptions.

Resource Description Framework (RDF): RDF provides the foundation for the processing and exchange of machine-understandable information on the Web. RDF can be used for cataloguing, for resource discovery, and by intelligent software agents in content rating.

Virtual Community: Virtual communities are communities of users that have the following characteristics.

1. They exist in cyberspace and the communication between the members of the community is computer mediated.
2. They use communication technologies, such as e-mail, message boards, blogging, and online chatting, for communication.
3. They develop largely through the activeness and interests of their participants. The content of virtual communities is formed through the communication between the members of such communities.
4. They lead their members to form sustained relationships as a result of their interaction.

Virtual Organization: An organization in which business partners and teams work together across geographical or organizational boundaries through the use of information technology. It is also a strategy for revolutionizing customer interaction, asset configuration, and knowledge leveraging.

Virtual Web: A form of virtual organization that belongs to the typology of dynamic networks and has the following properties.

1. The member organizations of the network perform separate functions that are performed by functional units in traditional organizations.
2. Brokers in a virtual web combine resources to build business units and subcontract to bring together the necessary functions available in the organization. They play a leading role in building business units and subcontracting for needed services.
3. Internal and external market mechanisms hold the network together and regulate its performance.

4. The information system is open, and there is free access to the web's joint knowledge base. Companies belonging to the network have integrated their information systems into the network's continuously updated information system via broadband access in return for a general payment structure for the value they add to the network.

Chapter 5.8

User Participation in the Quality Assurance of Requirements Specifications:

An Evaluation of Traditional Models and Animated Systems Engineering Techniques

Heinz D. Knoell
University of Lueneburg, Germany

ABSTRACT

Improper specification of systems requirements has thwarted many splendid efforts to deliver high-quality information systems. Scholars have linked this problem to, between others, poor communication among systems developers and users at this stage of systems development. Some believe that specifying requirements is the most important and the most difficult activity in systems development. However, limitations in human information processing capabilities and the inadequacy of the structures available for communicating specifications and obtaining feedback and validation help to exacerbate the difficulty. This chapter presents an overview of both longstanding and newer requirements specification models and evaluates their capability to advance user participation in this process and incorporate stated quality attributes. It also reports on preliminary evaluations of animated system engineering (ASE), the author's preferred (newer) technique, which indicate that it has the capability to improve the specification effectiveness.

INTRODUCTION

It is estimated that between 30% and 80% of software projects fail (Dorsey, 2003; Standish

Group, 1994), depending on whether the basis is budgets or number of projects. Many of these software projects fail because of their inability to adequately specify and eventually meet customer requirements (Zave & Jackson, 1997). The following quotation from The Standish Group (1994) provides an excellent summary of the situation and puts the problem in perspective:

> *In the United States, we spend more than $250 billion each year on IT application development of approximately 175,000 projects. The average cost of a development project for a large company is $2,322,000; for a medium company, it is $1,331,000; and for a small company, it is $434,000. A great many of these projects will fail. Software development projects are in chaos, and we can no longer imitate the three monkeys—hear no failures, see no failures, speak no failures.*
>
> *The Standish Group research shows a staggering 31.1% of projects will be cancelled before they ever get completed. Further results indicate 52.7% of projects will cost 189% of their original estimates. The cost of these failures and overruns are just the tip of the proverbial iceberg. The lost opportunity costs are not measurable, but could easily be in the trillions of dollars. One just has to look to the City of Denver to realize the extent of this problem. The failure to produce reliable software to handle baggage at the new Denver airport is costing the city $1.1 million per day.*
>
> *Based on this research, The Standish Group estimates that in 1995 American companies and government agencies will spend $81 billion for canceled software projects. These same organizations will pay an additional $59 billion for software projects that will be completed, but will exceed their original time estimates. Risk is always a factor when pushing the technology envelope, but many of these projects were as mundane as a driver's license database, a new accounting package, or an order entry system.*

The fact is that too many software projects fail, that these failures may be due to both technical and behavioral reasons. Obtaining accurate systems requirements (Zave & Jackson, 1997) and translating them into feasible specifications is a well-discussed problem; however, involving potential users in the development project is an important factor in this process. In Levina and Vaast's (2004) investigation of how innovations are brought into enterprises, they underscored the pivotal nature of user involvement in successful implementation.

The specification of the requirements of an information system occurs fairly early in the development lifecycle. To accomplish this task, users and developers collaborate to describe the processes and static structures that are involved in the application domain and define their relationships. Quite often both sides speak a different language, using terminology that may be unfamiliar to the other. Clients express themselves using (in the view of technocrats) informal business terminology; developers write system specification from a technical perspective. It is widely acknowledged that this miscommunication is the reason for the prevalence of poorly specified systems and the root cause of many of the failed information systems (Byrd et al., 1992; Raghaven et al., 1994).

To solve this problem, the information system community introduced several models to improve communication between developers and users, particularly the accuracy and understandability of the representation of the business process information that eventually will be used to create the design artifact. But even with these models, users often experience some difficulty in assimilating the essence of the specification details. Sometimes they do not participate in the process because of cognitive limitations and an inability to comprehend the models. However, user participation in this process is essential to the production of accurate specifications. This has intensified the need to provide representational schemes for communicating specifications that are both accurate and easy to understand.

This chapter uses a real life scenario to assess a variety of modeling techniques and tools that have been employed to improve the quality of systems specifications and their success at accommodating user participation to improve user-developer communication. It reviews the models and demonstrates how they represent the scenario details. The discussion is organized somewhat chronologically beginning with the earlier techniques and culminating with a more detailed description of a proposed set of methods — animated system engineering (ASE) — which the author believes may overcome many of the difficulties of earlier models.

USER INVOLVEMENT IN IMPROVING THE QUALITY OF REQUIREMENTS SPECIFICATION

Several quality assurance initiatives have been undertaken in information systems development since Dijkstra (1972) alluded to the “software crisis”. Earlier efforts focused on the quality assurance of computer programs. Soon it was recognized that this was far too late to be effective. Either programs were implemented with significant patchwork or they had to be extensively revised. In the worst-case scenarios, total recoding was necessary, which, according to Knoell and Suk (1989), was tantamount to sabotage. However, it has long been acknowledged that software quality assurance should at least begin with requirements specification (Karlson, 1997). At this point, there is already enough information compiled to necessitate a quality review.

While several well-established characteristics exist to assess the quality of a finished software product, these cannot be applied to requirements specification. The concern at this stage is how to drive toward the attainment of the eventual software quality by applying standards that will increase the quality of the deliverable at this stage of development. Scholars have begun to focus on this area. For example, Davis et al. (1997) identified several quality criteria related to software requirements specification, and Knoell et al. (1996) provided an ontology of quality terms in requirements specification to simplify and promote user understanding and participation in the process. In this chapter we refer to the quality criteria for requirements specification that have been suggested by the German working group of accounting auditors (IDW, 2001) because of their simplicity and absence of technical nomenclature. Table 1 summarizes these characteristics.

Despite the existence of these quality criteria, the problems with requirements enumerated by Dorsey (2003), which include incomplete and ambiguous specification and lack of change management and user involvement in requirements specification, are remarkably similar to those Boehm and Ross (1989) identified. This suggests that very little has changed within that last 15 years, and improper specification of software requirements continues to thwart many splendid efforts to deliver high-quality information systems (Dorsey, 2003).

Scholars have linked this problem to, among other things, poor communication between systems developers and users at this stage of systems development (Raghaven et al., 1994). Metersky (1993) and Zmud et al. (1993) believe that specifying requirements is arguably the most important and the most difficult activity in systems development. However, limitations in human information processing capabilities and the inadequacy of the structures available for communicating specifications to users to obtaining their feedback and validation help to exacerbate the difficulty.

This is because software requirements specification depends on the constructive collaboration of several groups, typically with different levels of competence, varying interests and needs (Knoell & Knoell, 1998). The challenge is how to effectively communicate the perspectives of all stakeholders, in a manner that is understandable to all, to help them participate in a process

Table 1. Quality characteristics of requirements specification

Quality Characteristics	**Meaning**	**How Determined**
Completeness	Inclusion of all information about work sequences and objects (transactions and entities), including a reliable catalog of all attributes of transactions, transaction types, entities, and entity types	When the attributes for application projects, processes, entities, transactions and functions are given content values in the validity range for the respective attribute.
Consistency	No contradiction in the information about transactions and entities in the catalog of all permissible transactions and entities	Cross-checking the attributes of the system components
Clarity	Precise and unambiguous statement of the system features in terms that can be understood by all those participating in the project	Verification of system specification with future users and through forward traceability into the design
Factual accuracy	The extent to which functions of the existing business system description are contained in the requirements specification.	Verifying that all the internal processing rules, operational procedures , and data are accounted for
Feasibility.	Whether the requirements are achievable with the available resources	Matching resources against project demands

of information sharing to rationally decide the correct approach and unearth creative solutions that may well involve non-technical issues such as new work flows and business process alterations. There is little doubt that user involvement in this process is pivotal and the models used to capture and present this perspective for effective user decision making even more so.

In the following sections, we provide an overview of traditional methods and then describe newer and less known models. The older ones are still useful in various contexts as we will describe; however, complex new systems also require other models to incorporate user participation in order to accommodate desirable quality characteristics and improve results.

OVERVIEW OF MODELS USED FOR SPECIFICATIONS

In order to more clearly demonstrate the techniques that will be described and make their underlying principles more concrete, the following real-life scenario will be used to construct a simple example of the models that will be discussed. These methods are flow charts and a modified version of the flow chart, data flow diagrams, entity relationship diagrams, decision tables, the use case diagram — one of the models from the family of the unified modeling language (UML) that supports object-oriented development — and Petri Nets, a modeling language used to graphically represent systems with facilities to simulate dynamic and concurrent activities.

This scenario involves requirements for a system at a non-profit organization in Germany, which supports grieving families after the loss of a child. Besides membership administration, the organization maintains lists of contact persons, rehabilitation hospitals, speakers, and seminars and distributes books, brochures, and CDs to interested persons and organizations. The three major tasks in the process of distributing informational material are order entry, order checking, and sending notifications about the status of orders.

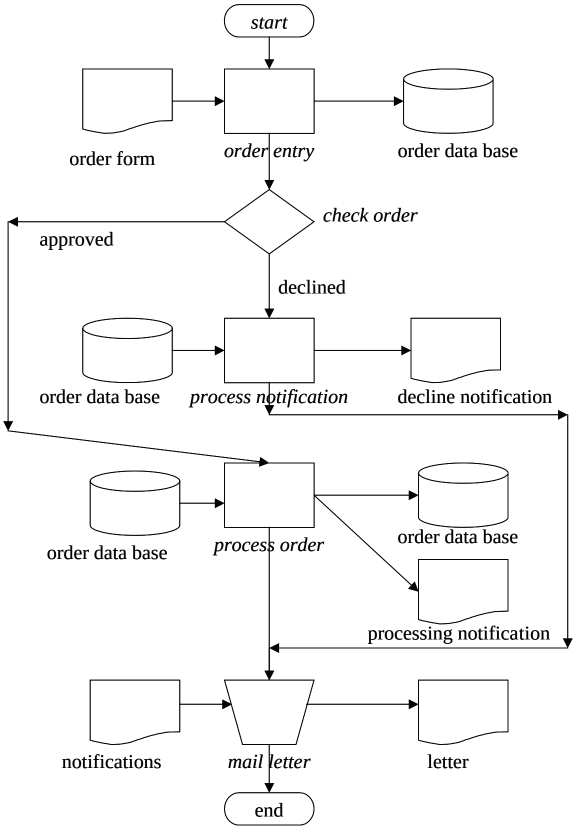
Flow Charts

The flow charting technique has been around for a very long time, so long in fact, that there is no "father of the flow chart" and no one individual is accorded rights of authorship. In general, a flow chart can be customized to describe any process in order to communicate sequence, iteration, and decision branches. It may be used in a variety of situations and is recognized as an excellent technique for helping to demonstrate processes in order to improve quality (Clemson University, 2004). Figure 1 shows the flow chart for our case study.

The Modified Flow Chart

The basic flow chart technique has been modified by Knoell et al. (1996) in order to enhance communication by the introduction of additional symbols that make it easier for non-technical users to understand. This modified technique distinguishes between objects (ellipse or oval) and actions (rectangle) by including icons, which symbolize the object and action, respectively. Figure 2 depicts the modified version. This representation has been used successfully in several projects and has been well accepted by non-technical users. It has also been used in the design phase, where several refinement levels have been added (Knoell et al., 1996).

Figure 1. Order processing flow chart



Data Flow Diagrams

Structured Analysis (SA) (DeMarco, 1979; Svoboda, 1997; Yourdon, 1979) has been developed to support systems analysis and particularly to demonstrate process and data structures in order to improve user-developer communication and understanding of the processes to be automated. Three basic models exist: (1) the data flow diagram, which supports requirements specification (and will be elaborated on later), provides a functional view of processes including what is done (processes) and the flow of data between these processes; (2) the entity relationship diagram, which provides a static view of data relationships; and (3) a transition diagram, which provides a dynamic view of when events occur and the conditions under which they occur.

The data flow diagram uses two symbol sets (or representation schemes) (Svoboda, 1997): one originated by Yourdon and DeMarco (DeMarco, 1979) and the other provided by Gane and Sarson (1977). We have selected the Yourdon-DeMarco notation in this chapter.

The description of the system is refined into as many levels as needed. The first is the context level data flow diagram (Figure 3), which depicts the interaction of the system with external agents that provide and receive information to and from it. This level is used to give a general overview of the system to be developed. It is the basis for the

Figure 2. Processing orders as a KS-Diagram (Knoell et al., 1996)

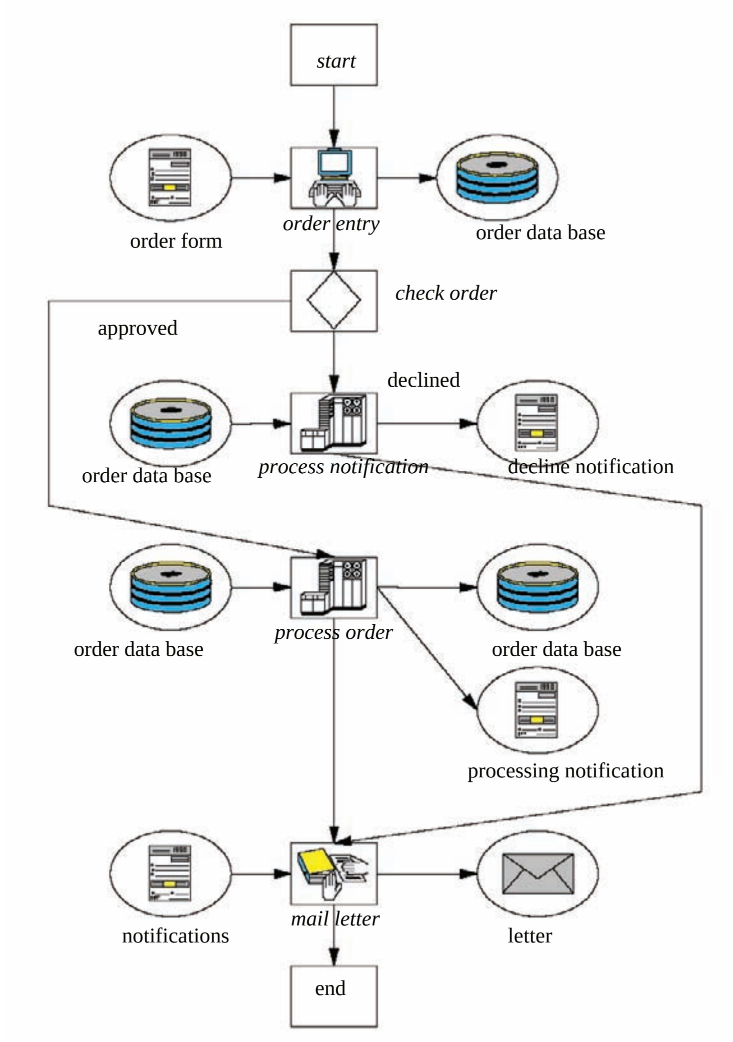


Figure 3. Context level data flow diagram

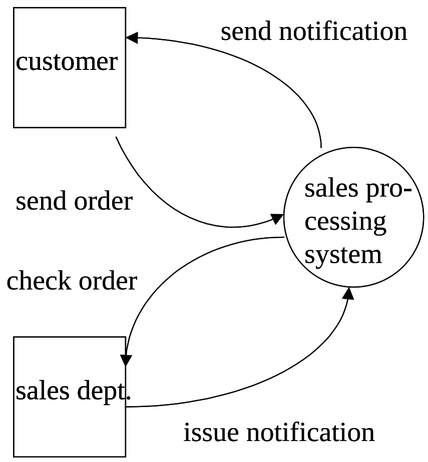
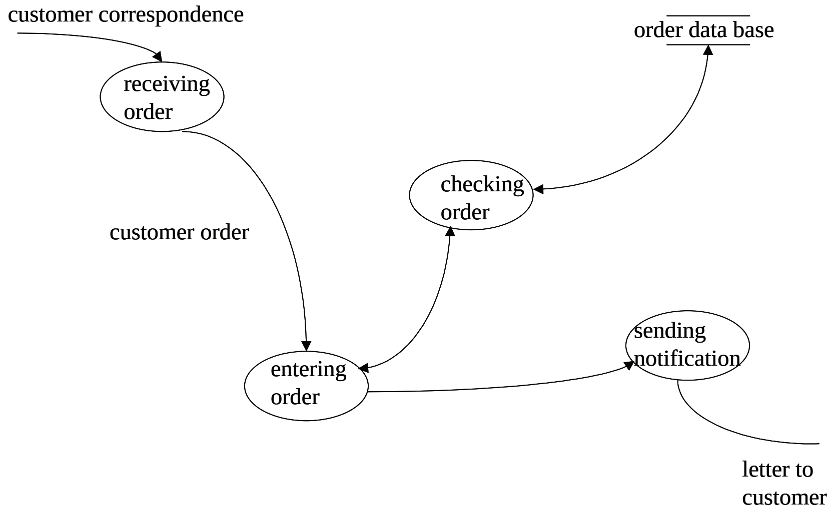


first meetings with users. As soon as this level is accepted by the users and acknowledged to be feasible by the systems analysts, the next level, a data flow diagram, is developed (see Figure 4).

The functions of the level 0 data flow diagram are shown in Figure 4. It is a high level view of the system. Each process can be elaborated in its own diagram until the so called "functional primitive" level is reached. At that point, there is little communication value in decomposing the process further.

In addition to data flow diagrams, which were very prominent in the 1980s and 1990s, several other methods have been used to support func-

Figure 4. Level 0 data flow diagram



tional analysis. Newer techniques, such as those provided by the Unified Modeling Language (UML), the de facto notations and modeling standard used in object-oriented development, have made structured techniques redundant in many cases. Although SA is still in use in industry, most universities have switched to UML. According to the experience of IT consultants (Berger, 2001; Kuehl, 2001), the SA Data Flow Diagrams have been harder for non-IT users than flow charts — "The average user thinks like that: I take A, perform B and the output is C" (Berger, 2001).

Entity Relationship Diagrams (ERD)

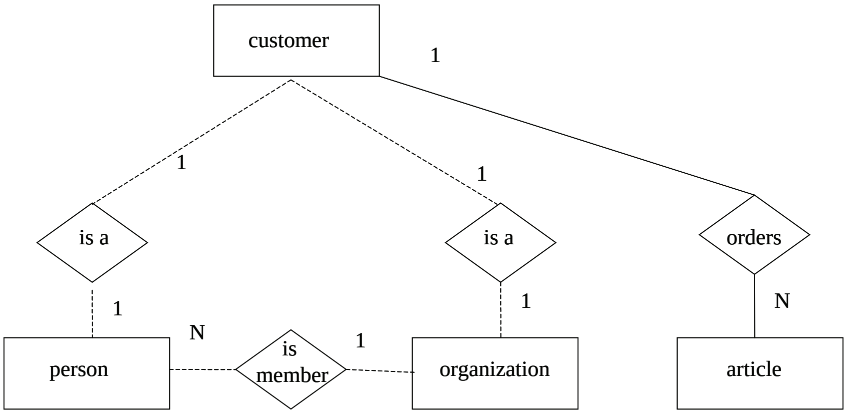
The data-oriented approach to requirements specification (Jackson, 1975) was introduced during the period when large software systems threatened to confound programmers, a phenomenon that Dijkstra (1972) dubbed the "Software Crisis." Chen (1976) helped to solve the problem of representing information in a way that systems analysts, programmers, and customers could all understand; this solution was the Entity Relationship Diagram (ERD) approach to database design, which was extended to the ERD technique for systems design (Chen & Knoell, 1991). The ERD approach enlightened both technocrats, who had struggled with a combination of hierarchical databases (and the emerging relational databases), as well as users, who began to understand the structure of data.

Figure 5 demonstrates the entities and their relationships involved in the scenario that is used as an example in these models. It gave the customer and the programmer a relatively simple way to discuss the requirements of the system to be built. Chen developed rules to create optimum databases out of the ERDs (Chen & Knoell, 1991), which helped the analysts and programmers develop normalized, non-redundant relational databases.

Decision Tables

Sometimes, because of the many rules to apply to certain decision points in a process, it is not useful to use diagrams with decision branches (such as flow charts, or UML and Petri Nets, which will be discussed later). A graphic representation of such complex decision processes is often difficult to understand, especially for non-technical users. In those situations decision tables, which have been the basis for program generators in

Figure 5. Entity-relationship diagram (Chen, 1976)



COBOL in the 1980s like Vorelle (mbp GmbH) and SWT (SWT GmbH) (Grawe, 2001), are far more suitable. A decision table is divided into quadrants: upper left (a list of conditions); upper right (the combination of conditions into rules); lower left (a list of possible actions); and lower right (the combination of actions according the rules — combination of conditions).

Unlike the methods described previously, a decision table is not suitable for outlining the logical structure of the information, or the flow of data, or the sequence of processes. It is an add-on to the other methods, used to describe the system's behavior at a certain point of the process flow. However, the decision table is well suited for specification negotiations with business users who are more accustomed to working with tables. If the process is very complex, nested decision tables may be used to decompose a very large decision into smaller, interdependent tables in which the master decision table contains the dependent decision tables as actions.

USE CASES FROM THE UNIFIED MODELING LANGUAGE (UML)

UML integrated the concepts of Booch (1993), Object Modeling Technique (OMT) (Rumbaugh et al., 1991) and Object-Oriented Software Engineering (OOSE) developed by Ivar Jacobson in 1992 (*Wikipedia*, 2004), by combining them into a single, common notation and modeling standard for object-oriented software development that is now widely used to model concurrent and distributed systems (Wikipedia, 2004) and was the basis for the Object Management Group (OMG) Unified Modeling Language Specification (OMG, 2003). Of the several UML models, the most popular is the Use Case diagram for requirements

Figure 6. Example of a decision table

Conditions	**Rule #1**	**Rule #2**	**Rule #3**	**Rule #4**	**Rule #5**	**Rule #6**	**Rule #7**	**Rule #8**
wholesaler	Y	Y	Y	Y	N	N	N	N
regular customer	Y	Y	N	N	Y	Y	N	N
order value > $ 10,000.-	Y	N	Y	N	Y	N	Y	N
actions								
3 % discount	-	X	-	X	X	-	X	
5 % discount	X	-	X	-	-	-	-	-
free shipping	X	X	-	-	X	X	-	-

specification, and, in the experience of the author, it is easily understood by users. In Figure 7 we have modeled the main processes of the system highlighted in the case scenario in an UML Use Case diagram. The model also further supports a narrative description of the use case (which is not developed here).

Rational Rose is one of the several tools that have been developed to support the construction of use case diagrams. It was developed by James Rumbaugh and Ivar Jacobson and later acquired by IBM and incorporated into the Software Group Division where it became an IBM software brand. Originally, Rational Rose was designed to support the development of ADA programs but later C++ and Java were added. In the newest version, Rational Rose supports the development of any object-oriented software system and allows animations of the designed UML diagrams in order to verify the process sequences and the associated data structures (IBM, 2004).

Petri Nets

The Petri Net models described below are methods for capturing and graphically representing requirements that attempt to facilitate better user understanding, assimilation, and assessment in order to increase the odds of accommodating quality attributes. Like the other tools, they assist visual communications but, in addition, can simulate dynamic and concurrent activities. Petri Nets are a well-known design method in Europe, though not as widely used in the United States. Originally they were used in technical computing (e.g., in switchboards); however, for the last 20 years or so, they have been used increasingly in information systems development.

The Petri Net methodology was developed by Petri (1962) primarily to show the behavior of finite state machines (a theoretical construct in computer science). Initially, its application was restricted to technological problems, but since the 1990s it has been used in the specification phase of information systems development. Petri Nets can be animated, but they are mostly used for the resolution of technical problems like concurrent, asynchronous, distributed, parallel, non-deterministic, and/or stochastic systems.

Nowadays, an abundance of Petri Net-based design tools are available. These range from open-source facilities in the public domain to expensive professional tools. Three such tools, that are outstanding for their animation features, are BaaN Dynamic Enterprise Modeler, Pavone Process Modeler, and Animated Process Illustration (APRIL).

The BaaN Dynamic Enterprise Modeler (DEM) (BaaN, 1999) is a graphic program, which is used for the representation of the company's business processes. This model is used to assist users to customize the BaaN system and for the

Figure 7. UML use case diagram

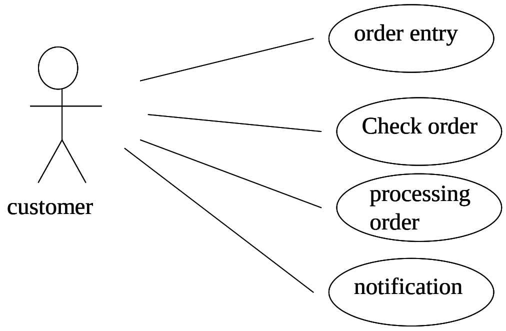


Figure 8. Petri Net

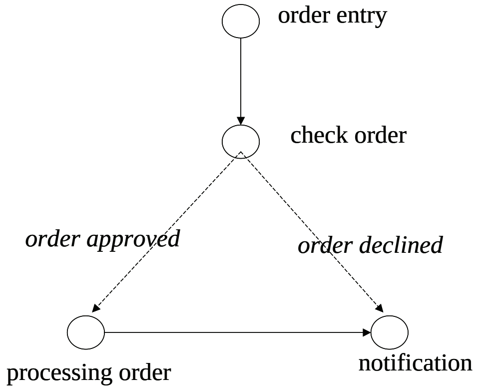
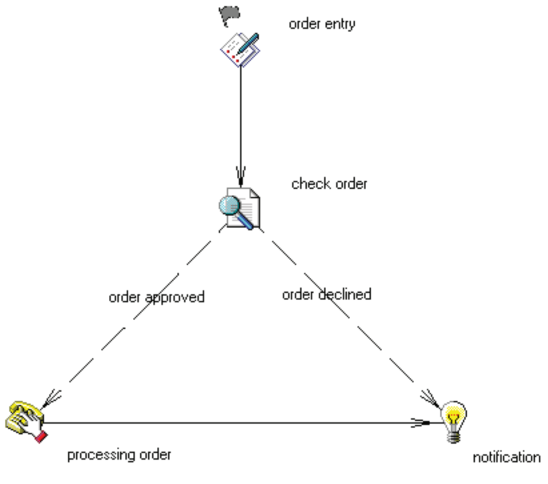


transfer of the business process model into the BaaN ERP system. The DEM has an animation mode in which users can check settings prior to the installation of the ERP software system. Furthermore, the graphic model is the user interface, from which users can trigger BaaN sessions.

The Pavone Process Modeler (Pavone, 2001) was developed to support the design of workflow in Lotus Notes applications. Figure 9 shows an example drawn with this program. For computer-naïve personnel, this depiction is much easier to understand as the Process Modeler uses icons to the differentiation of various processes. In addition, the persons or groups associated with the process have to be added. The Process Modeler also has an animation mode, similar to BaaN DEM, which is used to trace process flows, a feature is particularly helpful in communication with non-IT staff.

Animated Process Illustration (APRIL) is a Petri-Net-based approach to developing information systems that uses diagrams to make the process more transparent to both system engineers and users. The diagrams are used throughout the entire software development process. APRIL diagrams provide the means to simulate and analyze the system's behavior by synthesizing common techniques and adjusting them to each other and generating prototypes. The CASE tool NEPTUN is used in conjunction with APRIL to automatically generate a stand-alone platform and database system independently of the system's generic model (Simon et al., 1997). APRIL diagrams and the CASE-tool NEPTUN are integral parts of the Animated Systems Engineering Method, which is described in detail in the next section.

Figure 9. Modified Petri Net – Pavone Process (Modeler, 2001)



ANIMATED SYSTEMS ENGINEERING (ASE)

Animated systems engineering is based on the philosophy that prototyping in the problem definition, analysis, and design phases through animation will help to circumvent most of the communication and decision errors that are typical of participating stakeholders (Boehm & Ross, 1989). The term animation is used instead of simulation because no executable specification is generated based on the dynamic model (Marx, 1998). ASE uses a graphic method to give the vivid representation of the dynamic system behavior without programming. For quality assurance purposes, executable specifications are available too late in the software development life cycle to figure out misunderstandings in the actual state analysis regarding requirements definition.

The animation of a Petri Net allows one to visualize the performance of a system (e.g., user interaction and loops) and to find problems in the system. It provides a good opportunity to recognize missing or misunderstood parts in the model under construction, because of the needed knowledge about the correct order of actions and object flows and not only about the static structure. It will also be useful for management to prove the progress of a project.

Pahnke and Knoell (1999) found that the ASE method indirectly improved the quality of specifications during groupware development by:

- structuring the software development process under consideration of quality criteria;
- showing the dynamics of the groupware processes;
- reducing the impact of language differences, which increases user participation by promoting agreement among project participants;
- managing complexity with easy-to-understand graphic elements; and
- producing an early graphic prototype to develop an executable problem description or requirements analysis.

To effect these benefits, ASE includes several tools such as the METAPLAN-Technique, Petri Net diagrams, object modeling diagrams, animation, mask/screen and text generators, and a document management system with versioning. These are noted below:

- The METAPLAN (2003) moderation is a communication and discussion technique, which motivates a working atmosphere, within participating groups that are free of hierarchy influences (Pütz, 1999). In our students' projects the METAPLAN cards should be used in the form of prefabricated APRIL-Symbols to speed up the discussion.
- APRIL prototype from the Neptun Project of the University of Koblenz (Neptun, 2002) is used for the validation of ASE.
- Object Modeling Diagrams (OMD) are not directly needed for the core method, but they are useful from the detailed design phase and include the object oriented representation of the static view (data view), using classes, attributes and roles, as well as the graphic representation of association, aggregation, and inheritance.
- Animation is the core part of the ASE method. It is used to build and show scenarios during the investigation and analysis of the actual state. Scenarios show a sequence of events according to Rumbaugh et al. (1991). Animation is more effective than prototyping and provides more than the look and feel dimension of prototyping; its processes are performed on a higher level of abstraction. For user acceptance, this modeling approach needs easily understandable graphic elements. It should be used as late as possible (after a structure of the system is visible, but as early as needed) to get an overview of the dynamics of the system.

The following components of ASE are directly needed for quality assurance of specifications. They serve to fulfill the requirements for quality explanation according to ISO 12119 (ISO, 1994); the Capability Maturity Model (Paulk et al., 1993); standards in the pharmaceutical industry (which has very strict rules for software development, generally, and requirements specification, in particular; for example, ISO 10007, 1995); and European Community guidance note for Good Clinical Practice (APV, 1996; Committee for Proprietary Medical Products, 1997).

- The Mask/Screen Generator is needed to produce the graphic user interface as early as possible, to easily develop a simple representation of menus. This representation should help novice users to overview and develop a vision of feasible solutions.
- A Text Generator is also very useful for documenting the decisions of the development team participants. The ideal situation would be the capability to branch from the respective Petri Net or animation directly to these documents.
- A Document Management System with versioning is required to prove the changes during the phases and identify requirements. The Petri Net animation has to be integrated into a document management system, to allow versioning through an archive.

Indications of the Effectiveness of ASE

The motivation for recommending ASE as a possible cure for the communication problems that often beset requirements specification is based on indications of its successful use. Pahnke et al. (2004) reported on supervised students in two independent projects and further conducted a case study of a groupware development project at a pharmaceutical company in which ASE played a significant role in generating high-quality requirements.

In the two independent student projects, teams of students, each using a different method, generated the requirements specification of software systems. They were required to elicit requirements and present and discuss the specification with the future users. They then developed a prototype of the system. In both projects the teams using ASE were judged to be the ones that obtained the highest quality results and produced the best prototype (Pahnke, 2003).

The case study (Pahnke et al., 2001) was a more elaborate undertaking. It involved the pharmaceutical company, Merck KgaA. Merck has to meet quality standards specified by the US Food and Drug Administration (FDA). All of the drug studies submitted by Merck to the FDA and other regulatory agencies must satisfy good laboratory practice (GLP), good clinical practice (GCP), and good manufacturing practice (GMP). The FDA also requires that computer hardware and software used in drug studies satisfy good practices and conform to standards. The company uses several groupware and workflow systems and puts them through a quality assurance (QA) process using advanced QA concepts beyond the "fitness for purpose" requirement of ISO/IEC 12119 (ISO, 1994); these include user convenience, effectiveness, and data safety.

The company launched the Merck Electronic Document Management & Information System (MEDIS) to manage the global collection, electronic compilation, and dissemination of information through the planning, preparation, and publication of documents and dossiers, and related management processes including the preparation of all pharmaceutical submissions to regulatory agencies. Triple D (short name for Drug Data to Disc) was the project name for a document and workflow management system, developed to satisfy special needs of Merck's pharmaceutical submissions.

Merck adopted groupware as the management technology and implemented role-based privileges for managing the creation, and publishing of dossiers. An essential mandate of the FDA and other regulatory agencies is for dossier creation and submission to be under version control. In Merck's case, those allowed to create documents are able to build their own information workflows; however, the workflows for review and approval have to be predefined for some roles within a working group. The project therefore required the collaboration of several stakeholders and coordinated decision-making by several participants.

Merck decided to apply ASE after evaluating the presented examples in relation to the special QA needs of the MEDIS project. Participants were trained in ASE techniques and later determined the ASE features that would be required to monitor and achieve their quality requirements in all development phases. They selected a mask/screen generator and an integrated text generator as well as version management to support the QA requirement for traceability of documents.

ASE contributed to the success of the project by significantly lowering error rate and contributing to higher user satisfaction in comparison to previous projects in the company. Gunther Knabe, the project manager of MEDIS, expressed it thus: "We have never had such a smooth project like this before. At first sight ASE seemed to require greater effort. But finally these efforts paid off" (Knabe, 1999).

SUMMARY AND CONCLUSIONS

Software development efforts are often complicated by the fact that decisions taken early in the development process are pivotal to the eventual quality of the system. However, such decisions are often based on incomplete and insufficient information. This is related to the inadequacy of communication models to assist the capture and assimilation of information to guide the specification of requirements, an activity that is universally acknowledged as pivotal to successful outcomes. Wrong decisions from poor information typically cost organizations a great deal.

Several models have been used to assist users and developers communicate more effectively about, and specify, the requirements that are needed to produce useful and usable systems with high quality. However, despite the extensive use of these models over several years, indications are that inadequate systems, resulting from poorly specified requirements, are still very prevalent. Effective user participation in the specification phase of a software project contributes to the elimination of misunderstandings of the requirements in the earlier phases, the enhancement of quality, and saves time and money in subsequent phases. Effective QA depends on the definition of quality criteria in user language and a useful and understandable structure for depicting the specifications that can also identify deficiencies.

This chapter discussed most of the existing models that are used to promote user-developer communication during requirements specification under the umbrella of traditional (and popular) models and more recent (but less well known) ones. Some of the older models are still very useful; however, like information technology that has been coming at us at a rapid pace, we need to explore new and improved techniques to match the complexity of new systems and provide effective tools for accommodating desirable quality attributes into the process of specifying requirements. In this regard, our research presented in this chapter suggests that the set of ASE techniques has proven to be reasonably successful in circumventing some of the problems that have plagued other approaches.

Animation and virtual reality have been applied successfully in a variety of technologies to simulate actual usage experience of physical structures (for example, in computer aided design). We should make use of its capability to better incorporate user views and improve the accuracy in requirements specification. After all, most of the quality-enhancing methods in the later stages of systems development are still destined to failure if we cannot improve the quality of the specifications by affording users tools to better contribute their own information and assimilate the contributions of others in order to positively influence the completeness, consistency, clarity, accuracy, and feasibility of specifications.

The preliminary indications from our rudimentary assessment of ASE need to be followed by more rigorous research efforts to establish the limits of the efficacy of this approach and to provide insights into its strengths and weaknesses. It would be useful to conduct such studies with industrial strength applications and to apply it in combination with other techniques to evaluate whether some synergies would result from such applications. Other future research efforts could examine more sophisticated tools to enable more realistic animated simulations of IS in development and determine the effects on the quality of the deliverables they support as well as the quality of the final product.

Chapter 5.9

The Value of Information Systems to Small and Medium-Sized Enterprises:

Information and Communications Technologies as Signal and Symbol of Legitimacy and Competitiveness

Susan J. Winter
Portland State University, USA

Connie Marie Gaglio
San Francisco State University, USA

Hari K. Rajagopalan
Francis Marion University, USA

ABSTRACT

Small and medium-sized enterprises (SMEs) face more serious challenges to their survival than do larger firms. To succeed, SMEs must establish and maintain credibility in the marketplace to attract the resources required for survival. Most co-opt legitimacy by mimicking the cues that signal credibility to convince potential stakeholders that something stands behind their promises. This research examines the role of information and communications technology (ICT) in legitimacy-building from the perspective of both SME founders and customers. In-depth, semi-structured interviews were conducted in a variety of industries to determine whether the ICT-related legitimacy schema from the customers' perspective differs substantially from that of firm founders. Results indicate that customers compare the ICT information provided in SME's sales pitches to pre-existing ICT expectations about the nature of desirable sales transactions.

We describe the relationship between violations of ICT expectations, legitimacy, and purchase decisions. Implications for theory and practice are discussed.

INTRODUCTION

All firms want to survive and thrive. As new information and communication technologies (ICTs) are developed, attempts to understand their adoption and use by small and medium-sized enterprises (SMEs) have determined that many of the resources developed for larger firms to guide strategic IS planning, alignment and the evaluation of ICT investments are often inappropriate for SMEs (Wainwright, Green, Mitchell, & Yarrow, 2005) and have identified barriers to adoption including negative attitudes and financial and knowledge constraints (Parker & Castleman, 2007). Underlying this research is an emphasis on the role of ICT in deriving business value for SMEs by efficiently managing internal operations and supply chain activities to improve productivity and profitability (Levy & Powell, 2005).

Although SME success is related to internal operational efficiency and effectiveness, it also requires access to external resources such as labor, financing, and most importantly, a steady stream of income from sales (Harrison, Dibben, & Mason, 1997). For SMEs, most sales are made to other businesses (Levy & Powell, 2005) and success depends on the firm persuading potential customers to actually make purchases, a decision that hinges on perceptions of the firm's legitimacy (Suchman, 1995; Zimmerman & Zeitz, 2002). Legitimacy is especially important for new firm survival (most begin as SMEs) because smaller and newer firms fail at a higher rate which suggests that obtaining access to resources may be more difficult (Singh, Tucker & Meinhard, 1991). However, previous research on ICT use by SMEs has not considered its role in perceptions of legitimacy and purchase decisions.

New venture lore is replete with anecdotes relating how founders deliberately manage perceptions of legitimacy (e.g., Darwell, Sahlman & Roberts, 1998). In most cases, firms co-opted legitimacy (Starr & MacMillan, 1990) by garnering endorsements and associations and by mimicking the standards, practices, and cues of their relevant industries. This article investigates whether these standards include expectations regarding the use of ICT and whether ICT acts as a signal and symbolic of legitimacy among potential customers.

This approach extends the literature on SMEs and IS in an important way. The IS field has long recognized the symbolic meaning of ICT and its use as a signal by various stakeholders (Feldman & March, 1981; Kling & Iacono, 1988). Research on the computerization of work has explored what ICT symbolizes to employees, shareholders and developers or special interest groups (e.g. Jackson, Poole & Kuhn, 2002; Prasad, 1993; Ranganathan & Brown, 2006; Swanson & Ramiller, 1997). Missing from this research is a systematic exploration of the link between an SME's ICT, the customers' image of the firm, and the likelihood of purchase, a central concern for managers and researchers.

This work also extends the organizational theory literature in two important ways. First, it focuses on establishing legitimacy whereas the existing literature focuses on its maintenance and repair (Suchman, 1995). Secondly, we examine both how SMEs convey impressions and what potential customers expect to hear whereas the existing literature usually examines only one or the other (e.g., Arnold, Handelman & Tigert, 1996; Harrison et al., 1997).

If potential customers form impressions of an SME based on its use of ICT and these impressions are positively related to purchase behavior, managers who want to attract and retain customers may want to consider adopting ICT as a signal, not just for its productivity-related business value. If these impressions are negatively related to purchase behavior, SMEs may consider avoiding the ICT, or at least obscuring its use. Thus, the customers' perceptions of the symbolic meaning of ICT forms an important component of its total business value, which may include both improvements in internal operational efficiency and its ability to act as a signal and affect purchase behavior among external stakeholders.

The first two related research questions addressed here are: Do prospective SME customers infer legitimacy from the presence of ICT? Does this perceived legitimacy affect the likelihood that customers will make a purchase? To answer these questions, we investigate 1) whether these symbol meanings are tacit or explicit; 2) whether customers' and SME founders' views of ICT's symbolic meanings are sufficiently similar to one another to enable accurate signaling; 3) whether SME founders are aware of the customers' perspective and could purposefully manipulate their firm's images through their choice of ICT; and 4) what attributions about SMEs are drawn from the use of ICT emphasizing customer expectations and the implications when these are violated. The third research question addressed is: Why and how does ICT act as a symbol of legitimacy?

We begin by briefly describing the existing corporate image literature with particular attention to identifying the potential role of ICT in assessing firm legitimacy. This is followed by an in-depth presentation of an inductive investigation of why ICT signals legitimacy by investigating the importance of matching customer expectations. Although it is generated from the more specific results, the findings from this phase begin with the presentation of the abstract theoretical frame or paradigm model (as recommended by Strauss and Corbin, 1998), highlighting the importance of mental models in creating a corporate image and the symbolic role of ICT in judging legitimacy. Each element of the model is then described with supporting evidence and comparisons between the findings and existing legitimacy theory to identify areas of confirmation or contradiction, allowing the generation of an integrative, general and particularistic theory of the symbolic role of ICT in a corporate image of legitimacy (Martin & Turner, 1986). Finally, implications of this model for managers and directions for future theory and research are discussed.

BACKGROUND AND HYPOTHESES

Corporate Image

No existing theory has looked specifically at the role of an SME's ICT use in creating legitimacy and encouraging customers to make purchases. The ICT and SME literature has focused on the role of ICT in improving operational efficiency and overcoming barriers to adoption (Parker & Castleman, 2007). The ICT literature has investigated how ICT adoption and use have affected the views of various organizational stakeholders (e.g. Fichman, 2000; Orlikowski & Iacono, 2000), but has not focused on customers' views of a firm. The organizational literature has investigated how firms are perceived by stakeholders and the effects of these views on organizational members (Gioia, Schultz, & Corley, 2000), but has not considered the role of ICT and the customer perspective.

How a firm is perceived has been termed its corporate image and definitions of corporate identity and image[1] have been extensively debated. Briefly, corporate identity is a firm's personality or the essence of what the firm is (Albert & Whetten, 1985; Balmer, 1998). It is reflective of the firm-level mission, values, history, philosophy, culture, and behavior (Ind, 1992; Van Riel, 1997). Recent work in corporate brand management supports an inclusive and multidimensional conceptualization of corporate identity including the expression of a firm's: 1) corporate culture; 2) brand and organizational structure; 3) industry identity; and 4) strategic positioning; through 5) the behavior of the corporation, its employees, and managers; 6) corporate communication; and 7) corporate design, which includes corporate visual identity elements such as buildings, clothes, and graphics (Melewar & Karaosmanoglu, 2006).

Definitions of corporate image vary depending upon whose view of the corporation is emphasized. Consistent with the work of Berg (1985), our interest is in the views of customers. The perception of customers is the firm's corporate image (Melewar & Karaosmanoglu, 2006) and the importance of establishing a corporate image has long been accepted (Christian, 1959; Hatch & Schultz, 1997; Pfeffer & Salancik, 1978). The literature provides broad guidance on the dimensions of an SME that play a role in creating a corporate image but does not provide information about the detailed particularistic meanings of specific cues such as ICT.

Institutionalism and Firm Image

From a more macro perspective, institutionalism focuses on the social structure of the environment and its effects on individual behavior. Researchers have argued that managers' choices, such as those involving adoption of ICT, often represent attempts to manage external images of the firm held by stakeholders such as customers (Pfeffer & Salancik, 1978). A firm may differentiate itself in the marketplace by creating a distinct identity, managing its image by leveraging the symbolic and physical resources institutionalized in their business environment. Managers manipulate symbols to convey the impression that the firm adheres to customer expectations and codes of conduct, which have been identified as central to corporate identity (Pfeffer & Salancik, 1978). Success depends on whether the manager knows and understands customer expectations and which symbols convey the "right" impression (Feldman & March, 1981). However, previous investigations of ICT adoption and use by SMEs have not considered their effects on customer's images of the firm and the pressures these exert on decision-makers. If SMEs are aware of their customers' assumptions, they can adopt and use ICT to create a desirable corporate image that appeals to its target market (Dutton & Dukerich, 1991).

Legitimacy

One important task of SME founders is to create and maintain an image that attracts resources such as customers (Elsbach, Sutton & Principe, 1998; Meyer & Rowan, 1977; Starr & MacMillan, 1990). Legitimacy is a universally desirable corporate image that is judged based upon conformity to social norms and beliefs and is linked to purchasing and repeat business (Suchman, 1995; Zimmerman & Zeitz, 2002). Legitimacy is defined as a "generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, beliefs, and definitions" (Suchman, 1995, pg. 574). It is a quality of the firm, but is conferred by observers (who refer to a firm that is credible or real (Human & Provan, 2000)). Customers' assumptions about the appropriateness of adoption and use of ICT by an SME should affect their judgment of the SME as legitimate and desirable as an exchange partner (Dutton & Dukerich, 1991; Feldman & March, 1981; Winter, Saunders, & Hart, 2003) and influence the likelihood that they will make a purchase.

ICT and a Firm Image of Legitimacy

When examining the role of ICT in creating an image of a firm as legitimate, one is asking how SMEs can use ICT in ways that meet customer expectations. This study develops a particularistic account of the symbols that ordinary people use to convey and evaluate images of legitimacy, focusing specifically on the role of ICTs as a cue and their meaning. These results are then related to existing theories identifying areas in which the data confirm or contradict existing explanations (Martin & Turner, 1986), integrating the inductively derived concepts with abstract theory and providing analytic generalization (Yin, 1989).

METHOD AND RESULTS

An inductive grounded methodology (Eisenhardt, 1989; Glaser & Strauss, 1967; Martin & Turner, 1986; Strauss & Corbin, 1998) was used to discover the role of ICT in communicating image and triggering a sale. Inductive grounded techniques are particularly appropriate for investigating relationships among context (including customer expectations) and actors, providing particularistic details to elaborate abstract substantive theories (Eisenhardt, 1989; Martin & Turner, 1986). Semi-structured in-depth interviews enabled a greater depth of understanding than could be developed with a questionnaire. Inductive methods allowed identification of the dimensions and language that are meaningful to the informants with legitimacy and customer expectations acting as sensitizing concepts (van den Hoonaard, 1997).

Procedures

To control for issues unrelated to the use of ICT that could affect an SME's image (e.g. a previous track record) we focused on sales pitches of new firms. Sales pitches of new firms are particularly appropriate for studying the process of creating legitimacy and acquiring customers. Founders often recount how they managed impressions of their firms when making their first sales, so the phenomena should be familiar to them (Darwell, et al., 1998) and attempts to establish perceptions all begin at the sales pitch to which each party brings a set of assumptions, so it should be easier to identify participants' ICT assumptions. However, the meaning of ICT and the legitimacy images created are not expected to vary by firm age.

- **Informants:** Two kinds of samples were drawn: SME founders and prospective customers (experienced buyers who have purchased from new firms). This allowed cross-checking and substantiation of the resulting constructs (Martin & Turner, 1986; Strauss & Corbin, 1998). The goal was to map the diversity of responses and generate theory applicable to various contexts, so the sample was constructed to include variety rather than statistical representation. This practice (called theoretical sampling (Denzin, 1989)) precludes drawing inferences about the norms in specific industries. When new interviews failed to yield novel responses, dimensions, or relationships, data collection ended. Two rounds of data collection allowed refinement of the questions and expansion of the sample (Denzin, 1989).
  - **SME Founders:** Samples were drawn using the Dun and Bradstreet database[2]. The first round included 15 founders in the San Francisco Bay Area; the second included 18 founders in South Florida (in total, a 27% participation rate). Founders often work in excess of 12 hours a day and many were too busy to participate.
  - **Potential Customers:** The second round included purchasers at 14 businesses in South Florida (a response rate of 15%) who received sales calls from a variety of vendors, and had recently used at least one new firm. To avoid inflating the degree of agreement, we included three buyers who had done business with a new firm in our sample and eleven who had not[3]. As shown in Appendix A, the firms represented various sectors, scopes and sizes. Purchase decisions also were diverse and ranged from purchasing office supplies, business services, raw materials and finished goods for resale through sub-contracting portions of the firm's activities.

- **Procedures:** Sessions were conducted at the participants' places of business, lasted 45 to 90 minutes, were tape-recorded and later transcribed. The first round was performed by a trained master's student, the second by one of the authors.
- **First Iteration:**
  - **Data Collection:** The first round included only founders; open-ended questions encouraged respondents to talk about the issues that they considered important in convincing their first customers to place an order. Informants described the work their firm performs, their products, customers, competitors and the content of their first sales pitches. Probes asked about the most effective cues or tactics, including the role of ICT.
  - **Data Analysis:** The analysis proceeded iteratively; moving between the data, emerging theory and existing literature (Eisenhardt, 1989; Glaser & Strauss, 1967) allowing discrepancies to be reconciled, leading toward closure (Denzin, 1989). In open coding, categories were identified and microscopic data examination generated initial categories, recognized taken-for-granted assumptions, and identified other cases for theoretical sampling (Strauss and Corbin, 1998). Theoretical comparisons were made between the images created by visual identity symbols such as furnishings and wardrobe and those created by ICT. Data were coded for the importance of violations of expectations, a sensitizing construct linked to legitimacy. Concepts were organized by recurring themes, forming stable and common categories during axial coding (Martin & Turner, 1986; Strauss & Corbin, 1998) yielding broad categories and associated concepts that described the participants' understanding of the symbolic information transmitted by ICT and its role in the purchase decision.
  - **Findings[4]:** The first step in determining whether prospective legitimacy is inferred from the presence of ICT was to determine whether the signaling function of ICT was tacit or explicit. As shown in Table 1, 85% of founders in the first round of interviews indicated that ICT improved operations, mentioning this aspect a total of 32 times. Some denied that ICT had any symbolic value and insisted that its only value was its functionality, although many were forthcoming about the symbolic role of office attire, location, and office furnishings.
  - **Proposal Development & Presentation Training***:*

    The technology is essential … but it is simply the tool…The thing that gives us an edge is not the technology but the office space.

Table 1. Percent of 1st round SME founders (n=13) who discussed a category. Results of Fisher's Exact test of the difference between 1st and 2nd round founders also shown.

About a third (38%) said that ICT symbolized their firm's legitimacy (e.g. seriousness, professionalism, size, or financial strength).

These results reflect the norm of rationality in the U.S. and an emphasis on the functional value of ICT in improving SME operations (Feldman & March, 1981; Hirschheim & Newman 1991; Kling & Iacono, 1984; Levy & Powell, 2005; Winter, 1996). They are consistent with literature suggesting that the symbolic meaning of an artifact such as ICT is unlikely to be elicited through direct questioning because meanings are often deeply connected with assumptions about the way the world works (Schein 1985).

This raised questions about whether symbolism works differently for ICT than it does for other artifacts, whether SME founders are unaware of ICT's symbolic value to customers or whether the symbolic meaning is tacit and so cannot be readily articulated. Consistent with Strauss and Corbin (1998), we hypothesized that our results reflected a taken-for-granted assumption about ICT and collected additional data to better understand the symbolism of ICT.

- **Second Iteration:**
    - **Data Collection:** Consistent with Denzin (1989) the second round of data collection included both SME founders and potential customers and the data collection methods were changed to surface taken-for-granted assumptions. New questions reflected "breaking experiments" and used the flip-flop technique (Feldman, 1995; Garfinkel, 1967; Strauss & Corbin, 1998). Additional structured focus group techniques such as bounded and cued open-ended questions and providing background information were used (Krueger, 1998; Stewart & Shamdasani, 1990). Sentence completion and a projective technique (an analogy between a Ferrari and a Honda Civic) were also included and SME founders were asked to take the role of customers (Greenbaum, 1998; Krueger, 1998; Sudman, Bradburn & Schwarz, 1996). Questions are shown in Appendix B.
    - **Data Analysis:** Analysis of the second round proceeded much like that of the first with inductive open coding that included legitimacy, expectations and violations as sensitizing concepts (Martin & Turner, 1986). One author read the founder interview transcripts; another read those of customers. Each created a preliminary inclusive framework representing the features of the data and the distinctions made by the informants (Martin & Turner, 1986; Strauss & Corbin, 1998). Comments were coded based on apparent category membership and axial coding was used to organize concepts (Martin & Turner, 1986; Strauss & Corbin, 1998). The data gathered from founders and customers were compared to identify their degree of overlap and a single integrative framework was created when it became clear that they included similar concepts. Comparing the data to the emerging model and discussing disagreements about the elements allowed continued refinement of the typology. These networks of categories were used to create theoretical constructs and associated maps of causal elements that were constructed into a theory of the role of ICT in firm legitimacy and purchase decisions. A model of the important elements, their cues and interrelationships was developed. The resulting framework derives empirical validity from accounting for the data and provides a general pattern across the data sources (Martin & Turner, 1986).

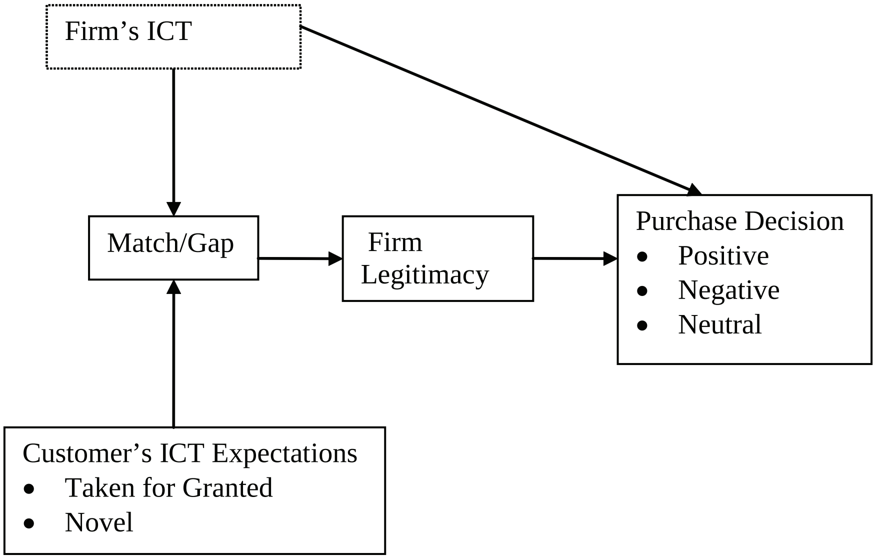
Transcripts were then coded for each element by the third author who counted the number of participants who mentioned a category and the number of times a category was mentioned. Fisher's Exact[5] tests were performed to determine whether the responses of second round founders differed from first round founders or from customers.

Findings – Theoretical Frame: Although developed later as an aggregation of the more detailed results, the abstract theoretical frame (paradigm model) that summarizes the theory is presented first (Strauss & Corbin, 1998). It shows how the elements of the constructs are connected and acts as a map to steer through the detailed results, which are presented after the model. At the highest level of abstraction, the purchase decision process (shown in Figure 1) resembles schema theory (Fiske & Taylor, 1991) and is influenced by the prototypes and mental models held by the prospective customer who infers SME legitimacy from the symbolic information provided by a firm's ICT.

The SME founders and potential customers have formed mental models about various kinds of firms and their activities. A mental model consists of sets of interconnected information elements (including ICTs) and a prototype is a typical set of elements for a category. This mental model includes possible firm categories represented as prototypes, some of which are more likely to result in a positive transaction experience than others. The firm may be a legitimate, serious, professional, adequately capitalized company or an illegitimate company, a category that includes both inexperienced undercapitalized hobbyists trying to become professionals and firms of dubious legality sometimes called fly-by-night.

SMEs use ICTs in providing their products or services including both office technologies (e.g. inventory management systems, cell phones) and production technologies (e.g. CAD/CAM, robotics). A firm's representative contacts a potential customer and makes a sales pitch describing the company and its products or services and may describe their ICTs or provide indirect evidence of them. During a sales pitch, the potential customer tries to learn what kind of firm he or she is dealing with to determine the likelihood that placing an order would result in a positive transaction. Potential customers match the firm's ICT to those expected in each prototype and categorize a firm as legitimate or illegitimate based on the characteristics shared. Some ICTs will be taken-

Figure 1. Model of ICT, customer expectations, firm legitimacy and purchase



for-granted or assumed to be in use, others may be novel or optional in that they may or may not be present. Once a firm has been categorized, it is assumed to have other characteristics of the category (honesty, trustworthiness, etc.) based on the interconnected information elements in the mental model, even if the potential customer has not experienced them directly. These inferred characteristics of the firm then influence the likelihood that a potential customer will actually place an order. In addition to corporate image effects, ICT has a direct effect on purchase decisions if customers find them more convenient.

In the following section, these concepts and their interactions are discussed in detail.

Findings – Model Elements: Participants were clearly more comfortable discussing the functionality of ICT than its symbolic meaning, suggesting that functionality is explicit and symbolic meaning is more tacit. However, we found four patterns linking ICT to corporate image. First, customers' symbolic meanings and those of founders were very similar suggesting that accurate signaling can occur and that the latter could purposefully manipulate their ICT use to create desired corporate images. Further, founders were aware of the customers' perspective and those meanings were instrumental in their ICT adoption decisions. Second, firm legitimacy characteristics are inferred from ICT and linked to decisions to support the firm. Third, three distinct patterns link violations of their expectations about a firm's ICT to its image. A firm could be missing an ICT whose presence had been taken-for-granted, include a novel ICT that detracts from a firm's image, or include a novel ICT that enhances its image. Each of these areas is described in more detail below.

Functionality vs. Symbolic Meaning: As shown in Table 2, an overwhelming majority of second round participants (97%) mentioned the functional value of ICT 126 times in total. How-

Table 2. Percent of 2nd found respondents who discussed a category broken down by SME founder vs. customer. Results of Fisher's Exact test of the difference between 2nd round founders and customers also shown.

* $p < .05$

ever, the use of focus group techniques yielded much more information about the symbolic meaning of ICT than was uncovered in the first round of interviews. As shown in Tables 1 and 2, the percentage of first and second round founders linking ICT to legitimacy increased significantly (1st round: 38%; 2nd round 87%; Fisher's Exact p<.05) and 90% of the second round participants linked ICT and legitimacy.

- **Similarity between Founder and Customer Views:** In the second round of interviews, participants articulated a consistent set of issues surrounding legitimacy, ICT and purchase decisions. Both founders and customers reported similar views of each of the ten elements of the model, but four of these elements appear to be more salient to customers than to founders. Customers were significantly more likely to identify ICTs that were novel and helped form a positive image of the firm (mentioned 16 times by 47% of founders vs. 56 times by 86% of customers), to link ICT directly to support (mentioned 26 times by 60% of founders vs. 99 times by 100% of customers), to discuss a positive link between ICT and making a purchase (mentioned 29 times by 33% of founders vs. 49 times by 79% of customers), and to identify ICTs that would have no effect on their decision to make a purchase (mentioned 10 times by 47% of founders 47% vs. 49 times by 93% of customers).
  Founders also indicated that they were aware of the customer's perspective and that ICT adoption decisions were influenced by the desire to create a particular corporate image.
  - **Medical Lab:** I think that to be in the business world you need a Web page and people do judge you … whether they be potential clients or whoever, and they'll look at your Web page and … there's a better feel for us as a company when they see our Web page.

This strong overlap between the views of founders and customers is not surprising. Shared meanings, communication, and organized action are reciprocally interdependent (Donnellon, Gray, & Bougon, 1986) and would be required for an SME founder to successfully create an image of legitimacy.

- **Legitimacy Inferred From ICT:** There was no difference between the percentage of founders (87%) and the percentage of customers (93%) who reported inferring an SME's legitimacy from its ICT. ICT acts as a cue symbolizing dimensions of legitimacy (Suchman, 1995), which was mentioned by the overwhelming majority (90%) of the participants a total of 92 times. Participants agree that legitimacy influences the firm's ability to attract customers, and often mention legitimacy elements (size, seriousness, professionalism, capitalization) and support together.
  - **Apparel Catalog:** It's the little things that make you aware of what type of company you're dealing with. Again, if they don't have voice mail, if they don't have a cell phone, if they don't have fax capabilities, e-mail capabilities, these are the signs. This is what you sense. This is how you know that this isn't a real big company. If they make the commitment to have a fax machine, to have everything in place before they start up then they are a little more serious and maybe you'll take the chance and take the risk of putting the product in the book… You know that they're not financed if they don't even have a fax machine

Although conceptually distinct, the elements of legitimacy are mentioned together and cued by the same symbol, suggesting that they co-occur in participants' mental models of legitimate and illegitimate firms. This is consistent with the retrieval of prototype characteristics as outlined in the earlier paradigm model (Fiske & Taylor, 1991). Large, serious, professional firms are often contrasted with "hobbyists" or "fly-by-night" firms, suggesting that these represent common firm prototypes. Consistent with previous research on legitimacy, no participants wanted to work with "hobbyists" or "fly-by-night" firms.

Our results suggest that the adoption and use of ICT is a form of behavior linked to judgments that a firm is legitimate, an image that is universally desirable and is central to a firm's success (Zimmerman & Zeitz, 2002). Customers' assumptions about the appropriate adoption and use of ICT affect their judgment of the firm as legitimate. If decision-makers adopt and use ICT in ways that are consistent with customers' assumptions about what is appropriate, they can create an image of legitimacy, avoid being labeled "fly-by-night", and improve the likelihood that they will receive customer orders (Dutton & Dukerich, 1991).

Creating and maintaining a corporate image requires SMEs to choose behavioral, verbal and non-verbal symbols to convey the impression that the firm adheres to the stakeholders' expectations and codes of conduct identified by institutionalism (Pfeffer & Salancik, 1978). These codes of conduct reflect the system of meaning that underlies the social construction of reality (Berger & Luckmann, 1967; Feldman & March, 1981; Schein, 1985) and allows actors to make sense of their world by interpreting symbols (Gioia, 1986). This article provides evidence that ICT is one of those symbols and that these expectations form accepted standards for ICT use (DiMaggio & Powell, 1983) informed by customers' mental models and SME prototypes. Legitimacy influences purchase decisions, a crucial determinant of SME survival.

- **ICT Linked To Purchase Decisions:** An SME's ICT can make purchase decisions more likely or less likely, often depending on the ICTs involved (although sometimes they have no effect). However, some participants linked support with specific ICTs, while others linked it to an SME being "high tech" reflecting the influence of a constellation of ICTs.

As previously mentioned and shown in Table 2, support issues were more salient to customers than to founders, but overall 79% of participants mentioned a link (positive, negative or neutral) between ICT and support 125 times. More specifically, 55% mentioned 61 times that some ICTs could increase the probability of support (often, this was stated in the negative in that they would not make a purchase from a firm that did not have an ICT, implying that having the ICT is positively related to support).

- ○ **System Integrator:** I can't imagine that they would want to do business with somebody that didn't use email.
- ○ **Promotional Products:** If a company now doesn't have a fax machine, I probably wouldn't do business with them

About two-thirds (69%) of participants mentioned 59 times that that having or not having some forms or ICT would have no effect on purchase decisions.

- ○ **Spa and Beauty Supply:** I don't expect it (fax machine, computer, beepers, cell phones) and I would not stop doing business with somebody because of it. Nor would I necessarily consider not doing business with them because of that.

A small percentage of respondents (14%) mentioned 5 times that some ICTs would decrease the likelihood of a sale.

- ○ **Community Association Manager:** I prefer a company that does not have voicemail, but they're hard to find.

Thus, ICT is among the elements considered by customers in deciding whether or not to place an order with an SME, an example of what the legitimacy literature calls providing active support (Suchman, 1995). Although conceptually distinct, many authors treat legitimacy and support of a firm as overlapping constructs and some indicators of legitimacy (e.g. certification) are also indicators of support (Suchman, 1995). The use of ICT may allow SMEs create an image of legitimacy (Pfeffer & Salancik, 1978) and provide a survival advantage because ICT's symbolic meanings increase the likelihood that an SME will attract customers.

- **Mismatches and their Effects on Corporate Image of Legitimacy:** Creating an image of legitimacy requires conformity with customer expectations (Meyer & Rowan, 1977; Pfeffer & Salancik, 1978; Suchman, 1995; Zimmerman & Zeitz, 2002). So, we examined the effects of mismatches between the use of ICT and customers' expectations, one of our sensitizing concepts. We found three different kinds of mismatches that affected legitimacy and purchase decisions. A firm could be missing an ICT that customers had taken-for-granted; include an ICT that is novel in that it is not taken-for-granted, but enhances the firm's image; or it could include an ICT that is novel and detracts from the firm's image.

Table 2 shows that both SME founders and customers had expectations about the kinds of ICT firms should have (mentioned 433 times by 100% of participants). Three distinct patterns link violations of expectations about firm's ICT to its image. First, 90% of participants indicated 254 times that some kinds of ICT are taken-for-granted.

- ○ **Environmental Clean-up Consulting:** [Didn't have e-mail?] 'Wow! Where have you been?' You know, it's like they should have it. Even if it's at hotmail.com … That's just, I expect it.
- ○ **Systems Integrator:** I can't imagine a company existing without pagers. I mean, we use pagers so you can send a message. I just can't imagine.

This is consistent with what Saga and Zmud (1994) have called the routinization stage of ICT implementation, and with schema theory, the use of mental models, and prototypes (Fiske & Taylor, 1991). Some ICTs have been so completely integrated into the business world that customers' SME prototypes invariably include this element. When a mental model of legitimate firms is accessed, these ICTs are among the characteristics assumed to be present, even if they have not been observed. SMEs that do not have them are less likely to be seen as legitimate. Their absence violates expectations and raises legitimacy concerns because of the symbolic meaning attached to the technology.

But, contrary to legitimacy theory, mismatches do not always lead to judgments that a firm is not legitimate and may not even reflect positively on the firm if the ICT is novel rather than taken-for-granted. About two-thirds (66%) of participants indicated 72 times that the symbolic meaning of a novel ICT is also considered and can lead customers to infer that a firm shares their values, and that they should place an order.

- ○ **Wireless Services Provider:** E-mail, yes. They don't have to have it but it's a one up, it's a plus if they do.
- ○ **General Contractor:** [Vendors who bring in results of computer runs] Gives us a comfort level as opposed to the one that's scratched out on a piece of paper.

Of course, the converse is also true. Customers use the symbolic meaning of novel ICT to infer that a SME's actions will be undesirable, although it may not reflect upon the firm's legitimacy. For example, customers often encounter automated call routing to answer incoming calls, so the presence of this ICT cannot be considered a violation of expectations. However, many infer that firms using call routing are large, uncaring and will treat them impersonally. Overall, 38% of participants indicated 14 times that a novel ICT can be considered detrimental to a firm's image without affecting its legitimacy.

- **Community Association Manager:** [Automated call routing indicates a firm is] too big. Unpersonal [sic]. Yeah, I don't like it. I hate it.

The determining factor is whether the underlying symbolic meaning ascribed to the novel technology is consistent with the customer's values and ideas about desirable firms. For example, if industry leadership is considered desirable, an ICT that signals this enhances a firm's image. If large, uncaring firms are considered undesirable, automated call routing ICT that signals this detracts from a firm's image. Thus, consistent with Saga and Zmud's (1994) implementation phases, ICT that is accepted, but not taken-for-granted, is viewed as novel.

Schema theory would suggest that these technologies are not elements of all SME prototypes, so their presence or absence is used in classifying firms according to their desirability as exchange partners (Fiske & Taylor, 1991). In contrast, legitimacy theory asserts that the presence of a novel ICT violates expectations, so the probability of a purchase should always be diminished (Suchman, 1995). Our data contradicts legitimacy theory by providing evidence that these mismatches can be positive, enhancing an SME's image, and increasing the likelihood of a sale depending upon the inferences that customers draw about the firm's values and the desirability of its actions based on the symbolic meaning underlying a novel ICT. When these are positive, the firm's image is enhanced. When they are negative, it is diminished. In contrast, violating expectations regarding a taken-for-granted ICT always diminishes a firm's image. This relationship is shown in Table 3.

- **How and Why ICT Acts as a Symbol:** Information about SMEs is stored as mental models comprising multiple elements. Pre-existing categories of firms form prototypes that reflect particular constellations of elements, including ICT artifacts which act as cues from which a firm's legitimacy dimensions (e.g. size, professionalism, seriousness, and capitalization) are inferred. These dimensions are bundled together in the mental model, along with additional details that are filled in (inferred). As the SME founder makes a sales pitch, customers glean information about the firm's ICT and compare it to their expectations regarding each ICT mental model element. The observed and inferred characteristics are used to categorize firms by comparison with existing firm prototypes (e.g. legitimate vs. hobbyists or fly-by-night). SMEs that share a large number of characteristics with the prototype for a legitimate and desirable exchange partner will be considered legiti-

Table 3. Relationship between ICT novelty, presence, and corporate image of legitimacy

ICT	Taken-for-granted	Novel	
		Positive	Negative
Present	Legitimate	Positive Image	Negative Image
Absent	Not Legitimate	Neutral Image	Neutral Image

mate and be preferred by customers. When customers and founders attribute similar meanings to ICT, the SME can better control the image communicated.

This process resembles schematic processing of symbols, which can include artifacts such as ICT and actions such as their use (Bargh, 1984; Gioia, 1986; Morgan, Frost & Pondy, 1983). Information processing begins with the classification of stimuli based on matching attributes with those of pre-existing categories stored in schemas. Once categorized, missing pieces are filled in with category-consistent information. When a potential symbol is encountered, it is compared to existing schemas to generate meaning (Gioia, 1986). When a symbol is associated with a schema, understanding occurs that guides interpretation and action in ambiguous or uncertain situations. The communicative power of symbols lies in the meaning attached to them, which, like schemas, varies in different situations or social groups.

In the absence of prior interaction with an SME, potential customers generate meaning by scrutinizing available signals, such as ICT (Synder & Stukas, 1999), compare this information to their schemas for the use of ICT by legitimate firms, classify the firm into an appropriate category, fill in missing information, and make inferences about the desirability of the SME as an exchange partner. Quite simply, legitimacy is judged based partly upon ICT whose meaning has been stored in schemas reflecting social institutions (Barley & Tolbert, 1997). The ICT acts as a symbol of conformity to the expectations and values of the perceiver for legitimate firms. To be judged desirable, a firm should match customers' schemas for desirable firms or violate them in a manner that indicates pursuit of goals that conform to market segment values. Thus, an ICT's symbolic meaning affects a firm's image and influences purchase decisions that determine survival.

Contributions and Limitations

We developed a general and particularistic model of the issues surrounding the symbolic value of ICT, legitimacy, and customers' purchase behavior. This study extends our understanding of the creation of legitimacy, mental models, and schemas to identify the language, behavior and symbols that ordinary people use to convey and evaluate images, focusing specifically on the role of ICT as a signal, the firm characteristics that are linked to legitimacy, and how ICTs carry meaning. In addition, it clarifies that mismatches between audience expectations about an SME's ICT are not always negative.

DISCUSSION

Our results show that ICT does signal legitimacy. When asked directly, participants suggest a purely functional explanation for ICT adoption, reflecting the norm of rationality and social desirability (Feldman & March, 1981; Kling & Iacono, 1984; Winter, 1996). However, less salient dimensions were elicited using focus group techniques.

The ultimate purpose of a sales pitch is to make a sale, but a proximal purpose is the display of symbols such as ICT that create a positive image of the firm. Potential customers clearly use ICT to infer legitimacy and fill in unknown details from existing prototypes. They seek to categorize the firm in terms of its type, based in part on a comparison of its ICT capabilities with those that were expected. Classification into the preferred exchange partner category is crucial to the survival of SMEs because they seldom have the resources to overcome a poor corporate image.

This study extends the literature on the symbolic meaning of ICT by considering the customer's view of SMEs and the effects of ICT on purchase behavior and extends the literature on corporate image to include the effects of ICT.

Implications for Managers

Purchase decisions are influenced by potential customers' images of the firm. Decisions about the use of ICT in SMEs should consider image issues and symbolic meaning in addition to operational efficiency and effectiveness concerns and executives must be familiar with their stakeholders' expectations regarding an ICT. As institutionalism predicts, an SME that fails to adopt an ICT that has become taken-for-granted will find it more difficult to make the sales required to survive. As schema theory predicts, for ICT that is novel, executives must understand the symbolic meaning underlying its use to ensure a positive interpretation. Managing corporate image through the use of ICT is particularly importance for SMEs that must create an image before they have established a reputation based on performance, a large customer base or a broad marketing campaign. SMEs must rely most heavily on signals and symbols and should include both the symbolic and the productivity dimension in any calculation of the business value of ICT.

Implications for Theory

This study found a strong relationship between the symbolic meaning of an ICT, a corporate image of legitimacy, and purchase behavior. SME's that wish to attract customers should consider the benefits of choosing ICT that creates a corporate image of legitimacy, even if the ICT yields limited improvement in productivity. To be most effective, an SME's ICT choices should be guided by customer expectations.

These results also contribute to our understanding of the relationship between symbolic meaning and action. Organizational cognition suggest that the symbolic meaning of an ICT will dominate diffusion before its productivity effects have been documented and may continue thereafter as the presence of an ICT innovation becomes an institutionalized norm. Corporate image forms a valuable link between the symbolic meaning of ICT and its diffusion. Integrating these fields clarifies how an ICT acquires symbolic meaning allowing it to be used by SMEs to create and maintain corporate images. Social cognition and the role of schemas in interpreting an ICT as a cue are central to the creation of perceptions that a firm is legitimate, is a desirable exchange partner and is more likely to be supported.

CONCLUSION

SMEs face particularly difficult survival challenges with success dependent upon persuading potential customers to actually make purchases, a decision that hinges on perceptions regarding the firm's legitimacy (Suchman, 1995; Zimmerman & Zeitz, 2002). Consequently, SME survival depends in large part on creating and maintaining impressions of the firm's legitimacy among external stakeholders (Darwell, et al. 1998). This study has shown that potential customers make snap judgments about a firm's legitimacy based on expectations regarding the use of ICT due to its symbolic meaning and begun to explore the processes by which ICT acts as a symbol. Future research should consider other valued organizational outcomes related to the symbolic meaning of ICT for external stakeholders, such as attracting valued employees, financing and accreditation or licensure. In addition, the meanings of ICT and mediating concepts of corporate image will likely differ by industry, time period and culture. To provide additional value in guiding practice, considerably more work is needed to map the meanings of particular ICTs to different contexts. Understanding the complex multidimensional costs and benefits of ICT will allow us to develop a more complete view of its business value.

ENDNOTES

[1] The term "corporate image" is widely accepted in the marketing literature, but is not meant to exclude not-for-profit, volunteer, or governmental organizations.

[2] Firms were 2 - 5 years old and experienced a rapid growth rate (annual sales of at least 25%). The focus on purchase decisions dictated that firms be at least 2 years old since they are likely generating income from sales.

[3] A list of potential customers was developed through referrals from SME founders and the local telephone book. Many would not knowingly support a new firm or were unwilling to make the time commitment.

[4] Percentages and counts suggest the extent to which perceptions were shared among the respondents, but do not represent population values or an issue's importance. Quotes provide a sense of the spirit of the responses.

[5] Differences in the percentage of participants mentioning a category could not be tested with Chi-Square because the relatively small sample sizes and uneven distribution of responses yielded a high number of cells with expected values smaller than five. Under these conditions Chi-Square values become unstable; Fisher's Exact test is preferred

APPENDIX A. INFORMANT CHARACTERISTICS

New Firm	**Products/Services**	**Market**	**Scope**
Seafood Wholesaler	Fresh Fish	Retail Groceries & Restaurants	Local
Wholesale Exporter of Textiles & Foodstuffs	Manage Exports of Mid-Sized Manufacturers, mostly to Mexico	Distributors	International
Electronic Components	Spot Market Broker	Large Computer Manufacturers	State
Skateboard Design/Manufacturer	Skateboards	Retailers and Distributors	National
Fiberglass Manufacturer	Custom Auto Parts	Consumers	Regional
Private Label Accessories Manufacturer	Handbags & Belts	Specialty Retailers	International
Electrical Contractor	New Construction Wiring	Construction Companies	Local
Environmental Engineering Contractor	Engineering Project Design and Management	Government	State
General Engineering Contractor	Environmental Clean-up & Construction	Large Primary Contractors	Local
Building Supply	Construction Supplies	Contractors	Local
Moving Company	Packing, Storage and Delivery Services	Consumers, Government, Businesses	Regional
Medical Lab	Renal Testing	Clinics	National
MRI Lab	Radiography Services	Doctors & Patients	Local
Dietary Supplements Wholesaler	Herbal Supplements	Grocery & Health Stores	National
Diabetes Supplies	Testing, Injection & Medication Materials	Patients	National
Internet Service Provider	Value-added Networks & Internet Backbone	Local & Regional ISPs & Businesses	National
Pager	Pagers & Services	Paging Services Providers	National
Systems Integrator	Systems Development & Maintenance	Mid-size Businesses	Local
Web Consultant	Web Site Development & Maintenance	Businesses	State
Software Development & Hardware Resale	Multimedia Applications	Businesses & Education	State
Software Development	Groupware	Software Consultants	National
Computer Systems Consulting	Hardware Resale, Systems Development & Support	Consumers & Businesses	National
Technical Systems Consultant	Install & Maintain Info. Systems	Mid-size Businesses	

APPENDIX A. CONTINUED

Graphic Design & Macintosh System Consulting	Print & Electronic Graphics	Businesses	Regional
Landscape Architecture	Landscape Designs	Developers	State
Temporary Agency	Temporary Workers	Businesses	Local
Legal Copying Service	Duplication	Legal Firms	Local
Community Association Manager	Groundskeeping & Maintenance	Businesses	Local
Music Content Recording	Recorded Music	Music Distributors & Film Producers	National
Film Producer	Production Services	Commercial Movie Studios	National
TV & Web Production	Program Production	Businesses	National
Proposal Development & Presentation Training	Grant Writing; Program Development; Evaluation Research	Non-profit & Govt. Agencies; Architecture, Engineering or Construction Mgmt Firms	Local
Niche Publications (pregnant women and new parents)	Pamphlets & Books	Businesses	

Customers	**Products**	**Market**	**Scope**	**# Vendors**
Flowers/Gifts Retailer	Fresh Flowers & Related Gift Items	Consumers	National	200-300
Promotional Products Distributor	Custom Promotional Products	Businesses & Resellers	Regional	1000
Food Import/Export	Processed Foods	Retail Groceries & Restaurants	Inter-national	200
Wireless Services Provider	Paging and Cell Phone Services	Consumers & Businesses	National	1000
Facilities Manager	Supervise Maintenance, Grounds Keeping & Supplies	Consumers	Local	10-15
General Contractor	Construction Management	Developers Owners & Public Agencies	National	800-1200
Environmental Clean-up Consulting	Engineering, Design, Consulting & Contracting	Major Oil Cos.& Firms w/ Underground Tanks	Southeast U.S.	200
Health Spa	Beauty, Spa, Fitness & Nutrition Services	Consumers	Local	50
Architecture/Interior Design	Architectural Plans, Interior Designs & Decoration Services	Consumers & Designers	Local	20-25
Apparel Catalog	High-end Apparel	Consumers	National	100

APPENDIX A. CONTINUED

Custom Linens	Bedroom, Bath, Table Linens, Upholstery, Drapes & Accessories	Designers & Consumers	Local	1000
Book Exporter	Foreign Language Lit.	Distributors	Inter-national	30-40
Fitness Center	Fitness Services	Consumers	Local	6-10
Metal Framing Contractor	Management of Residential & Commercial Framing & Finishing	Owners & General Contractors	Local	500

APPENDIX B: INTERVIEW QUESTIONS

Customer

A. BACKGROUND

1. Please tell me what business you are in and the types of products and/or services you provide to your customers.
2. What raw materials or finished products do you purchase? What do you do with them before they are sold to your customers?

B. SUPPLIERS

3. Can you tell me who are your major suppliers of raw materials or finished products?

4(a) About how many suppliers would you say you use in total? About how many are sole suppliers of a particular material?

4(b) When you are choosing among suppliers, are there many that offer very similar products or services?

4(c) Given a choice, would you say that you would prefer to stay with a single supplier or to spread your orders around to several suppliers?

5(a) On average, how many new suppliers do you use each year? Have you ever added a new supplier that was also a brand new company perhaps one for which you would be their first customer? If not, why not? If yes, how did it work out? Are they still an active supplier?

5(b) When deciding to use any new vendor, about how many meetings or conversations do you engage in before placing an order? How would this differ if the new vendor is also a new company and you would be their first customer? Would this depend on the size of the order and whether you had multiple sources?

5(c) During these conversations, what are you trying to learn about established new vendors? Would this differ from what you would try to learn about a brand new company? How would this be influenced by the size of the order and whether there were multiple vendors available?

6(a) What would you say your reputation is among your suppliers?

6(b) Why would you say that?

7(a) When you are contacted by a potential new supplier, what are the factors that you consider in deciding whether or not to place an order? What's on your mind when you are listening to their sales pitch?

For these next questions, I'd like you to think about switching to a new supplier that is a brand new start-up business maybe approaching you to be one of their very their first customers.

7(b) What are the factors you consider in deciding whether or not to place an order when the supplier is a new start-up business rather than an established firm?
7(c) When there are several new start-up businesses offering comparable products or services, what factors would be important in deciding which to use?
7(d) What assurances do you look for from a new venture?
7(e) What does a new venture founder have to say to you so that you are really convinced that he or she can deliver the promised goods or services?
On time? At cost? According to specifications? Any other factors?
7(f) How concerned are you about the longevity of a new venture, that is, that it will be around a couple of years from now? How long would you want a supplier to be around? How short would be too short?
7(g) What do you have to hear or see from a new venture so that you are really convinced that it will indeed be around long enough?
7(h) How important is it to you that a new venture review with you ahead of time how they might handle problems if they arise?
7(i) Do you do any background check on new ventures? If so, what kind?]
7 (j) What can new ventures do or say to give you permission to believe the assurances they provide to you? What cues can they provide to signal that they can handle your contract?
7(k) Of the things you've mentioned (read list) which do you think is the most important thing you want to know about a new supplier's capabilities? What was second most important? Third? etc.
Of course getting a good deal from your suppliers is important, but there must be more than one firm that could provide the same type of product or service.
7(l) When you choose among new ventures competing for your business, what little things do you believe tip the balance in favor of one company over their similar competitors or your current suppliers? In other words, what little extra do you look for? What factors would work against a new supplier?
7(m) Given that these were important things for a supplier to show you, how would you know about them? In other words, what cues would you have to see for a new supplier to give you permission to believe that their company has this extra edge and should win the contract? What else would you want to see? Of course, you would want a supplier to dress appropriately, but I'm sure that it is more than just their smile that allows you to believe in their company. What is the real key to believing in a new venture? How would you expect these cues be communicated?

C. ROLE OF TECHNOLOGY

We know that the technology a supplier has performs many important business-related functions. However, lots of things that we interact with are functional, but also act as symbols. For example, a Ferrari and a Honda Civic both provide transportation. You can get from point A to point B in either one, but doing it in a Ferrari symbolizes wealth and a certain style. Designer clothing keeps us warm, but also acts as a symbol.

8(a) Do you think that a supplier's technological capabilities helps convince you to choose them over their equally qualified competitors? Does it help you to believe that a new venture is better than its competitors? Why do you say that? What would you think of a new supplier if its representative talked a lot about technology-related subjects in their sales pitch?

8(b) What do you know or assume about a new suppliers' technological capabilities? How do you know about it? Did they provide any cues? If not, why not? What would it have meant to you if the supplier had highlighted their technological capabilities?

9(a) In your opinion, what is the difference between a Mac user and an IBM user?

9(b) In your opinion, what is the difference between a company that has ________ and one that does not? Cell phones, Pagers, Voice mail, E-mail. Do your suppliers give you their cell phone #, pager #, voicemail access, or e-mail address? Why do they do this? What would it mean to you if you did not get this information?

9(c) How important is it to you that the new venture have the ability to check things like inventory, order status, and prices immediately (on a laptop or palm top), or is it okay to get back to you later about this (within an hour or two)? How would your impression differ if they checked paper files versus doing it on a laptop or palm?

9(d) In your opinion, what is the difference between a company that uses Kinko's to send and receive faxes and one that has its own private fax? Do you send faxes from a private number? What would it mean to you if you received a fax from a potential supplier and saw that it was sent from, say, Kinko's instead of a private fax #? Would it mean different things for different suppliers? Why?

9(e) In your opinion, what is the difference between a company that has a Web page and one that does not? Do your suppliers have Web page addresses? What would it mean to you if you did not receive a Web page address from a supplier?

9(f) Would you consider contacting a potential supplier based solely on its Web page? Why do you say that?

9(g) What would you think if you called this supplier early in the day planning to leave a message that they would get at the start of business, but instead woke up the company's sole employee because the business was run out of his private home? Why do you say that?

10. I'm going to read you a list of technologies that may perform important functions that allow your suppliers to provide excellent products or services. Over and above their functional use, these items may also provide cues that would give you permission to believe that a supplier has the qualities that would be required to provide a better product or service than their competitors. For each one, please tell me if you would expect a supplier to have it, if it could act as a cue to allow you to believe in their abilities, and, finally, if you would just assume that they had it, or if you would ask your suppliers about them or hear about them during the marketing or sales pitch: Cellular Phones for Work, Pagers/Beepers for Work, Voice Mail, Answering Machine, Fax Machines, Photocopiers, Color Copier, Personal Computers, Laptop Computers, Palmtop Computers, Data/Graphics Scanners, Graphics Capabilities, Desktop Publishing, Modem, Fax Modem, Modem Links to Clients, Ability to e-mail clients, Internal e-mail, Connections to Internet, Presence on Internet (Web Page), Intranet, Electronic Data Interchange, Database Systems, Groupware (e.g., Lotus Notes), Workflow Software, Wireless Data Communications, Machines for Manufacture of Products or Services [ASK RESPONDENT TO DESCRIBE]

11. What technologies do you believe your suppliers ought to have, that is, the minimum items you believe are necessary to serve you?
12(a) Thinking about all the technology your suppliers have, are there any specific pieces that you believe are essentially standard in your industry, that is, having them helps suppliers achieve parity with their competitors? Which ones?
12(b) How do suppliers know that these are the standard choices?
12(c) Do any of your suppliers have exceptional technological capabilities? What are these capabilities and do they allow this supplier to serve you better?
13. Again, thinking about all the technology your suppliers have, are there any specific items that you believe would give them a distinct advantage versus their competitors?
Which ones? Why do you say that?
14(a) If you were planning to start a new venture to supply your current employer, what pieces of technology would you insist on having? Why?
14(b) Would you tell your customers about these pieces? Why do you say that?
15. If you were teaching a class of students who were thinking about starting a new business supplying companies in your industry, what would you tell them about how to use technology as a selling point with their potential customers?
16. By now you have a pretty good sense of what we're trying to study. Is there anything you think we should have talked about that we haven't asked?
17. Is there anything else we should know about your business or about your suppliers?

Founder

A. BACKGROUND

To start, I'd like to get familiar with your business and your customer base.

1. Please tell me about the products and/or services you provide to your customers.
2. Who are your customers?
3. Who would you say are your serious competitors? How similar are their products and services to yours?
4(a) What would you say your reputation is among your customers?
4(b) Why would you say that?

B. EARLY SALES

For the next few questions, please think about when you first started your business.

5. When you were preparing to contact your first potential customers, what were the things that you worried about? What did you want to accomplish?
6. Who were your earliest customers
7. Did you have competitors who offered a product or service that was quite similar to yours? Who were these competitors?

8(a).For the very first sales you made or were trying to make in those early days, could you walk me through your sales pitch?
8(b) What would you say were the most important things your early customers wanted to know about you and your company's capabilities?
8(c) Of the things you've mentioned (read list) which do you think was the most important thing your customer wanted to know about you and your company's capabilities? What was second most important? Third? etc.

Of course getting a good deal was important for your customers, but there must have been other firms that could provide the same type of product or service.

8(d) When your first customers were deciding who to buy from, what little things do you believe tipped the balance in favor of your company over similar competitors or over their current suppliers? In other words, what little extra did you provide? What factors do you believe worked against you?
8(e) Given that these were important things to show your customers, how did your customer know about them? In other words, what gave your customer permission to believe that your company has this extra edge? What cues did you provide to allow them to believe that you or your company possessed these qualities? What else did you do? You made sure to dress right, didn't you? But I'm sure that it was more than just your smile that allowed them to believe in your company. What was the real key to convincing your customers?

C. ROLE OF TECHNOLOGY

We know that the technology you have performs many important business-related functions. However, lots of things that we interact with are functional, but also act as symbols. For example, a Ferrari and a Honda Civic both provide transportation. You can get from point A to point B in either one, but doing it in a Ferrari symbolizes wealth and a certain style. Designer clothing keeps us warm, but also acts as a symbol.

9(a) Do you think that your technological capabilities helped convince your customers to choose you over your equally qualified competitors? Did it help your customer to believe that your company was better than your competitors? Why do you say that? Did you avoid any technology-related subjects in your sales pitch so that clients would not get the wrong impression of you or of your firm?
9(b) What do you think your customers knew or assumed about your technological capabilities as you made your sales pitch? How did they know about it? Did you provide any cues? If not, why not? What would it have meant to your customer if you had highlighted your technology?
10(a) In your opinion, what is the difference between a Mac user and an IBM user?
10(b) In your opinion, what is the difference between a company that has _________ and one that does not? Cell phones, Pagers, Voice mail, E-mail. Do you give your customers your cell phone #, e-mail address, voicemail #, or pager #? Why do you do this?

What would it mean to them if they did not get this information?

10(c)In your opinion, what is the difference between a company that uses Kinko's to send and receive faxes and one that has its own private fax? Do you send faxes from a private number? What would it mean to your customers if they received a fax from you and saw that it was sent from, say, Kinko's instead of a private fax #? Would it mean different things to different customers? Why?

10(d) In your opinion, what is the difference between a company that has a Web page and one that does not? Do you give prospective customers your Web page address? What would it mean to your customers if they did not receive a Web page address from you?

11. I'm going to read you a list of technologies that may perform important functions that allow your suppliers to provide excellent products or services. Over and above their functional use, these items may also provide cues that would give you permission to believe that a supplier has the qualities that would be required to provide a better product or service than their competitors. For each one, please tell me if you would expect a supplier to have it, if it could act as a cue to allow you to believe in their abilities, and, finally, if you would just assume that they had it, or if you would ask your suppliers about them or hear about them during the marketing or sales pitch. Cellular Phones for Work, Pagers/Beepers for Work, Voice Mail, Answering Machine, Fax Machines, Photocopiers, Color Copier, Personal Computers, Laptop Computers, Palmtop Computers, Data/Graphics Scanners, Graphics Capabilities, Desktop Publishing, Modem, Fax Modem, Modem Links to Clients, Ability to e-mail clients, Internal e-mail, Connections to Internet, Presence on Internet (Web Page), Intranet, Electronic Data Interchange, Database Systems, Groupware (e.g., Lotus Notes), Workflow Software, Wireless Data Communications, Machines for Manufacture of Products or Services [ASK RESPONDENT TO DESCRIBE]

12. What technologies do you believe your customers expect you to have, that is, the minimum items they believe necessary to service them?

13(a) Thinking about all the technology you have, are there any specific pieces that you believe are essentially standard in your industry, that is, having them helps you achieve parity with your competitors? Which ones?

13(b) When you purchased these items, was your choice pretty much the standard in your industry or did you choose them for other reasons?

13(c) How did you know that these were the standard choices

13(d) [FOR THOSE THAT WERE CHOSEN FOR OTHER REASONS:] Please explain how you chose this /these.

13(e) Do you think there was a carryover from your former company or job in terms of the technology you chose or not?

14. Again, thinking about all the technology you have, are there any specific items that believe give you a distinct advantage versus your competitors? Which ones? Why do you say that?

15(a) If you were starting this business today, what pieces of technology would you insist on having? Why?

15(b) Would you tell your customers about these pieces? Why do you say that?

16. If you were teaching a class of students who were thinking about starting a new business in your industry, what would you tell them about how to use technology as a selling point with their potential customers?

17. By now you have a pretty good sense of what we're trying to study. Is there anything you think we should have talked about that we haven't asked you about?
18. Is there anything else we should know about your business?
19. In order to get a complete picture of the challenges facing new companies, I would like to get the customer perspective on these issues. Do you know of any buyers who may be willing to talk with me about the factors they consider when choosing a new supplier?

Chapter 5.10

Patterns for Organizational Modeling

Manuel Kolp

University of Namur, Belgium

ABSTRACT

Business needs have driven the design, development, and use of Enterprise Resource Planning (ERP) systems. Intra-enterprise integration was a driving force in the design, development, and use of early ERP systems, but increased globalization, intense competition, and technological change have shifted to focus to inter-enterprise integration. Current and evolving ERP systems thus reflect the expanded scope of integration, with greater emphasis on things like supply chain management and customer relationship management. This manuscript explores the evolution of ERP, the current status of ERP, and the future of ERP, with the objective of promoting relevant future research in this important area. If researchers hope to play a significant role in the design, development, and use of suitable ERP systems to meet evolving business needs, then their research should focus, at least in part, on the changing business environment, its impact on business needs, and the requirements for enterprise systems that meet those needs.

INTRODUCTION

Twenty years ago supplier relationship management was unique to the Japanese (those firms who embraced the JIT philosophy), China was still a slumbering economic giant, the Internet was largely for academics and scientists, and certainly not a consideration in business strategy; the very idea of a network of businesses working together as a virtual enterprise was almost like science fiction, and hardly anyone had a cell phone. The world has changed. The cold war is over and economic war is on. We have moved rapidly toward an intensely competitive, global economic environment. Countries like China and India are fast positioning themselves as key players and threatening the economic order that has existed for decades. Information technology (IT) is more sophisticated than ever, yet we still struggle with how to best use it in business, and on a personal level as well. E-commerce (B2B, B2C, C2C, G2C, and B2G) has become commonplace and M-commerce is not far behind, especially in Europe and Japan. This is the backdrop against which we will discuss the evolving enterprise information system. At this point we will call it ERP, but is should become evident in the course of reading this manuscript that ERP is a label that may no longer be appropriate.

In this article we define ERP and discuss the evolution of ERP, the current state of ERP, and the future of ERP. We will emphasize how the evolution of ERP was influenced by changing business needs and by evolving technology. We present a simple framework to explain that evolution. Some general directions for future research are indicated by our look at the past, present, and particularly the future of ERP.

ERP DEFINED

The ERP system is an information system that integrates business processes, with the aim of creating value and reducing costs by making the right information available to the right people at the right time to help them make good decisions in managing resources productively and proactively. An ERP is comprised of multi-module application software packages that serve and support multiple business functions (Sane, 2005). These large automated cross-functional systems are designed to bring about improved operational efficiency and effectiveness through integrating, streamlining, and improving fundamental back-office business processes. Traditional ERP systems were called back-office systems because they involved activities and processes in which the customer and general public were not typically involved, at least not directly. Functions supported by ERP typically included accounting, manufacturing, human resource management, purchasing, inventory management, inbound and outbound logistics, marketing, finance, and, to some extent, engineering. The objective of traditional ERP systems in general was greater efficiency, and to a lesser extent effectiveness. Contemporary ERP systems have been designed to streamline and integrate operation processes and information flows within a company to promote synergy (Nikolopoulos, Metaxiotis, Lekatis, & Assimakopoulos, 2003) and greater organizational effectiveness. Many new ERP systems have moved beyond the backoffice to support front-office processes and activities. The goal of most firms implementing ERP is to replace diverse functional systems with a single integrated system that does it all faster, better, and cheaper. Unfortunately, the "business and technology integration technology in a box" has not entirely met expectations (Koch, 2005). While there are some success stories, many companies devote significant resources to their ERP effort only to find the payoff disappointing (Dalal, Kamath, Kolarik,& Sivaraman, 2003; Koch, 2005). Let us examine briefly how we have come to this point.

The Evolution of ERP

The origin of ERP can be traced back to materials requirement planning (MRP). While the concept of MRP was understood conceptually and discussed in the 1960s, it was not practical for commercial use. It was the availability of computing power (processing capability and storage capacity) that made commercial use of MRP possible and practical. While many early MRP systems were built in-house, often at great expense, MRP became one of the first off-the-shelf business applications (Orlicky, 1975). In essence, MRP involves taking a master production schedule, inventory records, and a bill of materials and calculating time-phased material, component, and sub-assembly requirements, both gross and net. Note the term "calculating" was used rather than forecasting. With a realistic MPS, lead times that are known and predictable, accurate inventory records, and a current and correct BOM, it is possible to calculate material, component, and assembly requirements rather than forecast them. The shear volume of calculations necessary for MRP with multiple orders for even a few items made the use of computers essential. Initially, batch processing systems were used and regenerative MRP systems were the norm, where the plan would be updated periodically, often weekly. MRP employed a type of backward scheduling wherein lead times were used to work backwards from a due date to an order/start date. While the primary objective of MRP was to compute material requirements, the MRP system proved to be a useful scheduling tool. Order placement and order delivery were planned by the MRP system. Not only were orders for materials and components generated by a MRP system, but also production orders for manufacturing operations that used those materials and components to make higher-level items like sub assemblies and finished products. As MRP systems became popular and more and more companies were using them, practitioners, vendors, and researchers started to realize that the data and information produced by the MRP system in the course of material requirements planning and production scheduling could be augmented with additional data and meet other information needs. One of the earliest add-ons was the Capacity Requirements Planning module, which could be used in developing capacity plans to produce the master production schedule. Manpower planning and support for human resources management were incorporated into MRP. Distribution management capabilities were added. The enhanced MRP and its many modules provided data useful in the financial planning of manufacturing operations, thus financial planning capabilities were added. Business needs, primarily for operational efficiency and, to a lesser extent, for greater effectiveness, and advancements in computer processing and storage technology brought about MRP and influenced its evolution. What started as an efficiency-oriented tool for production and inventory management had become a cross-functional information system serving diverse user groups.

A very important capability to evolve in MRP systems was the ability to close the loop (control loop). This was largely because of the development of real time (closed loop) MRP systems to replace regenerative MRP systems in response to the business need and improved computer technology—time-sharing rather than batch processing as the dominant mode of computer operation. On time-sharing mainframe systems, the MRP system could run 24/7 and update continuously. Use of the corporate mainframe that performed other important computing tasks for the organization was not practical for some companies because MRP consumed too many system resources. Subsequently, some opted to use mainframes (they were becoming smaller and cheaper, but increasing in processing speed and storage capability) or mini-computers (which could do more, faster than old mainframes) that could be dedicated to MRP. MRP could now respond to timely data fed into the system and produced by the system. This closed the control loop with timely feedback for decision making by incorporating current data from the factory floor, warehouse, vendors, transportation companies, and other internal and external sources, thus giving the MRP system the capability to provide current (almost real-time) information for better planning and control. These closed-loop systems better reflected the realities of the production floor, logistics, inventory, and more. It was this transformation of MRP into a planning and control tool for manufacturing by closing the loop, along with all the additional modules that did more than plan materials—they planned and controlled various production resources—that led to MRPII. Here, too, improved computer technology and the evolving business need for more accurate and timely information to support decision making and greater organizational effectiveness contributed to the evolution from MRP to MRPII.

The MRP in MRPII stands for manufacturing resource planning rather than materials requirements planning. The MRP system had evolved from a material requirements planning system to a planning and control system for resources in manufacturing operations—an enterprise information system for manufacturing. As time passed, MRPII systems became more widespread, and more sophisticated, particularly when used in manufacturing to support and complement computer integrated manufacturing (CIM). Databases started replacing traditional file systems, allowing for better systems integration and greater query capabilities to support decision makers, and the telecommunications network became an integral part of these systems in order to support communications between and coordination among system components that were sometimes geographically distributed, but still within the company. In that context, the label CIM II was used to describe early systems with capabilities now associated with ERP (Lope, 1992). The need for greater efficiency and effectiveness in back-office operations was not unique to manufacturing, but was also common to non-manufacturing operations. Companies in non-manufacturing sectors such as health care, financial services, aerospace, and the consumer goods sector started to use MRPII-like systems to manage critical resources, thus the M for manufacturing seemed not always to be appropriate. In the early 90s, these increasingly sophisticated back-office systems were more appropriately labeled enterprise resource planning systems (Nikolopoulos, Metaxiotis, Lekatis, & Assimakopoulos, 2003).

MRP II was mostly for automating the business processes within an organization, but ERP, while primarily for support of internal processes, started to support processes that spanned enterprise boundaries (the extended enterprise). While ERP systems originated to serve the information needs of manufacturing companies, they were not just for manufacturing anymore. Early ERP systems typically ran on mainframes like their predecessors, MRP and MRPII, but many migrated to client/server systems where, of course, networks were critical and distributed databases more common. The growth of ERP and the migration to client/server systems really got a boost from the Y2K scare. Many companies were convinced by vendors that they needed to replace older main-frame based systems, some ERP and some not, with systems using the newer client/server architecture. After all, since they were going to have to make so many changes in the old systems to make them Y2K compliant and avoid serious problems (this was what vendors and consultants often told them) they might as well bite the bullet and upgrade. Vendors and consultants benefited from the Y2K boost to ERP sales, as did some of their customers. Since Y2K, ERP systems have evolved rapidly, bringing us to the ERP systems of today. Present day ERP systems offer more and more capabilities and are becoming more affordable even for small-to-medium-sized enterprises.

ERP TODAY

As ERP systems continue to evolve, vendors like PeopleSoft (Conway, 2001) and Oracle (Green, 2003) are moving to an Internet-based architecture, in large part because of the ever-increasing importance of E-commerce and the globalization of business. Beyond that, perhaps the most salient trend in the continuing evolution of ERP is the focus on front-office applications and inter-organizational business processes. ERP is creeping out of the back office into the front and beyond the enterprise to customers, suppliers, and more in order to meet changing business needs. Front-office applications involve interaction with external constituents like customers, suppliers, partners, and more—hence the name front office because they are visible to "outsiders." Key players like Baal, Oracle, PeopleSoft, and SAP have incorporated advanced planning and scheduling (APS), sales force automation (SFA), customer relationship management (CRM), supply chain management (SCM), and e-commerce modules/capabilities into their systems, or repositioned their ERP systems as part of broader enterprise suites incorporating these and other modules/capabilities. ERP vendor products reflect the evolving business needs of clients and the capabilities of IT, perhaps most notably Internet-related technologies.

While some companies are expanding their ERP system capabilities (adding modules) and still calling them ERP systems, others have started to use catchy names like enterprise suite, E-commerce suite, and enterprise solutions to describe their solution clusters that include ERP among other modules/capabilities. Table 1 lists the various modules/capabilities (with modules deemed similar combined in cells) taken from the product descriptions of vendors like PeopleSoft, Oracle, J.D. Edwards, and SAP, who are major players in the ERP/enterprise systems market.

Perhaps, most notable about ERP today is that it is much more than manufacturing resource planning. ERP and ERP-like systems have become popular with non-manufacturing operations like universities, hospitals, airlines, and more, where back-office efficiency is important and so, too, is front-office efficiency and effectiveness. In general, it is fair to say that today's ERP systems, or ERP-like systems, typically include, or will include (per vendor plans), modules/capabilities associated with front-office processes and activities. Alternatively, ERP modules are packaged with other modules that support front-office and back-office processes and activities, and nearly anything else that goes on within or between organizations and stakeholders. ERP proper (the back office system) has not become unimportant because back-office efficiency and effectiveness was, is, and will always be important. Today's focus, however, seems more to be external, as organizations look for ways to support and improve relationships and interactions with customers, suppliers, partners, and other stakeholders. While integration of internal functions is still important, and in many organizations still has not been achieved to a great extent, external integration seems now to be a primary focus. Progressive companies desire to do things—all things—faster, better, and cheaper (to be agile), and they want systems and tools that will improve competitiveness, increase profits, and help them not just to survive, but to prosper in the global economy. Today, that means working with suppliers, customers, and partners like never before.

Table 1. ERP modules

Modules
Enterprise Resource Planning (ERP)
Customer Relationship Management (CRM)
Asset Management Financial Management
Supplier Relationship Management (SRM) Business Collaboration
Inventory Management Order Processing
Data Warehouse Knowledge Warehouse Business Information Warehouse
Business Intelligence Analytics and Reporting Data Mining
E-Commerce Sales Management Field Service Management Retail Management
Facilities Management Maintenance Management
Warehouse Management Logistics Management Distribution Management
Project Management
Human Resource Management

Vendors are using the latest technology to respond to these evolving business needs as evidenced in the products and services they offer. Will ERP be the all-encompassing system (with an updated name like ERPII) comprised of the many modules and capabilities mentioned, or will it be relegated to the status of a module in the enterprise system of the future?

ERP and the Future

New multi-enterprise business models like value collaboration networks, customer-centric networks that coordinate all players in the supply chain, are becoming popular as we enter the 21st century (Nattkemper, 2000). These new business models reflect an increased business focus on external integration. While no one can really predict the future of ERP very far into the future, current management concerns and emphasis, vendor plans, and the changing business and technological environments, provide some clues about the future of ERP. We turn our attention now to evolving business needs and technological changes that should shape the future of ERP.

E-commerce is arguably one of the most important developments in business in the last 50 years (it has been called the "Viagra" of business), and m-commerce is poised to take its place alongside or within the rapidly growing area of e-commerce. The Internet, intranets, and extranets have made e-commerce in its many forms (B2B, B2C, B2G, G2C, C2C, etc.) possible. Mobile and wireless technology are expected to make "always on" Internet and anytime/anywhere location-based services a reality, as well as a host of other capabilities we categorize as m-commerce. One can expect to see ERP geared more to the support of both e-commerce and m-commerce. Internet, mobile, and wireless technologies should figure prominently in new and improved system modules and capabilities (O'Brien, 2002; Sane, 2005; Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). Vendors and their customers will find it necessary to make fairly broad, sweeping infrastructure changes to meet the demands of e-commerce and m-commerce (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002; Higgins, 2005). Movement away from client-server systems to Internet-based architectures is likely. In fact, it has already started (Conway, 2001). New systems will have to incorporate existing and evolving standards and older systems will have to be adapted to existing and evolving standards, and that may make the transition a little uncomfortable and expensive for vendors and their customers. Perhaps the biggest business challenge with e-commerce, and even more so with m-commerce, is understanding how to use these new and evolving capabilities to serve the customer, work with suppliers and other business partners, and function internally. Businesses are just beginning to understand e-commerce and how it can be used to meet changing business needs as well as how it changes business needs, and now m-commerce poses a whole new challenge. It is a challenge for application vendors and for their clients. Back-office processes and activities and front-office processes and activities are being affected by e-commerce and will be affected by m-commerce. The strategic ramifications are significant as the Internet and mobile technology take a prominent place in the future of ERP systems. They will be key in meeting evolving business needs, and on the flip side, one can argue that the evolving technologies will give rise to new business needs.

The current business focus on process integration and external collaboration is a driving force for change that should continue for some time to come. Some businesses are attempting to transform themselves from traditional, vertically integrated organizations into multi-enterprise "recombinant entities" reliant on core competency-based strategies (Genovese, Bond, Zrimsek, & Frey, 2001). Integrated SCM and business networks will receive great emphasis, reinforcing the importance of IT support for cross-enterprise collaboration and inter-enterprise processes (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). Collaborative commerce (c-commerce) has become not only a popular buzzword, but also a capability businesses desire/need. c-Commerce is the label used to describe Internet-based (at least at present) electronic collaboration among businesses, typically supply chain partners, in support of inter-organizational processes that involve not just transactions, but also decision making, coordination, and control (Sane, 2005). ERP systems will have to support the required interactions and processes among and within business entities, and work with other systems/modules that do the same. The back-office processes and activities of business network partners will not exist in a vacuum—many will overlap. There will be some need then for ERP processes to span organizational boundaries (some do at present), requiring a single shared inter-enterprise ERP system that will do it (we might call it a distributed ERP), or at least ERP systems that can communicate with and co-process (share/divide processing tasks) with other ERP systems—probably the most practical solution, at least in the near future. Middleware and enterprise portal technologies will likely play an important role in the integration of such modules and systems (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). In short, greater external integration that complements internal integration will be important in the future of ERP, as providers strive to enable companies to communicate and collaborate with other entities that comprise the extended enterprise (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). Internet-based technologies seem a necessary ingredient in this integrated, cross-enterprise ERP capability.

It is not uncommon now for companies to select only "suitable" modules rather than purchasing a complete packaged system, which may not be necessary given the core business processes of a company. That said, module capabilities and prices vary widely among vendors, and ERP is not cheap. Whether a company buys a "complete" solution or select modules, it still face several challenges with the development and implementation of ERP systems including: (i) the cost of the systems, (ii) alignment between information and business models, (iii) implementation issues (like integration, interoperability, and resistance to change), and (iv) post-implementation problems.

Web services are expected to play a prominent role in the future of ERP (O'Brien, 2002; ACW Team, 2004). Web services range from simple to complex, and they can incorporate other Web services. The capability of Web services to allow businesses to share data, applications, and processes across the Internet (O'Brien, 2002) may result in ERP systems of the future relying heavily on the service-oriented architecture, within which Web services are created and stored, providing the building blocks for programs and systems. Web service technology could put the focus where it belongs: on putting together the very best functional solution to automate a business process (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). The use of "best in breed" Web service-based solutions might be more palatable to businesses, since it might be easier and less risky to plug in a new Web service-based solution than replace or add on a new product module. A greater role for Web services is expected, and that, too, would heighten the importance of an Internet-based architecture to the future of ERP.

All from one, or best in breed? Reliance on a single vendor would seem best from a vendor's perspective, but it may not be best from the client's standpoint. While it may be advantageous to have only one proprietary product to install and operate, and a single contact point for problems, there are risks inherent in this approach. Switching cost can be substantial, and if a single vendor does not offer a module/solution needed by the client, then the client must develop it internally, do without it, or purchase it from another vendor. At any rate, the client may be faced with trying to get diverse products to work together, and the problems of doing so are well documented. The single source approach means an organization must place great faith in the vendor. So what about best in breed? That approach will be good if greater interoperability/integration among vendor products is achieved (Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). There is a need for greater "out of the box" interoperability, thus a need for standards. Ideally, products will reach a level of standardization where software modules exhibit behavior similar to the plug-and-play hardware—you just plug in a new module, the system recognizes it, configures itself to accommodate the new module, and eureka, it works! While this is much to hope for, increased standardization brought about by developments like the Service-oriented architecture might make this a reality, though probably not anytime soon. The fact that many are embracing standards for XML and more does give one some reason to hope, but whether the future of ERP software trends toward the single source or best in breed approach remains to be seen. Regardless of the direction, integration technologies will be important in the new breed of modular, but linked, enterprise applications. Middleware providers see a significant opportunity here in that their products facilitate module interaction. Increasingly, modules and or entire systems are provided by a new breed of vendors called application service providers (ASPs). These companies typically deliver their services via the Internet, and may become "the way" business partners integrate their systems—all partners could use the same ASP and the ASP systems would be the integrating force.

Data warehouses, data mining, and various analytic capabilities are needed in support of front-office and back-office processes and activities involved in CRM, SRM, SCM, field service nanagement, business collaboration, and more. Likewise, they are important in strategic management. Data warehouses are expected to play an important role in the future of ERP, either as a capability within ERP, or by working with the ERP system to exchange data needed to support related activities and processes. Ideally, the data warehouse would be integrated with all front-office, back-office, and strategic systems to the extent that it helps close loops by providing timely data to support decision making in any context. Knowledge management systems (KMS) endowed with neural networks and expert system capabilities should play a key role in decision making as they become more able to capture, model, and automate decision-making processes. Data warehouses and KMS should enable future ERP systems to support more automated business decision making (Strategic Systems of the Future, 1999; Bhattacharjee, Greenbaum, Johnson, Martin, Reddy, Ryan, et al., 2002). More automated decision making in both front-office and back-office systems should eliminate/minimize human variability and error, greatly increase decision speed, and hopefully improve decision quality. Business intelligence (BI) tools, offered by some vendors and planned by others, take data and transform it into information used in building knowledge that helps decision makers to make more "informed" decisions—no pun intended. Current business intelligence (BI) tools are largely designed to support strategic planning and control but will likely trickle down to lower-level decision makers, where their capabilities will be put to use in tactical and perhaps operational decision contexts. BI tools use data, typically from a data warehouse, along with data mining, analytic, statistical, query, reporting, forecasting, and decision support capabilities to support managerial planning and control. In combination with the data warehouse, KMS and BI should contribute to faster, better, and less costly (in terms of time and effort involved) decisions at all organizational levels.

At least in the near future, it appears that greater emphasis will be placed on front-office systems, as opposed to back-office systems, and sharing data, applications, and processes across the Internet (O'Brien, 2002). Back-office systems will not be unimportant, but they are more mature as a consequence of past emphasis, and many work quite well. Emphasis will be on more thorough integration of the modules that comprise back-office systems, integration of back-office systems with front-office and strategic systems, and integration of front-office, back-office, and strategic systems with the systems of other organizations. At present, greater organizational effectiveness in managing the entire supply chain all the way to the end customer is a priority in business. The greater emphasis on front-office functions and cross-enterprise communications, and collaboration via the Internet, simply reflects changing business needs and priorities. A 2004 ITtoolbox survey of ERP users in Europe, North America, Asia, India, and elsewhere showed great interest in improved functionality and ease of integration and implementation (top motives for adding new modules or purchasing new ERP systems). Furthermore, the same survey showed greatest interest in modules for CRM, Data Warehousing, and SCM (top three on the list). The demand for specific modules/capabilities in particular shows that businesses are looking beyond the enterprise. This external focus is encouraging vendors to seize the moment by responding with the modules/systems that meet evolving business needs. The need to focus, not just on new front-office tools but also on strategy, will encourage greater vendor emphasis on tools like data warehouses and capabilities like business intelligence that support strategy development, implementation, and control.

The evolving environment of business suggests a direction for these comprehensive enterprise systems that would seem to make ERP less fitting as an appropriate label. The Gartner group has coined the term ERPII to describe their vision of the enterprise system of the future, with increased focus on the front office, strategy, and the Internet. ERPII is a business strategy and a set of collaborative operational and financial processes internally and beyond the enterprise (Zrimsek, 2002). Gartner projected that by 2005, ERPII will replace ERP as the key enabler of internal and inter-enterprise efficiency (Zrimsek, 2002). While the ERPII label may stick for a while, it is likely that ERP will be relegated to module/capability status, while a name more fitting for evolving inter-enterprise front office, back office, and strategic systems will replace the ERPII label, in much the same way that ERP replaced MRPII. Perhaps "enterprise systems" will be that new name, as it seems to be finding favor among vendors.

THE ERP EVOLUTION FRAMEWORK

This framework simply summarizes the evolution of ERP relating the stages in its evolution to business needs driving the evolution, as well as changes in technology. Table 2 presents the framework. As MRP evolved into MRPII, then ERP, and finally to ERPII (present state of ERP), the scope of the system expanded as organizational needs changed, largely in response to the changing dynamics of the competitive environment. As business has become increasingly global in nature, and cooperation among enterprises more necessary for competitive reasons, systems have evolved to meet those needs. One can hardly ignore the technological changes that have taken place, because the current state of technology is a limiting factor in the design of systems to meet evolving business needs. From our examination of the evolution of ERP, we would conclude that the next stage of the evolution will come about and be shaped by the same forces that have shaped each stage, that being evolving business needs and advances in technology. The future of ERP systems seems destined to follow one of two courses: ERP will be relegated to the status of module within some broader system, or ERP will evolve into that all-encompassing system, call it

Table 2. The evolution of ERP

System	Primary Business Need(s)	Scope	Enabling Technology
MRP	Efficiency	Inventory management and Production planning and control.	Mainframe computers, batch processing, traditional file systems.
MRPII	Efficiency, effectiveness and integration of manufacturing systems	Extending to the entire manufacturing firm (becoming cross-functional).	Mainframes and Mini computers, realtime (time sharing) processing, database management systems (relational)
ERP	Efficiency (primarily back office), effectiveness and integration of all organizational systems.	Entire organization (increasingly cross functional), both manufacturing and non-manufacturing operations.	Mainframes, Mini, and micro computers, Client server networks with distributed processing and distributed databases, Data warehousing and mining, knowledge management.
ERPII	Efficiency, effectiveness and integration within and among enterprises.	Entire organization extending to other organizations (cross-functional and cross-enterprise--partners, suppliers, customers, etc.).	Mainframes, Client Server systems, distributed computing, knowledge management, Internet technology (includes Web services, intranets and extranets).
IRP, Enterprise Systems, Enterprise Suite, or whatever label gains common acceptance.	Efficiency, effectiveness and integration within and among all relevant constituents (business, government, consumers, etc.) on a global scale.	Entire organization and its constituents (increasingly global) comprising supply chain from beginning to end as well as other industry and government constituents.	Internet, Web service Architecture, wireless networking, mobile wireless, knowledge management, grid computing, artificial intelligence.

ERPII or something else, that contains most or all of the modules discussed herein. We expect the former as opposed to the latter will occur, with ERP (the traditional back office system) taking its place with MRP and MRPII. The functions ERP systems perform will remain important and necessary as have the functions of MRP and MRPII, but ERP will become part of something bigger, taking its place as an integral part of the enterprise system of the future. Whether that all-encompassing system is called ERPII, Interprise resource planning, enterprise suite, enterprise system, or a name that currently resides in the back of some vendor employee or researcher's mind, remains to be seen. One thing seems certain, the next stage in the evolution will hinge on the same forces shaping systems of the past—business need and technological change.

CONCLUSION

ERP has evolved over a long period of time. MRP gave way to MRPII, then MRPII to ERP, and finally ERP to ERPII. It seems quite likely that ERPII will give way to a new label. MRP still exists as will ERP, but most likely as a module, or capability rather than the label applied to an increasingly broad set of capabilities and modules that support the back-office, front-office, strategic planning and control, as well as integrating processes and activities across diverse enterprises comprising business networks. Whatever the name, current trends suggest certain characteristics which we can reasonably expect. This future system will have to support e-commerce and m-commerce, thus wireless technology, including but not limited to mobile, and the Internet will be key in the evolving architecture. An Internet-based architecture seems likely, and it may be a service-oriented architecture, wherein Web services are key, ASPs, or both. The increased emphasis on front-office systems and strategic planning and control will likely influence new capabilities introduced by vendors for the next few years. Increased automation of decision making is to be expected with contributions from knowledge management and business intelligence systems fueled by advancements in the field of artificial intelligence. Greater interoperability of diverse systems and more thorough integration within and between enterprise systems is likely to remain a priority. An environment for applications much like the "plug and play" environment for hardware would make it easier for organizations to integrate their own systems and have their systems integrated with those of other organizations. Such an environment awaits greater standardization. This ideal "plug and play" environment would make it easier for firms to opt for a "best in breed" strategy for application/module acquisition as opposed to reliance on a single vendor for a complete package of front-office, back-office, and strategic systems. Moreover, such a development might move us closer to effective inter-organizational system integration and make fully integrated supply chain management a reality. Perhaps we might call the evolving system interprise resource planning to emphasize the inter-enterprise nature of these systems. Whatever they are called, it seems that what they will do goes far beyond what the enterprise resource planning (ERP) label would aptly describe, even when the "II" is appended.

From the discussion of ERP's future one can extrapolate certain desired capabilities for the enterprise systems of the future. Following is a list of desired/required capabilities:

- Facilitates an integrated supply chain
- Data transfer between modules is smooth and consistent
- Flexibility to support agile companies responding to dynamic business environment
- An architecture reflective of evolving enterprise models and evolving technology, like mobile wireless
- Database models/solutions support transaction-intensive applications (front office and back office), query intensive applications, and internal and external interaction with the database
- Systems take into account partnering enterprise characteristics like culture, language, technology level, standards, information flows, and provide flexibility to adapt as partnering relationships change
- Global vendor alliances to better meet needs of clients in any country
- Vendors and user companies adopt standards like XML, the Web service architecture, and evolving wireless standards with due consideration to global business requirements
- Greater flexibility and interoperability of modules, systems, and enterprises

For researchers and practitioners the advice is simple. There were two primary drivers in the evolution from MRP to MRPII, ERP, and finally ERPII. Those drivers were business need and technological change. Technological change made possible the development of systems to meet changing business needs. The needs may exist for a while before the technology can help meet them, and the technology can exist for a while before someone recognizes that it can be used to meet a current or evolving business need. In either case, the focus should be on monitoring business needs and monitoring technological change. Research that does both and is geared towards bringing the two together could make significant contributions to business. The Enterprise System of the future, whatever it is called, will be found at the convergence of business need and technological change. Perhaps researchers need to explore how we can do more to make that happen, rather than wait for it to happen and describe it as we have in this manuscript.

ABSTRACT

This chapter introduces a distributed framework for OKM (Organizational Knowledge Management) which allows IKWs (Individual Knowledge Workers) to build virtual communities that manage and share knowledge within workspaces. The proposed framework, called K-link+, supports the emergent way of doing business of IKWs, which allows users to work at any time from everywhere, by exploiting the VO (Virtual Office) model. Moreover, since semantic aspects represent a key point in dealing with organizational knowledge, K-link+ is supported by an ontological framework composed of: (i) an UO (Upper Ontology), which defines a shared common background on organizational knowledge domains; (ii) a set of UO specializations, namely Workspace Ontologies or Personal Ontologies, that can be used to manage and search content; (iii) a set of COKE (Core Organizational Knowledge Entities) which provides a shared definition of human resources, technological resources, knowledge objects, services; and (iv) an annotation mechanism that allows users to create associations between ontology concepts and knowledge objects. K-link+ features a hybrid (partly centralized and partly distributed) protocol to guarantee the consistency

of shared knowledge and a distributed voting mechanism to foster the evolution of ontologies on the basis of user needs.

INTRODUCTION

In the 1990s, Nonaka and Takeuchi proposed a new organizational paradigm (Nonaka et al., 1995). This paradigm identifies knowledge as a key resource for organizations and aims at establishing paths to be followed for better exploiting organizational knowledge. While earlier organizational models (Taylor, 1911) saw the organization as a box with the aim to maximize the output or as something that can be scientifically and rigorously managed, more recently the theme of managing knowledge has become more important (Simon, 1972) and the role of the organization in KM (Knowledge Management) processes has changed notably. The organization becomes a way to connect the knowledge of many subjects into a more complete understanding of the reality. Also the role of technologies has changed; they have become a way to increase people's rationality by enabling both knowledge management and exchange. Throughout the years, several other theories about knowledge have been proposed. A generally accepted classification proposed by Polanyi (Polanyi 1966; Polanyi 1997) and extended by Nonaka (1994) identifies on the one side "tacit knowledge" as the knowledge resulting from personal learning within an organization. On the other side, "explicit knowledge" is a generally shared and publicly accessible form of knowledge. Explicit knowledge can also be classified on the basis of the following forms: "structured" (available in databases); "semi-structured;" (generally available in Web sites: HTML pages, XML documents, etc.) and "unstructured" (available as textual documents: project documents, procedures, white papers, etc.). More recently, new importance has been given to social processes and to the CoP (Communities of Practice) as sources of knowledge. A CoP can be viewed as a group of people with shared goals and interests that employ common practices, work with the same tools, and express themselves in a common language (Lave & Wenger, 1991). In a CoP, individuals can produce and learn new concepts and processes from the community, allowing the same community to innovate and create new knowledge. This way, an organization can become a community of communities, offering space for creating autonomous sub-communities. The different types of technological solutions for managing knowledge should correspond to actual social interactions in KM processes. According to this consideration, technological systems for KM can be classified and inserted in a scheme reflecting the adopted social model. Therefore, on the one hand we have centralized systems that are practically identified with the EKP (Enterprise Knowledge Portal) and, on the other hand, we have DKM (Distributed Knowledge Management) systems. In this chapter, we will focus on the DKM approach since it naturally fits the process of creating knowledge. Following this approach, the individual is allowed to manage his/her knowledge without any superimposed schema. Therefore, he/she can share the individual knowledge by spreading it over the organization and making it an asset of the whole organization.

In particular, distributed applications for KM are based on the principle that different perspectives within complex organizations should not be viewed as an obstacle to knowledge exploitation, but rather as an opportunity to foster innovation and creativity. They are increasingly becoming popular since they permit an easy and quick creation of dynamic and collaborative groups (e.g., CoP) composed of people from a single or different organizations.

Moreover, in today‘s ubiquitous information society an increasing number of people work outside of the traditional office for many hours of the day. Current technologies do not properly support this new style of working and every day it is becoming harder and harder to exchange information in a labyrinth of network connections, firewalls, file systems, tools, applications, databases, voicemails, and emails. Individual Knowledge Workers spend much of their time finding and exchanging information or reaching people, and very limited time is left to actual productive work. To cope with these issues, many companies use technological solutions that include portals, extranets, VPNs, and browser-based application strategies that, at best, have been partially successful.

We argue that IKWs need a virtual workplace where the physical office can be recreated and where everybody and everything is easily available from anywhere at anytime. The *Virtual Office* approach (Marshak, 2004) can solve most of the aforementioned issues. A VO is a work environment defined regardless of the geographic locality of employees. A VO fulfils the roles of the traditional, centralized office although employees collaborate for the most part electronically with sporadic physical contacts.

P2P (Peer-to-Peer) solutions naturally fit the DKM and VO requirements, since they offer autonomy, coordination, and scalability features (Bonifacio et al., 2002). We designed and developed a P2P system named *K-link+* (Le Coche et al., 2006) that implements the VO model and provides users with a collaborative knowledge management environment. In *K-link+*, users can integrate different applications (knowledge sharing, messaging, shared boards, agenda, etc.) within a single environment and enrich the system with new tools that can be added as new components.

In *K-link+*, peers are allowed to concurrently work on the same shared KOs (Knowledge Objects). To foster peers' autonomy, different local replicas of a KO can be created, so concurrent access can affect data consistency if adequate mechanisms are not provided. Since peers can join or leave the system at any time, synchronization is required by peers that reconnect to the network and need to be informed about recent updates made on KOs by other peers. The *K-link+* system adopts a hybrid model to guarantee content consistency and peer synchronization. This model exploits the efficiency of centralized models, but at the same time includes decentralized features that assure scalability properties when the system size increases.

The basic concept under the *K-link+* Virtual Office approach is the workspace. A *K-link+* workspace can be viewed as a work area integrating people, tools, and resources. KOs created and exchanged within a workspace are provided with a semantic meaning through ontologies. In recent years, the knowledge management community has been considering ontologies as an adequate support to harness semantics conveyed by information (Fensel, 2001). An ontology (Gruber, 1993) is an abstract representation of a knowledge domain which allows its modeling in terms of concepts, relationships among concepts, class hierarchies and properties, and permits reasoning about the represented knowledge. Ontologies also offer a way for defining a set of possible instances of concepts and relationships, thus providing links between the model and the modeled reality.

K-link+ is supported by an ontological framework that allows to:

- Give a shared definition of knowledge domains relevant for the organization through the Upper Ontology (UO). So IKWs are provided with a common and well-defined knowledge background on knowledge domains of interest for the organization.
- Provide a shared definition of typical organizational assets (e.g., human resources, knowledge objects, services) within COKE ontologies. This way the retrieval of such assets can be done more effectively.
- Deepen aspects of the organizational knowledge domain in communities through Workspace Ontologies or on a personal basis through Peer Ontologies. Therefore, IKWs are endowed with a certain degree of autonomy in defining their own conceptual schemas (i.e., ontologies).

- Annotate COKE instances and in particular KOs (i.e., textual documents, emails, Web pages) to ontology concepts. Therefore unstructured and heterogeneous information is provided with semantically relevant metadata and can be retrieved on a semantic basis by specifying ontology concepts instead of keywords.

BACKGROUND

Most of the current architectures for content sharing and knowledge management are typically based on client/server architectures in which one or more servers act as central entities. In such architectures, knowledge handled by IKWs must be managed according to organizational guidelines. However, such centralized approaches do not reflect the social nature of knowledge (Bonifacio et al., 2002). As it is argued in (Nonaka & Takeuchi, 1995), the *seed* of new knowledge is *individual (tacit)* knowledge, but the importance of the knowledge increases when it becomes available to the whole organization. Therefore, the *externalization* of tacit knowledge is a quintessential process for creating new knowledge; this typically requires people to interact and collectively reflect on a problem or an idea. Such observations promote the demand for new technological architectures that place more emphasis on collaboration.

We argue that a P2P architecture that implements the VO model fits both the requirements of collaboration (synchronous and asynchronous) and knowledge sharing. In fact, P2P architectures naturally support the creation of communities (e.g., workspaces, peer groups) in which content and conveyed knowledge can be created, shared, exchanged, and transformed.

Content consistency is a fundamental reliability requirement for a P2P system. Current approaches depend on the scale of P2P systems. In a large-scale and dynamic system, it is complex and cumbersome to guarantee full consistency among replicas, so researchers have designed algorithms to support consistency in a best-effort way. In Datta et al. (2003), a hybrid push/pull algorithm is used to propagate updates, where flooding is substituted by rumor spreading to reduce communication overhead. SCOPE (Chen et al., 2005) is a P2P system that supports consistency among a large number of replicas at the cost of maintaining a sophisticated data structure. By building a RPT (Replica-Partition-Tree) for each key, SCOPE keeps track of the locations of replicas and then propagates update notifications.

Conversely, in a small- or medium-scale system, it is possible to adopt centralized schemes to guarantee a strong consistency model, which is often the *sequential* model (Lamport, 1979). In Wang et al. (2006), an algorithm for file consistency maintenance through virtual servers in unstructured and decentralized P2P systems is proposed. Consistency of each dynamic file is maintained by a VS (Virtual Server). A file update can only be accepted through the VS to ensure the one-copy serializability.

The *K-link+* system, which is mostly suited for small/medium enterprises, adopts a hybrid model which exploits the efficiency of centralized models, but at the same time includes decentralized features which assure scalability properties when the system size increases. This is accomplished by using: (i) a unique and stable server to maintain a limited amount of metadata information about shared objects; (ii) a number of interchangeable servers that maintain and manage the primary copy of shared objects; and (iii) a pure decentralized mechanism to allow P2P nodes to exchange up-to-date object copies when only read operations are required.

Another striking feature of *K-link+* is the use of ontologies for supporting OKM both at individual level, by Personal Ontologies, and within communities through Workspace Ontologies. Ontologies allow to “conceptualize” knowledge subjects, externalize them in terms of ontology primitives (e.g., concepts, relationships), and share knowledge through "the establishment of shared understanding" (Becerra et al., 2001). Ontologies can also be used to improve current keyword-based search techniques (Fensel, 2001), since they permit users to semantically annotate contents with respect to concepts. Conceptual search, that is, search based on meaning similarity rather than just string comparison, has been the motivation of a large body of research in the Information Retrieval field long before the Semantic Web vision emerged (Agosti et al., 1990; Järvelin et al., 2001). In the literature there are several approaches to ontology-based search (Guha et al., 2003; Vallet et al., 2005) that rely on queries expressed in formal languages, such as RDQL (Seaborne, 2004) SPARQL (Prud'hommeaux et al., 2006) or on a combination of formal queries with keyword-based queries (Castelles et al., 2007).

The approach we implemented is different from all these since we aim at creating semantic metadata associated to content (e.g., documents) by following the principle of superimposing information (Maier et al., 1999). We do not aim at explicitly populating the knowledge base of each peer with ontological knowledge, but rather at enabling users to quickly assign, by *annotations*, an immediate semantic meaning to both structured and unstructured content.

Concerning semantic-based P2P systems, there are several approaches that share common characteristics with *K-link+*. KEx (Knowledge Exchange) (Bonifacio et al., 2002) is a P2P system aimed at implementing knowledge sharing among communities of peers (called federations) that share interests. The system relies on the concept of context that peers exploit to represent their interests. KEx implements specific tools (e.g., context editors, context extractors) to extract the context of a peer from the peer knowledge (e.g., file system, mail messages). In order to discover semantic mappings among concepts belonging to different peer contexts, KEx exploits the CtxMatch algorithm. CtxMatch associates concepts with their correct meaning with respect to their context by exploiting WordNet and translates concepts in logical axioms in order to discover mappings. The algorithm implements a description logic approach in which mapping discovery is reduced to the problem of checking a set of logical relations. SWAP (Semantic Web and Peer to Peer) (Ehrig et al., 2003) aims at combining ontologies and P2P for knowledge management purposes. SWAP enables local knowledge management through a component called LR (Local node Repository), which gathers knowledge from several sources and represents it in RDF-Schema. SWAP allows searching for knowledge by using a query language called SeRQL, which is an evolution of RQL.

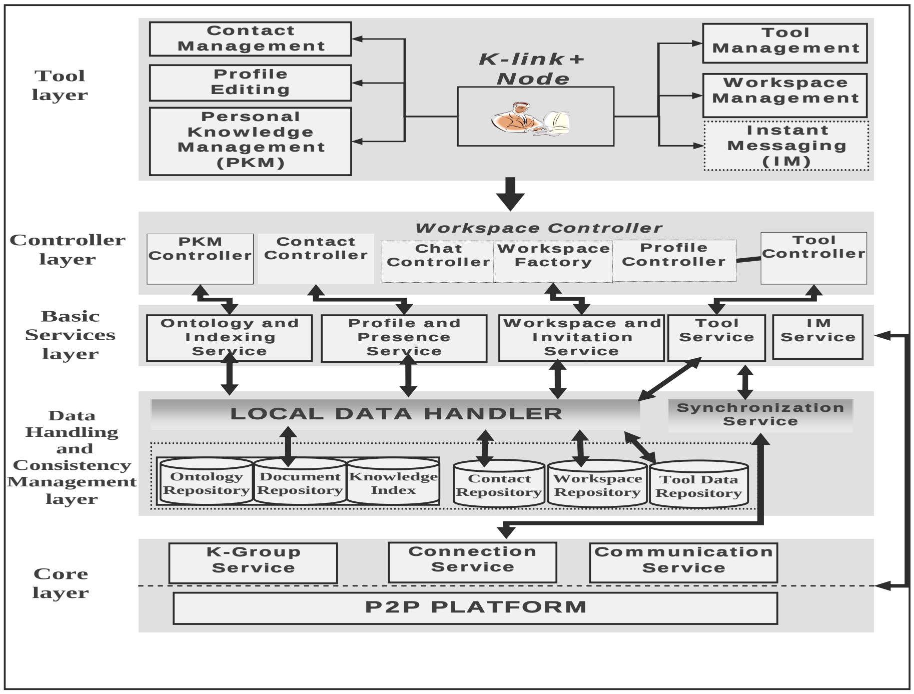
Different from these approaches, *K-link+* does not specifically tackle the problem of ontology mapping, since it can be time consuming thus affecting the requirement of quickness mandatory in a P2P environment. Conversely, we support a "mutual agreement" mechanism among participants since we build ontologies in a democratic way through a distributed voting mechanism.

K-LINK+ ARCHITECTURE

K-link+ is a collaborative P2P system that provides users with a Virtual Office environment in which content can be shared to enable collaborative work, and replicated, to foster peer autonomy. Different applications (document sharing, messaging, shared boards, agenda, etc.) can be integrated within a single environment (a *K-link+* workspace) and new tools can be added as new components to support emerging requirements. In this section, the system architecture is briefly presented. For a more detailed description of the *K-link+* architecture refer to the GridLab website, *http://grid.deis.unical.it/k-link*.

The *K-link+* architecture, shown in Figure 1, is based on five layers including basic grouping and communication services, data handling services, semantics services, workspace management

Figure 1. The K-link+ architecture



services, and a set of high level tools for content sharing and user cooperation.

K-link+ Core Layer

This layer defines the *K-link+* basic services whose implementation can be based on any P2P infrastructure (for the current version of *K-link+*, we use JXTA). Services provided by the *Core Layer* are exploited by higher layers. In particular, the *K-Group Service* allows *K-link+* Nodes (KLNs) to create new *K-Groups*, for example, communities or workspaces. The *Connection Service* allows KLNs to join the *K-link+* network by contacting a *K-link+ Rendezvous*. Features used to send and receive messages are provided by the *Communication Service*.

Data Handling and Consistency Management Layer

This layer is responsible to cope with concurrent access to shared objects, object consistency, and peer synchronization. This layer includes the *Local Data Handler*, which manages a set of local repositories to store information about contacts, workspaces, objects, and so on.

K-link+ Basic Services Layer

The services of this layer manage local and remote operations performed by a *K-link+* user. The *Ontology and Indexing Service* deals with operations involving ontologies (creation, update) that *K-link+* exploits to describe resources semantically. It also copes with the indexing of documents for keyword based searches. The *Profile and Presence Service* manages state check operations and enables users to create and publish their profile within the *K-link+* network. The *Workspace and Invitation Service* handles workspace set up and population by sending invitation messages to other KLNs. The *Tool Service* is used to add new tool instances to workspaces at run time. The *IM (Instant Message) Service* allows KLNs to communicate each other via a chat-like system.

K-link+ Controller Layer

This layer contains a set of controllers through which the system interacts with the *Data Handling and Consistency Management Layer* via a set of services (provided by the *Basic Service Layer*). The *Workspace Controller* manages workspace settings through the creation of *workspace profiles* that contain information about workspace topics, sets of tools, and the IKWs that belong to the workspace. The *Contact Controller* enables IKWs to discover other IKWs on the network and add some of them to a personal *Contact List*. The *PKM Controller* is delegated to manage the *Personal Knowledge* of an IKW. Finally, the *Tool Controller* is responsible for allowing users to handle operations (add, update, remove) on private and shared tools.

K-link+ Tools Layer

This layer enables the user to choose the set of tools to include in a workspace. Basically, *K-link+* enables workspace members to choose among a set of tools (file sharing, shared calendar, contact manager, etc.). Moreover, other tools can be developed and included in the system as components. In fact, the development of a tool in the *K-link+* system can be carried out by third parties with the only requirement that the *K-link+* tool interface must be implemented.

REPLICATION AND CONSISTENCY OF DATA IN K-LINK+

In *K-link+*, several users can work concurrently on the same shared objects. To favor the autonomy of users, the system allows users to create different replicas of the same object, so that they can work on their local copies. As mentioned in the previous section, the purpose of the *Data Handling and Consistency Management* layer is to ensure data persistence, consistency management, and data synchronization. In the context of *K-link+*, we adopt the *sequential consistency* model (Lamport, 1979), which assures that all updates performed on an object are seen in the same sequence by all peers. The model is implemented by associating to each object a KLN (named *Manager*), which is responsible for authorizing object updates and putting them in a given order. In particular, each object is assigned a *VN (Version Number)*, which is incremented after each successful update. To efficiently handle the consistency problem in the P2P environment, *K-link+* defines the following roles that can be assumed by workspace nodes:

- *Creator*. This role is assumed by a KLN that creates a shared object and specifies its *ML (Manager List)*, that is, the list of KLNs that can assume the *Manager* role for this object. Managers are ordered on the basis of their degree of responsibility in managing the object.
- *Rendezvous*. For each workspace, one rendezvous node maintains metadata about all the shared objects in a *Consistency Table* (described below) and provides such information to workspace members. The Rendezvous possesses up-to-date information about objects, in particular the identity of the node which is currently in charge of each object (i.e., the *Current Manager*) and the current VN.
- Manager. An object Manager is a KLN that manages the object life cycle and is contacted by KLNs when they want to propose an object update. An object can be assigned several Managers, but at a given time the *Current Manager*, which is the first online Manager in the ML, is actually responsible for the object. The Current Manager can decide whether or not to authorize an object update, according to the specific set of semantic rules associated to the object. KLNs are informed about the identity of the Current Manager by the Rendezvous.

- Broker. It is a KLN that maintains an updated copy of an object and can forward it to other KLNs. Whereas the Manager is a *static* role (i.e., it is assigned at object creation time), the Broker role is *dynamic*, since it is assumed by a node whenever it maintains an updated copy of the object.
- Worker. It is an ordinary KLN that can operate on an object, and possibly issue update proposals to the *Current Manager*. Workers can obtain an updated copy of an object by a *Broker*.

KLNs, as well as the *Rendezvous*, maintain information about the state of objects in a *Consistency Table*, whose structure is shown in Table 1. Each object is permanently associated to a *Consistency Entry* identified by a unique *ID* which is assigned when the object is created. Moreover, to keep trace of the object state, the Consistency Entry contains the Version Number, which is incremented at each object update, the *ID* of the Current Manager and the *Manager List*.

The definition of the mentioned roles enables three different kinds of interactions as shown in Figure 2. A *static centralized* approach is adopted when Workers interact with the unique and static Rendezvous. The aim of the Rendezvous is solely to provide information about Current Managers and object versions, but the management of each single shared object is delegated to the corresponding Current Manager. Such way of managing objects enables a *dynamic centralized* paradigm because object management can be dynamically switched among different Managers. This way, two common issues are solved: (i) we avoid the presence of a central bottleneck which would be originated if all objects were managed by a single node; (ii) we cope with the volatile nature of P2P networks, in which peers with Manager responsibilities can leave the network at any time.

A *decentralized* model is exploited by Brokers to provide updated object copies to Workers in a P2P fashion. We argue that the use of these three paradigms can represent a valid trade-off among different ways to face distributed object management. A detailed description and a performance evaluation of the consistency protocol can be found in (Mastroianni et al., 2007).

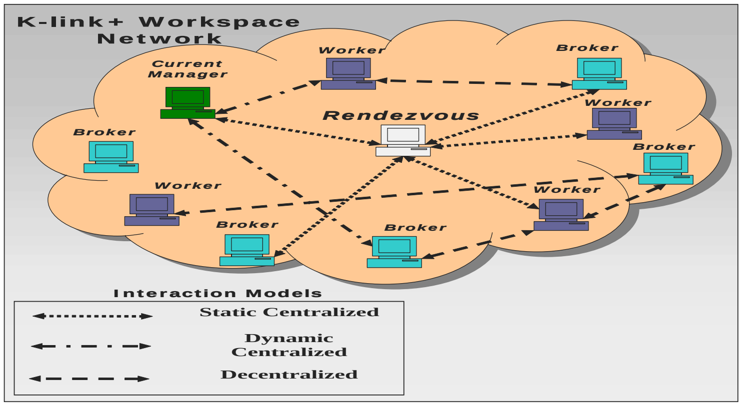
THE K-LINK+ ONTOLOGICAL FRAMEWORK

Most of the current approaches to collaborative work--while being worthwhile--do not take into account semantic aspects of knowledge management. A complete and useful collaborative system should be able to deal with both information and knowledge on a semantic basis. In recent years, the knowledge management community has been considering ontologies as an adequate support to harness semantics conveyed by information (Fensel, 2001). An ontology is an abstract representation of a knowledge domain which allows its modeling in terms of concepts, relationships

Table 1. Consistency table

Field	**Description**
Object ID	A unique ID that identifies the shared object
VN (Version Number)	Object version number, incremented at each object update
Current Manager	The first online node contained in the ML. This node is responsible for the shared object.
Manager List	An ordered list of nodes that can assume the Current Manager role
Creator	The node that creates the object

Figure 2. The K-link approach to data consistency. Different kinds of arrows are used to show the different models of interaction among K-link+ nodes



between concepts, class hierarchies, and properties, and permits reasoning about the represented knowledge. Ontologies also offer a way for defining a set of possible instances of concepts and relationships, thus providing links between the model and the modeled reality. *K-link+* provides an ontology framework organized in two layers as shown in Figure 3.

The first layer contains an UO and a set of COKEs represented as ontology classes.

The UO represents a basic set of meta-concepts relevant for an organization that are defined by domain experts.

Definition 1 (UO) (Upper Ontology)

- An UO is a five-tuple of the form UO=$\langle C,\leq_C, R,\leq_R,\varphi_R\rangle$ where:C is a set of concepts, defined by domain experts, which describe knowledge domains of interest for the organization.
- R:C→ C is a set of built-in relationships among concepts in C (e.g., represents, same-as, different-from, contains, associates, part-of, isa, related-to) arranged in hierarchies by means of the partial orders $\leq_C$, $\leq_R$.
- The function $\varphi R : R \rightarrow C\times C$ associates each relation $r\in R$ to its domain *dom*(r)=$\pi 1(\varphi R(r))$ and range *range*(r)= $\pi 2(\varphi R(r))$. The initial set of relationships included in the UO can be customized according to organizational needs.

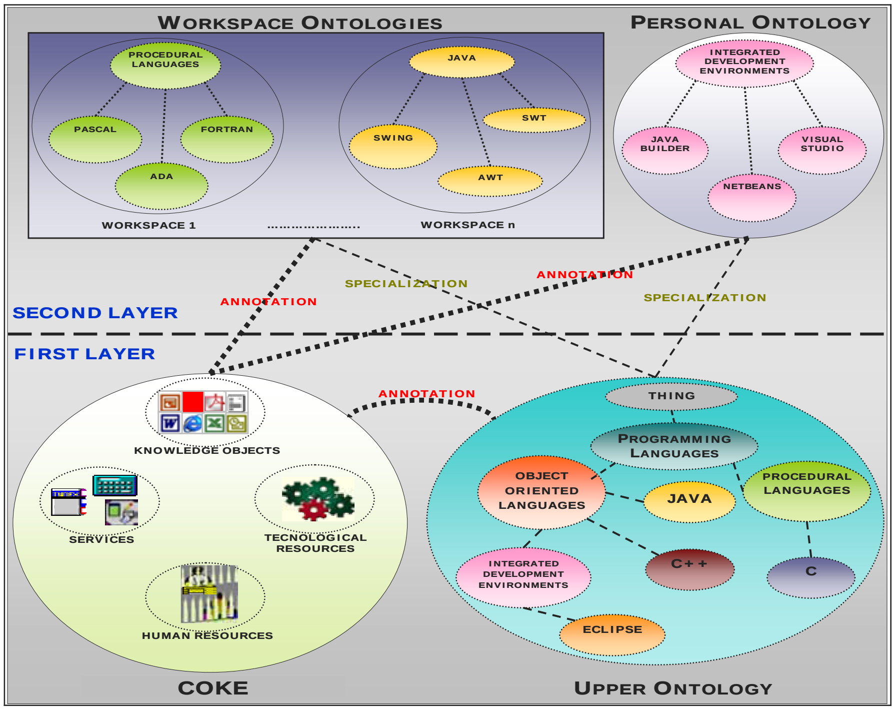
The UO can be viewed as a semantic network of concepts similar to a thesaurus. For instance, the UO for a health care organization will contain concepts and relationships related to diseases, clinical practices, drugs, surgery, and so forth.

COKEs aim at giving a semantic description of some organizational sources of knowledge.

We identified four COKEs:

- *The Human Resource COKE* describes organizational groups (Community of Practices, Project Teams) and individuals. For each IKW, personal data, skills, group memberships, and topics of interest are represented. A group is described through its objectives and topics and contains information about the participant IKWs.
- The *Knowledge Object* COKE describes textual documents, database elements, emails, web pages, through metadata (e.g., data of creation, document type, author, URI). In particular, the framework exploits this COKE for enabling advanced search and retrieval capabilities in *K-link+*.

Figure 3. The user view of the K-link+ Ontology Framework. This figure shows the relationships between ontologies belonging to the two layers. The user's Personal Ontology and the Workspace Ontologies are specializations of one or more UO concepts. For example, the shown Personal Ontology specializes the UO concept Integrated Development Environment. COKE instances are annotated to Upper, Personal, and Workspace ontologies concepts.



- The *Technological Resource* COKE describes tools through which knowledge objects are created, acquired, stored, and retrieved. For each tool, this kind of COKE provides information about version and features.
- The *Services* COKE describes services, provided by IKWs, in terms of provided features and access modalities.

However, each COKE has its own definition also in terms of attributes. For instance, the COKE KO, which describes different types of unstructured textual documents, contains attributes such as *name*, *size*, *author*, and so forth.

Instances of the same COKE share the same structure, so allowing for the management of implicit and explicit knowledge stored in structured, semi-structured or unstructured formats.

The *Annotation* relationships can be defined between the COKEs and the UO, which means that COKE instances can be semantically associated to the concepts of the UO by following the principle of superimposed information, that is, data or metadata "placed over" existing information sources (Maier et al., 1999). For instance, let us consider a human resource skilled in Java. An annotation relationship can specify that this human resource has a semantic annotation to the *Programming Languages/Object Oriented Languages/Java* concept contained in the UO. This way, *K-link+* can exploit this annotation to search human resources skilled or interested in Java. In general, queries can be performed using specific tools able to retrieve COKE instances, belonging to one or more of the four above mentioned classes, which are related to a specific concept.

The second layer of the ontology framework is composed of a set of UO extensions called *Workspace Ontologies*, and one or more *Personal Ontologies* for each IKW.

A PO (Personal Ontology) is the specialization of one or more UO concepts and is used to deepen a particular aspect of the knowledge domain in which an IKW is interested.

Definition 2 (PO)

A PO is a 4-tuple of the form *PO=<UO,UOC', UOP,UOR'>* where:

- UO is the UO as described in Definition 1.
- UOC' is the set of new concepts added by the peer.
- UOP is a set of attributes for concepts in UOC' added by the peer.
- UOR' is the set of relationships among concepts added by the peer.

A PO operates at individual level as semantic support for personal information management of IKWs that use the Organizational Ontology and need to extend it for their specific goals in the organizational activities. The PO can be used to annotate KOs with respect to PO concepts that describe their topics. The creation of an annotation is supposed to reflect the content of a KO and establish the foundation for its retrieval when requested by an IKW. This way unstructured information can be semantically enriched and its retrieving can be performed by specifying ontology concepts instead of keywords. However, it is expected that the annotation process can be automated to decrease the burden of the IKW. For this purpose, a method based on keyword extraction, as in (Popov et al., 2003) can be adopted. For instance, keywords extracted from the text of the KO can be viewed as descriptors of the content of the KO. Therefore, annotations between such descriptors and ontology concepts can be created.

In order to enhance social aspects of OKM, the framework allows users to create WOs (Workspace Ontologies). A WO specializes in one or more UO concepts and is used to support workspaces. IKWs can annotate COKEs instances relevant to the workspace, with respect to WO concepts, and retrieve them by specifying ontology concepts instead of keywords.

Definition 3 (WO)

A WO is a 2-tuple of the form *WO=<WB,WT>* where:

- WB has the same structure of the PO defined in Definition 2.
- WT is a set of basic concepts concerning workspace topics on which there is agreement among workspace members.

The relationships existing between the UO and the Workspace and Personal Ontologies are called *specializations* since such ontologies specialize in one or more UO concepts. For example, in Figure 3 the WO of *Workspace 1*, focused on procedural languages, specializes in the corresponding UO concept (*procedural languages*) by adding information describing further types of procedural languages.

HANDLING ONTOLOGY DRIFT IN *K-LINK+*

Although the structure of the proposed ontology framework has been designed beforehand, static or fully predefined ontologies in a dynamic distributed environment cannot satisfy the ever-changing requirements of an organization.

In *K-link+*, IKWs are allowed to propose extensions or modifications of an ontology according to their needs. Upon acceptance of such proposals, ontologies evolve in a collaborative and emerging way.

Ontology drift, that is, the evolution of an ontology, is managed in *K-link+* through a distributed voting mechanism (Ge et al., 2003). In *K-link+*, for each voting procedure, a *voting chair* is in charge of permitting or denying the voting process, collecting results and propagating them to participants. Before initiating a new voting procedure, an IKW obtains the authorization from the chair if there are no other voting procedures in progress.

An update proposal related to the UO is accepted if, within a specified amount of time, the majority of all the *K-link+* members, regardless of their workspace memberships, agree with the proposal. Similarly, to be approved, an update proposal related to a WO needs to be accepted by the majority of the workspace members.

A voting process within *K-link+* is divided into three phases:

1. *Set up phase*: in this phase the voting initiator contacts the voting chair which, if there are no pending voting procedures, forwards a “request for vote” message to all the involved IKWs. This message contains information about the update proposal along with the voting deadline.
2. *Voting phase*: IKWs vote to confirm or reject the ontology update proposed, and send their vote to the chair.
3. *Scrutiny phase*: when the deadline expires, the chair counts the votes and sends the result to the involved IKWs. If the update proposal has been accepted, the UO or WO is appropriately modified.

When IKWs, which were previously offline, reconnect while a voting procedure is in progress, they are made aware of the voting proposal by the voting chair and can join the voting process. If they reconnect when the voting procedure has terminated, they receive from the chair a notification containing information about the updated version of the ontology.

K-LINK+: A MOTIVATING EXAMPLE

As mentioned before, the Virtual Office environment provided by *K-link+* is based on the concept of *workspace*. A workspace can be viewed as a common *work area* accessible at any time from everywhere and composed by COKE instances (e.g., human resources, knowledge objects) that are annotated to WO concepts. A workspace provides a set of tools for creating and storing knowledge objects and for using services useful for the workspace members. Each KLN can be a member of a workspace under the following profiles:

- A *Workspace Manager* is a workspace administrator endowed with full capabilities for adding tools, inviting other KLNs or modifying the WO settings.
- A *Workspace Participant* is a workspace member with reduced but extensible (under Manager control) capabilities.

A workspace set-up procedure can be performed whenever a new organizational task must be carried out. For instance, let us consider a software company that must develop a graphical interface, written in Java, able to support the design of business workflows in a distributed environment. To deal with this task and fulfill the commitment requirements, the project leader can set up a proper workspace. The workspace must be associated to one or more concepts of the UO, and the WO represents a specialization of these concepts. For example, *Workspace n* of Figure 3 specializes in the *Java* concept by adding child concepts related to some available Java graphical libraries. A workspace creation is automatically followed by the creation of a group ontology instance in the COKE human resources ontology. This instance is semantically annotated to the *Java* UO concept.

Hereafter, by using the *K-link+* functionalities, the project leader:

- Chooses the existing literature and document templates concerning the project topic. In this case, it is valuable to populate the workspace document base with knowledge objects related to the concepts defined in the WO. Interesting knowledge objects can be discovered by the *K-link+ File Sharing Tool* which is able to handle keyword and semantic based searches.
- Defines an appropriate team of IKWs whose skills can be exploited to accomplish the commitments within the deadline. For the above mentioned example, the *K-link+* system should be able to find, through the ontology support, at least the following IKW profiles: experts in Java programming, experts in graphical interface development, and experts in workflow systems. People having the selected profiles become members of the workspace after receiving invitation messages sent by the workspace manager through the *K-link+ workspace and invitation service*.
- Designs an activity plan and assigns single activities to the IKWs by sending proper messages.
- Chooses a set of services for supporting the project. For example, the services ontology should contain a reference to a CVS (Concurrent Versions System) dedicated to the project. Services can be directly embedded in the *K-link+* workspace perspective that provides IKWs with a common work environment which gathers the needed applications.

Finally, the workspace manager or its delegates choose a set of tools through which the workspace members can perform the actual work. Such tools can be selected among a basic set of tools with which *K-link+* is endowed (e.g., file sharing, shared calendar, shared browser, sketch pad, etc.). Through these tools, IKWs can set project deadlines, project meetings, exchange documents, and so on. Furthermore, it is also possible to develop specific tools that can be plugged into the system as libraries at run-time. When a new tool is added to a workspace, the workspace members will automatically be informed and a local instance of the tool will be created. Afterwards, each tool update (e.g., adding a new project meeting to the shared calendar tool) will be forwarded to the workspace members that can store new information locally.

Each workspace is described by a *workspace profile* that includes the UO concept used to specialize in the WO, information about the participant IKWs and services and tools of the workspace. After creating the WO, its concepts can be used for semantically annotating new COKE instances created within the workspace. For example, a tutorial on the use of the SWT Java library can be annotated to the *SWT* WO concept.

K-link+ can be profitably used as an effective cooperative platform in organizations because:

1. It enables cooperation among IKWs by offering them an integrated and shared work environment in which they can concurrently work on the same shared objects and handle different sources of knowledge within the same environment. This way, the system avoids users to run several applications that cannot exchange data.
2. It allows providing contents (described by COKEs) with an immediate semantic meaning, by *annotations*. The principle followed by annotations is aimed at providing information with a sort of superimposed meaning. This aspect is particularly important since today information is for the most part in unstructured form and its retrieval mainly relies on statistical approaches (e.g., Information Retrieval approaches) that are not able to “interpret” its semantic meaning.
3. It fosters the retrieval of contents on a semantic basis by enabling concept based search. This is accomplished by coupling a shared

representation of organizational source of knowledge (e.g., COKE ontologies) with ontologies.

4. It enables the reusability of organizational knowledge. For instance, in the described example, if the company will deal in the future with a similar commitment, such as the development of a new Java application, a search can be issued for a workspace that contains in its profile concepts like *Java*, *SWT, Swing* and so forth. Thereafter the project leader can select the documents, templates and human resource profiles that can profitably be reused for the new project.

The abovementioned aspects make *K-link+* a system very useful for small-medium enterprises composed of different divisions that need to cooperate, share and exchange knowledge.

CONCLUDING REMARKS

This chapter discusses how ontologies can be combined with the P2P computing paradigm to support knowledge management within organizations.

In particular, ontologies have been adopted to define an ontological framework that allows peers to conceptualize knowledge domains in which they are interested, and to semantically annotate COKE instances w.r.t. ontology concepts. The framework has been designed on two levels. Each organization can define its own UO covering the domains of interest for the organization. Moreover, the COKE ontologies aim at representing a "consensus" in defining a structure for several sources of unstructured knowledge (e.g., knowledge objects). This unified view helps managing and sharing both structured and unstructured knowledge.

The second layer represents the part of the framework which fosters the creation of new organizational knowledge since it allows users to specialize in aspects generally covered by the UO. This can be done collaboratively through WOs. Workspace Ontologies allow participants of the same group to adopt the same terminology for describing knowledge of interest. This way, aspects of a particular knowledge domain (covered by a workspace) emerge and are defined on a collaborative basis. To enable more flexibility, the framework also allows individuals to define their own ontologies. Through *Personal Ontologies*, an individual can manage its personal knowledge according to their view on a particular knowledge domain.

A very prominent feature of the defined framework is the *Annotations* mechanism. Annotations allow users to associate COKE instances to ontology concepts. They capture and harness the semantic meaning of a piece of knowledge that can be a Knowledge Object, a Service, and so forth. This feature is very striking since today the main issue related to the retrieval of information comes from the fact that information is for the most part unstructured. The framework allows users to capture and/or update implicit knowledge connected with explicit knowledge contained in unstructured content of COKE instances.

On the other side, the P2P computing paradigm has been shown to be a valuable support for today's IKWs that often work away from their usual workplace. In particular, this chapter describes how the P2P can be exploited to implement a distributed VO whose aim is to support collaborative work within *workspaces*. Within workspaces peers can autonomously manage and share knowledge without relying on any central entity thanks to a hybrid content consistency protocol that guarantees consistency of shared contents and synchronization among peers.

The combination of the two abovementioned technologies (ontologies and P2P) allows users to implement the distributed knowledge management model that naturally fits the process of creating new knowledge by allowing IKWs, on the one side to manage their knowledge without relying on any imposed schema and on the other side to exchange and retrieve knowledge on a semantic basis by exploiting ontologies.

Chapter 5.12

Organizational Culture for Knowledge Management Systems:

A Study of Corporate Users

Andrew P. Ciganek
Jacksonville State University, USA

En Mao
Nicholls State University, USA

Mark Srite
University of Wisconsin-Milwaukee, USA

ABSTRACT

Knowledge is increasingly being viewed as a critical component for organizations. It is largely people-based and the characteristics of groups of individuals, in the form of organizational cultures, may play a key role in the factors that lead to either the acceptance or rejection of knowledge management systems (KMS). The primary objective of this research is to explore how dimensions of organizational culture influence factors that lead to the acceptance of KMS. While researchers have agreed that culture plays an important role in KMS, the literature has only recently begun to examine organizational culture within this context. We examined the effects of three dimensions of organizational culture through a research model that was tested and analyzed utilizing a field survey of corporate knowledge management users. Our results indicated that both process-oriented and open communication system organizational cultures significantly influenced the factors that led to the acceptance of KMS.

INTRODUCTION

Organizational culture can either facilitate or be a major barrier to knowledge management system (KMS) acceptance (De Long & Fahey, 2000;

Grover & Davenport, 2001; Ruppel & Harrington, 2001). On February 1, 2003, the space shuttle Columbia was lost during its return to Earth. The Columbia Accident Investigation Board (CAIB) concluded that NASA's organizational culture as well as the piece of Columbia's foam insulation that fell off during launch shared equal blame for the tragedy (CAIB, 2003). According to the CAIB, the prevailing culture at NASA was of a mindset that accidents were inevitable, which led to the unnecessary acceptance of known and preventable risks. Although a KMS to assist with hazard identification and risk assessment was available at NASA (the Lessons Learned Information System), personnel only used that system on an *ad hoc* basis which limited its usefulness (CAIB, 2003). NASA's organizational culture consequently interfered with open communication, impeded the sharing of lessons learned, caused duplication and unnecessary expenditure of resources, and prompted resistance to external advice (CAIB, 2003).

The Columbia incident is an illustration of knowledge management system use failure. The acceptance of KMS, however, is a pressing issue in organizations (Kwan & Balasubramanian, 2003; Money & Turner, 2005). As knowledge is increasingly viewed as a critical activity for decision making (Markus, Majchrzak, & Gasser, 2002; Miranda & Saunders, 2003), organizations are becoming more receptive to using technologies to facilitate knowledge management (Schultze & Leidner, 2002). KMS are often employed to enhance organizational performance (De Long & Fahey, 2000) and are a reason why the KMS market has become one of the fastest growing areas in software development. While it is widely recognized that information technologies have the potential to facilitate knowledge management, the management of knowledge-based systems is an intricate process that involves a complex interplay of technical and social factors.

Recent studies have begun to investigate a variety of social factors and phenomena related to knowledge creation, sharing, and transfer. For example, Wasko and Faraj (2005) studied how individual motivations and social capital influence knowledge sharing in KMS. Ko, Kirsch, and King (2005) found that individual communication capabilities, motivations, and interpersonal relationships affected the transfer of complex enterprise software knowledge. Bock, Zmud, Kim, and Lee (2005) found that subjective norms and organizational climate had a significant impact on people's intention to share knowledge. Kankanhalli, Tan, and Wei (2005) similarly discovered that several social factors, including prosharing norms, influenced knowledge contribution. These studies provided strong empirical evidence of the social influences in knowledge management. Some of the factors that have been examined are conceptually similar to organizational culture dimensions that have been identified in the management literature. A more systematic study of organizational culture on KMS acceptance would provide theoretical congruence to this recent literature.

The primary objective of this research is to explore how dimensions of organizational culture influence the factors that lead to the acceptance of KMS (e.g., perceived usefulness, perceived ease-of-use, perceived behavioral control, subjective norms). In our investigation, organizational culture is postulated as a distal determinant for an employee's intention to use a KMS. In the next section, we present a literature review to support our hypotheses, followed by a discussion of our research methodology. We then empirically test our hypotheses with a field survey of corporate KMS users, discuss the results, and finish with some concluding remarks.

LITERATURE REVIEW

Knowledge Management Systems

Knowledge is information that exists in the mind of individuals (Alavi & Leidner, 2001; Berman-

Brown & Woodland, 1999; Grover & Davenport, 2001; Ruppel & Harrington, 2001). Given the nature of knowledge, which is created and applied in the minds of human beings, it is extremely difficult to manage and control (Alvesson & Karreman, 2001; Grover & Davenport, 2001). Indeed, an organization's efforts to facilitate knowledge sharing can be a "central competitive dimension" for a firm (Kogut & Zander, 1992, p. 384). Consequently, KMS are an organization's efforts to facilitate knowledge sharing through the use of information technology (IT) in order to obtain organizational benefits.

There are a variety of KMS that exist, such as knowledge repositories, corporate directories, and knowledge networks (Alavi & Leidner, 2001; Grover & Davenport, 2001). Knowledge repositories, the type of IT examined in this study, are the most common KMS in Western organizations (Grover & Davenport, 2001). These systems are typically used to capture knowledge from employees for subsequent and extensive use by others within the organization to assist in decision-making. Examples of knowledge that are contained in such systems may range from best practices and lessons learned to organizational strategies and recruitment efforts.

There have been a number of KMS reviews and meta-analyses done in the information systems (IS) domain. Alavi & Leidner (2001) provided a review of the knowledge management literature in different academic disciplines that identified some key areas of research, which included the concept of knowledge in organizations, knowledge management processes (i.e., knowledge creation, storage/retrieval, and transfer), and KMS. They indicated that while the design of a KMS is important, the extent of use by its intended users would also have a significant impact on KMS acceptance. Schultze & Leidner (2002) also examined knowledge management research in the IS area. They identified and classified knowledge management research into four theoretical streams, which are normative, interpretive, critical, and dialogic discourses. Subsequent case-based research (Alavi, Kayworth, & Leidner, 2005-2006; Leidner, Alavi, & Kayworth, 2006) has found that differences in organizational cultural values leads to different uses of KMS. These research efforts demonstrated the importance and saliency of KMS in the IS context.

Organizational Culture

NASA's organizational culture had as much to do with this accident as foam did. Columbia Accident Investigation Report (CAIB, 2003)

As suggested in the quotation above, organizational culture is important and inextricably linked to KMS within organizations (Alavi & Leidner, 2001; Alvesson & Karreman, 2001; Cronin, 2001; De Long & Fahey, 2000; Grover & Davenport, 2001; McDermott, 1999; Tanriverdi, 2005). Organizational culture has been extensively studied in management research, and therefore, it is surprising that the relationship between KMS and an organization's culture has not been more thoroughly explored in the IS literature. Culture has historically been a factor that has received insufficient attention in the IS acceptance literature (Cooper, 1994; Robey, Wishart, & Rodriguez-Diaz, 1995a; Ruppel & Harrington, 2001), but is increasingly being viewed as a key ingredient for an organization's ability to embrace KMS (Cronin, 2001).

Organizational culture is widely believed to be a major barrier to KMS acceptance (De Long & Fahey, 2000; Grover & Davenport, 2001; Ruppel & Harrington, 2001). Without a match between an organization's culture and the cultural assumptions embedded within an IT innovation, costly implementation failures are likely to happen (Ruppel & Harrington, 2001). For example, in organizational cultures that are not suited to share and utilize knowledge (e.g., an organization where miscommunication is common and mistrust is prevalent), acceptance of a KMS can be problematic (Ruppel & Harrington, 2001). Without acknowledging cultural mismatches or modifying the organizational culture to better fit the IT, the impact on the organization could be disastrous, as evidenced in the Colombia tragedy.

Hofstede (1991) views culture as being collective, but often intangible and is what distinguishes one group, organization, or nation from another. There are two main elements of culture: the internal values of culture (invisible) and external elements of culture (visible), which are known as practices (Hofstede, 1991). Practices are particularly important to investigate because they are the most direct means for changing behaviors needed to support knowledge creation, sharing, and use (De Long & Fahey, 2000). Hofstede, Neuijen, Ohayv, and Sanders (1990) measured the perceived practices in employees' work situations in 20 organizational units and discovered six dimensions underlying organizational culture. Contrary to his dimensions of national culture (Hofstede, 1991), these organizational dimensions deal with key sociological issues. In favor of depicting a more manageable research model, we examine three dimensions of organizational culture, process-oriented vs. results-oriented, employee-oriented vs. job-oriented, and open communication systems vs. closed communication systems.

Technology Acceptance

Previous findings from the technology acceptance literature, which has been widely popular in the IS field for the past few years, suggest that for an advantage to be attained, the technology in question must be accepted and used (Venkatesh, Morris, Davis, & Davis, 2003). Organizations typically employ KMS to leverage their collective knowledge for competitive advantage (Alavi & Leidner, 2001). There has been relatively little research, however, that explicitly examines the influence that dimensions of organizational culture have on technology acceptance.

In the technology acceptance literature, a variety of psychological constructs have been examined with the goal of understanding how and why individuals adopt new information technologies. This has generated several competing models of technology acceptance, each with different sets of determinants for acceptance (Venkatesh et al., 2003). The following is a concise review of attributes that have been consistently shown to account for a significant amount of variance in the prediction of intentions and behaviors (Rogers, 2003; Tornatzky & Klein, 1982; Venkatesh et al., 2003).

Attributes of the Acceptance and Use of Technology

Based upon conceptual and empirical similarities across eight prominent models in the user acceptance literature, Venkatesh et al. (2003) developed a unified theory of individual acceptance of technology (the unified theory of acceptance and use of technology or UTAUT). The UTAUT theorizes four constructs having a significant role as direct determinants of acceptance and usage behavior: performance expectancy, effort expectancy, social influence, and facilitating conditions. Although we did not test the full UTAUT because the model was not published at the time of our data collection, each of the constructs that we did examine was conceptually similar. The four constructs that we utilized and their relationships to the constructs of the UTAUT model are discussed next.

The first construct examined in our model is perceived usefulness. Originally proposed in Davis' (1989) technology acceptance model (TAM), this is contained within the UTAUT construct of performance expectancy and is defined as "the degree to which an individual believes that using the system will help him or her to attain gains in job performance" (Venkatesh et al., 2003, p. 447). The second construct examined in our model is perceived ease of use. This construct, originally in Davis' (1989) TAM, is incorporated into UTAUT as part of effort expectancy which is defined as "the degree of ease associated with the use of the system" (Venkatesh et al., 2003, p. 450). Perceived ease of use has a significant direct effect on perceived usefulness (Davis, 1989).

The third construct examined, perceived behavioral control, indicates that a person's motivation is influenced by how difficult the behaviors are perceived to be, as well as the perception of how successfully the individual can, or cannot, perform the activity. Perceived behavioral control, originally in the theory of planned behavior (TPB) (Ajzen, 1985; Ajzen & Madden, 1986), is part of UTAUT's facilitating conditions construct which is defined as "the degree to which an individual believes that an organizational and technical infrastructure exists to support the use of the system" (Venkatesh et al., 2003, p. 453). Subjective norms, the fourth construct examined in this model, deals with the influence of important others, such as coworkers, supervisors, and top management. Subjective norms, originally in Fishbein & Ajzen's (1975) theory of reasoned action (TRA), are incorporated into UTAUT's construct of social influence, which is defined as "the degree to which an individual perceives that important others believe he or she should use the system" (Venkatesh et al., 2003, p. 451).

RESEARCH HYPOTHESES

Organizational Culture's Impact on Perceived Usefulness

An organization's attitude toward change, often elicited and reflected by the introduction of technology innovations, impacts the adoption of these technologies (Damanpour, 1991). Some organizations are relatively *process-oriented* and may have conservative attitudes toward innovation and its associated risk, exerting minimal effort while preferring the use of existing or well-known methods (Hofstede et al., 1990). Such organizations innovate only when they are seriously challenged by their competition or by shifting consumer preferences (Miller & Friesen, 1982). In contrast, *results-oriented* organizations are risk-oriented and foster an environment that encourages and actively supports the use of innovative techniques for the survival and growth of the organization (Hofstede et al., 1990). As an organization's policies and practices are perceived by employees to encourage, cultivate, and reward their use of a technology (e.g., KMS) the stronger that culture will be for the implementation of that technology (Klein & Sorra, 1996). Organizations that promote innovativeness and a willingness to try new things among their employees have been found to have better success with a KMS implementation (Ruppel & Harrington, 2001). Such organizations and individuals usually try to obtain a competitive advantage by routinely making dramatic innovative changes and taking the inherent risks associated with those innovations. Consequently, employees in a results-oriented organization are likely to believe that using KMS would enhance their job performance. On the other hand, knowledge sharing is risky from an individual employees' perspective because their value depends largely on the knowledge they possess (Stenmark, 2000). A work environment that is more process-oriented, consequently, would view KMS as a threat and to be less useful for making decisions. This leads to the following hypothesis:

H1: *Employees who perceive their work environment to be more* ***results-oriented*** *will have higher levels of perceived usefulness than employees who perceive their work environment to be more* ***process-oriented****.*

Organizational Culture's Impact on Perceived Ease of Use

At one end of a continuum, job roles in an organizational environment are routine and similar from one day to the next (*process-oriented*) (Hofstede et al., 1990). Employees in this environment are resistant to change, new technology, and risk and will only exert minimal effort. At the opposite end of this continuum, job roles bring forth new challenges daily (*results-oriented*) (Hofstede et al., 1990). Employees in this results-oriented environment embrace risk, are comfortable in unknown situations, and are likely to more quickly exploit any opportunity that a technology may offer. These individuals are likely to have more experience using innovative or relatively complex technologies, and as a result, have a relatively high belief that using other complex technologies would not be difficult. In fact, complexity is the degree to which an innovation is perceived as being difficult to use and has the opposite meaning of ease of use (Davis, Bagozzi, & Warshaw, 1989; Moore & Benbasat, 1991; Thompson, Higgins, & Howell, 1991). Therefore, employees who work in an environment that is characterized as a results-oriented organization where using new or complex technologies in their daily tasks is common are more likely to believe that KMS are easy to use. Hence:

H2: *Employees who perceive their work environment to be more* ***results-oriented*** *will have higher levels of perceived ease of use than employees who perceive their work environment to be more* ***process-oriented****.*

Organizational Culture's Impact on Perceived Behavioral Control

When employees are asked to put what they know into a KMS, they tend to feel as if they have lost ownership of the knowledge that they alone had previously controlled (De Long & Fahey, 2000). Individuals tend to resist such systems because when giving up control of their knowledge they may perceive their worth as an employee to be marginal, which is only propagated by the understandable fear that their job position has become interchangeable. In such circumstances an organization's culture is critical for the acceptance of KMS. As stated earlier, *results-oriented* organizations are risk-oriented, fostering an environment of daily challenges where employees feel comfortable in unknown situations (Hofstede et al., 1990). Although employees in results-oriented organizations may encounter more risky events, their capacity to tolerate risks is much stronger. Employees in this type of risk inclined environment would likely have strong beliefs in their ability to control outcomes (Delfabbro & Winefield, 2000) and hence, will be less worried about the potential negative issues associated with sharing knowledge. The more control an employee thinks they possess, the greater should be that person's perceived control over their behavior (Ajzen & Madden, 1986). Therefore, employees that work in an environment that is characterized as a results-oriented organization would believe that they can control the technology they use, which would make them more likely to use KMS. Hence:

H3: *Employees who perceive their work environment to be more* ***results-oriented*** *will have higher levels of perceived behavioral control than employees who perceive their work environment to be more* ***process-oriented****.*

Environments that typically do not favor KMS emphasize unilateral control, have high stakes for winning and losing, and attempt to minimize negative emotions (Ruppel & Harrington, 2001). Competition thrives in such environments and mistrust in others is high as sharing information or helping fellow employees is frowned upon because it creates a disadvantage for the employee being generous. A *job-oriented* environment exemplifies this scenario as it is an atmosphere where employees feel pressured to complete work (Hofstede et al., 1990).

On the other hand, an *employee-oriented* environment is one where individual personal problems are addressed and the organization has a genuine concern for the employee's welfare (Hofstede et al., 1990). This is critical particularly in the acceptance of KMS where employees must be able divulge, support, and trust the knowledge provided by other employees via the technology. The human relations management and job enrichment literatures (Hackman & Oldham, 1980) suggest that intrinsic rewards (e.g., employee of the month recognition) are at times more important than extrinsic rewards (e.g., salary raises, promotion). Resource-based theory also acknowledges the vital role that human assets/resources play in the contemporary hypercompetitive external environments where progressive organizations strive to keep their employees satisfied and thus retain top talent. Indeed, Ruppel & Harrington (2001) found that early adoption of KMS was most likely to occur in organizations where the culture was characterized as having a high concern for its employees and a setting of mutual confidence and trust. Consequently, employees who work in an environment that is characterized as an employee-oriented organization would be more likely to believe that they have access to greater opportunities and resources to perform a behavior than in a pressure-filled, job-oriented environment. Hence:

H4: *Employees who perceive their work environment to be more* ***employee-oriented*** *will have higher levels of perceived behavioral control than employees who perceive their work environment to be more* ***job-oriented****.*

Organizational Culture's Impact on Subjective Norms

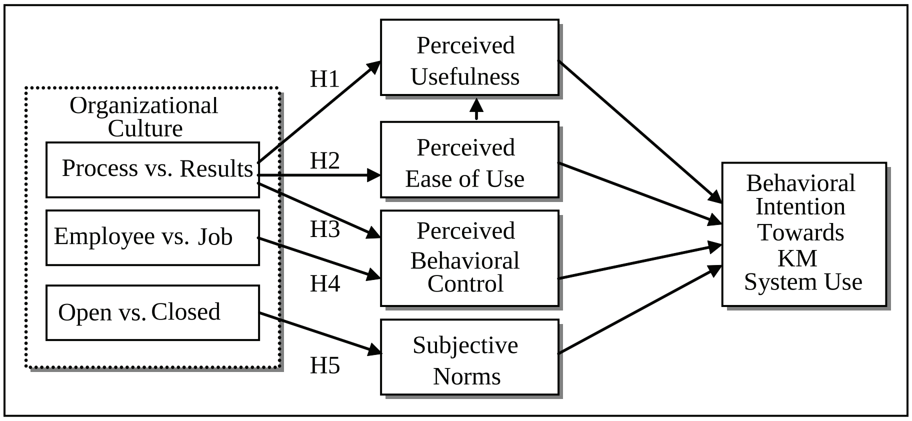
An organizational culture that discourages open communication engenders a context that undermines knowledge sharing (De Long & Fahey, 2000). This is similar to a *closed communication system*, an environment that is secretive and reserved and also one in which it takes a relatively long time for employees to "fit in" (Hofstede et al., 1990). For KMS to be widely accepted within an organization, it should have a culture that supports knowledge sharing from a wide spectrum of coworkers, supervisors, and managers. Without this support, employees may not be willing to share and disseminate their knowledge and experiences, thus making the KMS essentially useless. Indeed, instilling a culture of sharing and maintaining information is critical for KMS acceptance.

An *open communication system*, alternatively, is an environment that is characterized as being open to newcomers and outsiders where it takes a relatively short time for employees to feel comfortable in the organization (Hofstede et al., 1990). Employees in this type of environment are likely to more willingly share their experiences and to support one another when attempting to make decisions on complex and unknown topic areas (e.g., relevance and mastery of new technologies). It is reasonable to expect that users of KMS would be more willing and prepared to assume any challenges posed by the new technology environment in view of the support that they can expect from their colleagues. Employees who work in an environment characterized by an open communication system, therefore, are more likely to be influenced by the opinions of important others and be more likely to use KMS. Hence:

H5: *Employees who perceive their work environment to be more* ***open*** *will have higher levels of subjective norms than employees who perceive their work environment to be more* ***closed****.*

Consistent with the TAM, the TRA, the TPB, and the UTAUT, perceived usefulness, perceived ease of use, perceived behavioral control, and subjective norms are expected to influence behavioral intentions. Following the technology acceptance model, perceived ease of use is expected to influence perceived usefulness. These relationships as well as our research hypotheses are depicted in the proposed theoretical model (Figure 1).

Figure 1. Theoretical model



METHODOLOGY

This research utilized a questionnaire borrowing scales from prior literature. We adopted measures of organizational culture from Hofstede et al. (1990), perceived usefulness, perceived ease of use, and behavioral intention to use from Davis (1989), and perceived behavioral control from Ajzen & Madden (1986). The subjective norms construct contains two dimensions: normative beliefs (similar to the construct developed by Fishbein & Ajzen (1975) and motivation to comply from Bandura (1977). The subjective norms construct was formed by multiplying pairs of items (normative beliefs * motivation to comply). The order of the statements in the questionnaire was scrambled randomly to control for order effects. The dependent variable, behavioral intention was selected as it has been validated in prior literature as a reliable proxy for actual use in behavioral research (Magnus & Niclas, 2003). The questionnaire employed a 7-point Likert-style scale, anchored from 1 (strongly disagree) to 7 (strongly agree).

Data Collection

The instrument was pilot tested using 24 MBA students who were familiar with KMS. The reliability and validity of all eight research constructs were found to be acceptable. A field survey was then administered via two procedures within a 1 week period. We first surveyed KMS users from a leading user group in a major Midwestern U.S. city. The KMS utilized by the users were repository-based and included applications for sharing corporate knowledge, best practices, and lessons learned, among others. We distributed paper-based surveys after briefly explaining our research agenda. There were 64 attendees that were solicited to participate with 41 completing the paper-based survey, yielding a response rate of 64%.

The initial participants in the study were subsequently asked to recruit additional KMS users within their firms via an online Web-based survey, which had the same questions in identical sequence as the paper-based version. The participants represented seven companies from a variety of industries, including manufacturing, finance, consulting, and education. The Web-based survey provided an additional 144 completed surveys from 7 companies, yielding an approximate response rate of 29% (144/500). This resulted in a total sample size of 185 (41 paper and 144 Web). With the exception of a single item, out of 31 total items, there were no significant differences between the paper-based and Web-based surveys after performing a series of t-tests at both the construct and item levels. The single item was not removed from the analysis because dropping it lowered the reliability of its construct. The mean age of the respondents was 38, and 60% of the participants were female and 40% were male. On average, the respondents had 15 years of work experience, 13 years of computing experience, and 2 years of KMS experience.

Consistent with the technology acceptance studies, gender (Venkatesh & Morris, 2000), age (Gist, Rosen, & Schwoerer, 1988; Igbaria, Parasuraman, & Baroudi, 1996), and experience (Venkatesh et al., 2003) were tested as control variables to see if they had a moderating effect on behavioral intention to use. Following Venkatesh et al. (2003), a hierarchical regression analysis was used to test the direct and moderating effects because sample size considerations prevented us from running the interaction terms in LISREL (our primary analysis tool). The moderating effects were modeled as interaction terms between the moderators and perceived usefulness (PU), perceived ease of use (PEOU), perceived behavioral control (PBC), and subjective norms (SN). With direct effects, PU, SN, and PBC were significant. With both direct and interaction effects, PU, PU x gender, PU x age, PU x gender x age, and PBC x experience were significant.

Psychometric Measures

The data were analyzed using the structural equation modeling (SEM) technique, which is suitable because our research model contains latent variables. The model was tested using the two-step approach where the measurement model fit was first assessed followed by the structural model testing in which the path coefficients were estimated (Bollen, 1989). The reliability and validity of the data were tested before model assessment and the results demonstrated acceptable psychometric properties. The reliability coefficients of all eight constructs, with two exceptions, were above .70, which is an acceptable value as stated by Nunnally (1967). The employee-oriented vs. job-oriented and open communication system vs. closed communication system constructs were at .69. They were retained because they were close to the cutoff level1.

Construct validity was assessed by comparing the correlation coefficients within and between constructs. The average within construct correlation was .40, which is higher than the between constructs correlation of .19. The within construct correlations were higher than between constructs correlations, indicating construct validity. In addition, we examined convergent and divergent validity and tested the data for normality. Even though the maximum likelihood estimator performs relatively well under various conditions (Hoyle & Panter, 1995), it assumes the normality of the data. The mean skewness and kurtosis values were -.47 and .33 respectively, indicating that the variables approximate a normal distribution and were acceptable for LISREL analysis (Bollen, 1989; Byrne, 1998; West, Finch, & Curran, 1995).

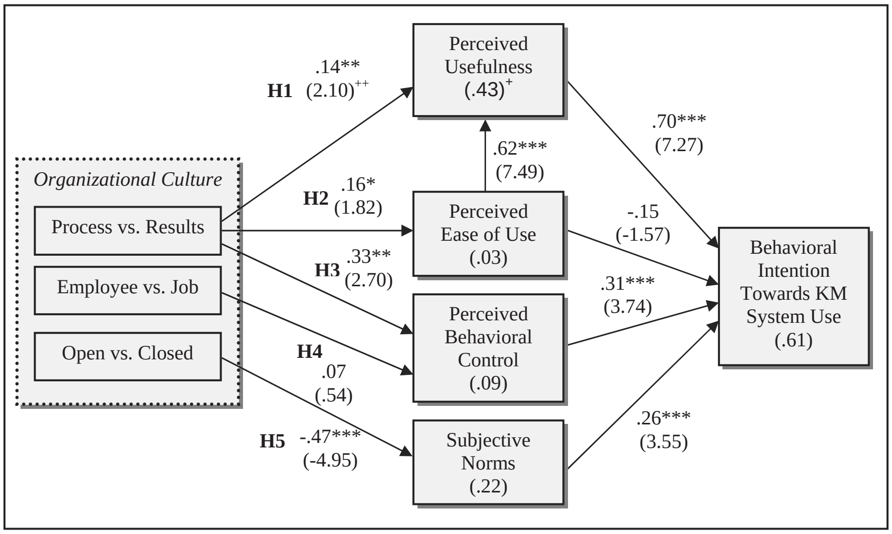
Chi-square goodness-of-fit statistic, comparative fit index, and the root mean square error of approximation were also assessed. Chi-square (χ^2) goodness-of-fit statistic assesses the degree of departure of the sample covariance matrix from the fitted covariance matrix (Hu & Bentler, 1999) . A nonsignificant and small chi-square is desirable. Because the chi-square statistic is a direct product of sample size, when the sample size is large and models contain a large number of indicators, the statistic can often be significant (Byrne, 1998). The comparative fit index (CFI) and root mean square error of approximation (RMSEA), however, are not sensitive to sample size. The comparative fit index is an incremental fit index that measures the improvement in fit by comparing a target model with a restricted, nested base model (Hu & Bentler, 1999). In addition, it is suggested as the best approximation of the population value for a single model (Medsker, Williams, & Holahan, 1994). The general accepted value is above .90. The root mean square error of approximation, a type of absolute fit index, assesses how well sample data are reproduced from an *a priori* model (Hu & Bentler, 1999). The general accepted cutoff is .10.

Using LISREL 8.54, we first tested the measurement model. Its fit statistics were χ^2 (406 df, N = 185) = 685.63, p < .001, CFI = .95, and RMSEA = .061. Overall, the statistics demonstrated good fit and the measures were acceptable for structural model assessment. Good model statistics are indicative of unidimensionality and convergent validity (Gefen, Karahanna, & Straub, 2003). Divergent validity was assessed by comparing the original measurement model with an alterative model that includes all items as one construct (Segars, 1997). The χ^2 was significantly smaller in the original measurement model ($\chi^2_{\text{Alternative}}$= 3234.07, χ^2 difference = 2548.44 with *df* change = 28, *p* = .00) establishing discriminant validity (Segars, 1997).

We assessed 10 paths in the structural model testing. The model fit statistics were χ^2 (421 df, N = 185) = 771.33, p < .001, CFI = .93, and RMSEA = .067. Overall, the statistics demonstrated a good fit of the model to the data. Figure 2 shows the estimated standardized path coefficients and their t-values in the structural model and the variance explained for each of the constructs. The asterisks on the path indicate the significance level and the variance explained are presented below the asterisks in parentheses. All links except those between an employee-oriented vs. job-oriented organizational culture and perceived behavioral control and between perceived ease of use and behavioral intention were significant. The model had adequate predictive power for several constructs, including perceived usefulness (R^2_{PU} = .43), subjective norms (R^2_{SN} = .22), and behavioral intention (R^2_{BI} = .61). However, the predictive power was somewhat less for perceived ease of use (R^2_{PEOU} = .03) and perceived behavioral control (R^2_{PBC} = .09). In regard to the variance extracted in behavioral intention, our model exhibited better predictive power (.61) than that shown in the hierarchical regression with direct effects (.48), as well as direct effects and interaction effects (e.g., age, gender, experience) combined (.58).

The theoretical model was modified to add direct paths of the cultural dimensions influencing behavioral intention. None of the direct paths

Figure 2. Structural path coefficients



* P < .10, ** p < .05, *** p < .001

from the cultural dimensions to behavioral intention were significant. The change between the theoretical model and the modified model in χ^2 was 5.49 with 3 degrees of freedom ($p = .1392$). This suggested that the effects of the cultural dimensions on behavioral intention were mediated and, consequently, the theoretical model was utilized.

DISCUSSION

There was support for four out of the five research hypotheses. These results suggest that the organizational culture dimensions play a key role in the factors that lead to the acceptance of KMS. Our research also examined several prominent technology acceptance relationships and had similar findings to other research that has investigated the applicability of such relationships with the user acceptance of a KMS (Money & Turner, 2005). The relationships between perceived usefulness and behavioral intention to use a KMS, subjective norms, and behavioral intention to use a KMS, perceived behavioral control, and behavioral intention to use a KMS, and perceived ease of use and perceived usefulness were all significant. The relationship between perceived ease of use and behavioral intention to use a KMS, however, was not significant although there was still a significant path through the model incorporating perceived usefulness. These findings are consistent with other studies of extended technology acceptance models (e.g., Adams, Nelson, & Todd, 1992; Hu, Chau, Sheng, & Tam, 1999).

In general, our model explained a reasonable amount of variation of the key variables. The variation in process-oriented vs. results-oriented organizational cultures (as well as the variation in perceptions of ease of use) explained 43% of the variation in perceptions of usefulness. Furthermore, the variability in process-oriented vs. results-oriented cultures explained 3% of the variance of perceived ease of use. Similarly, open communication systems vs. closed communication systems organizational cultures explained 22% of the variance in subjective norms and 9% of the variance in perceived behavioral control. The model accounted for 61% of the variability in behavioral intention to use. Most of the R^2 values are acceptable for technology acceptance research. The large amount of variance in behavioral intention to use is an indication that organizational culture, subjective norms, perceived behavior control, and technology acceptance together are strong factors to study with respect to KMS acceptance.

IMPLICATIONS AND CONCLUSION

In conclusion, our research found that organizational culture does significantly influence the factors that lead to the acceptance of KMS. Our research model was developed using commonly accepted measures from the technology acceptance and organizational culture literatures, tested by surveying corporate KMS users, and analyzed utilizing structural equation modeling. Our results indicated that both process-oriented and open communication organizational cultures significantly influenced factors that lead to the acceptance of KMS.

This research has relevance for both practitioners and researchers. In this article, we examine the influence that three dimensions of organizational culture have on KMS acceptance. It is necessary to examine organizational culture when investigating KMS because such systems are different from traditional information systems. Knowledge, which is information that exists in the minds of individuals, is inextricably linked to knowledge management systems. The emphasis on this human component may not be as prominent in other information systems, and suggests that we incorporate constructs, such as organizational culture, to match the nature of this technology.

This research builds upon the growing IS literature that examines organizational culture, which had historically received insufficient attention (Cooper, 1994; Robey, Wishart, & Rodriguez-Diaz, 1995b; Ruppel & Harrington, 2001). In this study, we have demonstrated that organizational cultural elements are important and should be considered in studies of technology acceptance. For researchers in the culture field, our study extends the importance of examining organizational culture with respect to information systems.

This research also offers several implications for practitioners. We identify different dimensions of organizational culture that lead to greater KMS acceptance. These organizational culture practices are particularly valuable because they are the most direct tools for changing behaviors needed to support knowledge creation, sharing, and use (De Long & Fahey, 2000). Although organizational culture is likely to be inherent in IS practitioner's day-to-day interactions with employees and IT, knowledge of more formally defined dimensions as investigated in this study could lead to better understanding and management of organizational cultural issues, such as office politics. In addition, it has been found that organizations that share common goals, principles, values, and language help facilitate IT relatedness, which can enhance knowledge management capability and ultimately, firm performance (Tanriverdi, 2005). The findings in our research reveal specific dimensions of organizational culture that can influence the knowledge management capability of an organization. Consequently, managers should strive to foster a more results-oriented and open communication system environment in the workplace.

To develop a more results-oriented culture, managers need to encourage behaviors that are less risk averse, such as experimentation and exploration. Instead of a static technology with a limited adaptability, a KMS that has been experimented with by its users will generate new and novel uses of the system. Technologies are often not accepted due to a perceived misfit between the characteristics of the technology and the culture of the organization. Allowing employees the opportunity to adapt to the technology as an outcome of a results-oriented culture can generate a better fit. Consequently, managers should be required to focus more on the goals of job tasks instead of the processes of achieving the outcomes. The schemes for incentives and promotions of KMS users should be compatible with such strategies.

Allowing users time to experiment and explore the features of a new KMS could lead to increased perceptions of usefulness and ease of use, which were also found to influence KMS acceptance. As users experiment and find novel features of the system, they will find it to be more useful. Additionally, the increased time spent on the system would allow for greater perceptions of ease of use. Support for experimentation by management implies a tolerance for mistakes. With the understanding that a certain number of experiments will not have desirable outcomes, users would nevertheless still perceive a greater degree of control over the operation of the system.

Open communication plays a significant role in the acceptance of KMS. To develop a more open communication system culture, a number of strategies can be implemented. Users need to freely interact with their important others (such as coworkers, supervisors, and top management) as well as being included in the design, development, administration, and support of the system. Companies should encourage open communication through the use of forums and newsletters and can even design such features into a knowledge management system. Management can also reward users for openness, such as for voicing opinions regarding the system, and making suggestions for system improvements. These policies will cultivate the tendency to increase subjective norms among users and hence, increase KMS acceptance.

A limitation of our research is that it investigated only a few organizational culture dimensions. We believe that the dimensions most appropriate for KMS were captured in our study and that the germane features of other competing dimensions may be largely encapsulated in the dimensions that we investigated (Chatman & Jehn, 1994; Hofstede et al., 1990). Nonetheless, future research may wish to consider other cultural dimensions to examine the influence that they may have on KMS acceptance. Research can also pursue additional relationships among the cultural dimensions examined in this research, which may provide further insights into the influence that they have on the antecedents of KMS acceptance. The variance extracted for perceived ease of use and perceived behavioral control was less than 10%. It is important to recognize that due to limited variance extracted, the process/result-perceived ease of use and process/result-perceived behavioral control links need to be interpreted with caution and closely examined in future research (Falk & Miller, 1992). Another limitation is that the source of our data may be too limited to claim any universality for our research model. Certain industries, such as health and welfare, government, and retail were not represented in our sample. However, we believe that our research model is robust and will be suitable for testing in other environments and contexts.

ABSTRACT

Implementing knowledge management or knowledge-sharing projects in an organization require significant organizational prerequisites. Lacking proper infrastructures and prerequisite, not only make the knowledge management process unprofitable, but might incur harmful effects as well. To decrease such risks, it is proposed to introduce the readiness assessment, in order to gauge a company's appetite for the work involved in implementing the knowledge management. In this research, critical success factors have been extracted from literature reviews and surveyed through a questionnaire, distributed among 130 knowledge management experts. Then, to validate the measurement of the multi-item constructs, exploratory factor analysis (EFA) was used. Identifying effective variables and their grouping onto related factors, the second questionnaire was employed for readiness assessment of an IT firm working in Iran and its results were presented with Radar diagrams. Finally, promoting propositions were provided based on the firm's current state.

INTRODUCTION

Knowledge management (KM) comprises a range of practices used by organizations to identify, create, represent, and distribute knowledge. In recent decades, there has been proliferation of KM projects in many organizations. Correspondingly, corporate spending on KM projects has increased substantially over the years (Ithia, 2003). The theoretical benefits of KM are clear; hence, in order to maximize internal efficiency, internal coordination, service to clients, and overall profitability, one needs to make tacit knowledge explicit, updated and accessible. Simple one might think but one must go through the reasons as why organizations fail to make KM work possible (Guptara, 2000).

There are several definitions and constructs of the term 'knowledge' and its importance for the firms. Kogut and Zander (1992) for instance, describe knowledge as an embedded resource of the firm. Birkinshaw et al. (2002) see it as 'contingency variable.' Like many other managerial innovations, KM also appears to be adopted first by manufacturing firms, and is beginning now to permeate the service sector, predominantly in professional services such as consulting firms (Hansen et al., 1999). Knowledge, and consequently its management, is currently being touted as the basis of future economic competitiveness. Many large companies have resources dedicated to knowledge management, often as a part of 'information technology' or 'human resource management' departments. Nevertheless, implementing KM projects or knowledge-sharing philosophies in organizations often require significant organizational changes. In essence, assessment of an organization's readiness could serve as a guideline to leaders as they plan and implement KM initiatives (Holt et al., 2004).

System Group Company was founded in 1988 as a small start-up IT company with the vision of establishing IT as an industry in the country. The company is currently the largest private software company in Iran providing IT solutions, specifically integrated business software solutions for vertical markets embodied in different industries. The company has developed a unique combination of the best breed of technology, professional services, and intellectual management in the science of application development. Currently, the company has eight active subsidiaries each specialized in different IT fields, 27 nationwide satellite companies providing after-sales services and 19 licensed companies providing sales and installations across the country. It has grown to become a company of 650 professional staff nationwide to reach its 4,500 customers. The company has received numerous high credentials and awards from Iran's National Council of Informatics and other high-ranking organizations as recognition for its quality software development and contribution to the IT society of Iran.

The firm as a software company faces the challenge of sustaining the level of competence. In fact, the company has problems keeping track of what this knowledge is, where it is, and who has it. A structured way of managing the knowledge and treating the knowledge and its owners as valuable assets could help the company leverage the knowledge they possess. As Rus and lindvall (2002) mentioned, a software organization's main asset is its intellectual capital and the major problem with intellectual capital is that it has legs and walks home every day. At the same rate experience walks out the door, inexperience walks in the door. Based on these facts, the company recognized the need for embarking knowledge management. But based on the dismal success rates of change implementation, managers are being encouraged to be proactive by utilizing change measurement instruments to gauge their organization's demeanor before implementing changes (Simon, 1996; Jansen, 2000) because of changes effect, which imposes risk and uncertainty onto organization.

KM assessment readiness provides thorough answers to two fundamental questions: What is a firm's current KM capability? And what changes must be in place before embarking on a KM initiative? An instrument to assess readiness should be developed based on the premise that KM is enhanced through the critical success factors (CSFs). Before investing scarce resources in such risky projects, corporate leadership is calling for a means to decrease uncertainty surrounding knowledge management.

A failure to assess organizational and individual KM readiness might result significant loss of time and energy of managers dealing with resistance to knowledge management. Knowledge may be accessed at three stages: before, during, or after knowledge-related activities. However, creating KM readiness before any attempt at organizational renewal necessitates later action to cope with resistance. An investment in developing KM readiness—at both individual as well as whole-of-organization level—can achieve double benefit.

KNOWLEDGE MANAGEMENT

As the economy shifts to the post-industrial era, intangible assets (such as knowledge) gain importance over more traditional resources (e.g., land and capital) in organizations (Alavi, 2000). Along with this, KM today emerges as one of the most popular, important areas of inquiry in academic researches and management practices (Ruggles, 1998; Argote, McEvily, & Reagans, 2003). KM first appeared in industries and functional areas that basically sell knowledge—professional services, pharmaceuticals, research, and development functions—in the late 1980s and 1990s. It is now quickly moving into other industries, including manufacturing, financial services, government and military organizations, and even non-government organizations (NGOs) (Grover & Davenport, 2001). Many organizations are increasingly viewed as knowledge-based enterprises in which, formal KM is essential. Being typically tied to organizational objectives, KM is rapidly becoming an integral business activity for organizations as they realize that competitiveness pivots around the effective management of knowledge (Grover & Davenport, 2001).

KM can also be more effective in integrating and administering a firm's information technology base as well as assisting to develop a systemized information model. KM systems (KMS) are becoming increasingly important to organizations, both for their strategic potential and as a crucial resource (Liebowitz & Wright, 1999; Apostolou & Mentzas, 1999a; 1999b; Ahn & Chang, 2004; Wasko & Faraj, 2005). These systems are important for organizations, primarily to help manage a key organizational resource—intellectual capital with the potential to produce a competitive advantage (Rao & Osei-Bryson, 2007).

Although, today there is a great deal of interest in knowledge management, there exists no universally-accepted definition of it (Earl, 1999). KM can be defined as "KM is the practice of selectively applying knowledge from previous experiences of decision making to current and future decision making activities with the express purpose of improving the organization's effectiveness" (Jennex, 2005, p. 15). Also, Alavi and Leidner (2001) defined KM as "managing the corporation's knowledge through a systematically and organizationally specified process for acquiring, organizing, sustaining, applying, sharing and renewing both the tacit and explicit knowledge of employees to enhance organizational performance and create value" (Allee, 1997; Davenport, 1998; Alavi & Leidner, 2001).

One of the key concerns emerging in KM is how to accomplish it. Many companies attempting to initiate KM are unsure of the best approach to adopt (Moffett et al., 2002). Literally, there seems to be general agreement that a combined social and technological approach is ideal one. Davenport and Prusak (1998) believe that KM projects have one of the three aims: a) to make knowledge visible and show its role in an organization, mainly through maps, yellow pages and so on; b) to develop a knowledge-intensive culture by encouraging and aggregating behaviors such as knowledge sharing and proactively seeking and offering knowledgep; c) to build a knowledge infrastructure used not only as a technical system, but also a connecting web of people by giving space, time, tools, and encouragement to interact and collaborate.

Nevertheless, knowledge is not easily measured or audited; therefore, organizations must manage knowledge effectively in order to take full advantage of skills and experiences inherent in their systems and structures as well as the tacit knowledge belonging to the firm's employees. The road to success is eminent. It will certainly go forward, if organizations are aware of the key factors that make its adoption successful.

KM READINESS

This section first deals with literature about critical success factors; then it goes ahead with readiness for knowledge management; and finally it provides measures extracted from the discussions.

Literature Review

The general definitions supplied in the existing literature use the word "readiness" as a necessary pre-condition for a person or an organization to succeed in facing organizational change (Holt, 2000). Knowledge management-readiness is the ability of an organization, department or work-group to successfully adopt, use and benefit from KM. It is important for companies seeking to adopt KM to analysis their businesses to ensure a productive and beneficial implementation of knowledge management. It is worth mentioning that the readiness assessment analyzes the organization's environment and readiness to adopt and support an enterprise-wide project management methodology.

KM strategies are getting mature including their ability to assess an organization's readiness for such systems (Ruppel & Harrington, 2001; Tsai, 2002; Siemieniuch & Sinclair, 2004). Since many KM initiatives did not evolve as successfully as their directors had planned, researchers explored potential barriers and facilitators of KS in organizations (Damodaran & Olphert, 2000; Desouza, 2003; Pumareja & Sikkel, 2005).

Critical enablers of KM have been validated and organized in an integrative framework along with organizational processes and performance (Lee & Choi, 2003). Jennex and Olfman (2000) studied three KM projects to identify design recommendations for building a successful KMS. Jennex and Olfman (2005) summarized and synthesized the literature on KM/KMS critical success factors into an ordered set of 12 KM CSFs. CSFs were ordered based on the number of studies identifying the CSF. There were 17 studies looking at over 200 KM projects. Based on the DeLone and McLean's IS success model, Jennex and Olfman (2006) extended their works with a KM success model and combined and utilized KM and KMS success (Jennex et al., 2007).

Siemieniuch and Sinclair (2004) propose a framework for organizational readiness, by introducing knowledge lifecycle management (KLM) processes. Hung and Chou (2005) give a three-dimensional KM pyramid model (KMPM) for assessing the maturity of its organizational capabilities. KMPM is comprises three components, that is, maturity levels, KM processes, and KM capabilities or enabling infrastructures. Holt et al. (2004) also did a study to develop an instrument for assessing KM readiness. This study draws on the literature dealing with KM and organizational change to propose a synergistic instrument to measure readiness for KM and apply it in an organizational setting. This instrument considers individual, context, content, process measures and KM attitudes.

Further Hung et al. (2006) examined the relationship between KM readiness and intellectual capital while Keith et al. (2006) accomplished a case-based field study from a large Fortune-500 financial firm transitioning its structure to SOE and considering agile software development methodologies. Survey data was collected along with a series of interviews with key managers and developers. Findings indicate significant statistical differences in KM readiness between groups and the need for alignment.

As explained, many instruments purportedly assessed readiness for an organization to embrace changes, but it was not surprising that these instruments were designed to assess readiness from some limited perspectives only, that is, technologic and typical information system, lacking enough considerations on special system and project.

KM Readiness Measures

Based on literature reviews on readiness and success factors in the proposed area, we listed measures influencing on KM readiness. These critical success factors have been extracted from various papers dealing with KM in general, KM success factors and KM readiness, in particular. Hence, this study provides a comprehensive view on KM for firms embarking to KM project. It is shown that firms need to be ready for KM which has specifically essentials with the research objective of identifying factors significantly influencing the KM process. Table 1 shows those extracted measures.

Table 1. KM readiness measures

Measures	Description	Sources
Trust	As maintenance mutual belief with each other based on intention and behavior	Lee and Choi (2003); Davenport et al. (1998); Andersson and Westterlind (1999); Chua and Lam (2005); Allee (1997)
Training	Appropriate training procedures and tools; provide self-training and self-learning environment, Encourage employees to participate in internal and external training	Hasanali (2002); Choi (2000); Chung et al. (2005)
A culture of altruism	Intending to collaboration without compensation	Andersson and Westterlind (1999); Davenport and Prusak (1998)
Open leadership climate	Openly discussion about vision, strategy and procedures and supporting of improvement and democratic leadership style	Chung et al. (2005); Davenport et al. (1998); Taylor and Wright (2004); Andersson and Westterlind (1999); Forcadell and Cuadamillas)2002); Brand (1998); Allee (1997)
Learning from failure	Openly discussing about mistakes and its causes	Taylor and Wright (2004); Soliman and Spooner (2000); Brand (1998)
Knowledge strategy	Specific strategy for knowledge management	Sunassee and Sewary (2003); Taylor and Wright (2004); Snyman and Krugere (2004); Chung et al. (2005)
Management support	The extent that organization's leadership and management were committed to and supported implementation of the prospective change	Davenport et al. (1998); Holt (2000); Chung et al. (2005); Chua and Lam (2005); Ross et al. (2005); Choi (2000); Streels (2000); Hasanali (2002)
Participation	What extent a respondent felt that he or she provided input and was allowed to participate in the change process	Chua and Lam (2005); Choi (2000).
Centralization	The location of decision rights, that is, the level of centralization. The one who makes a decision also has to have access to the right knowledge to make the best decision	Andersson and Westterlind (1999); Lee and Choi (2003); Forcadell and Cuadamillas (2002); Ruikar et al. (2006(; Walczak (2005).
Formalization	Degree that the job relation and decisions managing by standard procedure, policy and formal rules	Taylor and Wright (2004), Lang (2001); Lee and Choi (2003).

continued on following page

Table 1. continued

Measures	Description	Sources
Quality of information	The extent to which one felt that he or she had useful and meaningful information throughout the change process	Holt (2000); Hasanali (2002); Streels (2000); Davenport and Prusak. (1998); Gupta (2000)
Team work	Encourage knowledge creation teams, concern about teamwork experience and knowledge, evaluation on team coordination, cooperation and efficiency	Chung et al. (2005); Ross et al. (2005); Choi (2000); Soliman and Spooner (2000); Forcadell and Cuadamillas (2002).
Benefit	The extent to which a person feels that he or she will personally benefit from the implementation of the prospective change	Holt (2000); Hasanali (2002); Ross et al. (2005).
Appropriateness	The extent to which one felt that the change effort was legitimate and appropriate for the organization to meet its objectives	Holt (2000); Siemieniuch and Sinclair (2004).
Discrepancy	The extent to which one felt that the organization needed to change	Taylor and Wright (2004); Holt (2000).
Reward system	Is referred to pool of reward like gifts, bonuses or higher salary	Guptara (2000); Chung et al. (2005); Snyman and Krugere (2004); Wiig et al. (1997) Andersson and Westterlind (1999).
Information systems infrastructure accessibility	Referred to software, hardware and network that need to implement of knowledge management projects	Mathi (2004); Taylor and Wright (2004); Ruikar et al. (2006); Macdonald (1998); Hasanali (2002).
Verbal skill	Important factor for knowledge sharing is language that does through narrative and explanation, filtering and organizing information from cultural and physical domain and directing to be meaningful	Polkinghorne (1989); Lang (2001).
T-shape skill	This skill is based on two dimensions, depth (vertically) and width (horizontally) who have this skill can explore specific knowledge domain and application in specific products. They can consolidate knowledge assets. Also they enable to combine theoretical and practical knowledge	Chua and Lam (2005); Lee and Choi (2003).

METHODOLOGY

Sample

There are two basic respondent strategies: sampling and census. However, we decided not to apply any sampling approach or collect data from the whole population, due to required levels of respondent expertise and limited amount of KM expert in Iran as a developing country. The population includes KM experts from academic environment in Iran as well as those working in software companies and has already participated in several KM projects. The academic experts were selected based on teaching and research areas related to KM in various universities and research centers and KMS practitioners in software companies were selected based on experience in KM project implementation. Nevertheless, as discussed later, because expert selection was judicative, it may limit the validity of the findings.

The questionnaires were distributed among 130 experts with 93 surveys completed for a response rate of 71%. The average age and experience of the respondents was 39 years (SD=11 years) and 5.3 years (SD=1.9 years), respectively.

Instrument and Data Analysis

As mentioned earlier, critical success factors affecting KM readiness were extracted from literature reviews and questionnaire-based surveys. The responses about the agreement or disagreement were analyzed using a five-point Likert scale. Further, their reliability or internal consistency was assessed by Cronbach's alpha. It was observed that consistency was above 0.8 (0.86), higher than the 0.7 threshold normally considered as minimum (Nunnally, 1978).

To validate the measurement of the multi-item constructs, we used exploratory factor analysis (EFA), a procedure that allowed us to drop some invalid items from the scale and include valid items to the relevant groups. One variable (knowledge strategy) was deleted in this approach, while 18 variables including five factors remained there.

After identifying effective variables and their grouping onto related factors, the second questionnaire was employed for readiness assessment of an IT firm working in Iran (see Appendix). The questionnaire was designed based on above-mentioned factors and consisting a series of statements (92 statements) relevant to a particular area to which, respondents (or end users) from several functional units may either agree or disagree with varying degrees (using a five-point Likert scale). These questions were extracted from some reliable and valid instruments mentioned in references such as Clark (2003). Nevertheless, managers of the firms were also asked to comment on the questions and their relevance to factors wanted to measure. Assessment relies on the judgment of a respondent (or end-user) as to whether or not he/she agrees with the statement/s in the context of their department or work group. The respondent(s) need to ensure that their responses are consistent with their assumptions, for example, if responses are about the department (and not the organization), then that assumption must be reflected throughout. The extent to which the respondent agrees or disagrees with the statement is graded on a scale of 1 to 5, where: 1= Strongly Disagree, 2= Disagree, 3= Neutral, 4= Agree and 5= Strongly Agree. The statements are orchestrated in a way that a response of "strongly agree" generates the highest score of 5 points. An average score is also calculated for each category. The higher the average score the more likely it is that the firm is ready for knowledge management. Based on Ruikar et al. (2006), an average score greater than or equal to zero and less than 2.5 is weak, indicating that several aspects (within a category) need urgent attention to achieve readiness; whereas, an average score greater than or equal to 2.5 and less than 3.5 is medium, indicating that certain aspects (within a category) need attention to achieve readiness in knowledge management; and, an average score greater than or equal to 3.5 is high, indicating that the firm has adequate capability and maturity in these aspects and therefore has knowledge management-readiness (in those respects). On successful completion of the questionnaire, results are presented with radar diagrams that summarize overall KM readiness in each factor and its related variables. This allows companies to focus on, and improve on, those specific aspects within each category, even if they have achieved knowledge management-readiness in that category.

RESULTS

Factor Analysis Results

The critical assumptions underlying factor analysis were tested using the Bartlett test of Sphericity and the Kaiser-Meyer-Olkin measure of sampling adequacy (KMO=0.65). The independent variables were subjected to exploratory factor analysis using principal components analysis as the extraction method and Varimax rotation with Kaiser normalization. All factors which have the value greater than 0.5 were extracted. This iterative process is recommended as an effective way of deriving a stable factor structure (Sethi & King, 1991; Rai et al., 1996). After five iteration processes, all 18 variables were loaded satisfactorily onto the five latent factors. The factor analysis was also examined to ensure acceptable levels of variable communality and multi-collinearity. The factors are associated with culture, information infrastructure of the organization, vision of change, management support and structure, which explain almost 70 % of the variance of KM readiness. Table 2 shows exploratory factor analysis results.

Empirical Results

This section shows the findings on the KM readiness of a firm based on responses which includes the average scores of the firm in the categories including management support for change, culture of knowledge, structure, infrastructure and vision for change. The evaluations were conducted by managerial staffs (e.g., senior project manager, project director, senior systems manager, etc.) and bottom-line staffs in the relevant departments. Average scores obtained in each category are plotted on a radar diagram as illustrated in Figures 1 to 5. These figures highlight specific points within each category that need attention to achieve knowledge management-readiness.

As seen in Table 3, the firm's state of infrastructure factor is excellent. All measures of this factor are greater than 3.5 (even greater than 4.7) indicating that the firm has adequate capability and maturity. Also, the average scores of each item in change factor are high, that is, the firm can empower or devote the organizational resources on to the other factors.

Table 2. Results of exploratory factor analysis (EFA)

Items	**Factors**				
	Support for change	**Vision for change**	**Culture of knowledge**	**Structure**	**Infrastructure**
Training	0.79				
Management support	0.8				
Participation	0.79				
Reward system	0.78				
Benefit		0.84			
Appropriateness		0.87			
Discrepancy		0.88			
A culture of altruism			0.67		
Open leadership climate			0.87		
Learning from failure			0.82		
Trust			0.86		
Centralization				0.78	
Formalization				0.82	
Team work				0.814	
Quality of information					0.76
Information systems infrastructure accessibility					0.76
Verbal skill					0.73
T-shape					78.8
% of variance explained	14.93	12.81	15.85	12.36	13.75
Cumulative % of variance explained	14.93	27.74	43.59	55.95	69.70

Table 3. Readiness scores of the firm

Factors	Measures	Score	Readiness
Vision for Change	Benefit	3.9	High
	Appropriateness	3.3	Medium
	Discrepancy	3.9	High
Infrastructure	Quality of Information	4.8	High
	Information systems infrastructure accessibility	4.7	High
	Verbal Skill	4.8	High
	T-Shape	4.8	High
Structure	Centralization	3.9	High
	Formalization	3.3	Medium
	Teamwork	3.9	High
Support for change	Education	3.3	Medium
	Management Support	3.4	Medium
	Participation	3.7	High
	Reward system	3.1	Medium
Culture of knowledge	Trust	3.7	High
	Open leadership climate	3.9	High
	Learning from Failure	3.9	High
	A culture of altruism	4.1	High

All items in the management support factor are the least KM readiness with the lowest scores compared to the other four categories. Three measures are in medium state and only participation is high ready. In culture, all the items have high level of KM readiness with scores greater than 3.5. At the same time, verbal skill and T-shape have higher score in readiness assessment.

This firm tried to implement KM in 2004, but its first attempt failed because of its emphasis merely on technological aspects. Project failure caused to managers defines this research project to assess organizational dimensions, needed before embarking on the KM project. After identifying factors influencing readiness as well as weak areas in the firm, all the people involved in the first attempt seem to agree on weakness discovered by this assessment tool. Hence, managers defined projects to improve the current state of the firm to the extent to which all organizational functions and dimensions will be fully ready for this risky project.

CONCLUSION

This study is one of the first systematic studies to determine the KM readiness implementation in firms, especially in the SME[1] sector. This assessment survey profile offers a valuable source of information to firms, which are still lagging far behind when comes to KM practices.

Present research has identified five organizational antecedents to effective KM within the context. We have tried to illuminate the unique challenges managers encounter while implementing KM processes to the aforementioned dimensions. By investigating, managers acknowledge that they have considerable scope to improve current attitudes and practices within these constraints. They can use the developed instrument as a framework in assessing their current readiness in factors influencing on the success of KM project. The instrument in a way provides pointers to what needs to be addressed. The acquired results would help managers to facilitate its adoption and to prioritize its practices. At the same time, academics can use the outcomes to build models that would further expand the KM domain. Although technological infrastructure and KM systems are vital for successful implementation, firms should give more emphasis on soft components of organization such as people and culture because most failure is encountered from narrow view to such a project and a mere emphasis on technology. It causes to ensure the successful implementation of KM as well as to attain full advantages from KM in organization.

Limitations and Suggestions for Future Research

There are some limitations/constraints to this study, including its focus on one enterprise. In addition, self-selection bias not only limits to conclude the results of the study rather it might lead our choice of industry or firm narrow. Although, the instrument can be applied to IT firms, it must be handled prudently while applying in other industries. As a matter of fact, additional research must be carried out to validate conclusions and to add to our understanding about KM readiness in other commercial or governmental enterprises. It is believed that the number of KM experts and their responses was small since it is a new and emerging discipline, and not many SMEs have formally implemented it, especially in a developing country like Iran. Furthermore, we think that there are other influencing factors on readiness that were probably left out, especially environmental ones that were excluded because of difficulty in developing universally-applicable questionnaires, suitable to organizations. Finally, the assessment instrument applied in the firm was attitude-based, that, in reality, may be biased.

However, this instrument needs further improvement and evaluation. The instrument should be less attitude-based and rely more on current documents and statements of firms. Also, researchers are advised to implement those instruments in different areas of industries, in order to determine and enhance their applicability. Also, they should also work on developing comprehensive and integrated maturity model to help practitioners implement knowledge management. To that end, there is a growing commitment by scholars towards empirical and conceptual research especially in knowledge management.

ACKNOWLEDGMENT

The authors sincerely thank referees and the area editor for their valuable and constructive comments on an earlier version of this article. We are also thankful to all who participated and contributed during the course of this research.

APPENDIX

Respondents were asked to rate their agreements with the following statements, on a scale of 1-5.

Benefit	I believe in the value of such knowledge sharing changes.	1	2	3	4	5
	My future in this job will be limited because of such changes.	1	2	3	4	5
	I like the available situation.	1	2	3	4	5
	The time we would spend on such changes should be spent on something else.	1	2	3	4	5
	Such changes give me ability to make decisions as how my work is done.	1	2	3	4	5
	Changes that improve knowledge sharing will make my job easier.	1	2	3	4	5
	Implementation of knowledge sharing changes will disrupt many of the personal relationships I have developed.	1	2	3	4	5
	My past experiences make me confident that I will be able to perform successfully after such changes.	1	2	3	4	5
	I am worried I will lose some of my status in the organization when such changes are implemented.	1	2	3	4	5
Participation	The information I received about such knowledge sharing changes was timely.	1	2	3	4	5
	I am able to participate in the implementation of such changes.	1	2	3	4	5
	I have some control over the knowledge sharing changes that will be proposed.	1	2	3	4	5
	The information I received about such changes, has adequately answered my questions.	1	2	3	4	5
	The information I received about this changes, helped me understand changes	1	2	3	4	5
	When we implement such knowledge sharing changes, I feel I can handle it with ease.	1	2	3	4	5
	Trade planning has been done regularly and each person in the organization participates and includes in this process to some extent.	1	2	3	4	5
Discrepancy	There is a clear need to change knowledge sharing activities.	1	2	3	4	5
	Attempts to make things better are necessary around here.	1	2	3	4	5
	Our organization has problems about knowledge saving.	1	2	3	4	5
T-shape	I have the knowledge of my job.	1	2	3	4	5
	Familiar to other tasks in the organization it is useful for doing my job.	1	2	3	4	5
	I have general understanding of organizational processes.	1	2	3	4	5
Appropriateness	There are a number of rational reasons for such changes to be made.	1	2	3	4	5
	There are legitimate reasons for us to make changes that will improve knowledge management activities.	1	2	3	4	5
	Changes that will improve knowledge sharing, match the priorities of our organization.	1	2	3	4	5
	Managing knowledge is an organizational value.	1	2	3	4	5
	Applying new information technology is appropriate with organizational purpose.	1	2	3	4	5
	Change in information distribution is a major goal of the organization.	1	2	3	4	5
Management support	This organization's most senior leader is committed to such change.	1	2	3	4	5
	Management has sent a clear signal that this organization is going to make changes that will improve knowledge management.	1	2	3	4	5
	The top manager is committed to making such knowledge sharing change efforts a success.	1	2	3	4	5
	Major managers encourage everybody to the changes which improve knowledge management.	1	2	3	4	5
	Managers and leaders put their word into action.	1	2	3	4	5

continued on following page

APPENDIX CONTINUED

Reward System	Rewards are paid according to the needs of a person.	1	2	3	4	5
	People, who have more roles in the organization, are rewarded more.	1	2	3	4	5
	Rewards are paid according to the needs of a person.	1	2	3	4	5
	Based on experiences, the organization reward system do fairly.	1	2	3	4	5
	Organization has the pool of rewords.	1	2	3	4	5
Verbal Skill	In communication, I use words that others understand easily.	1	2	3	4	5
	My colleagues can understand the words I use.	1	2	3	4	5
Centralization	How much does the major manager of the organization directly control the decisions made by others?	1	2	3	4	5
	How much does your unit headman act freely and independently in employing or firing the personnel?	1	2	3	4	5
	How mach does the major manager of the organization act directly in collecting information for making his decision?	1	2	3	4	5
	Each one can be a decision maker in the organization without being controlled by others.	1	2	3	4	5
	How much does your unit head man act freely and independently in personnel's rewards?	1	2	3	4	5
	How much freely and independently does your unit head man act in evaluating his unit function?	1	2	3	4	5
	How much freely and independently does your unit head man act in evaluating his unit function?	1	2	3	4	5
Open leadership climate	Usually, some meetings are held in manager's presence to hear employees' ideas.	1	2	3	4	5
	Management encourages active participation in expressing ideas.	1	2	3	4	5
	Does the manager pay attention to employees' ideas with regard to work affairs?	1	2	3	4	5
	Do they behave honestly?	1	2	3	4	5
	Do employees express ideas freely?	1	2	3	4	5
	Do employees feel relaxed in expressing their ideas?	1	2	3	4	5
Team work	The organization uses different team in order to solve its problems and requirements.	1	2	3	4	5
	The organization focuses on the team work.	1	2	3	4	5
	To do work, team work is used instead of organizational hierarchy.	1	2	3	4	5
	Every one does his work in the team.	1	2	3	4	5
	Do teams have much power in relation to decision making and performance?	1	2	3	4	5
Formalization	Most will make their regulations on their own.	1	2	3	4	5
	Every one in the organization is permitted to work in the way they are satisfied.	1	2	3	4	5
	In order to deal with any condition, there are special procedures.	1	2	3	4	5
	The situation is available for the personnel to express ideas.	1	2	3	4	5
Trust	My success is important for my colleagues.	1	2	3	4	5
	I am sure my colleagues put their words into action.	1	2	3	4	5
	I am sure my colleagues hand me accurate information.	1	2	3	4	5
	I am sure my colleagues are honest with me.	1	2	3	4	5

continued on following page

APPENDIX CONTINUED

Learning of failure	The employees can detect other methods to do the affairs, without fear of being reprimanded for previous failure.	1	2	3	4	5
	In case of procedure failure, the organization encourages the employees to analyze it.	1	2	3	4	5
	The organization pays no attention to the cause of failed procedure of other organizations.	1	2	3	4	5
	The organization's patience to making mistakes is high.	1	2	3	4	5
	I am annoyed when others talk about my mistakes over and over again.	1	2	3	4	5
	The organization encourages creative endeavors even when they are not successful.	1	2	3	4	5
	I consider my failures as an educating source.	1	2	3	4	5
Education	In case of encountering questions, they are answered while the new systems are used.	1	2	3	4	5
	The organization holds training and introduction with the new technology courses for the employees.	1	2	3	4	5
	A lot of investment is done to educate the employees.	1	2	3	4	5
Information systems infrastructure accessibility	What extent are software systems of the organization capable of coordinating with the new systems?	1	2	3	4	5
	What extent are the internal nets in the organization capable of supporting the new systems?	1	2	3	4	5
	How is the quality of supporting the systems and the network?	1	2	3	4	5
Quality of information	How much standard is used for planning data in the organization?	1	2	3	4	5
	How is the security strategy to data in the organization?	1	2	3	4	5
	How much do you gain from the required information in the appropriate time?	1	2	3	4	5
	How much access do you have to your needed information?	1	2	3	4	5
	We have a well-defined good policy for using management information systems.	1	2	3	4	5
A culture of altruism	I help my colleagues without any rewards.	1	2	3	4	5
	I try to help others without any compensation.	1	2	3	4	5
	Helping my colleagues is enjoyable for me.	1	2	3	4	5
	Solving the problem of my colleagues is my job.	1	2	3	4	5

Chapter 5.14

The Impact of Institutions on Interorganizational IT Projects in the Mexican Federal Government

Luis F. Luna-Reyes
Universidad de las Americas-Puebla, Mexico

J. Ramon Gil-Garcia
Centro de Investigación y Docencia Económicas, Mexico

Mireya Estrada-Marroquín
Universidad de las Americas-Puebla, Mexico

ABSTRACT

Electronic government has the potential of transforming the way government works and interacts with citizens. However, recent research has found that the promised benefits are rarely completely achieved. Some of these studies highlight the importance of institutions in shaping the development, implementation, and use of information technologies in government settings. Based on a survey of Mexican federal government managers, this article explores the relationships between institutional arrangements, organizational forms, information technologies, and the outcomes of Mexican IT initiatives. Overall, it was found that there are important interactions among these variables and important similarities exist between developed countries and other realities, such as Latin America. The research presented here contributes to the field by testing causal relationships often cited in the digital government literature, but with little empirical quantitative exploration. Moreover, understanding those relationships offers guidance in the implementation of inter-organizational IT applications in government, potentially increasing their probability of success as well as the benefits for citizens and other stakeholders.

INTRODUCTION

According to Fountain (2001, 2004), information and communication technologies (ICTs) are one of the most important advances in this century and have the potential to significantly transform government. In fact, some government structures and processes have changed due to the incorporation of technological innovations such as the personal computer and the Internet (Fountain, 2004). Information technologies create interesting possibilities for government. They are used not only to improve the quality of services, but also to reduce costs and make policies and programs more effective (Gil-Garcia, 2006; Gil-Garcia & Helbig, 2006; OECD, 2003). Information and communication technologies are used as a catalyst for organizational change (Dawes, 2002; Holmes, 2001; Rocheleau, 2003). They are also considered a tool to improve democratic participation in a variety of political topics (Carbo & Williams, 2004; Gil-Garcia, 2005; Hiller & Bélanger, 2001).

The term "electronic government" or "digital government" emerged within this context, and is still evolving (Gil-García & Luna-Reyes, 2006; Schelin, 2003). OECD defines e-government as the use of information and communication technologies for a better government or to improve the quality of its services, especially through the use of the Internet and Web technologies (OECD, 2003). Some general characteristics of e-government are: (1) the use of information and communication technologies, (2) supporting government actions, (3) improving the relationships between government and citizens, and (4) following a strategy to add value for participants in the process. In contrast to electronic commerce, electronic government does not include only the transactional aspects, but also takes into consideration the democratic relationships between governments and citizens (6, 2001; Gil-Garcia, 2005; Scholl, 2002).

The implementation of these technological innovations has been challenging. In Mexico, information and communications technologies were first used widely in government in the '90s. However, it was only in 2001 when the secretary of communications and transportation created the e-Mexico project. The e-Mexico initiative fosters innovation in government through the use of information technologies and also promotes the use of the Internet by certain sectors of the Mexican society. New laws and regulations regarding electronic government in Mexico have supported this initiative. One important example is the Law for Transparency and Access to Government Public Information. The objective of this law is to establish the necessary mechanisms to guarantee any person the access to information from the different branches of government, autonomous constitutional organizations, and any federal agency (Poder Ejecutivo, 2002). The main objective of electronic government in Mexico is to use information and communication technologies to innovate and improve government and its relationships with citizens (OECD, 2005).

Therefore, the implementation of electronic government in Mexico needs to consider different factors such as laws and regulations, organizational structures, and the characteristics of the technologies themselves. This study proposes and empirically tests a model to explore the relationships between some of the factors that have an impact on information and communication technology projects in government. Institutional theory and Fountain's technology enactment framework provide the conceptual basis for this study.

After this brief introduction, the article is organized into five more sections. The following section presents a brief literature review of institutional theory and the technology enactment framework, as well as some of their applications to government settings. The third section describes the research model and hypotheses, and the fourth section includes a description of the research methods and procedures. Finally, the last two sections consist of a discussion of the main results and conclusions.

LITERATURE REVIEW

This study is based on institutional theory, particularly Fountain's technology enactment framework (Fountain, 1995, 2001). The concept of institution is central to these theories. According to North, "Institutions are the rules of the game in a society, or more formally, they are humanly conceived obligations, which configure human interaction" (North, 1999). Another definition says that institutions are the joint group of rules, application mechanisms, and organizations that reinforce each other (Scheela & Van Dinh, 2004). Barley and Tolbert (1997) state that institutions represent obligations created by the options that individuals and groups have, but these obligations are subject to change over time. They define institutions as shared and typified rules with identified categories of social actors, as well as their appropriate activities and relations (Barley & Tolbert, 1997). Institutions can also be seen as guidelines that have been created by society and the individuals who are part of that society (Giddens, 1979, 1984). These guidelines or rules are generated and maintained over time through the micro-activity of social actors. In contrast, for Bansal (2005), institutions include macro-level structures like governments, professional associations, public opinion, and the media. Current institutional approaches recognize the interplay between social structures (macro) and the actions and interactions among individual actors (micro). Therefore, the basic principle of institutional theory is that individual actions and organizations are shaped by institutions, which, at the same time, are either reproduced or modified through the collective action of individuals and organizations (Brinton & Nee, 1998; Giddens, 1984; Scott, 2001).

Institutional approaches have been used to understand a great variety of phenomena in multiple disciplines including economics (North, 1999; Rutherford, 1999), political science (Peters, 2001), and sociology (Brinton & Nee, 1998). Within organizational research, institutional theory emphasizes the social context in which organizations are embedded and highlights the influence of culture or laws on decision making and formal structures (Bansal, 2005; Powell & DiMaggio, 1991; Scott, 2001). It also recognizes the importance of external pressures generated by actors in the social and economic environments and their influence on organizational characteristics and performance (Khadaroo, 2005). Institutional theory has been useful to understand organizational change by identifying relevant aspects of the context in which information technologies are designed and implemented (Bennett, Bouma, & Ciccozzi, 2004).

This theory argues that organizations and individuals are constrained by a series of rules, values, norms, and assumptions, which are created by them through their actions and interactions (Barley & Tolbert, 1997; Giddens, 1979, 1984). These rules and values greatly influence how things should be done, but they do not totally determine human action (Barley & Tolbert, 1997). Therefore, institutionalization is a continuous process that can only be observed over time. It is also a cultural and political process related to legitimacy and power—and not necessarily to efficiency (Powell & DiMaggio, 1991). Organizations adopt business practices that are perceived as legitimate in society as a result of coercive, normative, or imitation pressures (Khadaroo, 2005). Accordingly, there are different mechanisms that influence organizational change—in particular, competition, normative isomorphism, coercive isomorphism, and mimic isomorphism (Bennett et al., 2004; Powell & DiMaggio, 1991). Due to its main focus on institutions, some scholars argue that institutional approaches have not adequately included the material properties of technological artifacts in their analyses (Garson, 2003). Other researchers consider that most studies using institutional theory need to explicitly and clearly explain how they are incorporating the role of human agency and the reciprocal relationships between institutions and individual actions (Yang, 2003).

Based on the institutional tradition and as an attempt to explicitly include the role of technology in a comprehensive approach, Fountain (1995, 2001) develops a framework that "pays attention to the relation among information technologies, organizations, embeddedness, and institutions." Using empirical evidence from government information technology initiatives in the U.S. federal government, Fountain (2001) proposes a new way to conceptualize technology within an institutional theoretical tradition: the technology enactment framework.

The technology enactment theory attempts to explain the effects of organizational forms and institutional arrangements on the technology used by government agencies (Fountain, 1995, 2001; Gil-Garcia, 2006). According to this theory, the "technology is enacted in political, social, economic, and organizational contexts" (Fountain, 2004). Fountain (2004) explains that "two of the most important influences on the enacted technology are organizations and networks," and provides examples of information technologies implemented in comparable organizational contexts but with very different results. The interactions among organizational characteristics, networks, and institutions may explain some of these differences. Based on the institutional tradition (Brinton & Nee, 1998; Powell & DiMaggio, 1991; Scott, 2001), she argues that the embeddedness of actors in social, cultural, cognitive, and institutional structures influences the design, perception, implementation, and use of information technologies. Each project is embedded in a certain organizational environment and is affected by specific institutional arrangements. As a result, each organization uses technology differently and obtains different performance, costs, and results (Dawes, 2002; Fountain, 2001). Therefore, organizational characteristics and institutional arrangements have an impact on the enacted technology (Fountain, 2001; Gil-Garcia, 2006; Luna-Reyes, Gil-García, & Cruz, 2006). These institutions could be seen as guides for action, but also limitations to those actions (Brinton & Nee, 1998; Fountain, 2001; Scott, 2001).

Fountain (2001) proposes an analytical distinction between objective technology and enacted technology. Objective technology is described in terms of its capacity and functionality—that is, hardware, software, telecommunications, and other material characteristics, independently of how people use them (Fountain, 2004). In contrast, enacted technology refers to how users perceive and act upon objective technologies. In this instance, the enacted technology could be conceived as a subset of the objective technology (Puron Cid & Gil-Garcia, 2004). However, social actors can also enact new uses that were not included as part of the original design and functionality (Fountain, 2001; Orlikowski, 2000). Therefore, the technology enactment is flexible and fluid and can be observed as it develops over time through interactions among social actors and between actors and technologies (Gil-Garcia, 2006; Orlikowski, 2000). The enacted technology is affected by social, cultural, cognitive, structural, and political factors, but it also affects these factors in a recursive relationship (Fountain, 2001, 2004). Social actors draw upon institutional arrangements and, therefore, the enacted technology is affected by institutions, organizational characteristics, and environmental conditions (Fountain, 2004; Luna-Reyes et al., 2006).

Fountain's analytical framework explains how social actors enact information technologies in order to adapt them to the existing organizational rules, routines, and relations (Fountain, 2001). These modifications are not necessarily optimal and make clear the influence of organizational and institutional arrangements on the selection, design, implementation, and use of information technologies (Fountain, 2004). In addition, organizational actors tend to enact technologies that preserve the current social order, networks, and structures (Fountain, 2001; Kraemer, King, Dunkle, & Lane, 1989).

In summary, Fountain's technology enactment framework argues that information technologies are embedded in organizational and institutional environments and it is very important to understand these environments (Fountain, 2004). Information technologies have the potential to change business processes, communication patterns, coordination mechanisms, hierarchical structures, and other organizational characteristics. However, information technologies are also affected by organizational and institutional factors (Fountain, 2001, 2004; Gil-Garcia, 2006). The technology enactment framework recognizes this bi-directional and dynamic relationship and suggests alternatives to incorporate relevant variables into analytical models.

RESEARCH MODEL AND HYPOTHESES

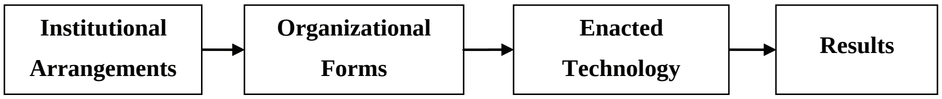
As mentioned before, the research model used in this research is based on institutional theory, drawing specifically on the technology enactment framework (Fountain, 2001) and extending it through a review of current literature on IT in organizations. According to the technology enactment framework, institutional arrangements and organizational forms have an impact on the selection, implementation, and use of information technologies in government.

Institutional theory proposes that the context in which organizations develop has an influence on them (Bansal, 2005). Technology enactment refers to the relationships among institutions (legal, cognitive, cultural, and social), objective information technologies (hardware, software, and networks), organizational forms (bureaucracy, relationships, etc.), and the activities of actors through the selection, design, implementation, and use of information technologies in government settings (Dawes, 2002; Fountain, 2001; Gil-Garcia, 2006).

On the basis of these ideas, Figure 1 shows the research model proposed in this article. In this model, institutional arrangements affect organizational forms and indirectly affect actors' choices about the conceptualization, design, and use of objective technologies, constituting a particular technology enactment. Then, the enacted technology influences organizational results such as efficiency or effectiveness.

In Figure 1, institutional arrangements are represented by procedures, habits, patterns, and regulations that serve as guidelines and constraints for action (Fountain, 2001; Gil-Garcia, 2006). In the particular case of information technology and digital government, the institutional support to IT initiatives and institutional support to a specific project are also being considered as institutional factors. Some of the projects included in the survey are systems mandated by law (such as the law regulating access to government information) or presidential initiatives (like some interorganizational projects conducted by the Ministry of Communications and Transportation). Other projects are also important from a single-agency perspective, but in most cases, decisions about technology not only depend on a single agency, but on several stakeholders, committees, bureaucratic rules, and the relevance of the project itself (Gil-Garcia, 2006). Institutional arrangements guide decisions about IT projects, such as size, goals, objectives, resources, and indicators of success (Fountain, 2001; Gil-Garcia, 2006). Goals, objectives, and resources are important organizational

Figure 1. Research model



characteristics for a particular project. In this way, the first hypothesis of this research relates to the impact of institutional arrangements (laws, regulations, institutional support, etc.) on organizational forms, including goal setting, recognition, or the adequacy of resources to accomplish the goals.

H1: *Institutional arrangements have an influence on organizational forms in inter-organizational IT projects.*

As mentioned before, enacted technology refers to specific choices about design and use of objective technologies, choices that can be observed through characteristics of the project's technology products (Puron Cid & Gil-Garcia, 2004). Enacted technology also refers to the use that different users decide to give to some objective technology (Fountain, 2001). Organizational forms directly influence these choices on design and use, and institutional arrangements also have an impact on the enacted technology, indirectly, through the influence that institutions have on organizational forms (Gil-Garcia, 2006). In this way, systems of goals, recognition, or the adequacy of resources (organizational forms) have a direct impact on specific choices or uses of technology (enacted technology) in a specific project. According to the enactment framework (Fountain, 2001), laws, regulations, institutional support, or other cultural factors (institutional arrangements) do not affect directly the technology choices (enacted technology), but indirectly through their influence on goals, objectives, and other organizational elements. These relationships are reflected in hypotheses 2 and 3.

H2: *Organizational forms affect the way in which technology is understood, designed, and used (enacted) in a particular inter-organizational project.*

H3: *Institutional arrangements have an indirect effect on the technology application and use (enacted technology) in an inter-organizational project through its influence on the organizational forms.*

Particular technology enactments, reflected in the usefulness or how easy it is to use a particular technical solution, are developed and subsequently used in order to have an impact on organizational performance and results. Better systems are designed to improve productivity, service quality, or efficiency (Fountain, 2001). Moreover, the context where a particular enactment takes place is the organization and, therefore, organizational forms also have an influence on the results of using information technologies. That is to say, the specific context (organization) has an influence on IT design, development, and use, but the technology itself also has an effect on performance (Fountain, 2004). In this way, specific enactments of technology have a direct effect on the expected results. The impacts of the organizational forms on the expected results are mediated by the enacted technology according to the enactment framework. Hypotheses 4 and 5 summarize these effects.

H4: *The enacted technology, which is the way technology is interpreted and used, has an effect on organizational results and performance.*

H5: *Organizational forms affect indirectly organizational results and performance through their direct effect on the enacted technology.*

RESEARCH METHODS

The research reported here constitutes the results of the second stage of a multi-method project developed in three stages. The first stage involved a series of interviews with project managers of inter-organizational projects in the Mexican federal government. The second stage encompassed a survey applied to participants in the projects identified during the first stage. The third stage consisted of conducting three case studies, including additional interviews with participants in some projects and document research. This article reports on the results of the survey conducted during the summer of 2006. This section of the article includes a brief description of the subjects, the survey, and the procedures followed in the research to gather empirical evidence for the relations in the hypotheses described in the previous section. It is started by describing the population and the sampling methods, and then the survey instrument and the procedures followed to apply the survey are described.

Sample

As mentioned before, the interest was to explore the effects of institutional arrangements and organizational forms on IT projects involving inter-organizational collaboration. An initial sample of projects was identified during the first stage. The projects were identified using the Internet as a search tool, and asking the project managers interviewed for additional projects to include, following a snow ball approach. In this way, 13 government agencies were identified as involved in inter-organizational projects at the federal level (National Bank for Savings and Financial Services, Ministry of Public Administration, Ministry of Transportation, Ministry of Health, Federal Institute for Access to Information, Mexican Institute for Social Security, INFOTEC, Ministry of Justice, Internal Revenue Service, Ministry of Education, President's Internet Office, Ministry of Economy, and Ministry of Finance). The survey database was put together by compiling names and e-mail addresses of project participants from the agencies Web pages or from lists provided by the project managers interviewed. The database included 1,216 people from federal agencies who participate in 13 inter-organizational projects, and it was decided to include all of them in the sample. Therefore, the study uses a purposive sample of public managers involved in well-known inter-organizational IT projects. Although the population is unknown, which may limit the generalizability of the results, this approach allows establishing a robust sampling framework for this research.

An electronic survey was developed and the usable response rate was 23.2% (n = 282). Forty percent of respondents reported having more than 10 years of working experience in the federal government, and 81% reported having more than 10 years of working experience in general. Fifty-five percent of respondents have experience in the area of informatics, 31% in policy making, and 25% in program development. Most respondents have a college education (97%), while 40% have a graduate-level education.

Survey Instrument

A survey instrument was adapted and re-designed from Fountain's original instrument (Fountain, McKinnon, & Park, 2003). The instrument included questions that sought to understand the effects of institutional arrangements and organizational forms in inter-organizational IT projects. The original instrument was first translated into Spanish and adapted to the Mexican context by the researchers. Then, to ensure content validity and comparability, the instrument was reviewed by two expert translators and four government officials in a two-stage process. Following their recommendations, the research team made adjustments and changes to the survey instrument for both content and format.

The final instrument had 35 questions;[1] five questions were associated with institutional arrangements, six with organizational forms, eight with enacted technology, and 10 with results. The questions related to institutional arrangements include perceptions about influences of government culture, legislation, support from congress, and institutional support for the use of IT. The questions in this scale showed a Cronbach-alpha value of 0.770 (see Table 1).

Organizational questions included aspects related to the definition of goals and performance indicators, adequacy of financial and human resources, and adequacy of recognition from managers. The alpha value for this scale was 0.733. Enacted technology was operationalized in the survey as a series of questions related to the quality of particular technology characteristics enacted in each project. Some of the main characteristics included were ease of use, usefulness, information quality, functionality, personalization, security, and privacy. The alpha coefficient for this scale was 0.932. Finally, results were measured as the level of project success in terms of productivity, cost reduction, transparency, citizen participation, effectiveness of government policies and programs, and quality of service. The alpha value for this scale was 0.905.

Procedures

As mentioned, the survey was administered electronically using a commercial service called SurveyMonkey. Potential respondents (1,216 people) were sent an initial e-mail invitation to participate in the survey during the summer of 2006, giving them the option of declining the invitation. A second e-mail providing the Web address of the survey to complete was sent. A total of three reminders were sent. The first reminder was sent a week after the Web address was sent. The second reminder was sent one week later, and the last reminder was sent a day before the survey was closed.

After the initial e-mail with the survey Web address was sent, 137 answers were received (11.3% response). The first reminder increased the responses to 221 (18.2% response). After the second reminder, the number of responses increased to 273 (22.5% response). With the last reminder, responses increased to 330 (27.1%). Unfortunately, 48 responses were blank with the exception of the first couple of questions, reducing the valid responses to 282. These usable responses correspond to a response rate of 23.2%, which is generally considered acceptable for a Web-based survey. Once the survey was closed, the database was cleaned and analyzed. The following section summarizes the main survey results.

RESULTS AND DISCUSSION

The e-government projects included in the survey are considered successful by respondents (respondents were either participants in the e-government projects or users of the e-government systems associated with the projects). The number of agencies involved in the projects surveyed varied greatly. Many projects involved collaboration between 10 or fewer agencies; three projects involved more than 50 agencies working together. Overall, 88% of respondents believe their project has well-defined goals, 84% believe it is feasible that their project will reach these defined goals, and 75% believe there are clear indicators for success. Most respondents consider that their project is important for the country.

Table 1. Cronbach-alpha values for main constructs in the model

Construct	Items in scale	Alpha value
Institutional Arrangements	5	0.770
Organizational Forms	6	0.733
Enacted Technology	8	0.932
Results	10	0.905

Although respondents consider their projects to be successful and to offer high-quality results, they also mention some problems. Problems are often associated with the lack of human and financial resources and mismatches between project goals and agencies regulations. In addition, respondents consider a variety of political factors, resistance to change, red-tape, and the influence of individual interests as important issues to consider when developing IT projects in government. Only half of the respondents believe the current laws support inter-organizational digital government initiatives, and about one-third (35%) believe legislators support these kinds of projects.

Table 2 includes descriptive statistics for the main constructs in the proposed model. Maximum values in the table coincide with the maximum values of each scale. The relative positions of the means in each scale with respect to the maximum value are in the range from 76% to 86%. The lowest relative mean corresponds to organizational forms, and the highest to enacted technology. Translating the mean values to a 10-point scale to better understand their meaning, respondents assigned an 8.0 to the adequacy of laws, government culture, congress support, and institutional support (institutional arrangements), a 7.6 to the definition of goals and performance indicators, combined with the adequacy of human and financial resources and systems of recognition (organizational forms). They assigned an 8.6 to the current design of the inter-organizational technologies in terms of ease of use, utility, quality, functionality, customization, security, and privacy (enacted technology), and an 8.3 to the success of the projects in terms of success measures such as cost reduction, effectiveness, increased productivity, or improved citizen participation (results).

Pearson correlation coefficients were calculated for all constructs (see Table 3). As shown in the table, the model constructs are moderately correlated. All correlations are significant at a $p<0.01$ level. The highest correlation exists between the enacted technology and the results, while the smallest correlation occurs between institutional arrangements and organizational forms.

In order to test the hypotheses posed by the proposed model, linear regression was used. Equations 1 through 7 show the main regression equations used in this research. Regressions 1, 2, and 3 are used to test hypotheses 1, 2, and 4. To test indirect effects in hypotheses 3 and 5, an approach proposed by Baron and Kenny (1986) was followed.

$$\text{ORG} = \beta_1 \text{ INST} + \varepsilon \tag{1}$$
$$\text{TECH} = \beta_2 \text{ ORG} + \varepsilon \tag{2}$$
$$\text{RES} = \beta_3 \text{ TECH} + \varepsilon \tag{3}$$
$$\text{TECH} = \beta_4 \text{ INST} + \varepsilon \tag{4}$$
$$\text{RES} = \beta_5 \text{ ORG} + \varepsilon \tag{5}$$
$$\text{TECH} = \beta_6 \text{ ORG} + \beta_7 \text{ INST} + \varepsilon \tag{6}$$
$$\text{RES} = \beta_8 \text{ TECH} + \beta_9 \text{ ORG} + \varepsilon \tag{7}$$

where,

ORG = Organizational Forms
INST = Institutional Arrangements

TECH = Enacted Technology
RES = Results

The approach consists of four steps that involve estimating independent regression coefficients to establish mediation. Consider for example the case of hypothesis 3, in which the effect of institutional arrangements on the enacted technology is mediated by organizational forms (see Figure 2). The first stage when testing this hypothesis involves testing relation "c" in Figure 2, showing that the institutional arrangements have an impact on the enacted technology. The second step consists of testing the relationship between institutional arrangements and the mediator, organizational forms (relation "a" in the figure). If any of these two relations are not statistically significant, then the data does not provide evidence of mediation. The third step involves testing the effect of the mediator (organizational forms) on the final variable (enacted technology), controlling for institutional arrangements (the initial variable). If this last relation is statistically significant, and the path "c" becomes zero when controlled by the mediator, then there exists full mediation. If both paths are statistically significant ("b" and "c"), there is partial mediation.

In this way, to test hypothesis 3, regressions (1), (4), and (6) will be used, testing the relation between institutional arrangements and the enacted technology, mediated by organizational forms. Regressions (1) and (4) must be statistically significant. In regression (6), β_6 needs to be statistically significant, and β_7 must be zero to show full mediation. If both coefficients β_6 and β_7 are significant, there will be only partial mediation. To test the relation between organizational forms and results, mediated by enacted technology, regressions (2), (5), and (7) will be used.

Table 4 summarizes the results of the seven regression models described. The first column in the table contains the regression equation number. The second and third columns represent the dependent and independent variables in each

Figure 2. Relations for testing indirect relationships (Baron & Kenny, 1986)

*** $p<0.01$*

**** $p<0.001$*

regression equation. Column 4 in the table presents the standardized regression coefficients for each model. The last two columns show the R-square value, and the F-test for each model.

Looking at the values in regressions 1, 2, and 3, it can be concluded that the survey data supports hypotheses 1, 2, and 4, finding significant direct relations between institutional arrangements and organizational forms, between organizational forms and the enacted technology, and also between the enacted technology and the results. It is important to notice that enacted technology explains more than 50% of the variance in results.

In the case of hypothesis 3, there is a significant relation between institutional arrangements and organizational forms, and also between institutional arrangements and enacted technology (regressions 1 and 4). Moreover, the relation between organizational forms and enacted technology is significant when controlling for institutional arrangements (regression 6). However, the relation between institutional arrangements and enacted technology is also significant when controlling for organizational forms. Therefore, the survey data supports a partial mediation of organizational forms on the effect of institutional arrangements on the enacted technology. It is important to note that the impact of institutional arrangements on enacted technology is greater than the impact of organizational forms on the same variable.

In the case of hypothesis 5, there is a significant relation between organizational forms and results (regression 5), and between organizational forms and the enacted technology (regression 2). Again, looking at the coefficients of regression 7, it is observed that survey data supports the existence of partial mediation of enacted technology over the relationship between organizational forms and results.

In summary, the regression analyses presented in Table 4 fully support hypotheses 1, 2, and 4, and partially support hypotheses 3 and 5, given that there is no full mediation, but only partial mediation of the relations in those hypotheses and, therefore, direct effects also exist.

CONCLUSION

Given the importance of information and communication technologies in government, it is also essential to understand key factors effecting its use and implementation. Five hypotheses based upon the technology enactment framework were proposed, in order to empirically test the theory, but also to get a better understanding of the relationships among institutional arrangements, organizational forms, enacted technology, and organizational results. In order to test the hypotheses, a survey was administered to participants of inter-organizational e-government projects in the Mexican federal government. Survey results allow to derive implications for both theory and practice.

Survey results suggest that the technology enactment framework (Fountain, 2001) can be potentially enriched with two additional causal relationships (see Figure 3). Although the original enactment framework suggests that the effects of institutional arrangements on the enacted technology are mediated by organizational forms, data from our survey also support a direct effect of institutional arrangements on the enacted technology. In fact, the effect of institutional arrangements is stronger than the effect of the organizational forms. Qualitative data from the survey and interviews to project managers support this additional causal relationship, too.

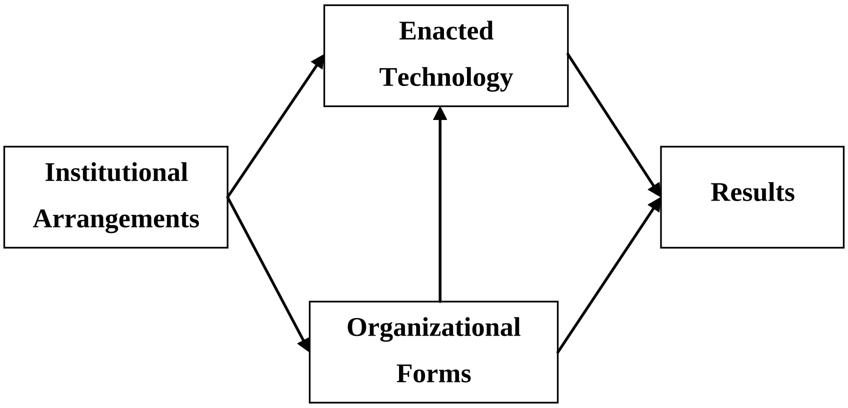
The whole Mexican IT strategy from 2000 to 2006 was driven by a presidential mandate. Moreover, particular technology enactments can be traced to mimetic mechanisms. For instance, many IT-related decisions are driven by best-practices research, or by current practices of a leading agency such as the Ministry of Finance, and sometimes it is difficult to trace IT-related decisions to specific problems or needs. As in many other countries, technology decisions and designs are either constrained or enabled by the legal framework and regulations. Budget cycles, for example, constrain the size of the IT project, which in most cases cannot extend for more than a year.

The second causal relationship suggested by the survey data establishes a significant relationship between organizational forms and results. More concretely, decisions on organizational structures, goals, and performance indicators not only affect a particular enactment, but also affect directly the results of the project. The e-Mexico program, for example, has as a strategic activity the installation of telecenters in the whole country. Accomplishing this task involves collaboration of the Ministry of Transportation, the Ministry of Education, the Ministry of Health, and the Ministry of Social Development, among others. Different organizational forms of these ministries have not only affected the particular enactment of the telecenters sponsored by each of them, but also constrained or enabled the impact of the telecenters in the community.

Thus, institutional arrangements have a direct impact on particular enactments, making lobbying activities even more important to ensure project success. Given that organizational forms constitute a context that also directly influences project results, process redesign is confirmed to be a key activity to succeed in e-government projects.

Additionally, survey data provides support for the direct affects of institutional arrangements on

Figure 3. Revised model as suggested by survey data



organizational forms, organizational forms on the enacted technology, and enacted technology on organizational results. Thus, culture, laws, regulations, and institutional support have an important effect on organizational forms as they are reflected in goals, defining indicators, or during human and financial resource allocation. Moreover, these organizational forms have an impact on the characteristics of particular enactments of technology. For instance, adequacy of human and financial resources, as well as well-defined goals and indicators, have an impact on technological characteristics such as utility, quality of information, or ease of use. Finally, characteristics of a particular enactment have an effect on the results of using technology in government. That is to say, system functionality and quality have a positive impact on the expected results as perceived by the respondents.

Although organizational forms and enactments are under the control of project managers, they usually have more difficulty influencing institutional arrangements in which the project takes place. However, those institutional arrangements effect and constrain the project manager's work. Thus, to be able to manage an effective project, every manager should use at least part of his or her time looking for strategies to promote institutional change. In the case of Mexico and the projects involved in this research, these institutional arrangements are especially important, considering that almost half of the respondents recognized that laws and regulations are in need of improvement. Moreover, intensive lobbying may be an important strategy, given the perception of inadequate support for e-government projects and inter-organizational collaborations from legislators.

On the other hand, survey results are encouraging in the sense that they support the idea that effective technology enactments will deliver results for government organizations. Then, given the adequate institutional arrangements, project managers can make organizational and technology choices to deliver results. Certainly, the promise is apparent if the technical requirements are well identified and proper project management techniques are used.

Finally, this work contributes to the field by providing empirical evidence for important causal relationships often cited in the literature, but with little empirical quantitative exploration. Furthermore, it provides empirical evidence of the existence of such relationships in a context different from the context in which the theory was created, providing evidence of the applicability of the theory in different digital government contexts, particularly in Latin America.

ACKNOWLEDGMENT

This study was supported by the National Council of Science and Technology (CONACYT-Mexico) under grant SEP-2004-C01-46507 and by the National Science Foundation (NSF) under Grant No. 0131923. The views and conclusions expressed in this article are those of the authors alone and do not necessarily reflect the views of CONACYT or NSF. This article is based on work contributed by Víctor M. Morán-Rodríguez, Bárbara Aguilera-Alcántara, and Cinthia B. Cruz.

Chapter 5.15

Strategic Alliance Capability:
Bringing the Individual Back into Inter-Organizational Collaboration

Christiane Prange
EM Lyon Business School, France

ABSTRACT

Internationalization has accelerated the speed of knowledge generation and innovation. Thus, companies increasingly need to pool and create new resources by engaging in alliances with various partners. However, high failure rates of strategic alliances imply that the degree of a company's collaboration success is related to the level of its alliance capability. While ”alliance capability” has largely been conceptualized from within the resource based and the dynamic capability view, one of the major drawbacks is the lack of micro-foundations, i.e. an explanation of individual knowledge and actions, which drive the development of alliance capability. A modified approach to the capability life-cycle is introduced, which aims at filling this gap. Finally, some implications for managerial practice and for future research are addressed.

INTRODUCTION

In the global marketplace, competitive advantages have become increasingly difficult to realize and many firms strive for new sources of knowledge and corporate growth. For many companies, strategic alliances have become a cornerstone in their expansion efforts because they facilitate access to new resources and wealth creation. Indeed, strategic alliances[a] can be considered a critical issue in the network economy, which is evidenced by both their rise in number and the variety of emerging forms, such as 'value networks', 'alliance networks' or 'alliance constellations' (Gomes-Casseres, 2003; de Man, 2005).

Motives for those 'loosely-coupled arrangements' (Weick, 1976) include easier access to foreign markets, economies of scale, accelerated development of technological capabilities, risk reduction and the acquisition and transfer of knowledge embedded in respective partners (e.g., Hamel, Doz and Prahalad, 1989; Larsson, Bengtsson et al.

1998). Yet, there is also widespread recognition that firms fail with roughly half of the alliances they form and there is considerable heterogeneity in terms of reported performance results (Bleeke and Ernst, 1993). Indeed, the inherent instability of strategic alliances has led both practitioners and researchers to focus on the intriguing question of what firms can do to enhance alliance results (Chang, Chen and Lai, 2008).

Previous research on the success factors of alliances has largely focused on structural and cultural aspects, presuming that these are the major drivers of effectiveness (Cartwright and Cooper, 1993). Only recently has attention been drawn to the fact that some firms are considerably more successful in managing alliances than others and the degree of a company's collaboration success has been linked to specific capabilities involved in managing these relationships (Wuyts, Dutta and Stremersch, 2004). With the recent hype of both the resource-based view (RBV) and the dynamic capability view (DCV) in strategy research, firm-specific factors, such as routines and capabilities, have been highlighted as antecedents of rent differentials (Nelson and Winter, 1982; Barney, 1991).

In this stream of research, the unit of analysis is no longer the relationship between firms, but a distinct organizational-level capability that is subject to dynamic processes of development, change, and improvement. Consequently, subsequent work has emphasized that alliance capability positively contributes to firm-level competitive advantage (Anand and Khanna, 2000).

However, it has also been suggested that the construct of alliance capability should be conceptualized on multiple levels, spanning individuals, groups, and organizations (Blomqvist and Levy, 2006). Unfortunately, studies which refer to *individual* alliance capability, or even comprise multiple level issues, are sparse and firms are left in the dark about adequate action perspectives for the individual manager (Johnson, Melin and Whittington, 2003). Part of the problem is due to the fact that traditional capability research adopts a collectivist focus, while neglecting micro-level foundations (Felin and Foss, 2004; Teece, 2007).

By building on these omissions, a deliberately individual focus is adopted to investigate the micro-foundations of alliance capability. This article provides the following contributions: *First*, a synopsis of previous research on alliance capability is presented and contributions and shortcomings are discussed. *Second*, by highlighting theoretical contributions from the RBV and the DCV, it will be shown that both offer valuable contributions to the conceptualization of alliance capability but do not sufficiently explain how capabilities develop. *Third*, by building on these omissions, a framework is proposed that considers individual contributions to the development of organizational alliance capabilities more thoroughly. *Finally*, some avenues for future research and some practical managerial implications will be suggested.

Strategic Alliance Capability: A Synthesis of the Literature

In this article, the terms of 'alliance capability' and 'strategic alliance capability' are used synonymously to signify those capabilities required to successfully manage a strategic alliance. 'Managing' is used as a generic term to incorporate all activities of an alliance life-cycle (see subsequent paragraphs). This section consists of a literature synopsis of the discourse domain (main terms, constructs, and developments). It further locates an important research gap in the lack of clear interrelations between individual-level origins and organizational-level alliance capability.

Definitions of Strategic Alliance Capability: The Formation of a Research Field

The recent literature on strategic alliances has paid considerable attention to either the very beginning of a collaborative activity and/or the ultimate end of the venture, while managerial issues in-between have been left understudied (Doz, 1996; Kandemir, Ghauri, and Cavusgil, 2002). For instance, Kogut (1988) adopts a life-cycle approach and describes the development sequences of joint ventures as those of creation, institutionalization and termination. Van de Ven and Walker (1984) introduce a stage model that explains the frequent decline of collaborative endeavours. They argue that the reason for the eventual dissolution is implicit in the formation stage, where structures are formalized and control mechanisms agreed. A number of authors have also gone beyond traditional linear stage models by suggesting cyclic relationships. For instance, Zajac and Olsen (1993) relate to the stages of initializing, processing and reconfiguration. During the initializing stage initial conditions are set. In the processing stage, learning takes place and first behaviour patterns evolve. Finally, in the reconfiguration stage, the collaboration is evaluated and this may lead to a revision of the original conditions. While all these research efforts have offered valuable insights into a large task-set associated with collaborative ventures, they fail to provide detailed knowledge of managerial responsibilities.

With the advent of ‘alliance or collaborative capability’, initial efforts were undertaken to fill this void. Focusing on specific capabilities to mange relationships became popular in academic discussion in the mid-1990s (Bucklin and Sengupta, 1993; Simonin, 1997; Lorenzoni and Lipparini, 1999). In the marketing and sales literature, interest concentrates on improving relationships between firms and their customers (Day, 1994; Storbacka, Strandvik and Grönroos, 1994; Crosby, Evans and Cowles, 1990; Sivadas and Dwyer, 2000). With regard to a firm’s business-to-business relations, Håkansson (1987: 124) defines ‘networking ability’ as “a firm’s ability to improve its position in a network (with regard to resources and activities) and its ability to handle individual relationships.” However, the concept remains rather vague and lacks operationalization.

In the management and strategy literature, Simonin (1997: 1151) was among the first to empirically investigate ‘collaborative know-how’, which he measures as the extent to which firms have skills in identifying, negotiating, managing, monitoring, and terminating collaborations. Subsequently, a large array of heterogeneous terms emerged, which amply illustrates the pre-paradigmatic stage of research. Some authors refer to ‘relational capability’ and argue that the ability to interact and share knowledge with other companies is a distinctive organizational competence for firms transactionally intensive in nature (Lorenzoni and Liparini, 1999; Dyer and Singh, 1998). Others use terms, such as ‘network management capability’ (Birkinshaw, 2000), or ‘network capability’ (Ritter, 1998; Walter, Auer and Ritter, 2006), ‘network ability’ (Håkansson, 1987; Hamel, 1991; Hamel, Doz and Prahalad, 1989) or ‘alliance capability’ (Draulans, de Man and Volberda, 2003; Kale, Dyer and Singh, 2002; Kale and Singh, 1999; Khanna, 1998). While the normal convention seems to be that alliances refer to bilateral and networks to multilateral relations, the use of terms has remained rather ambiguous.

Further research referred to ‘learning to manage alliances’ (Anand and Khanna, 2000) as an ability to anticipate and respond to contingencies that cannot be pre-specified in a formal contract. While the learning focus connects to dynamic cycles of alliance development, it has also been related to experience necessary to build alliance capability (Simonin, 1997; Kale, Dyer and Singh, 2002; Heimeriks and Duysters, 2007). Simonin concludes that a firm should first internalize collaborative experience before the lessons learned become useful for a firm’s future alliances. Others also focus on experience and learning effects and their presumed translation into future alliance success (Gulati, 1999; Kale, Singh and Perlmutter, 1999), but do not explain the associated aggregation problem. For instance, Gulati (1995) investigates the importance of prior ties and their influence on future modes of cooperation but does not explain *how* firms can successfully internalize experience. Anand and Khanna (2000) argue that experience plays an important role in the stability of inter-firm collaborations. As firms accumulate experience, their increasing abilities to anticipate and respond to critical contingencies are likely to enhance the chances of success in subsequent alliances.

In short, the majority of studies finds a positive and linear relationship between experiences and alliance performance (Anand and Khanna, 2000; Heimeriks and Duysters, 2007). However, it has also been argued that greater experience may be a necessary but an insufficient condition for firms to build alliance capability. This has been explained by the fact that firms differ in their abilities to appropriate knowledge from alliances (Kumar and Nti, 1998). As Chang, Chen and Lai (2008: 299) argue, “prior experience …may at best be a crude proxy for the precise mechanisms that build alliance capability [and] further alliance capability enhancement may rest upon how effectively a firm is able to capture, share, and disseminate the learnt know-how associated with prior experience”. In a related vein, relations between alliance experience and alliance performance have been found to follow a curvilinear pattern (Deeds and Hill, 1996; Hoang and Rothaermel, 2005) based on increasing conflict-resolution skills (Mohr and Spekman, 1994) and accumulated process know-how (Simonin, 1997).

Taken collectively, previous research has widely contributed to the formation of a new research field but developments have been hampered by scant attention given to precise definitions of alliance capability and its constituting elements. However, minimum consensus exists on the issue of alliance capability as being related to the stages of the alliance life-cycle. As succinctly summarized by Lambe, Spekman and Hunt (2002: 142) alliance capability is the “organizational ability to find, develop and manage relationships”. While this definition is useful because it includes dynamic aspects of change - which preview an investigation from a dynamic capability perspective (see subsequent chapters) - , it does not provide much insight into what *exactly* constitutes the construct of alliance capability.

Elements of Strategic Alliance Capability

What makes up alliance capability has so far remained rather elusive (Gulati, 1998). However, there have been a few selected attempts to more precisely identify its elements. For instance, Ritter and Gemünden (2003) distinguish between the tasks that need to be performed in order to manage a company’s technological network and the qualifications, skills, and knowledge that are required in order to perform these tasks. More precisely, tasks refer to relation-specific (e.g. initiation of first partner-contacts, exchange of products and information, coordination of exchange) and cross-relational tasks (e.g. analysis and planning, organizing and staffing). Network management qualifications involve a complex process, which requires specialist knowledge of the technical side of the relationship and social qualifications. Both types of elements are seen as being highly interdependent. While the authors conclude that their study highlights a firm’s ability to initiate, handle, and use a portfolio of inter-organizational relationships, they seem to confuse the individual and organizational units of analysis. Related research proposes that cooperative competency consists of the ability of the partners to trust, communicate, and coordinate (Sivadas and Dwyer, 2000) with social skills being explicitly emphasized as a complement to structure-related elements of alliance capability (Lawler and Thye, 1999; Prange, Bojkowszky and Wieshofer, 2004).

One of the most comprehensive investigations of alliance capabilities and their elements has been provided by Schreiner and Corsten (2004) and Schreiner (2004), who empirically investigated the components of what they call ‘collaborative capability’. They suggest that capabilities in a collaborative context consist of structural, cognitive, and affective elements.

Structural capabilities, according to their view, include the build-up and maintenance of human resources, partner-specific tangible and intangible assets, as well as time-management and investment strategy (so-called resourcing elements). Further, coordinative elements are subsumed under this category, e.g. partnership and task management, interaction routines, process standardization and personnel continuance. *Cognitive capabilities* refer to the existence of absorptive capacity as the ability to assimilate and exploit new information to foster learning (Cohen and Levinthal, 1990) and the potential to effectively communicate. Finally, *affective capabilities* consist of care-giving and empathic abilities. Again, this study provides important input for a better understanding of alliance capability but suffers from two major drawbacks: It does not clearly link alliance capabilities to the associated alliance life-cycle, and, more importantly, it neglects the linkage between individual skills and organizational routines.

Levels of Strategic Alliance Capability

The previous omissions are also prevalent in subsequent work, where either life-cycle and *organizational* capabilities or *individual* skills are emphasized. The former most often suggests improving specific tasks, such as the codification and transfer of information within ‘dedicated alliance functions’ (Anand and Khanna, 2000; Dyer, Kale and Singh, 2001) or implementing ‘organizing principles’ for the internalization of alliance management know-how (Kale, Dyer and Singh, 2002). These capabilities are seen as being embedded in organizational routines, which are repetitive activities a firm applies in order to deploy its resources available in and through alliances (Nelson and Winter, 1982). In addition, alliance training, alliance metrics and evaluation systems, best practice programmes as well as external support by consultants, lawyers, and financial specialists have been suggested to support those routines (Heimeriks and Duysters, 2007). Taken collectively, the locus of this stream of research remains an abstract phenomenon of alliance capability, which almost completely neglects the concrete contribution of the individual in inter-organizational research.[b]

On the other hand, there is a variety of studies, which places major emphasis on *individual* skills and their impact on collaboration. Scholars have argued that strong interpersonal ties provide channels through which partners learn about other firm’s competencies and reliability (Gulati, 1999). From this perspective, relational capital which rests upon close interpersonal ties at the dyadic level can also play an important role in creating and building larger alliance networks (Kale, Singh and Perlmutter, 2000: 218). Draulans, deMan and Volberda (2003) examine whether it may be useful to concentrate alliance knowledge and experience in certain individuals. While middle management is regarded as potentially suitable for such activities, they focus less on the respective capabilities for managing relations. McGee, Dowling and Megginson (1995) concentrate on experience-based collaborative capabilities and analyze the question as to whether inexperienced managers should cooperate to gain new knowledge or rather avoid it unless they are experienced enough to know what they don’t know.

In short, various research has emphasized elements and levels of alliance capability albeit in a rather disconnected manner. However, preliminary suggestions have been made to consider alliance capability as a *multi-dimensional* and *multi-level construct*, in which elements and levels are closely interlinked and mutually reinforcing (Schreiner, 2004; Blomqvist and Levy, 2006; Dansereau,Yammarino and Kohles, 1999). While studies tend to emphasize single levels of analysis or refrain from clear level specifications, a notable exception is the research by Buckley, Glaister and Husan (2002), who investigate managers' 'partnering skills' in cross-cultural joint ventures and distinguish between national and macro elements, industry or sector level factors, organizational and firm levels, and the perceptions of individual managers.

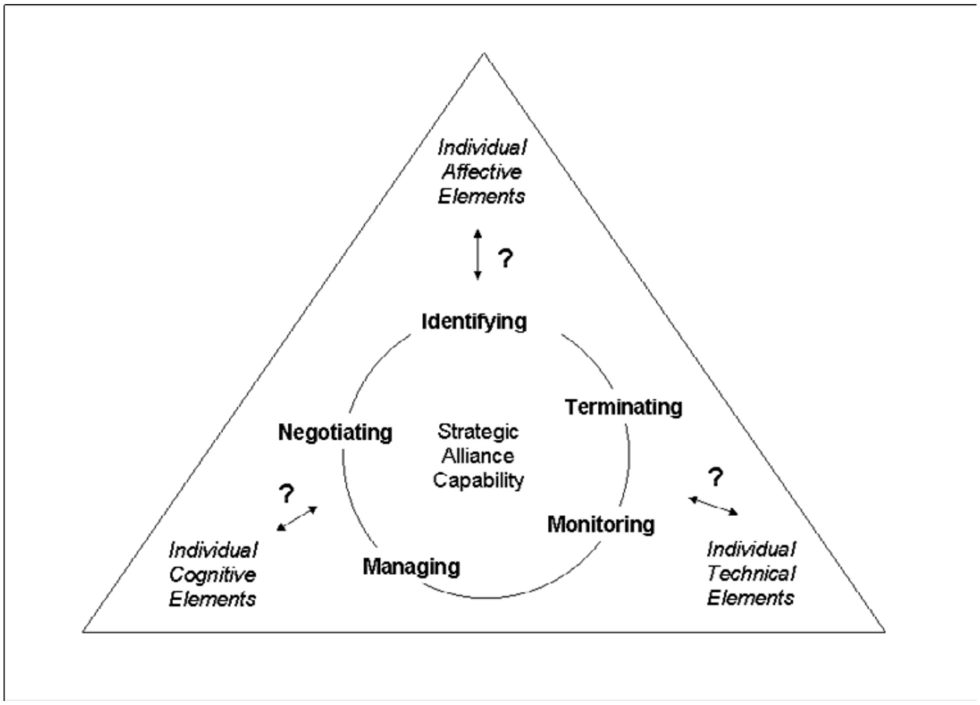
Figure 1 builds on this approach and provides a generic overview of the previous debate with a particular emphasis on the levels of the individual and the organization. Categorical labels for elements are borrowed from Schreiner (2004) but clearly relate to the individual. Further, the notion of structural elements is replaced by 'technical' because the former has too close an association with organizational structures. Arrows in the figure indicate that linkages between individual elements and organizational alliance capability are largely missing in the literature.

Part of the confusion on levels and definitions can be traced back to the theoretical origin of resource and capability definitions within strategic management research. Indeed, as research within the RBV and the DCV itself can still be considered in its infancy (Helfat, 2000), it is not surprising that theoretical contributions lack precise insights into the black box of alliance capability (Priem and Butler, 2001).

THEORETICAL FOUNDATIONS OF STRATEGIC ALLIANCE CAPABILITY

As a theoretical foundation of explaining alliance capability, both the resource-based view and the dynamic capability view of strategy have been suggested (Kale and Singh, 2007). The dynamic capability view extends the argument by departing from the static notion of resources.

Figure 1. Elements of strategic alliance capability



As capabilities for new market entry relate to multiple environments, it is important for a firm to constantly reconfigure its alliance capability. Hence, a dynamic capability view offers a suitable theoretical foundation as it suggests some leeway for learning, integrating, building and reconfiguring internal and external competencies (Teece, Pisano and Shuen, 1997).

Resource-Based View

The RBV considers firms as bundles of resources, which form a prerequisite for achieving and sustaining competitive advantage (Rumelt, 1984; Wernerfeld, 1984; Barney, 1991; Prahalad and Hamel, 1990; Amid and Schoemaker, 1993). The major argument of the RBV is that firms are able to accumulate resources and capabilities that are rare, valuable, imperfectly inimitable and imperfectly substitutable (Barney, 1991; Wernerfeld, 1984). Consequently, a firm's performance is fundamentally due to the heterogeneity of its resources and their persistence over time rather than to industry structure as argued in the market-based view of the firm (Porter, 1980). In exploring this approach, I concur with recent contributors to the literature, who distinguish capabilities from resources (Grant, 1991; Mahoney and Pandian, 1992; Teece, Pisano and Shuen, 1997). *Resources* refer to "all assets, capabilities, organizational processes, information, knowledge, etc. controlled by a firm that enable the firm to conceive and implement strategies" (Barney 1991: 101), i.e. assets pose an input to production. In contrast to resources, organizational *capabilities* refer to an organization's ability to perform a coordinated set of tasks, utilizing and leveraging organizational resources, for the purpose of achieving a particular end result (Amit and Schoemaker, 1993; Helfat and Peteraf, 2003).

The distinction is not completely selective but it has been recognized that capabilities are required to leverage resources and it is therefore capabilities, which provide the essential basis of competitive advantage. As related to alliances, it has been argued that the factual collaborative relationship should be considered a resource, while alliancing as a managerial process has tentatively been mentioned as a capability (Eisenhardt and Martin, 2000:1106). Further, it has been suggested to consider alliance capability as a *meta-capability* (Blomqvist and Levy 2006), directed at improving the lower-order capability of alliancing (Winter, 2000; Kale and Singh, 2007).

According to Simonin (1997), 'collaborative know-how' or 'alliance capability' also fits each of the criteria for turning resources into competitive advantage.[c] Managing alliances is obviously valuable as collaboration enhances a company's flexibility required for building future options. According to conventional logic, it is also a very rare capability given the extensive failure rates of cooperative undertakings. The third criterion, imperfect inimitability, relates to the fact that alliance capability is often complex knowledge rooted in the social fabric of an organization. Finally, alliance capability is difficult to substitute because it is acquired during a period of experiential learning, which is most likely company-specific.

Whether alliance capability is completely experience-based or can be acquired via training (Draulans, de Man and Volberda, 2003) and whether this knowledge can be transferred across companies is an issue which requires further research. This also refers to the nature of alliance capability as related to its transfer among different units within or between companies. The literature is full of classification schemes and examples of both resources and capabilities, which provide helpful guidance. Amit and Schoemaker (1993), for example, refer to capabilities as tangible or intangible assets, which are firm-specific and created over time. Hall (1992, 1993) further distinguishes between intangible/tangible and person-/non-person-based resources and capabilities. Tangible resources include technology, production machinery, facilities, etc. whereas intangible resources range from property rights, trade secrets, public knowledge to know how, organizational culture, etc. (Hall 1992: 135). Intangible resources, in contrast, rely more on a personal momentum whether this be perception, implicit knowledge or person-based learning (Itami and Roehl, 1987). Generally, it has been accepted that the value of a company derives to an increasing degree from its availability of those 'intangible assets' as proven in the difference between market and book value. The related distinction between person and non person-based resources and capabilities resembles the recent discussion in organizational learning and knowledge management. In this stream of research, scholars accept that organizational level constructs rely on individual processes, which have become institutionalized over time (e.g. Kim, 1993; Prange, 1999; Maier, Prange, von Rosenstil, 2001).

Dynamic Capability View

The DVC defines 'dynamic capabilities' as "the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments" (Teece, Pisano and Shuen, 1997: 516). It is explicitly mentioned that dynamic capabilities consist of specific strategic and organizational processes that create value for firms within dynamic markets by manipulating resources into new value-creating strategies (Eisenhardt and Martin 2002: 1106). Despite slight variations in definitions, consensus has emerged that capabilities are made up of organizational routines, which make use of and deploy combinations of various assets. Eisenhardt and Martin (2002) further argue that dynamic capabilities as such cannot be a source of competitive advantage, instead they need to be applied and the ability to change them quickly is a major asset. Collis (1994) is particularly explicit in making the point that dynamic capabilities govern the rate of change in ordinary capabilities given path dependencies and market positions.

Draulans, de Man and Volberda (2003) present an exceptional case, when they consider alliance capability from a DCV-perspective, emphasizing the development of capabilities by the absorption of inside and outside knowledge. This process supposedly consists of identifiable and specific routines which, at best, are deeply anchored within the organization. At a more strategic level, dynamic capabilities involve those routines that are required to reconnect single relationships into a web of collaborations between alliance partners to generate ever changing resources among businesses. In stable markets, alliance capability resembles the traditional concept of routines, i.e. repetitive action based on sophisticated organizing processes that rely on existing knowledge (Nelson and Winter, 1982; Eisenhardt and Martin, 2000). The situation is different, when firms operate in dynamic markets where capabilities require adaptation. As dynamic markets are not always predictable, these 'routines' are often simple, exhibit experiential components and are situation-specific applied (Eisenhardt and Galunic, 2000). This is why Eisenhard and Sull (2001) introduce the concept of 'simple rules' where competitive advantages come from successfully seizing fleeting opportunities. Guided by a few strategic processes, these simple rules should place a company where new challenges are swiftest and deepest.

This also previews particular developmental processes, which require multiple testing and imply several pathways to successfully creating relevant knowledge.

Figure 2 summarizes the previous discussion and presents some examples, where a distinction is drawn between both an alliance relationship (a resource) and the skills of managing it (a capability). Resource and capability are inextricably intertwined and exhibit both tangible and intangible components.

For instance, alliance mindset incorporates an understanding of alliances as 'first best strategy', which has been regarded as an important precondition for successful collaboration. Similarly, com-

Figure 2. Alliances as resources and alliance capabilities

	Alliances as a Resource	**Alliance Management as a Capability**
Intangible	Culture, alliance strategy, human resources dedicated to the alliance, etc	Alliance mindset (commitment/ trust); implicit and explicit learning about alliances, etc.
Tangible	Structure (nature of contract, governance structure, facilities, IT infrastructure), location, etc.	Codified alliance knowledge (alliance functions, databases, handbooks, guidelines), etc.

mitment and trust are further implicit components of alliance capability. These are complemented by hard factors, such as handbooks, guidelines, benchmarking procedures as to how alliances can best be implemented. These manifestations of alliance capability only contribute to performance outputs if related to the resources of the alliance, which consist of the factual alliance, i.e. its strategies, human resources, structures and governance issues, etc.

The resulting challenge for managerial practice remains how heterogeneous (alliance) capabilities like routines, guidelines or simple rules are supposed to be created by homogeneous individuals in firms - an implicit, but questionable, assumption of resource-based theorizing (Henderson and Cockburn, 1994) - , and how individual action can be transferred into successful organizational behaviour within inter-organizational settings. An answer to these questions is likely to arise from insights into how the collective construct of alliance capability emerges.

DEVELOPING ALLIANCE CAPABILITY: THE CONTRIBUTIONS OF THE INDIVIDUAL

Little is known so far how capabilities arise in the first place. Research from within the resource-based tradition has provided a few hints that, taken together with traditional approaches of knowledge management, present some input into the evolutionary process of alliance capability. Building on these inputs, I suggest a model of alliance capability development, which adds individual knowledge and action as antecedents. I further suggest a more detailed analysis of micro-foundations in order to understand alliance capability differentials between firms.

The Process of Capability Development

The process of capability development can start from different vantage points and often takes unique paths, i.e. it exhibits high degrees of equifinality (Eisenhardt and Martin, 2000). While the literature does not offer straightforward answers to the question of how capabilities are generated, authors seem to agree on repeated practice and experience. Thus, new routines or capabilities build on previous ones, i.e. “firms tend to do what they have done before” (Kogut and Zander, 1995: 425). In a similar vein, Zollo and Winter (2004) argue that ‘experience accumulation’ constitutes organizational routines by skill building based on the repeated execution of similar tasks, an insight shared with the literature on learning curves (Argote, 1999). They further emphasize that experiential learning is largely based on tacit knowledge, which is often applied in a semi-automatic way.

Apart from experiential learning, the authors introduce two further learning processes, borrowed from Nonaka's (1994) conception of knowledge management. First, 'articulation' is seen as a deliberate process by which individuals share their knowledge on what works and what does not. This may be facilitated through collective discussions, debriefing sessions, and performance evaluation processes which help to make implicit knowledge more transparent. Second, 'codification' occurs when individuals transfer their understanding into written tools, such as manuals, blueprints, or decision support systems. Through the co-evolution of these processes capability development is presumed to occur.

One of the few studies, which explicitly refers to alliance capability and its *developmental process* via institutionalizing was undertaken by Dyer, Kale and Singh (2001). The authors empirically investigated 78 companies and indicated that the investment in an alliance function serves as a vehicle for transferring individual into company-based collaborative know-how. Draulans, de Man and Volberda (2003: 152) argue that "like any other competence, the management of alliances is a skill that can be built up and can become a significant source of competitive advantage." Ritter and Gemünden (2003) relate to 'organizational' antecedents of network competence and identify access to resources, network orientation of human resource management and the integration of formal and informal structures as well as an openness of organizational culture as being important.

While there have been several attempts at explaining capability development, there is only anecdotal evidence of the important role of the individual. This is not surprising given the fact that collectivist notions of capability research typically sidestep critical individual-level considerations, including individual action and heterogeneity (Felin and Foss, 2004, 2005). But as the authors remark:

"individuals matter…[and] to fully explicate organizational anything – whether identity, learning, knowledge or capabilities – one must fundamentally begin with and understand the individuals that compose the whole, specifically their underlying nature, choices, abilities, propensities, heterogeneity, purposes, expectations and motivations" Felin and Foss (2005: 441).

The Capability-Life-Cycle Revisited: Towards Micro-Foundations of Alliance Capability

In order to more fully capture the role of individuals in the development of capabilities, the life-cycle approach, as suggested by Helfat and Peteraf (2003), is used as a basic model. Each stage of the original model will be complemented by individual antecedents that help to explain heterogeneity in alliance capability.

The concept of the capability life-cycle "depicts a general pattern and set of possible paths that characterize the evolution of an organizational capability" (Helfat and Peteraf, 2003: 1000), which can be related to the development-cycle of an alliance (see introductory sections) even though the two need not necessarily coincide. Organizations with no heritage in collaboration ('new to the world of alliances') start in the *founding phase* with no previous alliance experience that might influence alliance capability development. However, this stage cannot be seen as a clean slate as individuals may have previous experience with alliances obtained elsewhere.

Individual Level Contributions in the Founding Phase

Before joining an organization, several of the key elements of alliance capability may be influenced by individuals' earlier skills and knowledge related to specific alliance partners and individuals in partner firms. Adner and Helfat (2003) refer to this as 'managerial human capital', i.e. learned skills based on some investment in education, training, or learning. As identified earlier, there may be different types of individual skills, which influence the development of alliance capability. For instance, in a more general way, Castanias and Helfat (1991) distinguish between generic, industry-specific, and firm-specific skills. As shown elsewhere (Prange, Bojkowszky, & Wieshofer, 2004), there are some industries – like biotechnology – where industry-specific skills dominate all other elements of alliance capability. Thus, industry experience may be a selection criterion for prospective alliance managers.

Further, specific alliance roles may exist, e.g. as negotiator or implementer of an alliance, which require some leadership experience or the existence of specific personal traits. Indeed, Rosenbloom (2000: 1102) suggests that leadership by individuals may be a 'central element' in the more general dynamic capability development. There may also be self-selection processes in that only those individuals who have the presumed skills to manage an alliance enter the firm. This initial endowment with skills provides a source of heterogeneity to alliance capability development.

Iindividuals check available knowledge (e.g. via observation) and start a learning process on which they build their action ('learn-act-sequence'). This is the typical incremental and largely cognitive learning approach, which gradually develops knowledge through training and information search. From this initial starting point, two trajectories are possible. First, after reflection and continuous successful action, knowledge is transferred into organizational capabilities by processes of articulation and codification (Zollo and Winter, 2004). Installing these processes adds to the strategic development of knowledge in and about the alliance. As a result, emerging capabilities are made up of routines derived from thorough reflection and stable behaviour patterns. With repeated experience, accumulated knowledge eventually transfers into sedimented knowledge from which quasi-automatic behaviour is generated. In turn, these organizational routines influence individual action.

Secondly, when transferring experience in rather volatile environments, individual experimentation ('act-learn') may also lead to the establishment of simple rules as an expression of alliance capabilities. These are the bases of competitive advantage, where companies simply 'jump' into the market, experiment, test opportunities and shift frequently among partners and businesses as circumstances dictate. Still, there are some principle rules underlying this seemingly chaotic process, which could be the conscious play with market uncertainty, the seizing of several selected opportunities, strategic creativity induced on a permanent basis or the introduction of 'serious play' (Schrage, 2000) as a means of strategy formulation. All these simple rules open up scenarios without limiting a company's future choices by deadlocked routines.

Both reflective action and experimentation lead to different manifestations of alliance capabilities. In the same way as individual learning modes are dominated by one process or build on the logic of both 'thinking and experiencing', these different types of capabilities may interact over time, when flexible rules become more stabilized and stable routines need to be broken up to allow for more flexibility. For instance, when a firm opts to increase the heterogeneity of its alliance partners, past routines may prove detrimental as they do not capture what is new. When firm-level routines turn negative, differing personal endowments can prevent such a lock-in.

Individual Level Contributions in the Development Phase

Pursuing experimental learning processes in order to build 'simple rule-based capabilities' is closely linked to an individual's risk propensity as performance outcomes are highly uncertain. As outputs cannot be anticipated, a tolerance for mistakes is important. Most often, simple rules are tacit and it takes conscious effort to make them explicit and extend them as business unfolds. At the same time, these capabilities consist of a few rules that make them amenable for easy adoption. For instance, CEO Meg Whitman made Ebay's values explicit in simple rules that helped managers to predict what opportunities would work for the company and how they could be adapted (Eisenhardt and Sull, 2001). Given the fact that individuals need to actively engage in the articulation of tacit knowledge, motivational incentives become important (Osterloh and Frey, 2000) as well as cognitive skills, i.e. mental models and beliefs, which determine information search and opportunity seizing in the process of updating existing knowledge components (Hambrick and Mason, 1984).

In contrast, the emergence of stable routines may rather start from initial imitation of already existing capabilities in other organizations (benchmarking of best-practice alliance capabilities), where less individual creativity is required. In order to arrive at sufficient diversity in individual knowledge input, alliance human resource management is challenged to control adequate knowledge inflows. These are presumably tied to different types of motivational incentives.

Reaching maturity with a selected partnership, the development of capabilities may either come to a standstill as there may be satisfaction with what can be achieved, or is deliberately ceased in the process of alliance capability development. While current capabilities may be perceived as influential for performance outputs, this relationship could be blurred by perception gaps or aspiration level definitions. Therefore, complacency with existing capabilities could easily incur lock-in effects, which negatively impact alliance results.

Individual Level Contributions in the Maturity Phase

Individuals may exhibit different levels of skilfulness prior to reaching the full technical limits of capability development (Helfat and Peteraf, 2003: 1002). This may be due to differences in previous education and learning behaviour. Personal satisfaction levels may also differ due to cognitive processes like perception, sensing, opportunity seizing (Teece, 2007). When capabilities consist of simple rules, the problem of causal ambiguity emerges, i.e. comprehensive experiencing activities obscure the fundamental commonalities that drive the effectiveness of the capability. Thus, managers may not know themselves whether and why capabilities are successful and more cognitive effort is required to critically challenge established rules. Also, hierarchical positions in the organization may influence how far capability development is continued. For instance, the strength of influence from the top may have relevant consequences on capability development (Adner and Helfat, 2003: 24). Managers' ability to interpret their company's previous alliance experience also varies profoundly across hierarchical levels, with higher-level actors having more difficulty interpreting feedback from action than lower-level actors (Gavetti, 2005). Thus, variability in decision-making style, speed and implementation act as a driver of heterogeneity in alliance capabilities. Further, aspects of power and incentive systems are supposed to play a crucial role which warrants further attention (Shenkar and Ellis, 1995).

Figure 3 provides a summary of individual actions and some of their micro-foundations that influence the development of alliance capabilities.

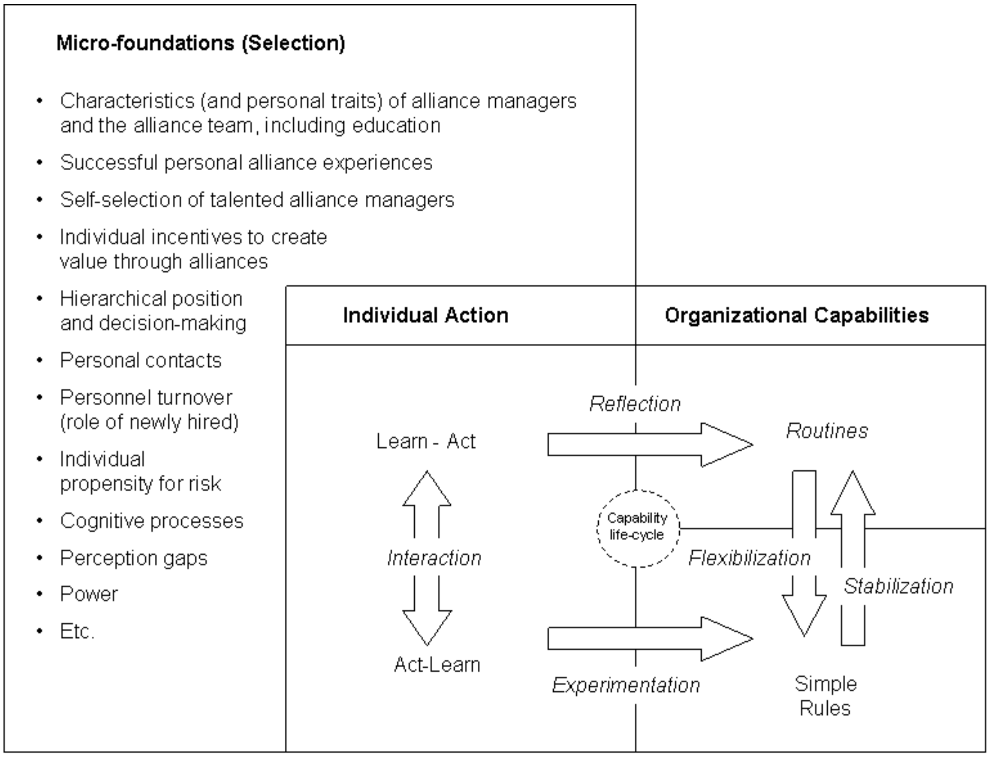
In short, the learn-act sequence pays attention to the fact that there are 'intendedly rational' individuals, who cognitively engage in knowledge generation as a basis for alliance capabilities. With a lower cognitive involvement, experimentation and tacit learning through trial and error contribute to a more flexible type of alliance capability, which is less subject to routine but could be equally effective in turbulent markets. This act-learn sequence can be characterized by an ongoing process of experimentation accompanied by retrospective sense-making and the repetition of successful behaviour sequences. In fact, different learning mechanisms contribute to different manifestations of capabilities (simple rules and routines) mutually related over time to avoid the pitfalls of over- or under-specification. While the role of the individual is emphasized in this figure and attention is directed to several micro-foundations, the opposite process from organizational capabilities driving individual behaviour, as one of the traditional assumptions of resource-based theorizing, still holds true but is neglected in the figure.

DISCUSSION AND CONCLUSION

This article has provided a discussion of the recently fashionable construct of 'strategic alliance capability', its conceptualization and theoretical origin. Resource-based and dynamic capability approaches were used to incorporate 'alliance capability' into the overall framework of resource and capability-based theories. Thereby, an analysis of alliance capability both benefits and suffers from the theoretical promises and pitfalls of resource-based theorizing.

As one of the major difficulties, it has been mentioned that the RBV defines resources and capabilities in a conceptually vague and non-operational way (e.g. Priem and Butler, 2001). Yet, strategic alliance capability exists in several exactly identifiable elements along the cooperative life cycle, which have selectively given rise to empirical studies. Further, the RBV has been criticized as being relevant only for stable markets. This criticism has been encountered by the DCV, which modifies the quest for sustainable advantage into a temporary one as resources and capabilities undergo constant changes. One of the major omissions in both the RBV and the DCV relates to the lack in dealing with individual-level antecedents of alliance capability. In order to fill this void, individual contributions on each stage

Figure 3. Individual foundations and processes of alliance capability development



of the alliance capability life cycle have been introduced.

Several questions can be derived from this model, constituting a future promising research agenda. First, differential learning processes pose several challenges, e.g. how do managers react to environmental turbulences and update their individual knowledge portfolio? Is there an optimal speed for experimental learning and are there given boundaries to the codification of individual knowledge into organizational routines? How do cognitive constraints influence processes like rapid learning, real-time information, multiple options and their impact on existing routines within an organization? When referring to reflective cognitive learning, it would be interesting to know how far previous education or industrial affiliation influences reflection processes? Further, are there previous personal contacts, which facilitate (or impede) the building of social skills as an important element of alliance capability?

As the concept of simple rules illustrates, there are different manifestations of capabilities and further research should more closely match these types of capabilities to specific contingencies. Closely related is the question whether it is generally valid to institutionalize knowledge in rapidly changing environments? Whereas previous studies suggest the implementation of a dedicated alliance function, which coordinates all alliance-related activity within the organization and initiates the transfer of both tacit and explicit alliance knowledge, the flexibility aspect has not been considered. The inherent danger might be inflexibility and overly bureaucratic procedures, which retard or prevent corporate flexibility. Thus, an important research direction is the exact interplay of more stable (routines) and flexible (simple rules) types of capabilities.

Finally, the exact sequence and the particular form of knowledge created and transferred in each step of the cooperative life-cycle both require further empirical analysis. This includes a specific emphasis on the contribution of individual knowledge components and learning processes as well as hierarchical positions and power relations which may have an impact. In more detail, several of the aforementioned micro-foundations pose a research agenda in their own right depending on the research question. For instance, hierarchical roles may serve as an important element of heterogeneity, which may be tailored to specific environmental setting and subsequent performance results. Also, the issue of personal traits offers intriguing challenges for future research, e.g. whether someone is particularly suited for combining different learning processes or whether these should be split between different people in order to guarantee a variety of alliance capabilities at the organizational level.

Also, several managerial implications spring to mind. Once precise micro-foundations of alliance capabilities are identified, human resource practices (selection, incentive systems, motivation) within alliances could be tailored to promote the development of required organizational level routines. As a result, the capability-performance link might be more effectively managed as the relation is highly dependent on environmental conditions and specific types of alliance capabilities. Finally, potential negative effects of (alliance) routines could be avoided by paying attention to those individual antecedents which stir up the system of stable but unproductive capabilities. Thus, management can add more flexibility to the process of capability generation and its dynamic adaptation to changing contingencies.

ENDNOTES

[a] In this research, 'strategic alliance' is used as a generic term to signify voluntary and planned inter-organizational collaboration between, at least, two partners (e.g. Contractor and Lorange, 1988; Yoshino and Rangan, 1995) and does not consider differences within individual forms, such as joint ventures (JVs), licensing arrangements, partnerships, and others. However, the researcher wants to attract attention to the fact that this is a worth-while effort, which should be undertaken in other studies.

[b] This is a typical approach in inter-organizational research. As Osborn and Hagedorn (1997: 271) in citing Larson (1992) say: "Almost lost in the empirical study of alliances is the importance of the experience and predisposition of the individual using them…The potentially important role of individuals in operating alliances remains virtually unexplored".

[c] Even though he does not further distinguish between resources and capabilities, in principle, I share his argument as applied to alliance management as a capability.

Chapter 5.16

Product Customization on the Web:

An Empirical Study of Factors Impacting Choiceboard User Satisfaction

Pratyush Bharati
University of Massachusetts, Boston, USA

Abhijit Chaudhury
Bryant University, USA

ABSTRACT

Choiceboards are Web-based systems that allow consumers to customize their orders. The study investigated factors that affect consumers' intention to use choiceboards. The research is based on Masons' theory and DeLone and McLean's model of information system use. It was found that intention to use is affected by overall satisfaction. In turn, these two factors are positively impacted by factors such as system quality and information quality. In spite of support from theory, the evidence for the factor, information presentation was weak.

INTRODUCTION

E-commerce is coming of age (Markillie, 2004). Sales in the year 2003 exceeded $55 billion, and revenues in 2004 are expected to be at least 20% higher (Syre, 2004). The total impact of e-commerce, however, cannot be expressed in simple sales figures; rather, it lies in changing consumer behavior. Increasingly, consumers visit the Web site of a company to familiarize themselves with the firm's offerings and prices before deciding to buy. A Web site is becoming the gateway to a firm's brand, even in the case of off-line firms. Companies that realize the importance of their Web sites use technologies such as e-mail, FAQ, online customer support, bulletin boards, and search engines to assist customers in the buying decision process and, obviously, to persuade a purchase of their product.

The choiceboard is a recent addition to this repertoire of technologies, aiding consumers in the decision-making process (Andal-Ancion, Cartwright, & Yip, 2003; Bharati & Chaudhury, 2004a; Collins & Butler, 2003; Liechty, Ramaswamy, & Cohen, 2001; Slywotzky, 2000). A choiceboard is a system that allows customers to design their own products by choosing from a menu of attributes, components, prices, and delivery options (Slywotzky, 2000). For example, in the automobile industry (buyatoyota.com), users can "build" or customize a Toyota and then follow up with a local dealer. In the construction industry (kitchens.com), users can get help to design a kitchen and actually place an order. In the apparel industry (acustomtshirt4u.com), users can select color, fabric, and a suitable logo and lettering. In the entertainment industry (www.apple.com/itunes), customers at the itunes music store can build customized CDs by selecting individual tracks from existing CDs. Finally, in information technology, the Web sites of most computer firms (e.g., www.ibm.com) present individuals with a basic configuration defined by a processor and then flesh out the full configuration with choiceboards, offering hard-drive size, memory, and add-ons such as CD/DVD drive, monitors, and printers.

Although choiceboard technology is being used widely to enhance the customer's experience, very little is known about the actual impact of this technology on overall user satisfaction or on the intention to use the choiceboard. Similar concerns have been expressed for Web-based decision support systems (Bharati & Chaudhury, 2004b). In particular, it remains unclear how the provision of more information, facilitation of decision making through what-if analysis, and choice comparisons through the use of choiceboard technology affects user satisfaction and the intention to use. In this research, the relationships are developed and operationalized between system-level factors (i.e., quality of the system and information in choiceboards and presentation of information) and user's decision making and interface satisfaction. Furthermore, the analysis investigates the relationship between information and decision-making satisfaction, with overall satisfaction and intention to use. The statistical analysis consists of path analysis, assessing a pattern of predictive relationships among the measured variables. This research employs the Structural Equation Modeling (SEM) technique to analyze the data and then to assess the pattern of predictive relationships.

The research views information systems' success in the new domain of e-commerce and, in particular, in the context of choiceboard systems. It attempts to understand how choiceboards facilitate user decision making in the Web-based environment. It then develops a conceptual model that relates system-level factors, user satisfaction factors, and use factors. Specifically, it investigates interrelationships between components of user satisfaction (i.e., interface satisfaction, decision satisfaction, and overall satisfaction) and their combined impact on intention to use.

LITERATURE REVIEW

The research is related to multiple theories such as the consumer decision-making model (Mowen, 1995), consumer information processing model (Bettman, 1979), cognitive decision-making model (Simon, 1955), and information systems (IS) success model (Delone & McLean 1992, 2002). According to Mowen (1995), a consumer transits through several phases, such as problem recognition, a search for alternatives, and an evaluation of alternatives, before making a choice; that is, there is an information-processing phase and then a decision-making one. In this process, a consumer tries to minimize the cognitive effort required to make a decision and yet maximize the quality of the decision reached (Bettman, 1990). Furthermore, Bettman (1990) suggests that because of bounded rationality constraint (Simon, 1955), consumers actually will trade off decision quality for a reduction in information processing effort.

Consumers employ decision aids such as calculators, spreadsheets, consumer guides, and Web-based comparison pricing in order to lessen the impact of bounded rationality constraints on decision quality. E-commerce retailers are incorporating choiceboards on their Web sites in order to assist customers in several phases of the decision-making process (Bharati & Chaudhury, 2004a, 2004b). The information search phase, for example, is facilitated by easy revelation of product alternatives, and the decision-making phase of alternatives evaluation is made easier by price and feature comparison. The IS success model (Delone & McLean 1992), with its focus on issues relating to information processing and decision making and its previous research on Web-based DSS (Bharati & Chaudhury, 2004b), is useful in investigating the role of choiceboards in assisting users. In the recent literature, this model has served as the basis for investigating similar research areas such as IS and service quality (Bharati & Berg, 2003). The research on quality of information systems services (Jiang et al., 2000, 2002; Kettinger & Lee, 1997, 1999; Pitt et al., 1995, 1997; Van Dyke et al., 1997, 1999; Watson et al., 1998) and WebQual (Loiacono et al., 2002) also has attempted to investigate this topic in a slightly different way.

Communications theory (Shannon & Weaver, 1949) was illustrated and modified in Mason's (1978) work to show that classes of information output are at the technical level, semantic level, and influence level. The IS success model (Delone & McLean, 1992, 2002) expanded the concept of levels of output in order to illustrate stages within those levels. Information is communicated to a recipient who either is influenced or not; he or she then impacts organizational performance. In other words, the information flows from its production to influence the individual and then the organization.

System quality and information quality both singularly and jointly impact use and user satisfaction. This research model is based on the IS success model and employs some of the constructs of that model, specifically at the technical level of system quality and information quality, in the context of choiceboards, and in their impact on different components of user satisfaction (interface satisfaction, decision-making satisfaction, and resultant overall satisfaction). User satisfaction then influences the intention to use. The next section explains the research model and hypotheses.

RESEARCH MODEL AND HYPOTHESES

The research model (Figure 1) shows that system and information quality and information presentation impact the different components of user satisfaction and then intention to use. The various constructs and the resulting hypotheses of the model are explained in this section.

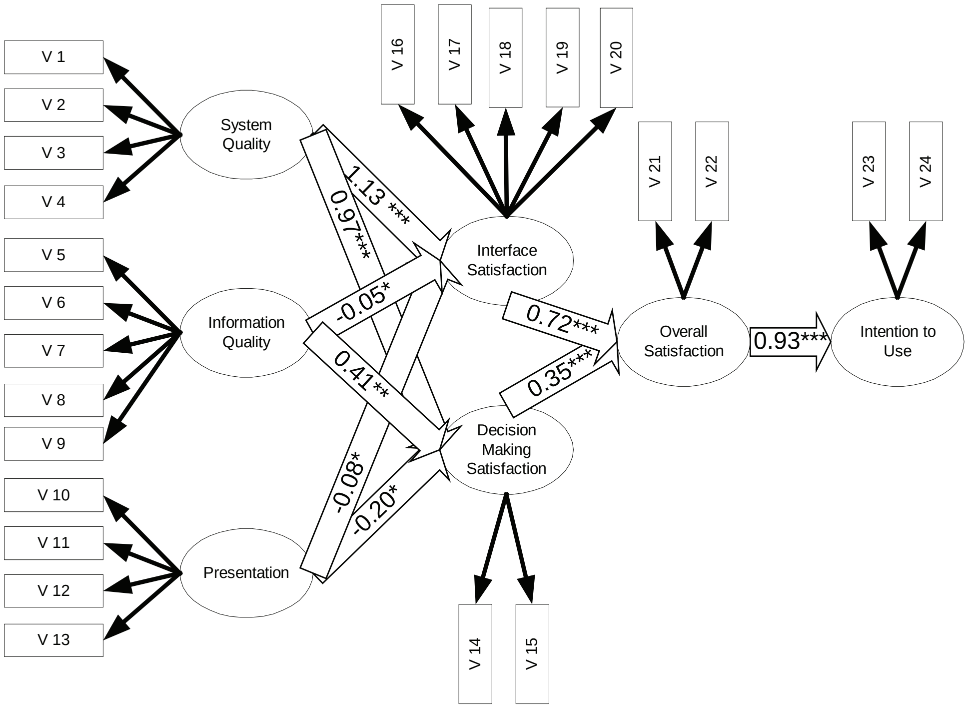
System Quality

System quality is the individual perception of a system's overall performance, which is itself a manifestation of system hardware and software. Ease of use (Belardo, Karwan, & Wallace, 1982), convenience of access (Bailey & Pearson, 1983), and system reliability and flexibility (Srinivasan, 1985) are measures employed for the service quality construct.

Information Quality

The user estimates the value of an information system after evaluating the quality of information it provides (Gallagher, 1974). Information accuracy

Figure 1. Model with results



*** $p < 0.01$; ** $p < 0.1$; * Statistically insignificant

(Bailey & Pearson, 1983; Mahmood, 1987; Miller & Doyle, 1987; Srinivasan, 1985), completeness (Bailey & Pearson, 1983; Miller & Doyle, 1987), relevance (Bailey & Pearson, 1983; King & Epstein, 1983; Miller & Doyle, 1987; Srinivasan, 1985), content needs (Doll & Torkzadeh, 1988), and timeliness (Bailey & Pearson, 1983; King & Epstein, 1983; Mahmood, 1987; Miller & Doyle, 1987; Srinivasan, 1985) are the measures employed in the information quality construct.

Information Presentation

In information presentation, the display of information based on formats, colors, and graphs vs. tables is examined (Vessey, 1994). The interface evaluation has included presentation, format, and processing efficiency characteristics of the interface (Swanson, 1985-1986). The measures used for information presentation construct are graphics, color, presentation style, and navigational efficiency (Swanson, 1985-1986).

Interface Satisfaction

The quality of the information system interface is measured in interface satisfaction. The indicators used to measure interface satisfaction construct are easy to work (Doll & Torkzadeh, 1988; Goodhue, 1990), useful format (Doll & Torkzadeh, 1988; Goodhue, 1990), user friendly (Doll & Torkzadeh, 1988; Goodhue, 1990), does what I want it to do (Davis, 1989; Goodhue, 1990), and clear and understandable (Davis, 1989; Goodhue, 1990).

Hypothesis 1: System quality will contribute positively to interface satisfaction.

Hypothesis 3: Information quality will contribute positively to interface satisfaction.

Hypothesis 5: Good information presentation will contribute positively to interface satisfaction.

Decision-Making Satisfaction

Decision-making satisfaction is the system's ability to support the user's decision-making and problem-solving activities. The system's support to the individual in recognizing problems, structuring problems, and making decisions related to the goal of controlling a business process are part of the construct (Garrity & Sanders, 1998). The construct measures the decision-making satisfaction using decision effectiveness (Chervany, Dickson, & Kozar, 1972) and decision confidence (Goslar, Green, & Hughes, 1986; Guental, Surprenant, & Bubeck, 1984; Zmud, Blocher, & Moffie, 1983).

Hypothesis 2: System quality will contribute positively to decision-making satisfaction.

Hypothesis 4: Information quality will contribute positively to decision-making satisfaction.

Hypothesis 6: Good information presentation will contribute positively to decision-making satisfaction.

Overall Satisfaction

Satisfaction is an important and widely used construct in the IS literature. Numerous researchers have modified the Bailey and Pearson (1983) user satisfaction instrument. The construct of overall satisfaction, a result of interface and decision-making satisfaction, was measured using extremely useful system (Sanders, 1984) and satisfactory in meeting user needs (Alavi & Henderson, 1981; Sanders & Courtney, 1985).

Hypothesis 7: Interface satisfaction will contribute positively to overall satisfaction.

Hypothesis 8: Decision-making satisfaction will contribute positively to overall satisfaction.

Intention to Use

Intention to use a system often has been employed as an important measure of IS success (Chang & Cheung, 2001; DeLone & McLean, 1992; Lucas, 1978; Van der Heijden, 2004; Welke & Konsynski, 1980). Possible to use and intend to use (DeSanctis, 1982) have been employed to measure the intention of the user to use the system construct.

Hypothesis 9: Overall satisfaction will contribute positively to intention to use.

RESEARCH METHODOLOGY

The instrument was constructed based on prior research, and most indicator items were adapted or borrowed from previously validated instruments. The survey was first pretested with a smaller sample and then subsequently refined. The survey was administered to subjects who were undergraduate and graduate students at two universities. They were selected as subjects, because they were users of or familiar with choiceboard systems. The experiment was conducted in a laboratory setting with PCs running on the Windows operating system. In conducting the experiment, the researchers adopted the following procedure.

First, the experimental procedure was explained to the subjects. Then, each subject was randomly assigned a Web site that employed a choiceboard that allowed the user to configure a product. The choiceboard sites were of a very similar nature, despite being owned by different firms. After configuring a product on the Web site, each subject completed a survey questionnaire. The total sample for the experiment was 192 subjects.

Structural equation modeling (SEM) was used to analyze the data. SEM subscribes to a causal indicator model with the operational indicators reflective of the unobserved theoretical construct. It allows the specification of measurement errors within a broader context of assessing measurement properties. Confirmatory factor analysis, content validity, unidimensionality analysis, reliability analysis, convergent validity, and criterion-related validity tests were conducted to evaluate the model and constructs (Anderson & Gerbing, 1988; Bollen, 1989; Chin, 1998).

DATA ANALYSIS

Confirmatory Factor Analysis

The measurement properties of the survey instrument were assessed with confirmatory factor analysis. A measurement model comprised of a weighted linear combination of the items in the scale was analyzed. In confirmatory factor analysis, each theoretical construct is specified and analyzed to assess the fit of the data with the measurement model (Ahire, Golhar, & Waller, 1996; Ravichandran & Rai, 1999; Venkatraman, 1989). For constructs with four or more indicators, these guidelines were followed. As some constructs have fewer than three indicators, these constructs were pooled with constructs having four or more indicators. This was done to ensure adequate degrees of freedom for estimation of the model.

Content Validity

Content validity is ensured when the constructs are defined using the literature. The construct should adequately represent and measure the domain of meaning that it is supposed to represent (Bohrnstedt, 1983). If all the items grouped together for each construct reflect the underlying meaning, then content validity exists (Dunn, Seaker, & Waller, 1994). Since there is no rigorous way to assess content validity, in order to ensure thoroughness, multiple items were used to measure the construct (Bohrnstedt, 1983; Churchill, 1979). The instrument employed in the research used several indicators for each construct that were derived from an in-depth literature review, and thus, content validity was ensured (Bohrnstedt, 1983).

Unidimensionality Analysis

A multidimensional construct helps with content validity and is acceptable as long as the scales are unidimensional. A scale has to be unidimensional in order to have both reliability and construct validity (Gerbing & Anderson, 1988). The condition for a unidimensional scale is that the items of a scale estimate one factor. The goodness of fit index (GFI) measures a good fit of the measurement model, as it indicates that all items load significantly on one underlying latent variable. There is no evidence of lack of unidimensionality when GFI is 0.90 or higher for the model. The GFI indices for all the scales are summarized in Table 1, and the results suggest that all the scales are unidimensional.

Reliability

Reliability of a scale is ensured, if the scale is dependable, consistent, or stable (Gatewood & Field, 1990). Cronbach's alpha coefficient was used to measure reliability, as the items of a scale explain the majority of the variation in the construct vis à vis measurement error (Cronbach, 1951). The results indicate that the scale is reliable, because the alpha coefficient is greater than 0.70 (Table 1).

Table 1. Tests for unidimensionality, reliability, and convergent validity

No.	Construct	No. of Indicators	Unidimensionality: Goodness of Fit Index (GFI)	Reliability: Cronbach's α	Convergent Validity: Bentler Bonnet Δ
1.	System Quality	4	.99	.72	.97
2.	Information Quality	5	.97	.84	.95
3.	Information Presentation	4	.91	.82	.89
4.	Interface Satisfaction	5	.94	.87	.94
5.	Decision-making satisfaction* - System Quality - Information Quality - Information presentation	2	 .95 .96 .91	.83	 .92 .95 .90
6.	Overall Satisfaction* - Interface Satisfaction and Intention to Use	2	.91	.89	.93
7.	Intention to Use - Overall Satisfaction and Interface Satisfaction	2	.91	.74	.93

** A combined model was used for this construct.*

Convergent Validity

Considering each item in the scale as a different approach to measure the construct usually assesses convergent validity. This was measured using the Bentler-Bonett coefficient (Δ)(Bentler & Bonett, 1980). The Bentler-Bonett coefficient (Δ) value of 0.9 or above means high convergent validity. All the scales had a Bentler-Bonett coefficient (Δ) of greater than 0.9 (Table 1).

Criterion-Related Validity

Criterion-related validity tests the degree to which the outcome is predicted by the constructs (Ahire, Golhar, & Waller, 1996; Venkatraman, 1989). Using SEM, the constructs are correlated with outcome constructs. As the correlation of the various constructs are positive and statistically significant (Table 2), criterion-related validity exists for these constructs.

SEM produces parameter estimates of links between the latent variables and so is also called latent variable analysis, or causal modeling. AMOS 4.0 and SPSS 10.1 (Arbuckle & Wothke, 1999) were employed for the SEM analysis.

RESULTS AND DISCUSSION

In summary, this research examined the impact of systems' quality, information quality, and information presentation on user satisfaction and intention to use in the context of choiceboard systems. The IS success model was used as the basis of the research model. The model was based

Table 2. Test for criterion-related validity

No.	Construct	Interface Satisfaction	Decision-making Satisfaction	Overall Satisfaction	Intention to Use
1	System Quality	0.66**	0.65**	-	-
2	Information Quality	0.54**	0.69**	-	-
3	Information Presentation	0.50**	0.44**		
4	Interface Satisfaction	-	-	0.49**	-
5	Decision-Making Satisfaction	-	-	0.51**	-
6	Overall Satisfaction	-	-	-	0.56**

** $p < 0.01$

on Shannon and Weaver's (1949) communication theory, Mason's (1978) theory, and the Delone and McLean (1992) model. The research model employed the constructs at the technical level (i.e., systems' quality and information quality) in the context of choiceboards and finally its impact on different components of user satisfaction such as interface satisfaction, decision-making satisfaction, and resultant overall satisfaction. The path coefficients calculated for the estimated model support the hypothesized relationships in both direction and magnitude with few exceptions. Overall, the statistical conclusions support the research model (Figure 1).

System quality is directly and positively correlated to interface satisfaction (H-1); so, an increase in the quality of the system leads to an increase in satisfaction in using the interface. Information quality is directly and positively correlated to interface satisfaction (H-3); so, an increase in the quality of the information leads to an increase in satisfaction in using the interface. Information presentation is not directly and positively correlated to interface satisfaction; (H-5); therefore, this hypothesis is not validated.

The path coefficients calculated for the estimated model also support the hypothesized relationships in both direction and magnitude in the case of decision-making satisfaction. Most of the hypotheses in the area of decision-making satisfaction have been validated using the data. System quality is directly and positively correlated to decision-making satisfaction (H-2); so, an increase in the quality of the system leads to an increase in decision-making satisfaction. Information quality is directly and positively correlated to decision-making satisfaction (H-3); so, an increase in the quality of the information leads to an increase in decision making. Presentation is not directly and positively correlated to decision-making satisfaction (H-6), as this hypothesis is not validated.

System quality includes system ease of use, convenience of access, and system reliability. Thus, a net positive effect from these factors will result in a positive effect on interface satisfaction and decision-making satisfaction. In choiceboards, as in other systems, the ease of use of the system, convenience of access, and system reliability are important considerations for the user. Information relevance, accuracy, completeness, and timeliness constitute the construct information quality. Thus, a net positive effect from these factors will result in a positive effect on decision-making satisfaction. Choiceboard systems should provide relevant, accurate, complete, and timely information for better decision-making satisfaction.

Graphics, color, presentation style, and navigational efficiency measures information presentation. Therefore, information presentation measures how information is displayed. It was hypothesized that a net positive effect from graphics, color, presentation style, and navigational efficiency would result in a positive effect on interface satisfaction and decision-making satisfaction. The data did not support this hypothesis.

The statistical conclusions support the hypotheses on user satisfaction. Interface satisfaction is directly and positively correlated to overall satisfaction (H-7); so, an increase in interface satisfaction leads to an increase in overall satisfaction. Similarly, decision-making satisfaction is directly and positively correlated to overall satisfaction (H-8); so, an increase in decision-making satisfaction leads to an increase in overall satisfaction. Overall satisfaction also is found to be directly and positively correlated to intention to use (H-9); so, an increase in overall satisfaction leads to an increase in intention to use. The results from the research model also demonstrate the relative weight of system quality compared to information quality. Interestingly, decision-making satisfaction of end users, the quality of the system, is more important than the quality of the information.

As with all regression and structural equation modeling techniques, correlation does not prove the causality of the relation. However, since these causal relationships are based on an established literature, and since the theoretical grounding of the causality is adequate, it is reasonable to concur with the causality, where it has been validated (Gefen, Straub, & Boudreau, 2000).

MANAGERIAL IMPLICATIONS AND FUTURE RESEARCH

The research results empirically demonstrate the relationships between interface satisfaction, decision-making satisfaction, system quality, information quality, and information presentation. It also demonstrates the relationships among variables such as interface satisfaction, decision-making satisfaction, overall satisfaction, and the intention to use. These relationships are useful in influencing the intention to use among users of choiceboard systems. IS professionals need to understand these relationships to help their firms design choiceboard systems that are effective. This research provides an understanding of those interrelationships.

In the context of choiceboards, the quality of information influences decision-making satisfaction. For example, for a choiceboard system that allows users to develop their own holiday itinerary, the research suggests that users would value complete, accurate, and relevant information about holiday sites, weather, local costs, flights, rentals, and hotels. Similarly, users will have better decision-making satisfaction with timely, accurate, and complete information as they develop alternative scenarios for their holidays.

The research suggests that ease of use, convenience of access, and system reliability also influence the decision-making satisfaction of users. A choiceboard, other than just being available and accessible, also should be easy to use. A user should not feel overwhelmed by available choices. The research also suggests that ease of use, convenience of access, and system reliability and flexibility influence interface satisfaction. The quality of the choiceboard system makes an impact if it is user-friendly, clear, and understandable. Interface and decision-making satisfaction influences if the choiceboard has been satisfactory in meeting user needs, which affects intention to use. For choiceboard users, it is not only important that the quality of the choiceboard system and the information it provides be adequate, but also that it provides them with interface and decision-making satisfaction. Thus, they will intend to use the choiceboard if they find it useful and if it meets their needs. This research shows that choiceboard users are deriving satisfaction with the system in a more complex fashion. If the choiceboard provides interface as well as decision-making satisfaction such that there is overall satisfaction, only then will they be a repeat user.

The empirical data suggest that the presentation of information is not important to the user in decision making. Users are not particularly impressed by color, graphics, and presentation style; they are more interested in the pertinent information being provided to them via the system. This is an interesting result, because in the recent past, there has been an increase in color and graphics on Web sites; but this presentation is of limited use if these Web sites are not able to provide the desired quality of information.

This research has examined the perceptions of users relative to their intention to use and how that perception is affected by overall satisfaction, which, in turn, depends on decision-making satisfaction and interface satisfaction. Much of the model has been validated by the data. Even the hypotheses that were not validated provide interesting insights. Studies should be conducted using other Web-based systems to test if the results of the present study can be extended to other situations. Qualitative studies also can be conducted to study choiceboard systems. These studies have the possibility of providing insight about choiceboard system users. These studies will help to build a wider body of research, which is needed for designing effective choiceboard systems.

Chapter 5.17

Investigating the Impact of Customer Relationship Management Practices of E-Commerce on Online Customer's Web Site Satisfaction:

A Model-Building Approach

ABSTRACT

This study addresses the effect of customer relationship management (CRM) practices on online customers' satisfaction with their experience in interacting with the company Web sites. Recognizing the importance of maintaining a healthy relationship with customers, companies are actively seeking ways to enhance the customer value of their offerings through relationship marketing. Since effective managing of customer relationships essentially involves managing customer information flow, Internet technologies have become an important element of a firm's CRM program. The company Web site is functioning as the focal point of contact for interacting with existing and prospective customers. An important concern is how the company Web site affects customers' overall perception of the

Web site. Using the concepts of Internet-mediated market orientation in marketing and user satisfaction in information systems, this study formulated and validated a theoretical model to analyze causal relationships between CRM practices, customers' perception of a Web site's online customer orientation and online customer Web site satisfaction. Based on the structural equation modeling analysis of the primary data collected in Taiwan, the study found that CRM practices positively impact online customers' Web site satisfaction through their perception of the Web site's customer orientation.

BACKGROUND

The Internet technology has evolved into a convenient platform for the development of corporate information infrastructures to support a wide range of innovative business strategies. The open and flexible communication protocols that collectively define today's Internet technology are now playing a vital role in processing highly distributed transactions, supporting knowledge-intensive decision making, and facilitating ambitious organizational collaboration (Turban, King, Lee, & Viehland, 2004). The ubiquitous connectivity and user-friendly interfaces have indeed offered a rich set of technological capabilities, allowing for development of value-creating systems to attract customers (Fahey, Srivastava, Sharon, & Smith, 2001).

In the e-marketing discipline, Internet technology is viewed as "a market space where a firm interacts, makes transactions, and builds relationships with suppliers, distributors, competitors, as well as consumers" (Min, Song, & Keebler, 2002, p. 3). In addition to the functional capabilities, the appeal of Internet technology also comes from the rapid growth of consumer acceptance it has enjoyed since the network was made available for commercial usage. An industry research from Jupiter Research (http://www.find.org.tw/), for example, indicates that annual online retail sales in the United States will reach 65 billion dollars during the year of 2004 and 117 billion dollars for the year of 2008 with the composite annual growth rate of 17%. According to this research, although the growth rate of first-time online shoppers in the United States will slow down as the Internet population saturates, the average purchasing amount is expected to increase steadily as a growing number of customers gain and feel satisfied with their experience with Internet shopping. The strategic role of Internet technology becomes even more obvious as one observes how companies in various sectors are integrating sophisticated knowledge management capabilities (e.g., online communities) into their new product development process and other customer-facing functions (Gebert, Geib, Kolbe, & Brenner, 2003).

An important e-marketing area that has received much attention from marketing researchers is relationship marketing. The aim of relationship marketing is to build long-term, mutually satisfying relations with customers, suppliers, and distributors with the objective to earn and retain their long-term preference and businesses (Kotler, 2000, p. 13). Today's highly competitive business environment requires the adoption of both offensive marketing strategy (recruiting new customers) and defensive marketing strategy (retaining existing customers) (Stefanou, Sarmaniotis, & Stafyla, 2003). To implement these customer-centric strategies, companies must have access to information about customers and provide customers with valuable knowledge to help them use the products they purchased from the company. In addition, instead of treating all customers equally, it is essential for companies to understand customers' requirements and customize the product and service offerings accordingly. Maintaining constant two-way communications with customers, therefore, is an important prerequisite for successful management of meaningful customer relationship.

A variety of information systems have been used to help with interactions with the customers. Often referred to as CRM systems, these systems are usually integrated under Internet protocols to provide user-friendly interfaces with customers, usually via a company Web site. From customers' point of view, a company's Web site represents the company itself. Customer satisfaction with or complaining about the ways the company Web site treats customers can lead to brand loyalty, repurchase intention, and repeat sales (Stefanou et al., 2003). An important concern, therefore, is how online customer's Web site satisfaction is affected by the company's CRM practices as demonstrated by its Web site design and management.

In light of the central role played by the Web site in a company's CRM practices, this study was conducted to examine the correlation and causal relationships between the CRM aspect of Web site design and management and online customers' satisfaction with their experience of Web site visits. For the purpose of measurement, the study adopts a framework proposed by Min et al. (2002), labeled "Internet-mediated Market Orientation (IMO)," to measure the construct of CRM practices.

The remainder of the article is structured as follows. The Literature Review section briefly describes the concepts of customer relationship management, Internet-mediated market orientation, and online user/customer satisfaction. This is followed by the section on research method, which includes the description of a theoretical model linking e-commerce companies' Web-enabled customer relationship management practices with the user/customer satisfaction. The section also describes the data collection method and instrument validation. The results of data analysis are then reported in the next section. The conclusion summarizes the study, elaborates on the implication of the findings, and suggests directions for future e-commerce research.

LITERATURE REVIEW

Customer Relationship Management

The theoretical foundation of customer relationship management (CRM) is relationship marketing. Shani and Chalasani (1992) defined relationship marketing as an integrated effort to identify, maintain, and build up a network with individual customers and to continuously strengthen the network for the mutual benefit of both sides through interactive, individualized, and value-added contacts over a long period of time. CRM is an amalgamation of relationship marketing and information technology. Whereas relationship marketing provides strategic foundation for the CRM concept, information technologies are used to automate and integrate marketing, sales, and service activities (Turban et al., 2004). A successful execution of the relationship marketing strategy often requires using sophisticated information systems to move information and knowledge smoothly across multiple complex customer-related processes. These CRM systems create customer value and contribute to company revenue by offering three categories of knowledge: knowledge for customers, knowledge about customers, and knowledge from customers (Gebert et al., 2003). At the core of CRM capabilities are the technological features that promote interactivity and customization (or even personalization). These requirements can be naturally fulfilled with "technology-enabled relationship management" (Schneider, 2002, p.159).

An important goal of CRM is to maximize customer retention. Since the best means to accomplish customer retention is to keep customers satisfied, it is reasonable to use customer satisfaction as an important criterion for measuring the success or failure of a firm's CRM practices (Stefanou et al., 2003). Furthermore, when the company Web site is used as the main interaction vehicle with customers, such as commonly practiced by many e-commerce companies, it is also reasonable to assume that customer satisfaction with Web site visits is a significant determinant of customer retention (Winer, 2001).

A comprehensive set of CRM programs usually consists of customer service, frequency/loyalty programs, customization, rewards programs, and community building (Winer, 2001). From the customer point of view, however, what matters the most is often their perception of the overall interaction experience with the firm. Customers shop for and are attracted to the vendors that maximize customer value. Much of the value-creating activities are related to information and knowledge flows (Winer, 2001). The company Web site, when properly designed and managed, can serve as a flexible and convenient mechanism for satisfying customers' requirements. The information and knowledge-intensive nature of CRM has been actively discussed in both marketing and information system literature (e.g., Gebert et al., 2003; Min et al., 2002; Romano & Fjermestad, 2003; Stefanou et al., 2003). Most discussions about CRM, however, are either conceptual or anecdotal in nature. More empirical studies are needed to verify the concepts and frameworks for the purpose of theory advancement.

Since the concept of CRM is strongly supported by the concept of market orientation, and the practicing of CRM via Web sites can be related to the concept of Internet-mediated market orientation, the following two sections discuss market orientation and Internet-mediated market orientation.

Market Orientation

A well-researched construct, the concept of market orientation is defined by some researchers as a component of organizational culture, consisting of a set of shared values and beliefs that put the customer first in business planning (Deshpade, 1999; Narver & Slater, 1990; Slater & Narver, 1994). The effect of market orientation on a firm's learning capability and innovative activity has been investigated by research in marketing. For example, Jaworski & Kohli (1993) identify market orientation as a significant determinant of overall business performance. Market orientation is also viewed as a fundamental concept underpinning a company's business strategy and innovative operations (Day, 1994; Han, Kim, & Srivastava, 1998; Harmsen & Hensen, 2004; Hurley & Hult, 1998; Farrel, 2000; Matsuno & Mentzer, 2000; Ruekert, 1992; Wu, 2004). Guided by the market orientation concept, companies recognize the value of the activities relating to collection, dissemination, and application of market information as they seek to improve their operational performance and competitive advantage (Kohli & Jaworski, 1990; Morgan & Hunt, 1994; Narver & Slater, 1990).

Market orientation is a composite concept. Researchers identify its components in an attempt to better relate this concept with other marketing concepts. Narver and Slater (1990) suggest that market orientation consists of five components: customer orientation, competitor orientation, functional coordination, long-term perspective, and profit orientation. Kohli and Jaworski (1990) also contend that market orientation is the manifestation of a firm's marketing concept and comprises five components: customer orientation, competitor orientation, intelligence gathering, interdepartmental information exchange, and responses to market intelligence.

In order to bring the market orientation concept to the operational level, Jaworski and Kohli (1993) define market orientation as a set of specific activities a firm carries out to put the marketing concept into practice, and that the concept may be measured by three sets of organization-wide activities: (1) intelligence generation, (2) intelligence dissemination, and (3) response design. These activities involve the collection and distribution of market information pertaining to current and future customer needs, and the use of the information in managerial action. This information usage perspective of the market orientation concept offers a convenient avenue for evaluating a company's marketing activities and thereby examining its impact on the other organizational concerns, such as business performance or learning capability.

Internet-Mediated Market Orientation

The mainstream of marketing research has examined the role of market orientation in the traditional business operational environment. Despite the success of various Internet-centric business models demonstrated by innovative companies, there are few, if any, attempts to examine the significance of the market orientation concept in the context of e-commerce. Min et al.'s (2002) theory of Internet-mediated market orientation represents the first attempt to explicitly take account of Internet technology and examines the role of market orientation in an e-commerce firm's online marketing activities. Internet-mediated market orientation essentially is market orientation in the Internet context.

At the implementation level, a firm's market orientation is witnessed by how it obtains market intelligence from its trading partners and other sources (Evans & King, 1999; Nordstrom & Pinkerton, 1999). As a convenient vehicle for interactive communications, Internet technologies have enabled the inclusion of a variety of forms of electronic communications such as videoconferencing, voice mail, Web casting, usenet, e-mail, bulletin board, and so forth, in a company's marketing activities. These new capabilities have essentially "transformed traditional ways of market information generation, dissemination, and organizational responsiveness to it into a networked computing environment in which a firm interacts and collaborates with end customers as well as suppliers, distributors, competitors" (Min et al., 2002, p. 3). As a result, numerous innovative business models have emerged, including the ones compiled by Turban et al. (2004): online direct marketing, electronic tendering systems, name your price, affiliate marketing, viral marketing, group purchasing, online auctions, and so forth.

Min et al. (2002) proposed the Internet-mediated market orientation theory by extending the concept of market orientation to incorporate Internet services. They defined Internet-mediated market orientation as "the Internet-mediated, information rich, seamless, agile, and boundary spanning process of generating, dissemination, and responding to market information on the Internet" (p. 3). Drawing from the major research literature on market orientation, they developed a conceptual framework to highlight the significant benefits of an Internet-mediated market orientation process: improved customer service, reduced marketing cost, and overall business performance. Hoping to advance the theory to a better maturity level, they call for more systematic inquiries to be conducted in both inductive and deductive manners to challenge or strengthen their framework: "Future research is called for to … empirically test the theory with proper measures for solid deduction" (Min et al., 2002, p. 8).

We contend that, since the three dimensions of the Internet-mediated market orientation (market information generation, market information distribution, and organizational response to market information) are essentially about interacting with customers through information exchange and the subsequent application of the market information, they ought to be investigated within the broader framework of CRM.

Online User/Customer Satisfaction

Customer satisfaction is a perceptual measure of the effectiveness of an organization's customer relationship management. A satisfied customer tends to return for future business and thereby contributes to the retention rate of the existing customers. In addition, a satisfied customer is likely to offer positive word-of-mouth service about the experience of interacting with the vendor. A number of previous researchers have consistently demonstrated that customer satisfaction is an important means for firms to gain an overall competitiveness in today's information and knowledge economy (Berry, 1995), contributes to a firm's profitability, and is increasingly becoming a critical organizational objective in pursuit of a sustainable competitive advantage.

The World Wide Web represents a virtual market space for customers to search for and purchase products and services. Shankar, Smith, and Rangaswamy (2003) investigated the unique characteristics of online shopping and the differences between online and off-line shopping environments. They found no significant difference with regard to customer satisfaction. Szymanski and Hise (2000) conducted focused group studies with selected online shoppers to identify the significant components of the customer satisfaction framework for the online shopping environment. Most of the components they identified are related to the customer relationship management concept, including Web site convenience, provision of product information, Web page design, and security concerns.

In the field of information systems, user satisfaction has been on the research agenda for more than 20 years (Khalifa & Liu, 2004). Early studies examined satisfaction of primary users who dealt with the information products generated by the systems (Davis & Olson, 1985). The target of the study was a specific type of information systems or information technology applications. For example, DeSanctis and Gallup (1987) measured manager (decision maker) satisfaction with a group decision support system. User satisfaction is generally defined as the "multidimensional attitude towards various aspects of MIS such as output quality, man-machine interface, EDP staff and services, and various user constructs such as feelings of participation and understanding" (Raymond, 1987, p. 37). With the subsequent proliferation of personal computing and end user computing, the main focus of user satisfaction research was the individuals who directly interacted with the information system. Several factors have been examined to account for the direct interaction between end users and specific technology applications (e.g., content, accuracy, format, ease of use, and timeliness) (Bollen, 1989).

The recent emergence of e-commerce has further blurred the distinction between end users and online customers due to the use of Web-based user interfaces for both internal and external communications. Not only have customer-facing applications of information technology been constructed to operate under the integrating framework of Internet protocols, back-office applications are also being hyperlinked to Web browser interfaces to provide stakeholders with single user interface. The technological integration is leading to the integration of the information systems and marketing theories. The traditional information system models for user satisfaction research that mainly focused on system/information characteristics are no longer sufficient to explain user/customer satisfaction in the new online environment (Palmer & Griffith, 1998). The traditional focus of marketing on product/service features also must be expanded to incorporate system and content characteristics. Therefore, a growing number of information system studies have adopted the marketing approach to measure online user/customer satisfaction. Many of the recent researchers used the disconfirmation model, a primary theory in marketing literature for explaining customer satisfaction, to examine various aspects of user satisfaction (e.g., Khalifa & Liu, 2004; Mckinney, Yoon, & Zahedi, 2002; Susarla, Barua & Whinston, 2003).

The literature reviewed above led to the conceptual framework for the study, formed by three research constructs (CRM practices, customers' perception of e-commerce firm's customer orientation, and customer Web site satisfaction) and their relationships. Three research hypotheses were formulated to represent these presumed relationships. The conceptual framework, research hypotheses, data collection, and analysis methods, as well as validation of measurement instrument are described in the next section.

RESEARCH DESIGN

Research Constructs and Hypotheses

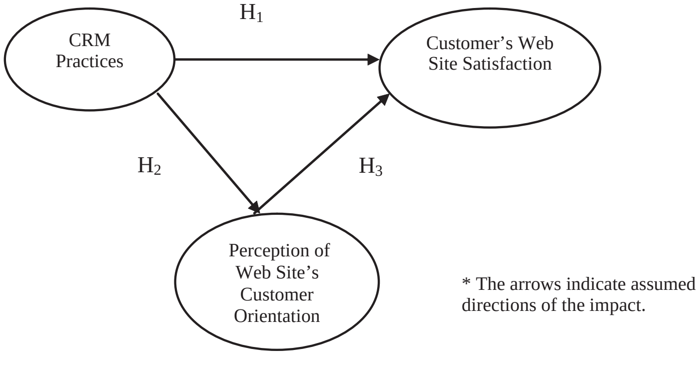
Customers satisfied with their Web site visit experience are more likely to repeat their visits and also more likely to purchase products. The immediate goal of CRM implementation is, therefore, to increase Web site visitors' satisfaction with their visiting experience. E-commerce companies would like to assume that everything they do with their Web site is aligned with customers' characteristics and requirements. Literature has suggested that customer satisfaction might be affected by their perception of the firm's customer orientation. The objective of this study was to clarify these speculations. Figure 1 is a graphical depiction of the relationships between the three research constructs. Following is a list of our three research hypotheses:

- **H_1:** Online customers' Web site satisfaction with their Web site visit experience is positively affected by the CRM practices of the e-commerce firm.
- **H_2:** Customers' perception of customer orientation of an e-commerce firm is positively affected by its CRM practices.
- **H_3:** Online customers' satisfaction with their Web site visit experience is positively affected by customers' perception of customer orientation of the e-commerce firm.

The construct CRM Practices consisted of three dimensions: market information generation, market information dissemination, and organizational responses to market information. All three dimensions were evaluated from the user/customer perspective. Generation of market information represented availability of market information and was gauged in terms of the richness of the information content on the Web site. Dissemination of market information was judged by how rapidly the Web site updated and shared its market information. The organizational response was measured by the Web site's rapidity in responding to customer inquiry or request for information. Each of these three dimensions was addressed by three question items in the questionnaire.

Perception of online customer (or e-customer) orientation was operationally defined as the extent to which an e-commerce company sought to satisfy its e-customers' needs and to enhance e-customer value, and was measured by three question items: (1) "The Web site understands and satisfies customers' needs," (2) "The Web

Figure 1. Research framework



site seeks to enhance customer value," and (3) "The Web site frequently evaluates its customer satisfaction situation." Customer satisfaction with the Web site visit experience was defined as the subjective evaluation of the overall value perception resulting from the interaction experience. Three question items were devised to represent this variable: (1) "I enjoy the experience visiting the Web site," (2) "I am satisfied with the services I received from the Web site," and (3) "I trust the correctness of the content." All variables are subjectively measured using the Likert Scale, with 5 representing "Strongly Agree" and 1 for "Strongly Disagree."

Data Collection and Data Analysis

The primary data were collected from college faculty, staff, and students in Taiwan in the Summer of 2004. The respondents were instructed to use one of their favorite Web sites as they responded to the questionnaires. Most respondents referred to popular local portal Web sites or major global e-commerce Web sites such as www.amazon.com and www.e-bay.com. As noted in Jih (2002, 2003, 2004), e-commerce is a major thrust in Taiwan's economic, educational, and public sectors. Most people in the college population have had some e-commerce experiences. The development of the survey instrument involved three steps.

- **Step 1:** An initial version of the survey questionnaire was designed to identify the question items synthesized from the literature. This version was presented to three practitioners and two academicians in the e-marketing and e-commerce fields. The questionnaire was revised to incorporate their feedback.
- **Step 2:** 100 copies of the revision were distributed to the students in e-commerce and e-marketing classes. This pilot testing resulted in further modification and improvement of the questionnaire.
- **Step 3:** The new version of the questionnaire was then tested online with the college students with e-commerce experience, who were instructed to evaluate a Web site of their own choice. More modifications to the questionnaire were made to accommodate feedback from the online respondents. The final version of the questionnaire was administered to another group of college students and university employees, who were invited via e-mail to participate, during the period of April and May of 2004. A total of 160 effective questionnaires were obtained and used for analysis after removal of the incomplete ones.

Two statistical analysis software packages, SPSS 10.0 and AMOS 3.6, were used to analyze the collected data. The Cronbach's α value was calculated as the reliability indicator for each research variable. The validity of the variable measurements was quantitatively tested using exploratory factor analysis, correlation analysis, and confirmatory factor analysis, in addition to the qualitative assessment of the experts in the field. The validation of the theoretical model was then performed using structural equation modeling analysis. For the model-testing study, Hair, Anderson, Tatam, and Black (1998) suggested an appropriate size from 100 to 200. Structural equation modeling analysis using a large sample (sample size > 200) might result in poor fitness of the model. The sample size 160 used by this study satisfied this requirement. Among the respondents, 43% were males, 57% were females, 30% were ages 19 or below, 37.5% were ages 20-29, 20% were ages 30-39, and 12.6% were ages 40 or above.

Reliability and Validity of Variable Measurements

An exploratory factor analysis was performed to identify the dimensions of the latent variable that represented the research construct CRM practices. The resulting dimensions were then evaluated by a confirmatory factor analysis. As shown in Table 1, the result of principal component analysis identified three factors (dimensions) from the nine question items. The accumulated variance was 72.99%, an indication of high construct validity. The reliability measures of the three factors were 0.835, 0.766, and 0.810, respectively. These reliability measures were greater than the commonly accepted minimum of 0.7, demonstrating a good reliability of our measurement of CRM practices. All factor loadings associated with each of the three factors were greater than 0.7, an evidence that the CRM practices measurement in this study possessed both convergent validity and discriminant

Table 1. Reliability, convergent validity, and discriminatory validity measures of CRM practices dimensions

Construct Dimensions	Measurement Items	Exploratory Factor Analysis	Confirmatory Factor Analysis		Cronbach's α
		Factor Loading	Standardized Structure Coefficient	T value	
Generation of Market Information	The Web site provides detailed product/service information.	0.874	0.838	Fixed*	0.835
	The Web site always has the information I need.	0.834	0.739	9.367	
	The Web site provides plenty of useful information.	0.802	0.806	10.029	
Distribution of Market Information	The Web site frequently mails me information, saving me time and effort.	0.826	0.675	7.539	0.766
	The Web site frequently mails me information on new product, new technology, and something educational.	0.783	0.705	7.800	
	The promotion information from this Web site works for me.	0.767	0.786	Fixed*	
Organizational Responses to Market Information	The Web site responses to competition in the market.	0.836	0.741	9.758	0.810
	The Web site responds to customer complaints and suggestions.	0.792	0.666	8.655	
	The Web site is sensitive to changes of customers' requirements for products and services.	0.700	0.881	Fixed*	

Note: Values on the diagonal are extracted variances. The rest are correlation coefficients.

validity. The convergent validity and discriminant validity of the CRM practices measurement were further confirmed by the fitness indices produced by the confirmatory factor analysis: specifically, the goodness-of-fit index (GFI) and the adjusted goodness-of-fit index (AGFI). The GFI represents the amount of variances and covariances in the sample covariance matrix, which can be used as an estimate of the population matrix. In essence, the GFI is analogous in interpretation to the R^2 in the multiple regression analysis. The AGFI is GFI that has been adjusted for degrees of freedom, and is essentially analogous to the adjusted R^2 in multiple regression. The cutoff value for GFI is usually considered to be 0.9, and for AGFI, it is 0.8 (Sharma, 1996). In this study the GFI value was 0.943, and the AGFI value was 0.893. Additionally, all t-value estimates were significantly greater than zero, with the exception of the reference indicators which were fixed at 1 for each of the latent variables. These characteristics of the measurements allowed for using the mean values of the three question items as the measures of the observable variables for CRM practices.

The factor analysis procedure was applied to confirm the constructs for our theoretical model: CRM practices, perception of online customer orientation, and customers' Web site satisfaction. Each analysis produced exactly one factor, with 1 used as the threshold value of the eigenvalues (Table 2). This result confirmed the single dimensionality of the factors. The high factor loadings and extracted variances of all variables and model constructs indicated a good convergent validity of the variable and construct measurements. Table 2 also showed that, with the exception of CRM, which was close to 0.7, all other constructs had a Cronbach's α greater than 0.7. Our evaluation of discriminant validity of the measurements was based on Fornell and Larcker's (1981) work, who suggested that the discriminant validity between two constructs was good when their extracted variances exceeded the squared correlation coefficient between the two constructs. Table 3 showed that the constructs in our theoretical model passed this test: the extracted variances (values on the diagonal) were all greater than the squared correlation coefficients (the rest of the values in the table).

Table 2. Reliability and validity tests of model constructs

Research Constructs	Measurement Items	Factor Loadings	Cronbach's α	% of Extracted Variance
Customer Relationship Management Practices	Organizational response to market information (crm1)	0.864	0.699	62.62
	Distribution of market information (crm2)	0.771		
	Generation of market information (crm3)	0.733		
Perception of Online Customer Orientation	Web site understands and satisfies customer needs (occ1)	0.890	0.828	74.46
	Web site seeks to enhance customer value (occ2)	0.862		
	Web site frequently evaluates customer satisfaction situation (occ3)	0.837		
Customers' Web Site Satisfaction	I enjoy visiting this Web site (cws1)	0.902	0.870	79.41
	Web site offers satisfying services (cws2)	0.899		
	I believe that I've made the right choice using this Web site (cws3)	0.872		

Table 3. Discriminant validity test of model constructs

Constructs	CRM Practices	Online Customer Orientation	Customers' Web Site Satisfaction
CRM Practices	0.626		
Perception of Online Customer Orientation	0.366	0.745	
Customers' Web Site Satisfaction	0.319	0.454	0.794

Note: Values on the diagonal are extracted variances. The rest are correlation coefficients.

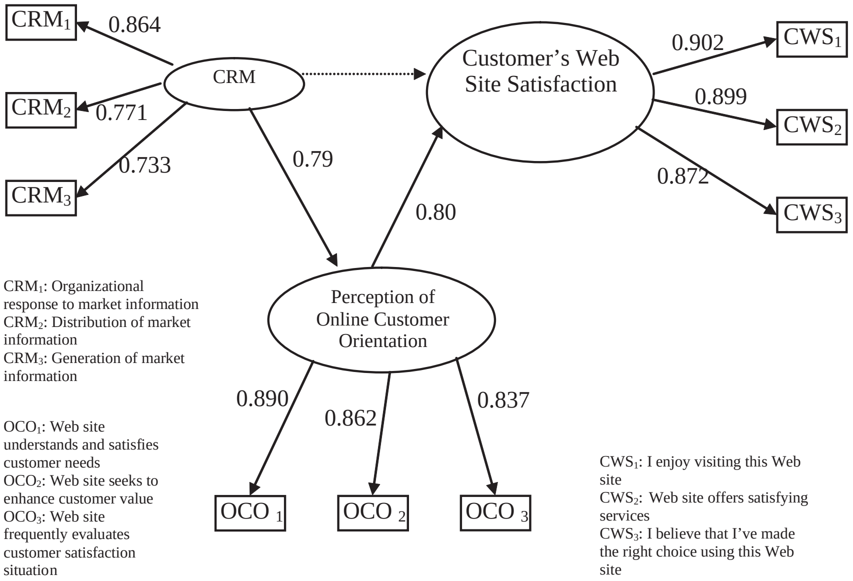
MODEL VALIDATION

James, Mulaik, and Brett (1982) recommended that testing a causal model required a two-step approach: The first step was a confirmatory factor analysis to obtain evidence for determining whether the indicators (or observed variables) appropriately measured the latent variables.

Once an appropriate measure model was identified, items could be combined to form scales of the latent variables. The second step then utilized these scales to test the hypothesized structural models. The theoretical model of this study consisted of three constructs (latent variables), each of which in turn was represented by three observable variables. The latent variables, the relationships to be tested between these three latent variables (expressed as oval symbols), and their corresponding observable variables (expressed as rectangular symbols) are graphically depicted in Figure 2. The factor loadings of the observed variables are indicated on the arrowed lines.

In order to determine the relationships between the three latent variables, the statistical analysis software AMOS 3.6 was used to test the research hypotheses. In addition to the chi-square test sta-

Figure 2. Result of model validation



tistics, six fitness indices were used to evaluate the adequacy of the theoretical model. The χ^2 test evaluated the discrepancy between the theoretical model and the collected data. The smaller the χ^2 value, the better the model fit. According to Carmines and McIver (1981), the χ^2 to degrees of freedom ratios (χ^2 /d.f.) around 3:1 or less were indicative of an acceptable model fit. The χ^2/d.f. in this study is 1.6272, an indication of an acceptable fitness of our theoretical model with the data. The results of testing the three alternative models are summarized in Table 4. Model 1 consisted of all three relationships represented by the three research hypotheses, and therefore was the first one tested. The results showed that both the absolute and incremental fitness indices indicated good fitness of the theoretical model. The absolute indices were GFI (0.945), AGFI (0.898), and RMSEA (root mean square error of approximation = 0.063). Ideally, both GFI and AGFI should be greater than 0.9. The GFI value was greater than 0.9, and the AGFI value was close to 0.9 in this case. The very small value of RMSEA (< 0.08) also confirmed adequate model fit. The incremental indices used in the study included NFI (normed fit index = 0.946) and CFI (comparative fitness index = 0.978 > 0.95). Both values were high enough to present consistent evidences in support of adequate fitness of the theoretical model (Bollen, 1989; Hair et al., 1998).

Table 4 also shows that, of the three research hypotheses in the first alternative model:

Table 4. Validation of three alternative models

path	hypothesis	expected sign	model 1		model 2		model 3 (rival)	
			Standardized Regression weights	t value	Standardized Regression weights	t value	Standardized Regression weights	t value
CRM→ Customer's Web site satisfaction	H_1	+	0.17	1.20	Not Applicable	Not Applicable	0.281	3.31*
CRM→ Perception of online customer orientation	H_2	+	0.78	6.24*	0.79	6.23*	Not Applicable	Not Applicable
Perception of online customer orientation → Customer's Web site satisfaction	H_3	+	0.65	4.35*	0.80	9.29*	0.691	7.62*
χ^2 / d.f.	Acceptable if < 3:1		1.6409		1.6272		4.6999	
Fit index	Critical value		Goodness-of-fit		Goodness-of-fit		Goodness-of-fit	
GFI	>0.9		0.945	good	0.945	good	0.878	poor
AGFI	>0.9		0.898	acceptable	0.901	good	0.780	poor
NFI	>0.9		0.946	good	0.946	good	0.840	poor
NNFI	>0.9		0.967	good	0.968	good	0.810	poor
CFI	>0.95		0.978	good	0.978	good	0.868	poor
RMSEA	<0.08		0.063	good	0.063	good	0.153	poor

**Level of significance = 0.05*

- **H_1:** (Online customers' Web site satisfaction with their Web site visit experience is positively affected by the CRM practices of the e-commerce firm.) was rejected due to the low structural coefficient 0.17 (t-value is 1.20) and was dropped from the subsequent analysis. Both H_2 and H_3 passed the statistical significance test and therefore were accepted.
- **H_2:** The perception of online customer orientation of an e-commerce firm is positively affected by its CRM practices ("CRM --> perception of online customer orientation," structural coefficient = 0.78, t-value = 6.24).
- **H_3:** Online customers' satisfaction with their Web site visit experience is positively affected by the perception of customer orientation of the e-commerce firm ("perception of online customer orientation --> online customer Web site satisfaction," structural coefficient = 0.65, t-value = 4.35).

With H_1 removed from the theoretical model, the second alternative model consisted of only two paths: CRM -> online customer orientation (H_2) and online customer orientation -> online customer satisfaction (H_3). Both hypotheses passed the significance test. In addition, all fitness indices passed the fitness evaluation criteria. The AGFI value (0.901) with this model was better than this value (0.898) with the first alternative model. In short, the second alternative model had a better model fit than the first one.

Despite the acceptance of both Model 1 and Model 2, a theoretical possibility still existed that CRM and perception of online customer orientation individually might directly impact online customer satisfaction. Morgan and Hunt (1994) pointed out the possibility of an antecedent directly impacting a consequence in some structural models and the significance of formulating and testing such a rival model. The rival model tested in this study, as the third alternative model, was formed by H_1 (CRM -> online customer Web site satisfaction) and H_3 (perception of online customer orientation -> online customer Web site satisfaction). However, although the structural coefficients of both hypotheses passed the significance test, the ratio of χ^2 to degrees of freedom (4.70) was higher than 3. In addition, none of the fitness indices passed the evaluation criteria. The rival model was rejected based on these results. The second alternative appeared to be the best theory; that is, CRM practices did not directly impact online customers' satisfaction. Instead, online customers' Web site satisfaction was affected by the CRM practices indirectly through an intervening variable, perception of online customer orientation.

SUMMARY AND CONCLUSION

Following the rise and fall of public expectations for the Internet's revolutionary impact on traditional business models at the turn of the century, researchers have reminded us that the Internet would not render traditional economic and business principles obsolete (e.g., Litan & Rivlin, 2001; Porter, 2001). Rather, the convenient communication capabilities and user-friendly interfaces provided by the Internet technology only represent a collection of technological capabilities that enables the implementation of innovative applications for businesses in all sectors to strengthen their competitive advantage in the knowledge economy. Identifying the synergy between traditional business wisdom and new information technologies is a core organizational competence that can only be learned through aggressive and creative experimentation.

Emerging as a strategic initiative involving the integration of a variety of information technologies with relationship marketing, CRM has received much discussion from both practitioners and academicians. Using various technological tools such as Web site design, database, data mining, software agent, and group work software in their marketing activities, companies are seeking to increase existing customers' loyalty while attracting new customers' attention at the same time. In light of the central role played by the Web site in the CRM practices, this study was conducted in an attempt to contribute to the understanding of the role of e-commerce Web sites in the CRM practices and the customers' satisfaction with their Web site visit experience. We constructed a tentative theoretical model based on the literature in marketing and information systems. The model links three research constructs: CRM practices, perception of the Web site's customer orientation, and customer satisfaction with Web site visits. We then used structural equation modeling analysis to validate the model. The result of model validation generated evidence for rejection and acceptance of the research hypotheses. The first hypothesis, "Online customers' Web site satisfaction is positively affected by the CRM practices of the e-commerce firms," was rejected. The other two hypotheses were both accepted: "The Perception of online customer orientation of an e-commerce firm is positively affected by the CRM practices of the firm," and "Online customers' satisfaction with their Web site visit experience is positively affected by the perception of customer orientation of the e-commerce firm." Interpreted collectively, these results indicated that the customers' Web site satisfaction was not affected directly by CRM practices, and the effect was made indirectly through the perception of online customer orientation. In other words, the perception of a Web site's online customer orientation played a pivotal role in the impact of CRM practices on the customer Web site satisfaction.

An important implication for e-commerce managers may be drawn from the research results. The study confirmed that the traditional wisdom about customer satisfaction is applicable as well to the e-commerce as to the traditional business environment. E-commerce companies must actively engage themselves in interacting with customers to ensure that what they do with their Web sites is all aligned with what the customers want and need. Furthermore, the challenges of time compression in transaction processing and the lack of physical contact in the e-commerce environment require even more careful design and monitoring of customer-facing business processes than in the pre-Internet era. The focus on customer requirements must be emphasized constantly to ensure that the information flows both ways via the Web site in the optimal fashion. After all, the Internet-enabled cyberspace now provides an information-symmetric scenario for both consumers and suppliers. Customers can freely switch between vendors. Customer relationship management is not just a smart business slogan. It must be thoroughly blended into the organizational culture and drives every major business decision made by the organization.

This study contributes to e-commerce research by demonstrating the use of a model-building method to test hypotheses regarding the impact of a major business initiative on customer satisfaction. CRM has received much attention in the management literature. Most discussions are conceptual or anecdotal in nature. Systematic inquiries involving empirical data are needed to verify the relationships between the concepts and, thereby, further this interdisciplinary field to better maturity.

The linkage between CRM and Internet-mediated market orientation is also a new adventure in e-commerce research. Min et al. (2002) proposed the concept of Internet-mediated market orientation to extend the traditional market orientation to the Internet-enabled business environment. They discussed the concept and called for more follow-up research to be conducted to validate their framework. This study built on their framework and used it to measure the information aspect of CRM practices.

Readers are cautioned in generalizing the findings reported herein for several reasons. First, the use of college faculty, staff, and students as respondents limits the generalization power of the research results. Second, the subjective nature of the responses may further pose another limitation on the external validity of the study. Third, since the data was collected in Taiwan, the research must be replicated in other cultures in order to expand the scope of applicability. Despite these limitations, since the study is confirmatory in nature, the significance of the study should not be severely reduced.

Promising directions for further research are suggested in the following directions. For a relatively new theory such as CRM to become well-established, more deductive and inductive inquiries are needed to advance the theory to a more mature level. The specific context of inquiry in this study is general Web site visit experience. Other contexts, such as online purchasing or online auction, may be used to obtain evidence from different angles of observation. Findings from research conducted in a variety of contexts will increase the theory's generalization power. Another area of research is using the controlled experiment approach to investigate issues surrounding CRM concepts. The controlled experiment research methodology complements survey research by keeping irrelevant factors under control in a lab setting. Examples of significant issues for controlled examination are the effects of different personalization designs, frequency of Web site update, and extent of Web site update on customers' perception of market orientation and their Web site satisfaction. The third area for future research concerns gathering data in different cultural settings to allow for cross-cultural comparison. With the global nature of e-commerce, an in-depth understanding of cultural impact on Internet-enabled CRM practices is an essential capability to operate in today's highly global business environment.

Chapter 5.18

Ethnographic Discovery of Adverse Events in Patient Online Discussions:

Customer Relationship Management

Roy Rada
University of Maryland, Baltimore County, USA

ABSTRACT

A healthcare provider can extend its customer relationship management program by sponsoring an online, patient discussion group. In those groups, patients may discuss adverse events that are inadequately addressed in the literature. The author, as a cancer patient, joined two online, patient discussion groups and identified four types of such adverse events. For each such adverse event, the patient findings, the medical literature, and the implications are noted. Extracts from the literature that were provided to the patients were welcomed by the patients. A literature review of one of the adverse events has been published in a medical journal. Factors are presented for healthcare providers to consider in deciding whether or not to sponsor an online, patient discussion group.

INTRODUCTION

Customer relationship management (CRM) systems are used in healthcare systems around the world (Alshawi, Missi, & Eldabi, 2003; Calhoun, Raisinghani, Tan, Untama, Weiershaus, & Levermann, 2005; Banaszak-Hol, & Hearld, 2006). A typical approach to CRM is to survey patient satisfaction and to address management steps to improve the results of the next survey (Zineldin, 2006). Data mining of Web information is an alternative way to learn what consumers think. In the financial sector, consumer views on particular investments have been assessed through the comments that those consumers make in online, discussion groups (Antweiler & Frank, 2004).

Many online patient groups are established by volunteers on free sites, such as groups.yahoo.

com (Rada, 2006b). However, some healthcare entities maintain patient online discussion groups. For instance, the Joslin Diabetes Center runs an online, diabetes discussion group for the public, and experts from the Center provide feedback online. Kaiser Permanente Health Plan maintains numerous discussion groups moderated by Kaiser's professionals, but access is restricted to enrollees in the Kaiser Plan.

Healthcare professionals in online moderator roles address adverse events, among other things. An adverse event occurs when some intervention by a healthcare provider produces an unwanted reaction. For instance, radiation treatment for oral cancer can cause obstructive sleep apnea. The literature on adverse events addresses their causes, how to reduce them, and the impact they have on patients, staff, and healthcare organizations (Misson, 2001). Typically, healthcare professionals investigate adverse events through the medical record (Duff, Daniel, Kamendje, Le Beux, & Duvauferrier, 2005).

Listening to patients is a key to reducing adverse events (Cleary, 2003): "by relying on the observations and insights of patients such as Mr. Q., the physicians and staff will be able to close the gap between Mr. Q.'s experience and what they can achieve." The book *Partnering with Patients to Reduce Medical Errors* (Spath, 2004) emphasizes the role of patients in reducing adverse medical events.

Patients in online groups hold a unique and valuable position because of their sheer numbers and an intense focus on their shared illness. Patient groups may have contact with larger numbers of disease-specific patients than many physicians and have the luxury of spending many hours discussing similarities and differences. After hundreds of hours of conversation, patterns can begin to emerge. These patterns might lead to new insights about adverse events. Members of an online patient discussion group explored their treatment and made discoveries that were incorporated in a scholarly journal article (Ferguson, 2002).

This article explores the means by, and extent to, which participants in online patient-patient discussion groups provide useful information about medical adverse events. The hypothesis is that patient online group information can stimulate the discovery of important gaps in the medical literature. More generally, the argument is that these online groups can be an important resource for both patients and healthcare providers.

METHOD

The author is a medical doctor and a head-and-neck cancer (HNC) patient. As doctors become ill and see the world from the patient's side, they often have useful insights to share about the relationship between patients and healthcare providers (Rosenbaum, 1988). This author joined two HNC online patient discussion groups as a patient.

Since an online discussion group is self-documenting by nature, the opportunity exists for a participant in a group to review the discussion and to engage in a kind of retrospective ethnographic analysis. Studying online groups via ethnography is in many ways easier than studying face-to-face groups (Paccagnella, 1997). The term 'netnography' has been coined to apply to such ethnography (Kozinets, 2002): "As a method, netnography is faster, simpler, and less expensive than traditional ethnography and more naturalistic and unobtrusive than focus groups or interviews."

In the context of this research, an online group uses a software system that provides a searchable archive of previous messages. Members of the group create messages and post them to the system, and the system in turn distributes these messages to the group. The system may interface to a group member via an e-mail client or a Web site. The online groups noted in this article may include patients, a patient's family or friends, and others who want to help. This population will be typically represented with the umbrella term 'patients' with its meaning apparent in the context.

The two HNC groups that the author joined explicitly welcomed any group members to use personally de-identified information in the online messages for research purposes. The author read the patient messages, identified messages of interest, studied relevant clinical, journal articles, and where appropriate shared extracts from the literature with the group. The author identified four cases where the information needs of the HNC patients led to the discovery of adverse events and gaps in the medical literature. For each case, the patient findings, the medical literature, and the implications are noted.

RESULTS

The four cases follow:

1. Patients in both groups frequently discussed ways to cope with their fatigue. Many patients reported signs and symptoms consistent with obstructive sleep apnea (OSA) in relation to this fatigue. The literature reveals incomplete information about OSA in HNC patients. Two articles provide interestingly different perspectives on OSA as a complication of the treatment of HNC. In one article, the incidence of OSA is 92% in patients treated for HNC (Friedman et al., 2001), while in the other article, 8% of treated HNC patients develop OSA (Rombaux et al., 2000). The literature at that time provided no mention of a radiated-only patient developing OSA, but one of the patients in the online group developed OSA after only radiation. Extracts of the literature were shared with the online group, and the patients expressed gratitude for that literature information. Furthermore, the observation of a gap in the literature became the basis of a published, medical, journal article (Rada, 2005a) and book chapter (Rada, 2008). In other words, the experience had two positive outcomes: increased patient satisfaction through knowledge gained and contributions to the medical literature.
2. Hyperbaric oxygen treatment (HOT) for osteoradionecrosis (ORN) of the mandible is routine in the United States. A patient in a discussion group presented his concerns about HOT for ORN and said: “Every dentist that I have seen in San Antonio has recommended HOT, but does anyone know if HOT is worth the $50,000 cost?” The patient went to Mexico and was told HOT for ORN was unnecessary. European studies have shown that HOT is not appropriate for ORN (Annane et al., 2004), but the American literature defends HOT (Mendenhall, 2004). Differences in the standard of care in one country versus another and the standard of care versus the ability to pay for the care create a kind of adverse event for the patient. Again, when extracts from the literature about HOT and ORN were shared with the patients, they replied with messages including a ‘thank you.’
3. Multiple participants (all older than 40) had initially gone to the doctor with a lump in the neck and been told that they had a branchial cleft cyst. As the cyst grew over months after the initial diagnosis, each patient sought further medical help and received the correct diagnosis of cancer. The medical literature reports that “80% of so-called branchial cleft cysts in the over 40s’ age group are malignant (Andrews, Giddings, & Su, 2003).” The literature does not address the frequency of misdiagnosis, though this misdiagnosis is an important adverse event. After information from the literature was shared with the patients, some committed themselves to working with their communities to increase awareness of the danger signs of HNC.
4. Two patients reported shock (anaphylaxis) in response to a drug (amifostine) that was first being used during HNC radiotherapy.

> The literature at the time suggested that severe reactions to amifostine were rare in HNC patients: "Amifostine administration was well tolerated, with a low incidence of side effects" (Antonadou, Pepelassi, Synodinou, Puglisi, & Throuvalas, 2002). A year later the results of a clinical trial were published which confirmed what the patients feared (Rades et al., 2004): "Administration of amifostine during radiotherapy for HNC is associated with a high rate of serious adverse effects." When a new drug use appears, detecting uncommon adverse events may be supported by having patient groups monitoring and discussing their reactions to their treatments. Some of the patients took this group information to their doctors and found that their doctors appreciated this information.

These four cases show, at least, three positive outcomes:

- Patients appreciated receiving extracts of the medical literature that pertained to their questions
- Secondary to their online participation, several patients became involved in community initiatives to detect HNC early
- Scholarly reviews of the medical literature have been published based on the gaps in the literature identified by the patients

When patients are confused about an adverse event, the possibility exists that healthcare professionals are also confused about these particular events and are unable to help. In a patient group, the patients may find opportunity to explore these troubling matters at length. From this study, patient groups can promote understanding about topics in which patients felt particularly unable to get adequate explanations from their healthcare professionals. The medical literature shows that these topics were little understood. For example, one journal article said the incidence of OSA secondary to HNC treatment was 92%, while another said the incidence was 8%, and very few other articles addressed this topic.

The majority of the discussion in the two HNC groups was not about the preceding, four adverse events. Much of the discussion was about emotional topics, such as a patient reporting the good news that the latest checkup with the oncologist revealed no progression of the disease and other patients congratulating the patient on the good news. Patients often complained about the loss of saliva (xerostomia) secondary to the cancer treatment. However, this adverse effect is well documented in the literature, and the patient discussion did not shed new light on xerostomia nor suggest a gap in the literature.

CATEGORIES AND PROCEDURES

Each of the preceding adverse events concerned more than one clinical specialty. The adverse events from the HNC groups might be categorized as follows:

- *A diffuse symptom*: OSA secondary to treatment for HNC may tend to be overlooked by otolaryngologists because the symptoms are diffuse and OSA is often addressed by sleep specialists rather than otolaryngologists.
- *Standard of care*: HOT, as part of the national standard of care for ORN, is not supported by clinical trials internationally, but the practicing otolaryngologist is not expected to dispute the national standard of care.
- *Primary care provider misdiagnosis*: A misinterpretation by the primary care provider might not be extensively documented or analyzed by the otolaryngologist.
- *Uncommon reaction to new drug*: When the drug amifostine was initiated for a new purpose, researchers needed further experience to uncover adverse events.

The foremost causes of adverse events as reported by the U.S. Institute of Medicine (Kohn, Corrigan, & Donaldson, 2000) are technical errors, diagnostic errors, failure to prevent injury, and medication errors. That classification is, however, not necessarily the optimal one for understanding what can be gleaned from patient online groups.

If a provider has decided to support an online discussion group and to provide moderators, then it might guide moderators relative to the findings of this study. To find evidence of adverse events that are inadequately appreciated in the literature, a healthcare professional might:

1. *Join an online discussion group for patients with a particular chronic disease.*
2. *Identify a finding that is highlighted by a patient as a problem*. Findings may include symptoms, signs, laboratory or test results, observations, or specific events (such as hospitalization or receiving a bill). A finding is a problem when a patient says so.
3. *Review the medical literature to determine whether a medical intervention experienced by the patient might have a causal relation to the problematic finding.* Relevant PubMed 'Medical Subject Headings' are identified, a query is posed to PubMed, and full-text copies of journal articles are retrieved through membership in a medical library subscription program. Temporal relationship, strength of association, biological plausibility, and other relationships contribute to a judgment of causality (Darden & Rada, 1988).
4. *Determine whether the literature provides conflicting or unclear guidance*. Sometimes the published literature suggests conflicting algorithms for diagnosis or treatment, and more research is needed to harmonize the literature.
5. *Extract information from the literature and return that information to the group.* The extract should be clear to the intended audience, embedded within a personal context, and made as a reply to recently posted message that has not already received a similar response.

If an extract from the literature is simply posted without context or explanation, then the impact, as measured by patient response, is less. Information systems can support this work by parsing patient messages and semi-automatically linking to relevant citations from PubMed (Rada, 2005b).

DISCUSSION

If one takes the preceding categorization of adverse events from online groups and tries to generalize further, one might note that the problems occur where the otolaryngologist's responsibility is blurred because someone else is also responsible. In general, adverse events may be least well understood where 1) the responsibility for the adverse event falls among several medical specialties and 2) the medical specialists inadequately communicate with one another. The four misunderstood topics discovered in this study were about patient conditions that require the coordinated attention of healthcare professionals from different disciplines, and this multi-disciplinary character of the topics may partly account for the relative lack of understanding about the topics.

The data from the online groups leads to qualitative results. For instance, the incidence of OSA in HNC patients is not expected to be the number of patients in the HNC groups that reported OSA because participants may have had OSA and not known it or did not mention it. In online groups, most participants are typically lurkers (Preece, Nonnecke, & Andrews, 2004). To obtain accurate incidence data, clinical trials might be needed. The online patient information supported the identification of a problem which further research might solve.

If a healthcare provider wanted its employees to moderate online patient discussion groups with the intent of also helping identify adverse events, then a proposal to the provider's institutional review board might be in order. The patients joining the group would be provided a consent form that detailed the conditions, the patient alternatives, and other components of a proper consent form. Given that patients had to register to join the group, their successful registration would only occur after they noted online that they consented.

While patients might be asked to sign a consent form, they are not invited to the online groups to get a diagnosis or a treatment. Rather the groups support patient-patient interaction, and the patients are responsible for the content of the message that they share. If a knowledgeable person brings extracts from the literature to the discussion, those extracts cite the original source and are informational only. Responsibility for taking action based on the information rests with the patient.

The Johns Hopkins Department of Pathology hosts some online patient discussion groups. The Department has found that patients may express their gratitude for this service via financial donations to the Department. Thus, the costs associated with maintaining the discussion Web site may be offset by patient financial contributions. This observation links to the economics of religion. Interestingly, online patient groups have some socio-economic characteristics in common with the socio-economic characteristics of religious groups (Rada, 2006b), and the opportunity exists to exploit the literature on the economics of religion (Iannaccone, 1998) in understanding the economics of online patient groups.

A healthcare entity that wants to sponsor an online discussion group has many options. For instance, the entity might or might not assign a healthcare professional as a moderator to the group. Providing a moderator is costly. Healthcare professionals have many demands on their time and often do not see participation in an online patient discussion group as a cost-effective use of their time. For the typical healthcare provider in the United States, efforts invested in an online discussion group cannot be billed to a health insurance company on behalf of the patients in the group. On the other hand, some healthcare entities have found that the goodwill generated by sponsoring an online discussion site stimulates financial donations from patients. A financial cost-benefit analysis that considered a wide range of factors, such as staff cost and patient loyalty, would be appropriate before an entity decided how much, if anything, to invest in online patient discussion groups.

CONCLUSION

Customer (or patient) relationship management is important to healthcare providers, as is minimizing adverse events secondary to healthcare decisions. One source of information that has been largely overlooked by the healthcare industry comes from online patient discussion groups. Online patient groups may provide an opportunity for healthcare providers to both build customer relationships and explore adverse events.

The author participated as a patient, though he is also a doctor, in two head-and-neck-cancer online patient groups. Patients discussed various types of adverse events, but four types were particularly intriguing for the gaps between what the patients needed to know and what the literature offered. These adverse events have been categorized as involving a diffuse symptom, a standard of care, a primary-care doctor's misdiagnosis, and uncommon reaction to a drug. The cases are multi-disciplinary in nature. The gaps in the literature create an opportunity for someone to produce a synthesis of the literature that highlights the gap and to publish that synthesis in a scholarly medical journal.

As measured by their responses, patients appreciated receiving information from the literature about their adverse events. A systematic approach to identifying such adverse events and providing relevant literature to patients is sketched based on the experiences of the author. Software can support the retrieving of relevant literature, but posing the response in the context of the patient's concerns requires human judgment.

One could continue this work in several directions. Patients in online groups typically focus on sharing empathy and information (Ebner, Leimeister, & Krcmar, 2004). Under what conditions do members of a group want primarily empathy or primarily information? What kinds of information are most useful? Some preliminary experimental results on identifying patient groups that prefer information over empathy have been established (Rada, 2006a).

Patients will have questions and comments about the quality of and cost of care from various providers. This kind of information may be comparable to what healthcare entities want from patient satisfaction surveys. To what extent and how can that kind of information be systematically mined from patient online discussion groups?

People seeking health-related information on the Web are one of the most common users of online discussion groups. Healthcare entities might benefit by paying further attention to the content of these discussion groups. This article has presented insights about dealing with adverse events in these groups and, more generally, framed some of the issues that a healthcare provider should consider.

ACKNOWLEDGMENT

The author thanks the Editorial board and particularly Prof. Joseph Tan for valuable feedback on earlier versions of this manuscript.

Chapter 5.19

Capturing and Comprehending the Behavioral/Dynamical Interactions within an ERP Implementation

James R. Burns
Texas Tech University, USA

Don G. Jung
MyongJi University, Korea

James J. Hoffman
Texas Tech University, USA

ABSTRACT

The behavioral and dynamic implications of an ERP deployment are, to say the least, not well understood. Getting the switches set to enable the ERP software to go live is tedious. But the difficult part is understanding all of the dynamic interactions that accrue as a consequence. Connectionist and causal models are proposed in this article to facilitate an understanding of the dynamics and to enable control of the information-enhanced processes to take place. The connectionist model facilitates the understanding of the dynamic behavioral implications of the larger ERP implementation installation per se. The underlying connectionist model will observe and detect information transfers and workflow. Once maps of the total infrastructure are determined by the models, an analyst can suggest improvements. The models become decision support aids for process analysts in situations where ideal process flows/information transfers are sought. INTRODUCTION

A class of packaged application software called Enterprise Resource Planning systems (ERP) seeks to integrate the complete range of a business's processes and functions in order to present a holistic view of the business from a single information and IT architecture. ERP systems are integrated, enterprise-wide systems that automate core corporate activities such as manufacturing, human resources, finance/accounting and supply chain management (Klaus, Roseman, & Gable, 2000). A brief history of ERP is provided by Jacobs and Weston (2007). Additionally, a discussion of a recent ERP implementation with focus on end-user training can be found at www.diplomica.com (2007).

From a research perspective, several longitudinal studies have been conducted of ERP systems to ascertain how well they achieved their objectives (Holsapple & Sena, 2003a; Holsapple & Sena, 2003b; Lonzinsky, 1998). Other more recent studies have examined research questions such as: (1) how change management issues relate to federated ERP systems (Abels, Brehm, Hahn, & Gomez, 2006); (2) what determinants of ERP implementation success are (Cegielski, Hall, & Rebman, 2006); (3) what factors bring about a successful implementation of a collaborative technology that results in productivity improvements in small businesses (Jones & Kochtanek, 2004); and (4) how organizational knowledge is shared during ERP implementation (Jones & Price, 2004). Hendricks, Singhal and Stratman (2007) provide an excellent discussion of how enterprise systems (ERP) affect corporate performance.

ERP is an important area of study since large organizations world-wide have already adopted ERP and increasingly, small- and medium-sized enterprises (SMEs) too are finding it cost effective and a competitive necessity to follow suit. Current ERP solutions are based on a three-tier client-server architecture, in which the data, the applications and the presentation layers form three logically independent levels, each distributed from the other. Typically, the data management layer contains the database and the applications layer contains the business logic, with each allocated to separate distributed servers. The applications server often contains a portion of the presentation layer in that it serves out Web pages. The final physical component is simply the Web browser which is also a part of the presentation layer, but resides on a different processor—the client.

The comprehensive functionality of any ERP system requires a corresponding reference model for the whole enterprise. In addition to the usual software documentation, the supported processes and organizational structures as well as the structure of the data and objects are usually depicted in a reference model called the Enterprise Model. This model enables rapid access to the functionality and allows navigation through different abstraction levels and between different views in the Enterprise Model.

Enterprise Modeling is the construction of an enterprise model as a limited system that represents the larger system in question. The purpose of Enterprise Modeling is to understand and improve the enterprise, that is, to improve the symbiosis of the individual business processes and objects. In this sense, improvement means any change in coordination among the business processes and between objects that increases the benefits of symbiosis. The methodology of Enterprise Modeling is the construction of a set of views of the enterprise considered as a system. The resulting enterprise model contains business processes and objects and their relationships. Enterprise Modeling is the tool of business engineering and reengineering.

Enterprise Modeling has been one of the main themes of research in ERP, BPR, Software Engineering and IT Project Management areas, and as a consequence there are many different reference models and methodologies for enterprise modeling. Although there are numerous models and methodologies for enterprise modeling, their general structures are all similar and one of the most important components that they usually include is the business process model.

In this article, our purpose is (1) to present an efficient and robust mechanism that can capture the patterns of information transfer between business processing entities and (2) to extract behavioral implications from them within an ERP framework. For the purpose of this research, we integrated existing practice results from ERP enterprise and business process modeling with research we did on CIROS (Connectionist Inexact ReasOning System) for inexact reasoning (Jung, 1990; Jung & Burns, 1993).

This article consists of the following contents: in the next section (section two), we examine business process models for BPR within an ERP framework. In doing so, we focus on the problems and misuses and the possible causes for those problems and misuses in existing ERP systems. Also, we briefly review existing and industry-wide-adopted business process models.

In the third section, we present an information architecture for the prototype system to be proposed and suggest how this system would exist as a software layer juxtapositioned between other software layers so it can capture transaction traffic. We suggest that this layer will serve as a silent observer/recorder of all that goes on in terms of information transfer and workflow within the larger ERP system.

In the fourth section, we present a simplified business process model for our research purpose by modifying existing ones. The result is a Simplified Business Process Model (SBPM). Although it has a simple network structure, consisting of only two components—process nodes and links between nodes—we believe it serves well our research purpose and has enough scale-ability for practical applications.

In the fifth section, we briefly review the CIROS model and its underlying theoretical elements, and then modify the CIROS model to fit our current research concern. We combine the SBPM and CIROS models, and the result is a new connectionist model, called CLEAROS (Connectionist LEArning and ReasOning System), that has the capability of inferencing and learning for BPR[1] within an ERP framework.

In the sixth section, we suggest some further possible analyses that can be done based on the outputs of CLEAROS. In the seventh section, we provide an illustrative scenario of how the methodology could be used. In the final section, we summarize the research concepts and present some further issues extending the research result here.

BUSINESS PROCESS MODELS FOR BPR WITHIN AN ERP FRAMEWORK

The languages and methodologies for describing/modeling business processes are very diverse. [2] The types of models required to design, analyze and operate business enterprises have been discussed by numerous researchers (Jonkers & Franken, 1996; Kettinger & Grover, 1995). The general conclusion is simply that different models are required for different purposes. Thus, a critical research issue is to identify which type of model should be used for what purpose.

As stated previously, business processes can be described or modeled in various different ways for various purposes. However, our primary concern is the patterns of information flow between/among business processes and the behavioral ramifications that are consequences of these patterns, within an ERP framework. For that purpose, we are going to review a real business process model from an ERP software company and then, we build and present a business process model for our research purpose by simplifying it, which is the task described in Section 3. In the following, we briefly review and describe the business process model from SAP R/3 known as Business Blueprint (Curran & Keller, 1998).

SAP R/3 Business Process Model

A tool for business process engineering (and reengineering) in the SAP R/3 system is Business Blueprint. It includes various components for BPR. The language and methodology of Business Blueprint is based on a concept called EPC (Event-driven Process Chaining).

EPC is based on four key elements: events (when should something be done?); tasks or functions (what should be done?); organization (who should do what?); and communication (what information is required to do the right task?). Events are the driving force behind a business process, prompting one or more activities to take place. The EPC provides the interconnections between tasks, data, and organizational units and the logical time sequence involved to define a business process.

An event always triggers a task. It is important for each task to begin with at least one event (the start event) and to end with at least one final event (the finish event). The organizational units (departments, people, etc.) responsible for doing the task are added to the model of the business process to show a complete picture of how the business process is structured and performed.

When companies are faced with the complexities of creating a business information construct, however, different issues require different analyses of aspects of the business. To fill this need, the Business Blueprint of the SAP R/3 system provides the users with the capability of modeling from various viewpoints the business functions and application components, business organizations, data, business processes, and interactions of the various components. Each view answers a distinct question about the interaction of business processes. Accordingly, the users of the Business Blueprint can produce different models from each view, (i.e., application component model, organization model, data model, process model and interaction model). Among these the process view is the central view, and hence the process model incorporates the other models to give the users an integrated view of the whole enterprise under consideration.

Problems with Existing ERP Systems for BPR

ERP software projects often deliver disappointing organizational results, even if the information systems work well technically. One explanation is that companies use technology to automate old, ineffective processes. Moreover, BPR has had a high failure rate with consultants estimating that as many as 70% of BPR projects fail (Hammer & Champy, 1993).

It is well known that the implementation of any ERP software system will drive changes to existing processes. Necessarily, those business processes must morph to accommodate the new software system. The real question is, did the changes required result in any improvement in overall performance? A study described in Gattiker and Goodhue (2002) suggests that the process changes necessitated by the implementation did NOT result in any improvement in overall performance, in spite of the fact that the ERP-imposed processes were supposed best practices. The study rejected the hypothesis that ERP-driven changes in business practices resulted in positive performance impacts from using the software. These results illustrate just how much more work needs to be done to truly discover how to maximize the potential benefits of ERP systems.

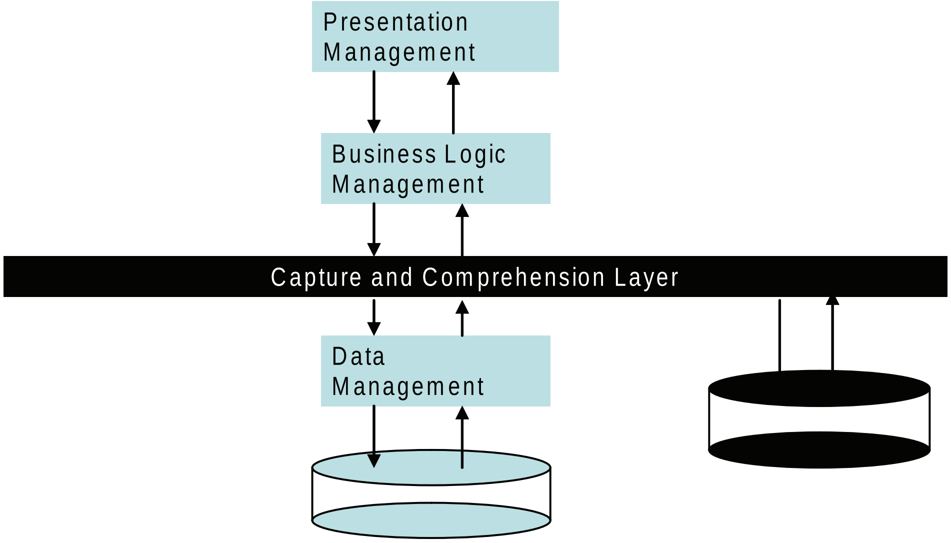
Research in artificial intelligence and expert systems (Holsapple &Whinston, 1996, pp. 462-490) suggests that if one were to ask managers how they react to a given scenario or situation, they could tell you, albeit incorrectly. It becomes necessary, therefore, to observe the managers at work and to record their responses from what is observed rather than from what they might say. This becomes even truer when more than one human decision maker or manager is involved in making a complex, chain-of-organizational decisions. Such "distributed human organizational knowledge" can only be captured through repeated observation. The concept of using artificial intelligence to comprehend the collective decision-making paradigms of an entire organization has yet to fully emerge as a discipline. In this work, we propose a mechanism for doing just that—undoing the reductionist approach to distributed decision-making by capturing the actions of every decision-making node in the entire process and performing analysis upon those actions. By examining the actions of the whole process, the collective behavior and dynamics of the whole process can be understood. In the next section, we present an architecture for capture and comprehension of the individual actions/decisions leading to an understanding of the organizational performance as a whole.

An Information Architecture for this Research

We are proposing that a connectionist model and its data-capture/storage module exist as a "layer" of software that interoperates between the business logic and the data management components of any ERP application. The layered information architecture for the system is exhibited in Figure 1. The dark layer, labeled the "Capture and Comprehension Layer" in Figure 1, is placed between the data management and business logic management layers of the traditional ERP architecture so that it is in a position to observe all the transaction traffic. Transaction traffic would include all client-initiated queries, all e-mails and their attachments, all purchase orders/invoices as well as other business documents, all "pushed" as well as "pulled" content.

The Capture and Comprehension Layer exhibited in Figure 1 observes all of the transaction activity and records the origin and destination of every such transaction, the time and date of the transaction, while classifying the transaction as to type and content. Each transaction is seen as an output from an origin node and as an input to a destination node. From these output/input records involving a pair of nodes, the proposed "system" will infer input/output records for any given process node. Moreover, input/output records are constructed for an entire network of nodes (to be defined subsequently). It is these collections of input/output ((or stimulus/response)

Figure 1. Location of the capture and comprehension layer (black) within the ERP architecture (grey)



records that the "system" uses to create a picture of what is related to what and who is making what decisions in terms of stimulus/response. How the collective decision-making is affecting the overall dynamical behavior of the organization in question is discussed next.

A Business Process Model for this Research

In this section, we define a generic business process, identify some important components of a business process, and then present a Simplified Business Process Model (SBPM) for our research purpose. The SBPM is based on SAP's Business Process Reference Model and the definition/characteristics of the prototypical business process as specified in the next section.

Definition: Business Process. A business process is a specified activity in an enterprise that is executed repeatedly. Business processes have the following characteristics (Martin, 1993; Taylor, 1996; Scheer, 1992, 1994).

- Business processes have definable beginning and end points, called nodes.
- Nodes exist wherever processing takes place; the nodes pass information to each other vis-à-vis a network.
- Business process nodes have inputs consisting of information, material, energy, and so forth, which they transform into outputs that also consist of information, material, energy, and so forth The transformation adds value to the outputs.
- Business processes are created by higher level business processes that monitor and control their operation (i.e., business processes are structured in hierarchical organizations).
- Business processes consume resources that are allocated to them by their higher level controlling business processes.
- Business processes report their status to their higher level controlling business processes.
- Business processes consist of sequences of events—instants in time at which the process undergoes state change

Accordingly, a business process model should incorporate a network structure and include process nodes and the relationships between the process nodes as a minimum. In addition, events, resources such as information, actor or owner, and information storages can be included as the modeler requires.

Process structure. A given business process can be thought of as a network of processing nodes. The process dependency model shows how business processes relate to each other and how they are dependent on each other. A given process is dependent on another process in the sense that the process in question cannot take place until the other process has completed for whatever reason. Basically, process dependency is determined by the business rules of the enterprise. Because business rules are very important in building the business process model, a thorough explanation will be given next. For the description of the process dependency, we use an example of a business process diagram shown in Figure 2.

There can be several forms of process dependency. In Figure 3, the single arc proceeding from process node 2 to process node 3 exhibits one-to-one process dependency. Node 5, with its many inputs from Nodes 1, 2 and 4, exhibits many-into-one dependency. Node 2 initiates nodes 3 and 5 and thus exhibits one-into-many dependency. We will visit Figure 2 again when we discuss a possible scenario involving our system in the last section.

What we wish to propose in this article is mechanisms to capture and comprehend the transaction traffic between the nodes.

Figure 2. A business process diagram

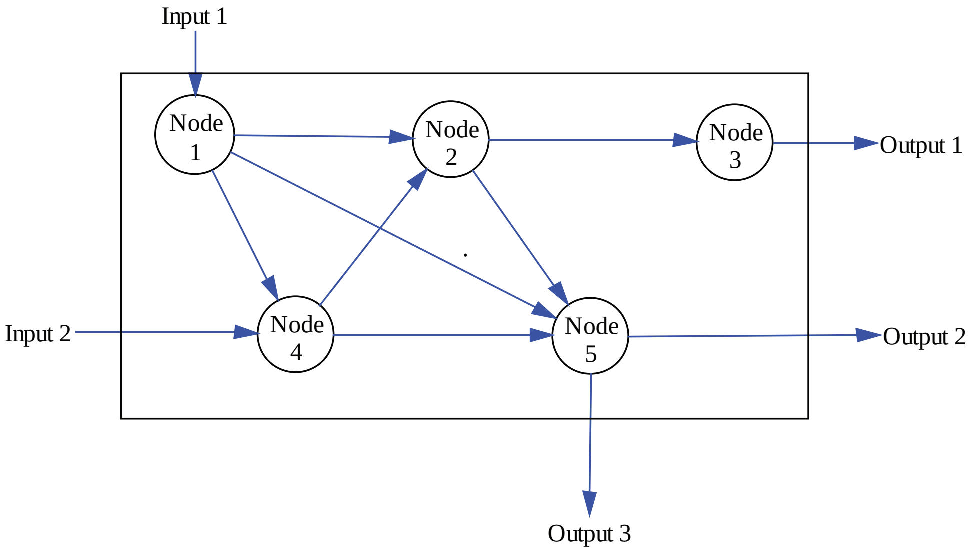


Figure 3. Process node architecture

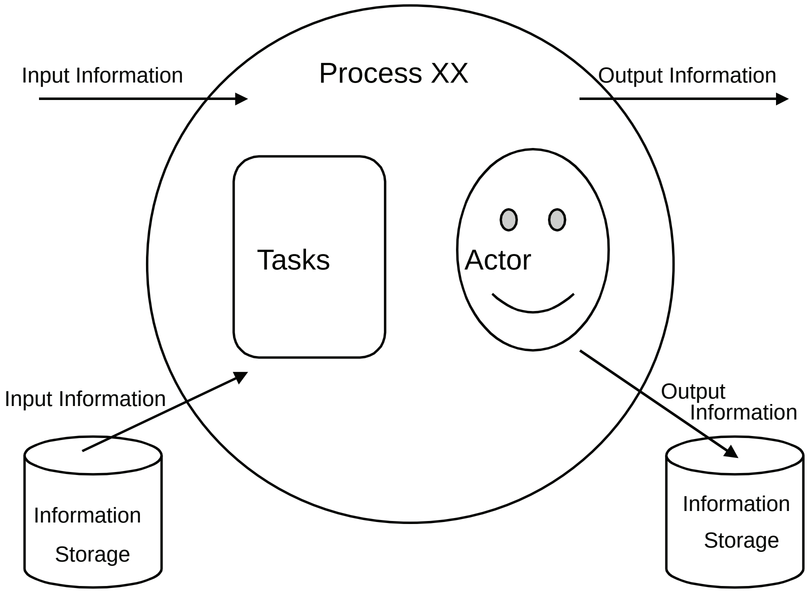


The business rules. The enterprise has a set of business rules representing the conditions, constraints, and policies that control its organization, direction, and operation. Business rules are, in a sense, a shorthand language for expressing the business knowledge. One place business rules can be found is in the policy and procedure manuals of the organization. Such manuals contain the written operating policies of the firm. Carried to its logical extreme, the set of business rules of an enterprise can act as the declarative script of the enterprise. No matter what happens, one or more business rules would control what happens after that (Gale & Eldred, 1996). A contemporary discussion of business rules can be found in Von Halle, et al. (2006). Debevoise (2005) provides an excellent discussion of business process management utilizing a business rules approach.

The enterprise is an example of a general system. Any general system can be analyzed in terms of three perspectives: a structural perspective, a functional perspective, and a behavioral (or dynamical) perspective. Business rules apply to any or all of the enterprise perspectives. Thus, a given business rule may roughly be classified in one of the three perspectives.

Structural business rules are related to the structure of the enterprise. The structure of the enterprise is its set of entities and their relationships at a specific point of time. Structural business rules maintain the integrity of enterprise entities. Examples of structural business rules are as follows:

- The enterprise should consist of: marketing department, personnel department, finance department, accounting department, and customer service department. (Organization rule)
- Annual Total Profit = Annual Total Revenue – Annual Total Expense (Entity definition)

Functional business rules are the business rules that specify the goals and objectives of the enterprise. Basically, they collectively define the "what should be done (by whom)". Examples of these rules are:

- The marketing department should maintain at least 35% of the domestic market of product A.
- The management of human resources is the responsibility of the managers throughout the company (as opposed to being established as a separate organizational unit).

Behavioral business rules are used to control the preconditions and post-conditions of the state changes of the enterprise. A typical behavioral business rule has the following form: when certain events occur and certain conditions hold true, then the system states change. Behavioral business rules are closely related to the business process chains. In fact, the relationships between different business processes and chaining of the business processes are solely determined by the behavioral business rules of the enterprise in our Simplified Business Process Model (see the following subsection).

A Simplified Business Process Model (SBPM)

A simplified business process model that is sufficient for our purpose can be constructed as follows. The whole business process under consideration consists of smaller (sub) process nodes and relationships between them. The relationship type between two process nodes that is captured in this model is the triggering control sequence. That is, there should be an event or a set of events between the two process nodes that satisfy some predefined (according to some business rules) pre- and post-conditions for the relationship between the two nodes.

Moreover, because the relationship type is a kind of triggering control sequence, it should have some temporal sequence (i.e., the process node before the occurrence of the event (or transaction) originates the event and then the other process node after the occurrence is the destination) and therefore can be represented as a directed link. If we represent the process node as a circle and the relationship between two nodes as a directed link, a typical business process can be diagrammed as in Figure 2. We shall refer to this as a "knowledge network" and it is logically structured to cohere with our knowledge of the physical system that it represents. Thus, every transaction will have an origination node and a destination node.

Each process node must have as its components a task function that is basically a set of services that are expected to be done at this node: an actor who is in charge of or responsible for the task of this process node (an actor may be a person, an organizational unit, or an artificial software agent), and information storage(s) to read input information from or to store output information in. Here, the output information simply means the information resulting from the execution of the node's task (or function). The information storage(s) and the information stored in the storage(s) may be owned (or used) by the process node only, but is usually shared by other process nodes.

The input information may be an input from another node (or from outside of the whole business process in consideration) or read-in records or documents from the permanent storage(s) used by the node. The output information may be some temporary results to be delivered to the nodes that are linked to this node, or some permanent results that should be recorded and kept in a database as a record of a table or a document. Therefore, output information of a process node can be either temporary or permanent and, if permanent, must be deposited in the information storage. The structure of our Business Process Model is shown in Figure 2. Additionally, each business process node will have a very simplified internal architecture as shown in Figure 3. This figure shows us where we can insert a monitoring mechanism that will capture the transaction traffic; clearly, this will occur at the points where we see an input or output arrow. Software that can capture this traffic works as follows; the transaction is sent, not only to its destination but also to a system that records the origin and the destination of the transaction. The software is also capable of detecting the type of transaction as well as important content within the transaction. Additionally, each transaction is date-stamped and time-stamped so that durations can be determined. Of interest would be the length of time an information packet spends in some non-value adding activity such as in storage. All of this data would be placed in database tables, as suggested in Figure 1, utilizing standardized records. This concludes our discussion of the detection and capture mechanism; we describe next several possible comprehension mechanisms.

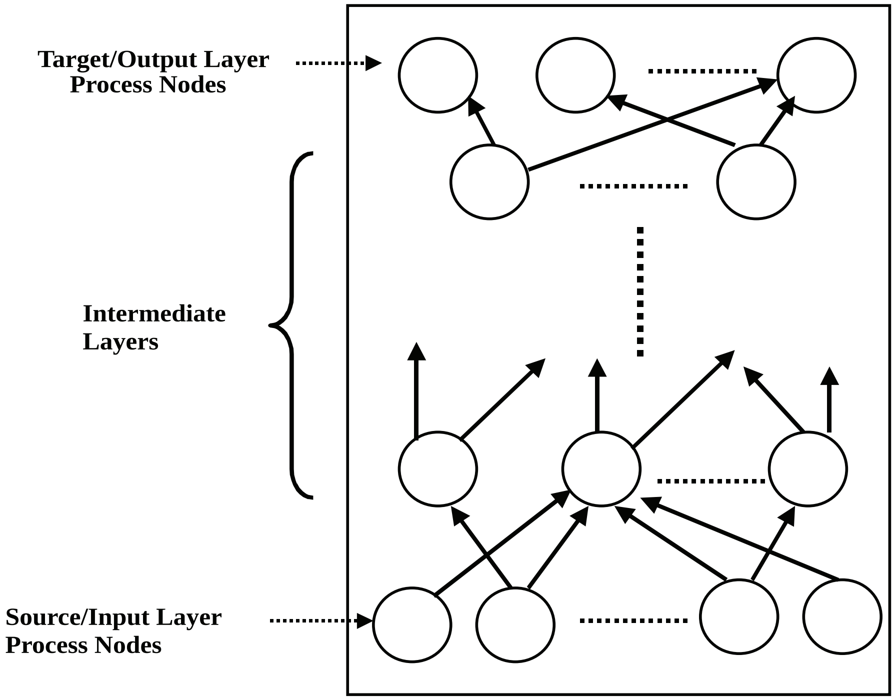
A Connectionist Approach to Business Problem-Solving and BPR

In this section of the article, we consider the network structure (topology) of the whole business process. Usually, this network of process nodes will have a mesh topology and might contain loops or cycles. We use the term "loop" to mean the link starts from a node and comes back directly to the same node. On the other hand, a cycle is a path (a sequence of links) on the network that starts from a node and ends with the same node but with at least one visit to another node. These definitions are used in the material to follow.

The fundamental structure of CLEAROS is exhibited in Figure 4. It is basically a layered, acyclic knowledge network. At the bottom is the input layer that represents the collection of source or input process nodes. The top layer is the output layer that represents the collection of target or output process nodes. Between the two layers are one or more intermediate layers that represent various classes of intervening process nodes. ERP process analysts will decide upon the initial structure of CLEAROS, in which each node represents a process of interest, possibly through use of SAP Business Blueprint and commercial tools like it. The structure must be acyclic because the learning (training) and inferencing algorithms require acyclic networks.

To capture and represent knowledge about the behavior of the ERP system, CLEAROS uses a connectionist model (Waltz & Feldman, 1988—see Appendix I for further discussion of connectionist models and of how CLEAROS works operationally) that makes the following assumptions:

Figure 4. Connectionist structure of CLEAROS



1. The domain knowledge (K) consists of two components, the set (V) of business process nodes and the set (E) of relationships (links) among the business process nodes. Mathematically, K is a diad of V and E (K = <V, E>). The links of the digraph may represent any natural cognitive ordering that is consistent, meaning each link must represent the same relation.
2. The whole node set consists of three mutually exclusive subsets: input (or source) process node set, output (or target) process node set, and intermediate process node set. A process node in CLEAROS should belong to exactly one of these subsets at a time (or in a session of running). See Figures 4 and 7 for depictions of how these nodes interact.

   An input (or source) process node represents a business process that captures or generates ultimate source information in the ERP system. Ultimate source inputs are generated and captured inside of the whole business process under consideration. One possible source input would be POS (Point-Of-Sale) data; another is EDI (Electronic-Data-Interchange) data that is transported across organizational boundaries.

   An output (or target) node represents a point at which transactions leave the system of interest. It is a point where measurements are taken because managers or analysts have concerns. It may also be a "natural" output of the collection of processes networked together—the end product of a supply chain, for example.

   An intermediate process node represents one of the middle steps to reach the target process node from the input nodes. Since there are usually many intermediate nodes by which to reach the target, they collectively determine the behavior of the target.
3. The relationships taken into account in CLEAROS may represent information transfers or actual flows or money, material

or product. The relationship between two process nodes in CLEAROS represents a triggering (or "invoking" in programming terminology) sequence (i.e., if the preceding process is finished and a certain condition holds true then the (directly) succeeding process should follow):

As we have seen in the BPM section of this article, the relationship between two process nodes is determined by the business rules of the enterprise. In fact, the whole business process dependency structure of an enterprise is determined by the whole set of business rules of the enterprise and represented as a network topology (See the item (1) in the following description).

Based on the fundamental assumptions about the knowledge of enterprise business processes, CLEAROS represents its knowledge as follows (design constructs of CLEAROS).

1. Network representation of knowledge

Knowledge about the enterprise's business processes may be represented in a network of process nodes and directed links (some other authors use the term "arc" or "connection" or "edge" instead of "link," but in this article, the term link is used consistently). The process nodes and their links constitute the network topology. The knowledge network initially constructed within CLEAROS is patterned after the enterprise's actual business process network as discerned by use of SAP's Business Blueprint.

2. Representing the influence of a link by weight values (learning)

Associated with each link is its value from the continuous range of [0, +1], called the "weight value" or WV. The weight of a link in CLEAROS measures and reflects the relative degree of influence by the preceding process node on the succeeding process node. The weight value +1 of the link from the preceding process node to the succeeding process means that the preceding process node has the maximum degree of influence on the performance of the succeeding process node. Zero weight means that the preceding process node has no influence on the succeeding process node.

3. Representing the relative importance of each process node (inferencing)

Associated with each node is its value taken from the continuous range of [0, +1], that represents the degree of the importance of the process node in terms of its relative criticalness over the whole business process (under consideration), where the value +1 means that it is a process with the highest degree of importance over the whole business process under consideration, and where the value 0 means that the process has no contribution (no value addition) to the whole business process under consideration. This number will be called the "PF" (Performance Factor) of the process node and will represent the degree of the contribution (value addition) to the whole business process under consideration.

4. Acyclic layered network

As discussed in the BPM section of this article, the original business process diagram under consideration, if represented in a network, might involve loops or cycles, and thus violates the assumptions made in CLEAROS. So it will be assumed, initially, that our business process model does not involve any loop or cycle. If a business process appears to involve loops or cycles, this concern can be addressed by consideration of the abstraction level of the process nodes. A method that can resolve the problem of loops is suggested in (Jung & Burns, 1993) and in the Appendix to this article. By picking a high-enough abstraction-level, the loops and cycles disappear as they are contained within the process nodes. In any case, the knowledge network in CLEAROS will be assumed to be an acyclic network. Causal models of the enterprise will, however, contain the cycles and loops, thereby enabling analysis both with and without loops. This approach offers the best potential for fully understanding the interactions between nodes.

5. Knowledge update by inferencing (update of fact-type knowledge)

CLEAROS changes (or updates) its knowledge in two ways: (1) by learning, and (2) by inferencing. Knowledge updates by inferencing in CLEAROS mean changing (or updating) the PF values of its nodes.

6. Knowledge update by learning (update of rule-type knowledge)

CLEAROS can modify its pattern of connectivity as a part of its learning process. Modifying the pattern of connectivity (thus learning) means changing (or updating) all or part of the weight WV values associated with the links in CLEAROS.

Initialization of the CLEAROS Knowledge Network

For CLEAROS to do its main job, inferencing, its knowledge network (knowledge base) should first be structured and then initialized. The starting rule used for structuring the knowledge network is to use a separate node for each process and/or processor in the real network. Once the node structure is determined, the initialization of the CLEAROS knowledge base is just the initialization of all its weight values. The weight values initialization in CLEAROS can be done basically in three ways.

One way is assigning a weight value for each link. The initial weight value of each link may be supplied by human experts who are in charge of the process. Another way is that we calculate the data traffic rate for each link between two process nodes and normalize it, and then assign the normalized value to the weight. The last method is by using the CLEAROS learning mechanism. To use the CLEAROS learning system, we should have enough learning records. The specific learning method of CLEAROS is explained next.

Learning

Learning requires building and updating the knowledge structure. Because CLEAROS represents its knowledge structure as a network of process nodes and relationships between these nodes, its structural change assumes adjustment and update of relationships between the process nodes. In CLEAROS, this is done by adjustment of weight values between the nodes in different layers. Therefore, learning in CLEAROS requires updates of its weight values. These adjustments permit CLEAROS to perform correct inferencing.

Learning in CLEAROS takes place as follows. Once the structure of the knowledge network has been determined and initialized, learning is required to establish the weight values of the links. Learning requires a table of input/output records. CLEAROS is exercised by exposing it to each set of inputs in a single record, one record at a time. The outputs produced by CLEAROS are then compared with the actual outputs contained in each record. Learning takes place through adjustment of the weight values so as to minimize the error between the predicted outputs of CLEAROS and the actual outputs.

There are many theories, methods and algorithms for learning in the connectionist paradigm. The learning method adopted in CLEAROS is the Generalized Delta Rule or back-propagation algorithm as suggested in Rumelhart, Widrow and Lehr (1994). Back-propagation is currently the most important and most widely used algorithm for connectionist learning. It is an algorithm for learning in feed-forward networks (like CLEAROS) using MSE (Mean Squared Error) and gradient descent. For a detailed introduction to the back-propagation method, readers may consult chapters 11 and 12 of Gallant (1993). For a detailed explanation about the application of the back-propagation method to reasoning system designs, readers are referred to Jung (1990). A thorough illustration of initialization, learning and usage of connectionist models like CLEAROS is found in Jung and Burns (1993).

Inferencing

This step can be applied after initialization and learning have been undertaken. One of the main purposes of CLEAROS is to find the relative degree of performance (i.e., the PF) of a business process node and the relationships among different process nodes in terms of contribution or value addition (again, the PF). In other words, managers or analysts who are concerned about the overall performance of the whole business process (under consideration) may want more detailed information about the relative performance or contribution of each component process and once they get this information, they can do whatever they think appropriate based on the information.

The inferencing mechanism of CLEAROS can provide that kind of information that managers or analysts need. There are basically two types of inferencing tasks that are possible in CLEAROS. These inferencing tasks in CLEAROS can be grouped into two groups. The first group involves forward-chaining computation and the second group involves backward-chaining computation. For fundamental computational mechanisms of connectionist models like forward- and backward chaining and for various learning models, readers may consult Gallant (1993). For hyper-fast inference engine architectures see Burns, Winstead and Hayworth (1989).

1. Forward-chaining computation:
    - Find the effect of input/source process nodes;
    - Calculate the Performance Factor of the target process nodes;
2. Backward-chaining computation
    - Find the causes or paths for a target process node; and
    - Produce justifications/explanations for the conclusion.

Finding the effect of input/source process nodes means finding the paths from a given source process (or set of source nodes) to the target process nodes. This task is needed when managers or analysts want to understand the exact (partial) process chain and the effect of change in some processes. Calculating the effect of input/source process nodes is needed when a manager or analyst wants to get information on the effect of the source process' PF (or the change of their values) on the target process.

Finding the causes or paths for a target process node is similar to the task of finding the effect of input/source process nodes but, in this case, search direction is the opposite one (from target/top to source/bottom). This task is needed when managers or analysts want to find an answer to the question such that "Given a process with a problem, what process chain do I need to address to resolve the problem?" Producing justification/explanation is similar to the task of finding the causes or paths but during learning, CLEAROS calculates the weight values WV of all the links and the performance factor PF values of all the nodes along the chain and shows them to the users. For a more detailed explanation about each of the inferencing tasks presented in this article, readers should consult Jung and Burns (1993).

Analysis of the Discovered Knowledge Network

Three-pronged analyses of the knowledge network created by CLEAROS are possible. First, through the use of simulation and system dynamics (see Sterman (2000), Senge (1990)), the performance and behavior of the associated processes will be assessed. The assessment begins with a determination of the criteria by which performance is assessed (what is the bottom line)? Once the criteria are known, a performance criterion can be constructed. The basic causal structure of the system dynamics model can be discerned from the density/character of the transaction traffic between the identified nodes. A stock-and-flow diagram and subsequent simulation model could then be constructed, tested and utilized to comprehend the underlying dynamics. Are there other networks/rules that might achieve better performance? What is the bottleneck or impediment that prevents performance from being better? Are there networks that might perform equally well at considerably less cost? This analysis type would address such questions.

A second possibility is to perform value analysis[3] on the implied value chain embedded within the knowledge network. Nodes with low PF's and/or links directed toward or away from them with low WV's would be good candidates for elimination. Such an analysis might reveal that a particular node adds no customer-perceived value and thence can be removed. Another possibility might reveal that a simplified knowledge network will achieve the same result, reducing process cost, cycle time while improving quality. Value analysis can contribute significantly to the simplification of the knowledge network. The problem of complexity in large ERP systems is a huge one and this analysis type alone can have a significant impact on the bottom line. It is complexity that adds so much cost and time to the testing and debugging effort. As the ERP software system increases in complexity, the expected time to find a bug increases from days to months.

Still, a third possibility is to perform carbon/silicon replacement analysis on the network. Such analyses might reveal where an expensive carbon-based processor (i.e., a human) or node could be replaced with an inexpensive silicon-based one (i.e., a computer). This might be possible when the business rules of a carbon-based processor are observed to be deterministic and programmable.

THE METHODOLOGY IN PRACTICE: A STEP-BY-STEP EXAMPLE

In what follows, we shall use the word "training" to connote learning as discussed earlier. The basic steps of the methodology would be the following:

1. Determine the structure of the knowledge network and initialize all of its WV's and PF's
2. Monitor the transaction traffic for at least a month
3. Study the transaction traffic and create input/output records for training
4. Layer the knowledge network based on the transaction traffic
5. Train the connectionist network to the transaction traffic using CLEAROS so that values are established for all WV's
6. Perform inferencing on the trained network so as to find all of the PF's
7. Analyze the fitted network using the analyses suggested (system dynamics, value analysis, carbon/silicon replacement)
8. Propose a simplified/restructured knowledge network
9. Test the simplified/restructured knowledge network in off-line simulative fashion
10. Implement the simplified knowledge network
11. Monitor and measure the simplified/restructured knowledge network to ascertain if it achieves goals

We will begin with the process diagram shown in Figure 2. Assume that the knowledge network exhibited in Figure 2 produces the following record of transaction traffic shown in Table 1 next.

The nodes correspond to the following functions. Node 1 receives returned items. Node 2 does all manufacturing and rework. Node 3 ships returned items back to customer. Node 4 receives incoming purchase orders. Node 5 does all outgoing new order shipping.

In analyzing the transaction traffic, we learn that a rework item was inputted to Node 1. Node 1 logs in the item, examines the item and decides whether the item can be reworked or not. If the item can be reworked, it is transferred to node 2, where manufacturing reworks the item. If the item cannot be reworked, it is discarded and a notice is sent to Node 4 resulting in the manufacture of a new item as a replacement. Once reworked at Node 2, the item is transferred to Node 3. At Node 3, the reworked item is then packaged and shipped back to the customer.

In Table 1, we also see that a purchase order was entered at Input 2. This resulted in orders being transmitted to Nodes 2 and 5. As can be seen, the knowledge network processes returns and purchase orders coming in from customers. However, it does not do it efficiently. For example in Table 1, we see that more than a month was required to process order #21345 (from 8/15/2007 until 9/26/2007) and roughly three weeks were required to process the returned item (from 8/13/2007 until 8/29/2007). Most of that time is consumed at Node 2. Thus, there is clearly a bottleneck at Node 2.

Next, we examine the transaction counts for a period of a month, as shown in Table 2 (step 2).

We learn that there were 395 product returns during the month and 1945 purchase orders. We also observe that of the 395 returns, 295 were reworkable and 100 had to be discarded, resulting in new products being built for the customer. We can discern this by observing that Node 1 transferred 295 transactions to Node 2, and 100 transactions to Node 4. We also notice that during this month, only 90 reworked items were returned to their owners, while 1788 new items were shipped out. Clearly, there is a significant number of orders-in-process as well as rework-in-process, but we cannot tell how much. It is impossible to tell from the transaction counts how much product is currently “in the system” because we don”t know how many transactions were in the system to begin with.

Table 1. Transaction traffic for simple knowledge network exhibited in Figure 2

Input Node	Output Node	date	time	Urgency	Content	Order #
Input 1	1	8/13/2007	8 a.m.	Expedite	Rework	225
Input 2	4	8/15/2007	9 a.m.	Normal	Purchase Order	21345
1	2	8/16/2007	8:10 a.m.	Immediate	notice	225
1	4	8/17/2007	2:00 p.m.	Normal	notice	None
1	5	8/16/2007	8:15 a.m.	Normal	notice	None
2	3	8/29/2007	4:30 p.m.	Normal	notice	225
2	5	9/5/2007	4 p.m.	Normal	notice	21345
3	Output 1	8/29/2007	5 p.m.	Normal	Rework Returned	225
4	2	8/19/2007	1:30 p.m.	Normal	order	21345
4	5	8/19/2007	1 p.m.	Normal	order	21345
5	Output 2	9/26/2007	4:30 p.m.	Normal	order filled/shipped	21345
5	Output 3	9/16/2007	5 p.m.	Normal	adj AP & Cash	21345

Table 2. Transaction counts for all arcs in Figure 2 over the period of a month

ARC	Input Node	Output Node	Traffic/mo
Input 1 to 1	Input 1	1	395
input 2 to 4	Input 2	4	1945
1 to 2	1	2	295
1 to 4	1	4	100
1 to 5	1	5	10
2 to 5	2	5	1895
2 to 3	2	3	92
3 to Output 1	3	Output 1	90
4 to 2	4	2	1822
4 to 5	4	5	25
5 to Output 2	5	Output 2	1788
5 to Output 3	5	Output 3	1788

Training the connectionist model CLEAROS with an identical network topology to that of Figure 2 yields the result shown in Figure 5 in which the thick, bold arcs/nodes show us what arcs/nodes received the most weight as a result of the training and inferencing. The training (step 5) utilized the data in Tables 1 and 2 after that data had been reorganized into input/output pairs (step 3). This picture, again suggests that Node 2 is a bottleneck as it is given the highest weight among all of the nodes. Evidently, CLEAROS ignores transaction counts of 25 or less as being too insignificant to be considered here, eliminating arcs 1 to 5 and 4 to 5. CLEAROS would tell us (step 6) that purchase order transactions starting at Input 2 result in shipped orders coming out at Output 2 about a month later. CLEAROS also tells us that rework transactions result in reworked product being shipped back to the customer 75% of the time (at Output 1) and in new product replacements 25% of the time, coming out at Output 2. Further, observations at Node 2 revealed that rework jobs essentially brought the line to a halt while technicians diagnosed and then repaired each reworked unit. The rework jobs were curtailing throughput of the new orders.

Based on the information highlighted in this example, process analysts would decide (step 7) to separate the Rework from the Purchase Order Fulfillment and simplify the total process, as shown in Figure 6. In Figure 6, Nodes 1, 2 and 3 do all of the Rework processing while Nodes 4, 5 and 6 do all of the purchase order processing. Obviously, Nodes 1 and 3 would do the receiving, Nodes 2 and 4 the rework or manufacturing, while Nodes 3 and 6 would do the shipping. This improved knowledge network (step 8) would then be tested in an off-line, simulative fashion (step 9).

By comparison with Figure 5, Figure 6 is referred to as “layered”. Layering often helps process analysts to gain additional insight, to see their processes in a whole new way. Algorithms for layering are discussed in Jung (1990) and Jung and Burns (1993) as well as the Appendix.

Simulation studies of the reengineered processes shown in Figure 6 might suggest that purchase order cycle time could be reduced from one month to three days, mostly as a result of eliminating the bottleneck at Node 2. Substantial improvements in throughput would then be realized as well. The simulation studies also might suggest that increases in the capacity at Node 2 would further reduce purchase order cycle time without creating too much resource idleness. In addition, improvements in outgoing quality would be significant now that manufacturing has segregated its rework from its primary responsibility of filling orders. Finally, by placing the Receiving (Nodes 1 and 4), Manufacturing (Nodes 2 and 5) and Shipping (Nodes 3 and 6) nodes in close proximity, it is possible to utilize sharing of resources. The revised, simplified knowledge network would be implemented (step 10) and monitored to ascertain that it achieves its objectives (step 11).

SUMMARY

In this article, an enterprise architecture that automates the process of capturing what information/data professional people and managers are using, and comprehending how they are reacting/responding to that information, is described. The basic idea is to (1) capture all of the transaction traffic between and among the nodes of an ERP system and then (2) to use various models including a connectionist model as discussed in Jung (1990) and Jung and Burns (1993) to "comprehend" the structure of the interactions that exist within the process. The Capture and Comprehension Layer exhibited in Figure 1 observes all of the transaction activity and records the origin and destination of every such transaction. The transaction is seen as an output from an origin node and as an input to a destination node. It is thus able to construct input/output records for any given node. Moreover, input/output records are constructed for an entire network of nodes as defined by CLEAROS. It is these collections of input/output ((or stimulus/response) records that CLEAROS uses to create a picture of what is related to what and how the collective decision-making is affecting the dynamical behavior of the organization in question.

With regard to process structure, the unknowns are the human information processors in terms of what information they take in as inputs and the information they put out as outputs. The rest is reasonably well known; specifically, the business rules are known. Once the process structure is known, there is opportunity to understand why the total process behaves as it does and why performance is less than desirable, as well as how performance can be improved.

Analysis of the process begins once the total process is known. Three-pronged analyses are possible in which overall process performance is assessed first. First, process dynamics can be understood using system dynamics. Alternate process structures can be modeled and tested for possible improvements in performance. Then, value analysis of the implied value chain is possible, revealing where processing at certain nodes adds no customer-perceived value. Finally, carbon/silicon replacement analyses can be performed, resulting in substantial reductions in cost as carbon-based units are replaced with silicon ones.

Overall, it is hoped that this article has highlighted the challenges associated with ERP implementation. Additionally, it is hoped that the ideas developed in this article aid researchers and managers in better understanding how to successfully implement ERP in organizations.

Finally, this article launches an entirely new discipline, which we refer to as distributed natural/artificial intelligence. By our definition, distributed natural/artificial intelligence studies the collective performance implications coming forth from a network of intelligent nodes, each making decisions that affect the overall performance of the larger network as a whole. In this way, we hope to comprehend why certain behaviors, dynamics are being observed in the system.

[3] Industrial engineers call this “value stream mapping.”

APPENDIX I

The generic structure of CLEAROS follows that of a connectionist model. CLEAROS uses a connectionist model rather than a neural model because synapse firings do not contribute to our understanding of the process being modeled.

As mentioned in the main body of this article, two steps are required to formulate the CLEAROS connectionist model. A third step is the one that actually uses CLEAROS to model/simulate the distributed infrastructure. The steps are: (1) initial structure and weight values WV; (2) learning; (3) inferencing. We discuss each of these in turn.

Initial Network Structure and Weights

The initial structure of the acyclic knowledge network is determined by process analysts who may use commercial products like SAP's Business Blueprint. Additional input to this process is the expert knowledge of the process analysts. The output of this process is a knowledge network that is free of loops/cycles and is a layered network. The network structuring and initial weight determination process consists of three tasks: structuring the initial network, removing all loops/cycles in the initial network, layering the network and establishing the initial weights.

Next, the structure must be examined. The original knowledge structure, if represented in a network, might involve loops of cycles. In CLEAROS, it is restructured to resolve the abstraction level imbalances of the variables that are represented by cycles or other contradictions to the assumptions before it performs any inference or learning process. Thus, cycles/loops must be removed by "condensing" them down to a single node. Layering the network means (1) that all layers have the same number of nodes and (2) no link extends for a distance longer than the next succeeding layer. Thus, links cannot extend to nodes that are not in the next immediate layer, if the structure is to be "layered." This is the way we have drawn the structure in Figure 7.

Figure 6 would be considered "layered" but Figure 5 would not be. Actually, layering is optional, but for large networks becomes necessary in order to keep the computational time for learning and inferencing within reasonable bounds. Assume a structure with L layers and N nodes. Without layering, the computational complexity is of the order of O[N(L-1)], whereas the computational complexity of a layered network is of order O[N]. Layering frequently results in additional nodes being added. As was observed in the main body of the article, layering actually helps analysts to gain additional insight into their processes as each layer is given meaning in the context of the entire knowledge network. Thus, new perspectives and perceptions can be gained from this step. In summary, what the initial structuring step does is to take unstructured, messy managerial knowledge and arrange that into a logical, sound, layered hierarchical structure that facilitates computerized learning and inferencing.

Learning

Learning involves finding the weight values WV through fitting to input/output records of data. Based on these values, a new structure may emerge. Structural change involves adjustment and update of the relationships between variables. In CLEAROS, this is done by adjustment of weight values between cells in different layers (recall that weight values are associated with the links in the knowledge network). The learning method adopted for CLEAROS is the generalized delta rule or back-propagation algorithm as suggested in Rumelhart et al. (1986). This algorithm finds weight values WV that enable the outputs of the knowledge network to match the outputs in the input/output records when the knowledge network is stimulated with the corresponding inputs. Associated with each link is a weight value from the continuous range of [-1, 1]. The value 1 means a perfect (positive) correlation between the two variables that are connected by a link and -1 means a perfect (negative) correlation between the two variables. Zero weight means no correlation (or independence) between the two variables. By weight, we mean that strength of connection of the degree of belief in the (causal) relationship between two variables that is represented as a link in network representation of knowledge.

Inferencing

The main purpose of CLEAROS is to find causes within the frame of discernment for the observed symptoms. In pursuit of this purpose, CLEAROS infers the performance factors (PF) associated with the nodes, especially those nodes representing causes. Each node or cell in CLEAROS represents a single process or processor (silicon or carbon). It does not incorporate distributed representations of a process or processor. The inferencing is actually a computational algorithm for finding the ultimate causes. The task is the following. In the Cartesian space S x C, where S is the space of all possible symptom elements and C is the space of all possible cause elements, find a subset of S x C that correctly captures the symptom/cause pairs. This task is a problem of graph search, involving either breadth-first or depth-first search. Both algorithms have the same computational complexity: O(max[n,e]), where n is the total number of nodes and e is the number of links in the digraph. Both lines of reasoning can be pursued in parallel because of the natural parallel computational structure employed by CLEAROS. For the calculation of performance factors, it is computationally more convenient and efficient to use a completely layered knowledge network like that shown in Figures 4, 6 and 7. In what follows, a mathematical formulation of the computation process is presented, followed by an example.

The inference computation process can be mathematically expressed as a system of equations that involve a weight matrix $\mathbf{W_k}$ for each layer k. In addition, the inference algorithm also needs as input, an activation level for each cell, represented by y_{ki} of the *i*th cell in the *k*th layer. The standard graph-theoretic formula (Harary, Norman, & Cartwright, 1965) is known to be

$$y_{ki} = \sum_{j=1}^{N_{(k-1)}} w_{kij} y_{(k-1)j} \qquad k = 1, \ldots, L,\ i = 1, \ldots, N_k, \tag{1}$$

where w_{kij} is the weight of link ij directed from the jth cell in the (k – 1)th layer to the ith cell in the *k*th layer, and $y_{(k-1)j}$ is the output level of the jth cell in the (k – 1)th layer. If vector/matrix notation is used, Eq. (1) becomes

$$\mathbf{y}_k = \mathbf{W}_k \mathbf{y}_{k-1},\ k = 1, \ldots, L, \tag{2}$$

where $\boldsymbol{y}_{k-1}$ is the activation vector of the k-1th layer, $\mathbf{W}_k$ is the weight matrix, and $\mathbf{y}_k$ is output vector, both for the *k*th layer

For a computational example, we shall consider the knowledge network depicted in Figure 6. In this case, the input set Y = {returns, purchase orders}. Assume that the input vector is

$\mathbf{y}_o = [\ 100, 500]^T$。

These values connote weekly returns and weekly purchase orders. Then, iteratively and successively, the activation level of layer 1 is $[100, 500]^T$. This can be interpreted as the net influences of the input set on the two receiving nodes (see Figure 7), nodes 1 and 4. For simplicity, the output values coming out of Nodes 1 and 4 are simply the input values going into nodes 2 and 5; thus, $\mathbf{y}_1$ is a function of $\mathbf{y}_o$, $\mathbf{y}_1 = \mathbf{f}(\mathbf{y}_o)$, and we will assume that function to be simply a linear function. Thus,

$$\mathbf{y}_1 = \mathbf{W}_1\, \mathbf{y}_0 = \begin{bmatrix} .99999 & 0.00001 \\ 0.00001 & .99999 \end{bmatrix} * \begin{bmatrix} 100 \\ 500 \end{bmatrix} = \begin{bmatrix} 100.004 \\ 499.996 \end{bmatrix}$$

Assume that learning (back propagation) has found weight values for $\mathbf{W}_1$ to be

$$\begin{bmatrix} .99999 & 0.00001 \\ 0.00001 & .99999 \end{bmatrix}.$$

Next,

$$\mathbf{y}_2 = \mathbf{W}_2 \mathbf{y}_1 = \begin{bmatrix} .75 & 0.00001 \\ .25 & .99999 \end{bmatrix} * \begin{bmatrix} 100.004 \\ 499.996 \end{bmatrix} = \begin{bmatrix} 75.008 \\ 524.992 \end{bmatrix}.$$

Assume that learning has found weight values for $\mathbf{W}_2$ to be

$$\begin{bmatrix} .75 & 0.00001 \\ .25 & .99999 \end{bmatrix}.$$

Notice, in Figure 7, that learning has found a relationship between node 1 and node 5 of weight .25. Next,

$$\mathbf{y}_3 = \mathbf{W}_3 \mathbf{y}_2 = \begin{bmatrix} .99999 & 0.00001 \\ 0.00001 & .99999 \end{bmatrix} * \begin{bmatrix} 75.008 \\ 524.992 \end{bmatrix} = \begin{bmatrix} 75.0125 \\ 524.9875 \end{bmatrix}.$$

Assume that learning has found weight values for $\mathbf{W}_3$ to be $\begin{bmatrix} .99999 & 0.00001 \\ 0.00001 & .99999 \end{bmatrix}$.

It should be apparent from the earlier that, in the manufacturing stage, it is discovered that roughly 1 out of 4 returned items cannot be repaired, so that customer gets a new one. The result is, an initial order vector of 100 returned items and 500 new orders actually results in 75 returned items being repaired and returned to customers and 525 new items being sent out. Clearly,

$$\mathbf{y}_3 = \mathbf{W}_3 \mathbf{y}_2 = \mathbf{W}_3\, \mathbf{W}_2 \mathbf{y}_1 = \mathbf{W}_3\, \mathbf{W}_2\, \mathbf{W}_1\, \mathbf{y}_0 = \mathbf{W}\, \mathbf{y}_0.$$

When we carry out the indicated multiplications in $\mathbf{W}_3\, \mathbf{W}_2\, \mathbf{W}_{1,}$ we get the following result:

$$\mathbf{y}_3 = \mathbf{W}\, \mathbf{y}_0 = \begin{bmatrix} .7499875 & 0.000029999 \\ 0.250012 & .99997 \end{bmatrix} * \begin{bmatrix} 100 \\ 500 \end{bmatrix} = \begin{bmatrix} 75.01375 \\ 524.9863 \end{bmatrix}.$$

The same result is obtained for the output vector $\mathbf{y}_3$.

What we conclude from this series of vector/matrix multiplications is that reworked returns are strongly influenced by the number of incoming returns and the number of manufactured products is strongly determined by the number of incoming purchase orders. Further about 25% of returned items cannot be reworked, so they are replaced with a new one. Notice, though that the relationships are not perfect in the sense that very weak connections of the order .000001 were found. These are just computational errors.

Functional Comparison of CLEAROS with Other Analysis Tools

The overall architecture of CLEAROS resembles causal diagrams used in system dynamics or other causal modeling methodologies. However, there are a number of important differences between CLEAROS and these causal models: (1) the main purpose of building CLEAROS is to capture unknown organizational knowledge (that is heuristic and experiential) and then do subsequent inferential computation on it. On the other hand, the principal purpose of casual models is to capture the causality inherent in systems; (2) CLEAROS is designed to handle a large number of relevant variables, and more importantly the relationships between these variables need not be limited to causal relationships, while those in causal models are; (3) CLEAROS assumes hierarchical, layered and acyclic network structures with synchronous timing in updating their status. On the other hand, causal models assume general network structures with asynchronous timing in updating their status; (4) CLEAROS supports weighted relationships (representing degree of influence) whereas the signed digraphs utilized in causal models do not.

Enterprise Information Systems Change, Adaptation and Adoption:

A Qualitative Study and Conceptualization Framework

Boris Jukic
Clarkson University, USA

Nenad Jukic
Loyola University Chicago, USA

Miguel Velasco
Loyola University Chicago, USA

ABSTRACT

This article introduces and discusses the process and system conceptualization framework for adoption and ongoing evaluation of enterprise information systems, based on the series of recursive high and base-level conceptualizations of organization's existing (as-is) and desired (to-be) processes and systems. The motivation for the framework is provided by a qualitative study that reveals two distinct approaches to the organizations' systems adoption and change. The approaches are labeled as systems view and process view, centered on organizations' processes and systems respectively; where process oriented approach is more likely to result in better fit between the adopted systems and corporate needs. Consistent with this finding, the purpose of the introduced framework is to guide organizations toward embracing the process-centric approach to the adoption of enterprise information systems, by placing particular emphasis on processes' and supporting systems' fit with organization's strategic goals.

INTRODUCTION

Continuous pressures to cut costs, increase productivity and capture a competitive edge in global markets are among the main drivers of ongoing investment in change and adoption of information systems and system components in many enterprises. Nevertheless, the success rates of enterprise systems implementation have been fairly low with respect to a variety of evaluation criteria, such as on-time and on-budget completion, system match with functional requirements, and cancellation rates (Hong & Kim, 2002; Legris, Ingham & Collerette, 2003). Reported failure-rates vary somewhat, but typically are estimated at 30-50% (Surmacz, 2003). Consequently, a great deal of research has explored the factors influencing the effectiveness of managerial decisions about information system adoption, as well as the quality of the implementation of these decisions.

This problem has been approached from many perspectives using a host of methodologies. Many different empirical models have been published, including cognitive models at an individual level such as the Technology Acceptance Model (TAM) (Davis, 1989), behavioral models such as the Theory of Planned Behavior model (Ajzen, 1991), and firm resource-based models (Srinivasan, Lilien & Rangaswamy, 2002). This large and diverse body of research has added much to our understanding of technology adoption on an organizational level, especially in the identification and classification of a variety of factors according to their source (internal vs. external to the organization), size, explanatory power, and level of managerial control in influencing their size and impact (Champy & Hammer, 1993).

Some empirical research has recognized the importance of organizational contexts in determining the success of information systems planning. A study (Hong & Kim, 2002) has concentrated on the influence of organizational fit on success of system implementation. In this study, organizational fit was defined as the degree of alignment between the existing software package and organizational needs in terms of data, processes, and users. The authors recommended that the implementation team as well as top managers should undertake this assessment of fit, ahead of the actual adoption process, with continuous measurements during the implementation phase. This, and similar, studies touch on the issue of alignment among organizational strategy, business processes, and enterprise systems.

In addition, recent published work investigated the relationships among strategic goals of an organization, its business processes and structure, and its information systems. According to Attaran (2004), the role of information technology capabilities is emphasized in process planning and redesign. Information technology is described as a critical enabling tool to advance firm performance through business process reengineering by facilitating communication across functions, improving process performance, and by helping management to model, optimize, and assess the consequences of business process change. In Attaran (2004) these processes were described as tools for organizations to achieve success.

Given the known connections among strategies, processes, and systems, why is change and adoption failure still common? Perhaps there are additional factors that have not yet been widely recognized and accepted by the industry. In particular, the importance of the conceptualization of processes and systems at multiple levels of complexity is an important, but often underappreciated, factor in system change and adoption. The conceptualization process can often be a moderating factor in success, in that other established success factors are enhanced by the organizational commitment to conceptualization of processes and systems. This article introduces a framework that outlines, in an increasing level of detail, the recommended flow of conceptualization efforts in an organizational system change and adoption process, the constituencies involved in the different stages, and appropriate methodologies. Our framework complements and extends the conceptual models of process and systems planning and implementation that exist in the research literature by binding them together in an ongoing organizational practice of continuous reexamination of processes and systems in a non-disruptive, constructive manner.

The arguments for our framework start with a brief discussion of business and systems architecture, their interdependence and the need for a comprehensive view that accounts for both. Next, the actual change planning and decision making process is delineated, and observations about corporate practices are presented based on qualitative research. Thirdly, a simple competitive space matrix is presented to clearly identify the issue of fit among organizational strategies, processes and systems. We propose and address four questions that address key aspects of this fit at different stages of system planning and deployment. The conceptualization framework based on the four questions is then presented. This framework is designed to facilitate the organization-wide commitment of planning for the change of information systems. It is presented as an important component of a multi-level effort that encompasses strategic goals, business processes, and information systems planning. The presentation of conceptualization framework is followed by the discussion of different modes of conceptualization. Finally, a comparison between the conceptualization framework and the existing approaches is presented, followed by the summary and conclusion.

BUSINESS AND SYSTEMS ARCHITECTURE AND BUSINESS PROCESSES

The architectural components of a modern enterprise are defined in the literature in many ways. An important distinction is the differentiation between *business* and *system* architectures. Architecture is defined as the fundamental organization of a system embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution (IEEE, 2004).

Business architecture, specifically, defines the business system in its environment of suppliers and customers, and, if applicable, taking into account the regulatory and legislative policies. According to Aerts, Goossenaerts, Hammer, and Wortmann (2004), the business architecture consists of processes, organizational rules, people, and resources, while Herman (2001) defines business architecture as consisting of processes, technology resources, governance structure and information flow. The architecture of a business captures its major components (and their responsibilities and relationships) as well as its major mechanisms and processes that enable the firm to collaborate to meet the requirements of the business enterprise (Firesmith 2005). The common thread among the various definitions of business architectures is the recognition that business processes often cut across traditional functional boundaries. This recognition of process centrality with respect to business architecture is common across organizational functions, roles, and relationships, including day-to-day operations, transactional systems infrastructure (such as production, logistics, and customer service), or managerial processes dependent on information and decision making infrastructure (such as communication, coordination and planning).

System architecture describes the information system in terms of its logical (e.g., functional) and physical (component) architecture. While some definitions are limited to software and hardware architecture, we argue that architecture is more complex in terms of its components and their relationships. In Aerts, Goossenaerts, Hammer, and Wortmann (2004), two types of system architecture were defined: application architecture, describing the application components and how they interact with each other, and information and communications (ICT) architecture, which was defined as a generic resource layer describing hardware (computers, networks, peripherals) and software (operating systems, DBMS) infrastructure. Another layer of system architecture, suggested by Firesmith (2005), includes the database components describing type, location, overall content, and usage. Finally, Firesmith (2005) suggests additional layers of architecture of application data components, labeling this as information architecture, as well as a distinctly defined user interface architecture, including type, technologies, structure, and navigation.

The empirical studies on individual and organizational adoption of information technology often have had a much narrower view of system architectures, dominated by only one of its components. For, example, studies concentrated on verification of TAM and similar models often focus on the user interface architecture, taking into account only the components that are directly exposed to the end user, without accounting for the value of the enterprise architecture. Another narrow view of corporate information resources is centered on the hardware and communications architecture. This focus has driven an opinion, as stated by Carr (2003), that since information resources can be easily commoditized, they are devoid of strategic importance. This impression, if widespread, can lead to the view that information systems planning, implementation, and deployment efforts should be evaluated strictly on the basis of immediate cost. This impression may be one of the causes of the current trend towards standardization and/or outsourcing of systems and system capabilities.

Our view is that only a comprehensive consideration of all the elements of business and enterprise system architecture and their many complex interrelationships can reveal the true magnitude of the strategic impact of information systems and resources on an organization and its strategic goals. Such analysis must adopt a view of systems architecture that includes all of its constituent elements. Since the systems are complex and diverse, any worthwhile analysis of corporate systems architecture needs to be done at multiple levels of detail and points of focus and should provide a concrete methodology for recursive consideration of business and systems architectural elements (the framework presented later in this article adopts this approach).

The argument for looking at business and systems architecture as a part of the same system has been raised by many academic and professionals. For example, an article (Davenport & Short, 1990) argued that IT should be viewed as more than an automating or mechanizing force. This article defined a recursive relationship between IT and business process design and engineering. This relationship illustrates how advancement of IT should be assessed in terms of how it supports new or redesigned business processes instead of merely supporting organizational entities or functions. Exercising this recursive relationship helps to ensure that business process redesign is applied feasibly and that IT does not generate misguided or impractical solutions. Despite these and other similar recommendations, the corporate practice of designing, purchasing or outsourcing systems or their components often does not reflect this interdependence between the business and systems architectures. The next section will illustrate this reality.

PROCESS VS. SYSTEM DRIVEN INFORMATION SYSTEMS CHANGE

The term Enterprise Information System (EIS) refers to an information system that facilitates business processes and functionalities on an enterprise level (i.e., spanning across the enterprise). The term can include collection of systems supporting specific functions such as CRM, Supply Management, Finance, Accounting, Sales, Manufacturing, and Human Resources. These systems can work either as collections of "best of breed" units or they can be modules of a larger (single vendor) fully-integrated system. The common thread is the enterprise-wide nature. For example, if the Financial Management System encompasses financial transactions throughout the enterprise (by communicating and exchanging information with other relevant systems), we consider it a part of an EIS. Similarly if a multi-function integrated system supports its functions throughout the enterprise we consider it an EIS. In the following paragraph we will look at some of the possible ways to configure an EIS.

An EIS can be implemented as an ERP System, where suites such as SAP, Oracle Applications, or M1, provide function-specific modules integrated into a larger system. For example, Oracle Financials and Oracle Human Resource are two of many modules available in the Oracle Applications ERP suite, while SAP Financials and SAP HR are two of many modules available in SAP ERP Suite, and M1 Labor Management and M1 Inventory Management are two of many modules available in M1 ERP suite. Typically, ERP modules can be used as-configured by the vendor or they can be partly-customized. An EIS can also be created as a collection of function-specific (“best of breed”) commercial off-the-shelf software (COTS) systems, such as C2 CRM system or i2 Supply Chain Management system. And finally, an EIS may also be custom-developed as either a collection of custom-developed units that are custom-integrated or as a single fully-integrated custom-developed multi-functional system.

A general rule should hold for each component of systems architecture, whether it is custom-designed, acquired as an ERP or other semi-customizable software module, or installed as COTS adapted to organizational use. Every component should be justifiable by demonstrating a clear improvement of the process it supports, or showing that it is an enabler of new processes that have a clearly understood purpose and primary benefit to the organization. However, a closer look at the details of organizational decisions to build, acquire or redesign systems suggests that organizations often make these decisions without formal analysis of existing systems and processes or without the clear understanding of the new system’s details. Decisions are often made by “gut feelings” or intuition, rather than quantifiable criteria (Mahmood & Mann, 1993). Even when quantifiable criteria are used, they are not always firmly tied to the actual details of how processes are to be performed and how systems will support those processes. One of the common themes revealed by the interviewees in our study, was that this disconnect often occurs in the case when only financial quantifiable criteria, such as return on investment (ROI) or net present value (NPV), are used as the decisive evaluation factors. Use of operational quantifiable criteria, such as order cycle time, error rates or customer satisfaction metrics is more likely to require clear understanding of the details of existing and new processes and systems. However, the understanding of actual details of how processes are to be performed and how systems will support those processes may still be absent even in this case. This absence of the unambiguous and comprehensive cognitive understanding of the processes and systems during the decision making stage is notable in a large variety of publicly available descriptions of corporate system adoption.

To further explore the nature of enterprise information system change in practice, we conducted, over the period of 17 months, a number of interviews with managers and IT professionals from midsize to large organizations who were involved in adoption of new enterprise systems (the list available at gsbdata.wt.luc.edu/~nenad/framework/appendix.pdf). The analysis of gathered narratives, combined with an analysis of published corporate cases and other academic and practitioner articles (referred to in this article), supports classification into two general approaches. We label the prevalent organizational view that guides the system change or adoption process as the System View. We will contrast this with the process-centric view of enterprise systems adoption/change that we will argue presents a better alternative. We label this approach the Process View. We use the term Process View as it refers to the approach to the change and adoption of information systems. This term has been used in the IS literature in other contexts. For example, in (Kruthcen 1995) the term Process View is used for a completely unrelated concept in software architecture that captures software engineering issues such as performance and fault-tolerance.

The System View often results in a change or adoption process that is based on indirect measures of system success rather than direct observations and understanding of how systems operate and support the processes. In many cases, our interview data suggest that the driving force and underlying motivation is fairly narrow and the changes in existing corporate systems are often initiated by a single event. The structural changes initiated by a single event are often reactive, and some of the observed examples include: a response to a regulatory change, external change in competitive landscape, or IT personnel attrition reaching the point where existing staff is not able to support legacy technologies.

Often the systems change is initiated by changes in corporate strategy (acquisition, international expansion, etc.), or one particular development that is the result of implementation of corporate strategy. A typical example of a system change being driven by implementation of corporate strategy is a change motivated by the strategy of growth. Our survey indicated that the resulting growth of an organization often led to a perception of inherent inadequacy of existing systems. The managers with whom we spoke often expressed this inadequacy as insufficient scalability of the systems. The scalability issue then became the central driver of the decision to redesign, change or completely upgrade a corporate system or some of its crucial elements. Yet another observed change motivator was a result of real or perceived competitive pressures. Our interviews suggested that these pressures often became apparent through perceptions that the existing software applications did not fulfill the functional needs of the processes they were supposed to serve. Managers stated that new application software was then adopted primarily because of its improved process functionalities such as “better reporting functions”, “the ability to exchange data with other applications,” “better process and cost tracking,” “user interface ease and intuitiveness of use,” and “the presence of process (industry) specific options to enter track and report relevant information.”

These examples share a common thread. At a certain point in time, organizations conclude that current systems are inadequate to support their existing processes and organizational strategies. This motivation to change, dominated by the perception of systems inadequacy, is typical of the System View. It is based on the evaluation of the current organizational systems in terms of managerially observable and quantifiable measures of success, often neglecting to sufficiently analyze the core organizational processes first (day-to-day, as well as communication, coordination, and managerial decision making processes) and the ability of these processes to support organizational strategies. The conceptualization-driven progress from strategy to process to systems is not followed. As a result, single-issue drivers often trigger decisions. Consequently, the system change initiatives driven by this view have a high probability of a post-deployment experience that does not match the envisioned organizational goals. In addition, lack of complete understanding of processes and existing systems often results in ignoring the abilities of existing systems to support process changes as demanded by new strategies. For example, one of our observed scenarios of system change involved a decision at the highest level of management to change to a system that would “provide uniform service across locations (stores)”, and “centralize customer service decisions” without consultation with internal IT staff about the ability of *existing* systems to support this strategic goal.

In contrast to the System View, the Process View is an idealized, benchmark approach that should start with the conceptualization at the business process level, accompanied by (1) the key organizational strategic goals and resulting business processes (2) the abilities of the current enterprise systems to support key processes, and (3) the potential of feasibly obtainable improvements to current enterprise systems or their possible replacements. The vision of potential changes to existing enterprise systems should be based on the improvement of existing processes or facilitation of new processes, consistent with organizational strategies. This thorough understanding of process requirements and system abilities should then lead to clear and unambiguous conceptualization of system and business architecture, and as a result, an effective specification of the components of the enterprise information system.

In essence, we argue for reinvigoration of the concept of Business Process Reengineering insofar as it envisions a formal and systematic approach that integrates all of the strategic, operational and information systems dimensions. In a recent evaluation of the relationship between IT and BPR (Attaran, 2004), the role of information technology in fostering process thinking was emphasized. We extend this idea by arguing for more direct understanding of the measures of system success in terms of the clear visualization of actual process improvements. Only after that has been achieved, can truly meaningful financial and/or operational measures be derived. Also, the Process View encourages the continued evaluation of processes and systems, resulting in ongoing decisions to upgrade, modify or replace existing processes and systems. This approach requires a higher level of involvement by the internal IT staff as well as the key process owners in making the process and systems decisions.

Table 1 compares and contrasts the two views of the information systems change: the Process View and the System View. The factor listed in the first row of the Table 1 (Current and Future Process and System Conceptualization) refers to the organizational ability to achieve a clear understanding of both existing and desired business processes and related systems. We divide the remaining observed factors into two groups; observed outcomes, that is, results of adopting the System View in contrast to the Process View; and observed indicators, that is, factors that may serve as indicators whether an organization has adopted the System View or the Process View.

As stated above, the majority of corporate situations we observed may be classified into the System View category, with low level of commitment to self-examination through deliberate and ongoing process and systems conceptualization. As a result, measures of success are often indirect: operational or financial (factor 1); and the timing of change decisions is relatively sudden (factor 2), and driven by perceived inadequacy of current systems rather than the understanding the true nature and needs of business processes (factor 3).

In contrast, the Process View approach, as a result of conceptualization efforts, uses measures of success (factor 1) that can be expressed as concrete improvements of existing processes or clear understandings of a new processes and their benefit to the organization. These improvements can then be translated into operational and financial measures that, being based on clear views of new or improved processes and systems, are justifiable and logically explainable. The ideal Process View approach should be based on ongoing routine evaluation of organizational processes and needs. These routines should result in a smoother progression towards decisions to implement changes (factor 2) based on an understanding of organizational processes as well as the current state of available system technologies (factor 3).

Our analyses of scenarios that represent the System View approach suggest that there is, at best,

Table 1. System vs. process view of information systems change

	System View	Process View
Current and Future Process and System Conceptualization	Not Likely	Necessary, at varying degrees of formality
Observed Outcome Factors:		
1. Ex ante measure of success	*Indirect*: ROI or some other explicit financial or operational metric: operating cost reduction, order cycle time, customer satisfaction metrics, sales increase, labor cost reduction.	*Direct*: Specific process improvement or process change, driven by a clear vision of the new or improved process in comparison to the existing one. Indirect measures follow, with greater degree of justification.
2. Progression of the decision to change	Single event or a sequence of events in a short span of time, sudden.	Ongoing, regular process.
3. Main decision driver	Realization that "systems are inadequate". External Event: merger, managerial fiat or "challenge" by upper-level management	Understanding of the needs of business processes and abilities of all feasibly available system technologies
4. Probability of the fit between adopted systems and organizational goals	Low to Moderate	High
5. Likelihood of problematic organizational adaptation to software	Moderate to High	Low
Observed Indicators:		
6. Level of internal IT staff involvement in the process planning stage	Low	Moderate to High
7. Internal IT excellence, strong IT leadership, and understanding of organizational structure and processes	Not Likely	Highly Likely
8. Key decision makers	*External*: Vendors, Consultants	*Internal*: Process Owners

a moderate probability that the adopted systems and the processes they support are consistent with organizational strategic goals (factor 4). We will argue and demonstrate throughout this article that a Process View approach has a higher probability of achieving such fit.

Interestingly, our analysis also suggests that the System View leads to an increased probability of packaged software adoption (such as ERP or CRM packages) in an *indiscriminate* fashion (i.e. adjusting process to fit the package vs. the other way around). As stated in Hong and Kim (2002), there are essentially two alternative approaches to implementation of packaged software: package adaptation to organizational needs or organizational adaptation to the package. Vendors often discourage package adaptation to organizational needs (Hong & Kim, 2002), and often the latter (opposite) approach is adopted. Consequently, the adoption of highly standardized systems may in turn end up constraining and commoditizing the processes of the organization. The end result might still be positive, since packaged solutions essentially represent the established processes and rules in a given industry. And indeed, many organizations are quite happy to copy other organizations' business process designs. The adoption of a packaged solution may also be the most rational choice for organizations that do not possess strong IT leadership and/or internal technological capabilities. Unfortunately, a System View often leads to the adoption of a perceived “default package”, while other options do not even get serious consideration. This causes the possibility of problematic organizational adaptation to software (factor 5), where organizations find themselves trying to change their processes to fit the chosen software even in cases when some of their processes do not benefit from the required changes.

The Process View can, depending on circumstances of each case, lead into a number of different adoption outcomes (such as standard ERP package adoption, adoption of an ERP package with some customization of certain modules, or design and implementation of a customized system) but in each case the probability of the fit between the adopted systems and organizational goals (factor 4) is high and, subsequently, the likelihood of problematic organizational adaptation to software (factor 5) is low. The Process View can require organizational adaptation to software, but such adaptation is much more likely to be of a smooth nature resulting in actual improvements to the processes. Note that, like a System View, a Process View can indeed lead to the adoption of the “default standard package”, but Process View is much more likely to lead to this outcome in cases when such outcome is the right fit for the organization.

The process that is commoditized by the implementation of the packaged software may be an outcome that is completely acceptable to an organization, and is already a de-facto requirement in some commodity industries (Davenport, 1998). Nevertheless, each organization should go through a formal evaluation process and study the implications for its own competitive position. Therefore, we conclude that even in the cases where packaged software adoption initially appears to be the most rational decision, a formal planning and decision making process should be undertaken that involves all decision levels of an organization.

In addition to outcomes, our exploratory study identified several factors that can serve as clear indicators of organizational adoption of the System View versus the Process View. For example, in the System View, the observed level of internal IT staff involvement in the planning stages of business process modification or new process creation (factor 6) is low, as is the overall level of internal IT excellence and the strength of IT leadership (factor 7). In contrast, the Process View demands a significant level of IT staff involvement, even in the early process planning stages, and depends on a high level of IT excellence and leadership. These resources demand technical competency and detailed understanding of organizational processes and structure. Finally, organizations using the System View for the change and adoption of information systems often explicitly or implicitly relinquish the key decision making authority regarding customized design or the choice of system packages (and in many cases the decisions regarding their business process themselves) to external decision makers: consultants and/or package vendors (factor 8).

In summary, our investigation of the very diverse set of corporate motivators and mechanisms that initiate change in corporate information systems has revealed that organizations in our sample primarily used the System View. As a consequence, organizations typically do not undertake the formal conceptualization of processes and systems on multiple levels, either prior to the decision process or during the change to or adoption of the new system. This observation underlines the importance of a common framework for conceptualization of current corporate processes and systems across different architectural dimensions. The remaining sections of this article will introduce a methodology for conceptualizing organizational strategy and antecedent goals in terms of concrete outcomes and measures of success. This framework ties the managerial vision that is centered on strategic goals and specific business outcomes (such as cost reduction, market share increase, or improved customer satisfaction) with precise consideration of concrete business process goals that finally enables the framework to transform transforms itself into specifications for changes of the system and system components.

Number of authors have written about the need for conceptualization at the business process level as the essential part of developing information systems for the enterprises, which is at the core of the approach that we labeled in this article as Process View. This approach is reflected in comprehensive frameworks such as TOGAF (TOGAF, 2003) and Zachman (1987; 1997; 2000) that cover a broad spectrum of issues related to the architecture and development of information systems. The topics included in these frameworks range from the development of data and applications architectures and the development of technology architecture (including network and hardware configurations) to the guidelines about the roles, skills and experience of the staff involved. The methodology framework that we will introduce in this article is more focused in its scope, as it targets the *change* in the corporate information systems. We are motivated by the results of our own surveys and analysis of previously published corporate cases and academic articles, which include observations such as in (Zachman, 2000) where the author calls for the academic community to expose the correlation between the inability to deal with complexity and high rates of change and the lack of proper approach to the process of planning and design of information systems.

STRATEGIC FIT: STRATEGY, PROCESSES, AND SYSTEMS

Process and systems conceptualization can provide significant value to the achievement of organizational strategic goals. How? By reducing poor choices that lead to improper fit between the organization's strategic goals, business processes and supporting systems. In this section, we briefly discuss, using a competitive strategy example, the notion of strategic fit between an organization's business processes and its strategy. We use a two-dimensional matrix where one dimension is a generic dimension of process "quality," which may correspond to either a dominant quality dimension of process enabled by information systems (such as process completion time or consistency of process outcome) or a compound measure of process quality consisting of multiple dimensions (such as overall process quality score taken as a subjective measure of process perception by process stakeholders, or a weighted score encompassing individual process metrics.)

The second dimension of the two-dimensional matrix is labeled as process cost. For externally visible processes, especially those that are directly related to products or services consumed by customers, the process costs may be directly related to the price of the product/service, a more direct dimension that influences competitive position. For internal processes, the cost may be related to price less directly.

In Table 2, we divide the competitive space in four quadrants, corresponding to four possible combinations of process cost and quality. The perceptions of high/low quality and cost are subjective (especially for externally visible processes) and relative to the quality and cost of

Table 2. Process cost and quality matrix

		PROCESS COST	
		High	**Low**
PROCESS QUALITY	**High**	**High Quality/ High Cost**	**High Quality/ Low Cost**
	Low	**Low Quality/ High Cost**	**Low Quality/ Low Cost**

processes of other competitors. This position will change over time, meaning that a company may lose its preferred position in the matrix if it does not change the quality and/or cost of its processes. In particular, new technological generations of systems will change the definition of high and low process quality and cost. As a result, if managers fail to change processes and systems, their firms may lose their favorable positions in the competitive space. During periods of technological and architectural stability, most organizations should be able to eventually move to the upper left quadrant of high quality process at a low cost. In the short run though, while companies strive to occupy the upper right quadrant of high quality and low cost, the feasible rational choices are different high/low tradeoff combinations of quality and cost: low quality/low cost and high quality/high cost. In this period, organizations can choose their position in the two general tradeoff quadrants.

We argue that in order to provide the correct assessment of the position of their processes as well as the direction of the movement in this or any other strategic continuum, organizations need to adopt formal policies and methods of analyzing their processes and systems. An essential part of this practice should be process-and-system conceptualization through abstract modeling or other approaches. The importance of modeling was traditionally argued to have system implementation value, making sure that systems work in a manner consistent with specifications that are coming from an external source. However, we argue that modeling and abstraction create even greater value in providing a vision of the exact process that a system is supposed to support, as well as of the system itself, with a clear understanding of how the process impacts the organization's position along the relevant strategic dimensions.

Requirements engineering should be a tool to achieve an informed commitment to a certain system rather than detached consent from the management (Jerva, 2001). Our interviews suggested that managerial commitment is often based strictly on the promised outcomes without real insight as to how those outcomes are to be achieved. We postulate that four key questions should be raised during system and process planning and development. These questions signify key points in the planning and development process at which a conscious conceptualization effort should be undertaken. The questions should address the fit among strategy, processes, and systems. The questions are sequential, whereby posing of each subsequent question implies that the previous one is answered in the affirmative:

Question 1: Are current business processes consistent with organizational strategy? (Consider external factors and developments, including new technological trends in systems, applications, and technical infrastructure.)

Question 2: Given that current business processes are consistent with organizational strategy; can the business processes be improved with the existing enterprise systems? (Consider how the cost/quality mix of business processes can be moved further to the upper right quadrant of the matrix.)

Question 3: Are business processes supported properly by current systems? (Consider if the enterprise systems architecture is consistent with the organization's business architecture.

Question 4: Given that the enterprise systems in general provide proper support for organization's business processes; can the enterprise systems be further improved? (Consider if the cost/quality mix of business processes can be moved further to the upper right quadrant of the matrix by additional improvement in system components.)

In the next section we propose a conceptualization framework as an activity workflow model that is based on the constant recursive flow of conceptualization activities on different levels. We put the emphasis on differentiating between "As-Is" conceptualization with "To-Be" conceptualization (Aerts, Goossenaerts, Hammer

& Wortmann, 2004; Ceronsek & Naiburg, 2004; Okrent & Vokurka, 2004). "As–Is" conceptualization facilitates the development of clear process vision and the understanding of existing processes and systems. "To-Be" conceptualization enables proper design and implementation of new processes and systems.

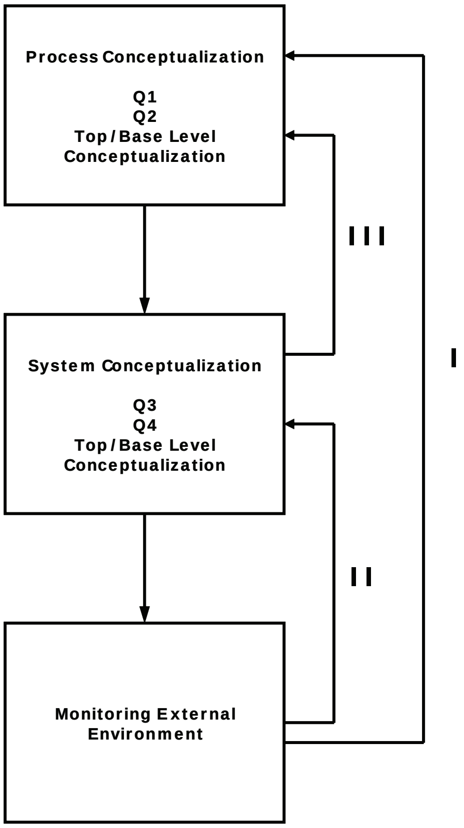
A CONCEPTUALIZATION FRAMEWORK: FROM STRATEGY TO APPLICATIONS

The conceptualization framework we propose is a series of multi-level diagrams depicting organizational efforts to achieve a clear vision of business strategy, processes and systems, as captured by four questions listed in the previous section. Each level contains the set of activities centered on sequences of "As-Is" and "To-Be" abstractions, with inclusion of additional means of conceptualization in the stages focusing on the systems. The main purpose of the "As-Is" abstraction at each level is to reveal improvement opportunities, by determining whether the current processes and/or systems are aligned with corporate goals, and if not, revealing the reasons why those processes are not performing according to the corporate goals. The goal of "To-Be" conceptualization is to create an alternative vision of processes and/or systems in response to this realization.

This framework will be described at three levels of detail. Figures 1 and 2 correspond to the high and medium level of detail, while the remaining figures (Figure 3, 4, 5 and 6) represent a more detailed view of individual set of activities as envisioned by our framework. Each figure contains solid rectangles that represent a set of activities that is centered on one or more conceptualization activity. The unidirectional lines represent the progression from one set of activities to another. They include the feedback lines representing recursion from the subsequent activity to its predecessor.

Figure 1 captures the high-level view of our conceptualization framework, where squares are used to depict three major sets of activities. The first set of activities is based on Process Conceptualization (PC), which is motivated by Question 1 (fit between processes and strategy) and Question 2 (having established general fit between business strategy and processes, how can processes be further improved). It is followed by the second set of activities that is based on System Conceptualization (SC) and motivated by Question 3 (fit between processes and systems) and Question 4 (further improvement of systems). The second set of activities is followed by the third set of activities representing the monitoring of the competitive and regulatory environment as well as the monitoring of technological developments that may influence the current and future abilities of the enterprise's information systems.

Figure 1. High level model



There is a feedback loop from the monitoring activities into the PC driven activities (recursion I) and SC driven activities (recursion II), as well as between the SC and PC driven activities (recursion III). Recursions I and II are driven by a reconsideration of processes and systems due to observed changes in the external environment. Recursion III represents process reconsiderations as driven by changes in underlying systems. The existence of feedback between the activities depicted in Figure 1 *does not* imply continuous (never-ending) *changes* of processes and systems, but rather ensures that no external (I and II) or internal (III) development of significance is neglected in its possible impact on organizational processes and underlying information systems.

Figure 2 displays a more detailed division of conceptualization activities. The first four stages (rectangles) correspond to one of the four questions listed above. Each of the four rectangles represents a set of activities motivated by the conceptualization of business processes and/or systems. The level of conceptualization changes from high (Top Level) to low (Base Level), both in the Process Conceptualization and System Conceptualization stages.

The internal feedback lines for each activity set (labeled as IV) have specific meaning as well. Our framework allows for each of four main sets of activities to have more than one level of conceptualization complexity at each stage, if needed. In that case the terms Top Level and Base Level can represent several grades of complexity, ranging, for example, from high to medium (for Top Level) and from medium to very detailed (for Base Level). The recursive efforts at each level ensure that no external (I and II) or internal (III) development of significance that might affect the organizational processes or information systems is neglected. The intensity and number of conceptualization activities at each of the four main levels will differ from one case to another, depending on the size and complexity of an organization and its processes and systems. The general rule should hold that the next set of activities should not start until the question that motivates each stage is answered affirmatively and with a level of certainty that is acceptable by the organization.

Our framework allows for various levels of change to be dealt with in a different way and at the appropriate level. First, any significant change observed through monitoring activities should be followed by high level reconsideration of key business processes, as represented by the feedback line (Ia) between the monitoring activities and the top level process conceptualization (TLPC) driven activities. Second, any significant technological change in the abilities of elements of enterprise systems or other external developments that are disruptive enough to affect the fit between processes and strategy can initially be analyzed at the high level, while other resulting analysis and process and system changes considered can be disseminated between the remaining activity sets. Third, less comprehensive technological changes in abilities of systems and system components as well as external developments that are deemed not to be of strategic impact may initiate the reconsideration on the lower (individual) process level or the system level itself. These are depicted in Figure 2 as feedback lines between the monitoring

Figure 2. Mid-level model

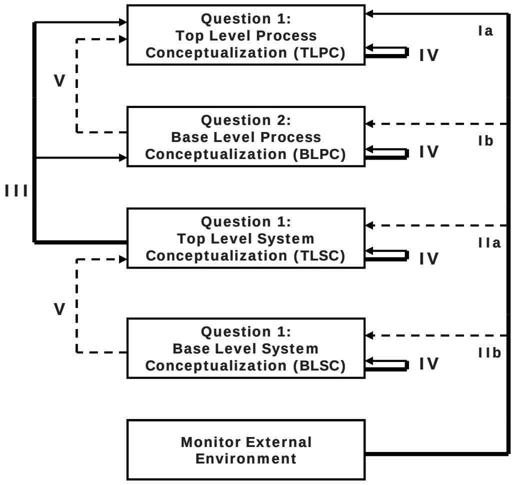


Figure 3. Top level process conceptualization (TLPC)

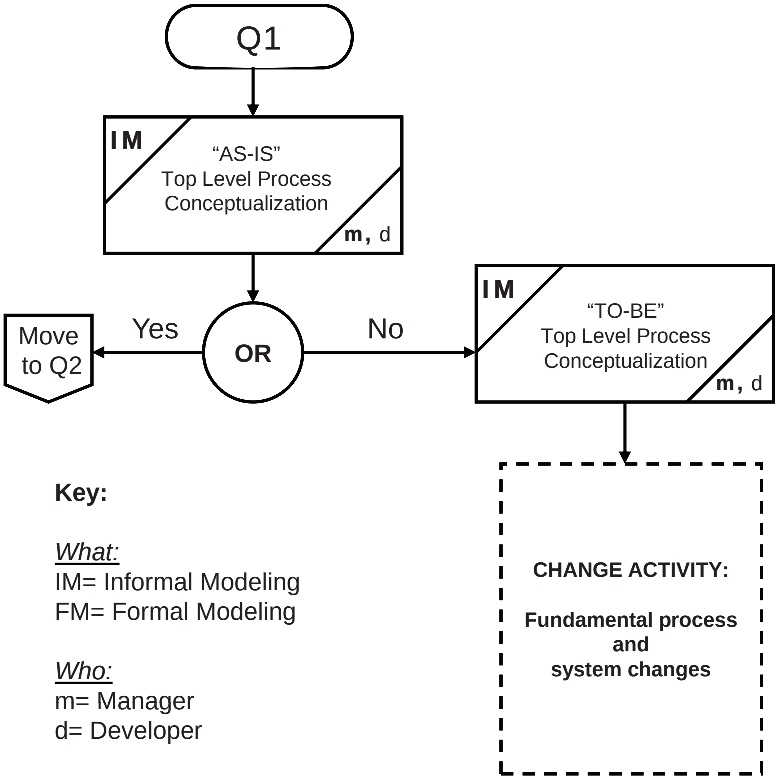


activity and activities motivated by Questions 2, 3, and 4, labeled as Ib, IIa and IIb respectively. These dashed lines represent alternative or non-mandatory feedback paths, since an organization may (or may not) adopt a policy to account for every external and technological development by reconsideration of processes and systems at every level. This may not be practical in every case, and each organization should choose the proper level of analysis in response to each individual external event and technological change. Less comprehensive technological changes in abilities of systems and system components as well as external developments that are deemed not to be of strategic impact may initiate the reconsideration on the lower (individual) process level or the system level itself. These are depicted in Figure 2 as feedback lines between the monitoring activity and activities motivated by Questions 2, 3 and 4, labeled as Ib, IIa and IIb respectively. These dashed lines represent alternative or non-mandatory feedback paths, since an organization may (or may not) adopt a policy to account for every external and technological development by reconsideration of processes and systems at every level. This may not be practical in every case, and each organization should choose the proper level of analysis in response to each individual external event and technological change.

Figure 2 also contains optional dashed feedback lines, labeled as V between Base Level and Top Level activities if there is an indication that a change in the process or supporting system may have implications that need to be reconsidered at the preceding level. These optional feedback lines allow for the entire process to be more complex than the single pass progression of activities motivated by Questions 1 through 4. For example, activities motivated by Question 4 may demand additional reconsideration of Question 3 and possibly other questions in return as well. If that is the case, the levels of abstraction in such an iterative process may not always follow a single descending path from the very general view of processes and systems, down to the individual organizational rules, process specifications and application elements. Again, the level of recursive reconsideration will vary greatly, depending on the size and complexity of the organization and its processes and systems.

The recursion between System Conceptualization and Process Conceptualization is captured by the feedback line III. This feedback loop ensures that the fit of the enterprise system architecture is verified by the conceptual reconsideration of the processes that the system supports.

It is important to note that the existence of multiple feedback loops in our framework does not imply that we recommend a seemingly endless cycle of analysis. Indeed, some processes and systems are so expansive that, if the impacts of every development on every feature were evaluated by multiple repetitions of conceptualization activities at each stage, the paralysis by analysis is certain to cripple the effort. Ultimately, the implementation success of this framework depends on managers and developers finding the right blend for each unique situation—one that balances analysis/conceptualization depth and its utility. On balance, however, our observations indicate that the prevailing problem is in organizations not doing enough (rather than doing too much) to understand organizational processes and systems, and in many cases a critical process or system feature may only become apparent after repeated reconsideration.

The remaining figures (Figures 3-6) represent a more detailed depiction of each conceptualization activity. In addition to the rectangles and progression and feedback lines, additional notation is used at this level of detail. We adopted a notation from EPML introduced by Dalal, Kamath, Kolarik, and Sivaraman (2004) for the purpose of Enterprise Modeling. Its versatility and ability to capture necessary detail were the main reason for our choice of this notation, even though the context and level of analysis are somewhat different from the one in which it was originally introduced. In our notation, each rectangle contains the description of the activities it contains, with the symbols representing the conceptualization method included in the upper right corner, and the symbols representing the constituents that are most likely to be involved in the effort in the lower right corner (with expected level of involvement indicated by the symbol size). The decision symbol used is a non-exclusive "OR" operator, signifying that a parallel progression of activities may occur, if the answer to the current question is part "Yes" and part "No". In the following discussion, as it relates to Figures 3-6, questions 1-4 will be repeated, for readability.

Figure 3 captures the activities motivated by Question 1, starting with the "As - Is" top level conceptualization of business processes.

In many cases, the most likely conceptualization method at this stage would involve use of informal modeling tools. The resulting vision may often be in the form of high-level visual depictions of main features of key organizational processes extracted from narratives and conceptualization sessions. This information is more likely to be drawn from the management rather than from the potential internal and external systems developers. The role of system experts, while not dominant, is still crucial at this stage, since they ensure that all participants have clear understanding of the current state of the relevant technologies and the potential impact of those technologies. The conceptualization at this stage, paired with the knowledge of existing technological trends and other external factors, should provide the direction of the remaining conceptualization activities.

One reason for a negative answer to the question of fit between the processes and business strategy may be a result of new technological developments that are of a revolutionary, disruptive nature, and render existing processes obsolete simply through opening opportunities for processes to be conducted in a fashion that is clearly superior to the existing practice. The simple existence of potentially better processes in this case may render the existing processes out of alignment with organizational strategy. Other reasons for a negative answer to the question of fit between the organizational strategy and its processes may include major changes in corporate strategy or some other disruptive external development.

If this approach is adopted and it is conducted in an ongoing fashion, the state should eventually be reached where the process and subsequent systems reconsideration cycle is only initiated by external events, rather than internal systemic weaknesses (which will be eliminated). The key is to build the ongoing reconsideration of processes and systems into organizational policies and implement them so that they do not become just another meaningless part of bureaucratic tedium. Thus, this framework can become an expression of organizational culture of seeking a clear mental picture of current processes and systems as well as the readiness to envision how any significant change should affect them. If adopted in this way, it can, in turn, gradually eliminate internal sources of imbalance among organizational strategy, processes and systems. In essence, the goal of this approach is the elimination of the System View, where the emergence of single-event issues often finds organizations unprepared for change and result in systems and process redesign efforts that never seem to be adequate, solving one set of problems while causing another.

As stated above, the answer to the question of fit between processes and systems may not be a definite “Yes” or a definite “No”, if the analysis reveals that the consistency between processes and organizational strategy is partial. If the answer is not categorical, in some cases progression to next activity set may be halted until all the aspects of all processes are brought into agreement with organizational strategy. More likely though, an organization may be able to proceed on both “tracks” simultaneously, addressing some processes at a high, strategic level (where the answer to Question 1 was a “No”) while moving on the next level of analysis for others (where the answer to Question 1 was a “Yes”).

As shown in Figure 3, this framework anticipates that top management will be responsible for the issue of the fit between key organizational processes and organizational strategy. In most cases, participation by the system development community, even at this very high level, should be welcomed, especially if emerging technologies are showing potential to affect the strategic fit. In other cases however (where the strategic fit is affected by external competitive developments of regulatory changes, for example), the process redesign at this high level will be motivated by non-technological issues.

In the early conceptualization stage level, the participants will most likely be inclined to uses informal ways of creating a conceptual vision of those processes, both as they are (“As-Is” conceptualization), and as they ought to be (“To-Be” conceptualization). More formal methods, with explicit rules and strictly defined semantics are more appropriate later in the process, when process and system details are being considered. A variety of informal techniques exist for eliciting requirements in early planning stages, such as flow charts and decision maps. These are in addition to formal and semi-formal modeling techniques such as E-R models and data flow diagrams (Giaglis, 2001).

A change activity in response to the findings of the high-level “To-Be” conceptualization effort is captured by a dashed rectangle in Figure 3. It may include significant reorganization efforts throughout the organization, such as:

- An overhaul of existing organizational processes and/or creation of new ones
- A change in governance structure through reorganization of corporate hierarchy and/or reporting practices/paths.

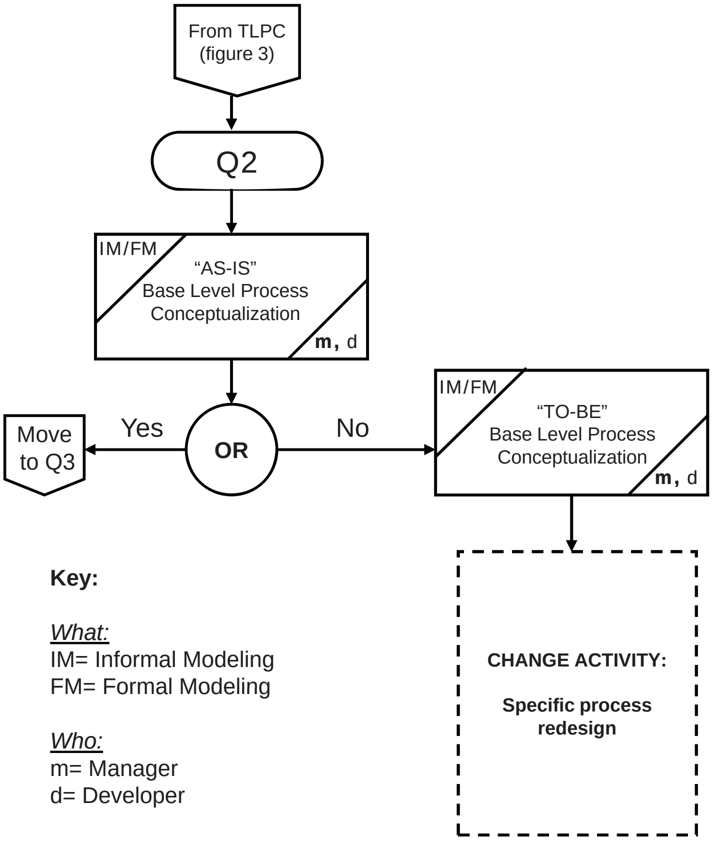
In the process of this structural reorganization, the conceptualization efforts should again be present at each stage of process and systems redesign. "As-Is" process and system conceptualization will facilitate the identification of the aspects of processes and systems that can be retained and those that require change. The sequence of conceptualization activities will create a complete list of reasons *why* the current processes and systems are inadequate and need to be overhauled. The focus of the "To-Be" conceptualization activities in this case will be on creating a clear vision of desired processes and following it with system conceptualization designed to fit the process vision. In essence, a whole new sequence of activities will be spawned, following the same progression as that shown in Figures 1 and 2.

Figure 4 depicts the activities motivated by Question 2, assuming that the question of the fit between organizational key processes and its corporate strategy has been resolved.

In this phase, the main goal is to examine processes at a greater level of detail, and look for the improvement opportunities. At this stage, either informal or formal modeling techniques, or some combination of both, may be appropriate, depending on the complexity of the process being considered, the desired level of precision, and the accepted level of modeling skill and understanding within the group involved in this stage.

Often, key contributions will be needed from management and the systems development community. Here, it is important that everyone has the same unambiguous picture of the processes being considered. A more detailed and consequently,

Figure 4. Base level process conceptualization (BLPC)



more accurate picture of processes may lead to a negative answer to Question 2, revealing potential areas of process improvement, without the need for a change in supporting systems. When the satisfactory answer to Question 2 is achieved, possibly after several iterations of process conceptualization and improvement activities, the next phase is entered, where the focus is shifted towards the analysis of current organizational systems, first at the higher level (motivated by Question 3) and then in more detail (motivated by Question 4)

The dashed rectangle in Figure 4 represents the set of activities that are undertaken in response to the “As-Is” conceptualization at the base level model of processes. These activities reveal that processes as currently in place do not optimally support the objectives of an organization, and drive the subsequent creation of the vision of the improved processes through “To-Be” Base Level Process Conceptualization. The actions in this activity set should be centered on a specific process redesign that represents an improvement in its support of the organizational goals. In short, the actions taken in response to a negative answer to the Question 2 ensure that the organization does not waste time and resources by hastily moving on towards the design and improvement of underlying information systems that will automate and otherwise support processes that were not fully suitable in terms of optimal support for the organizational goals.

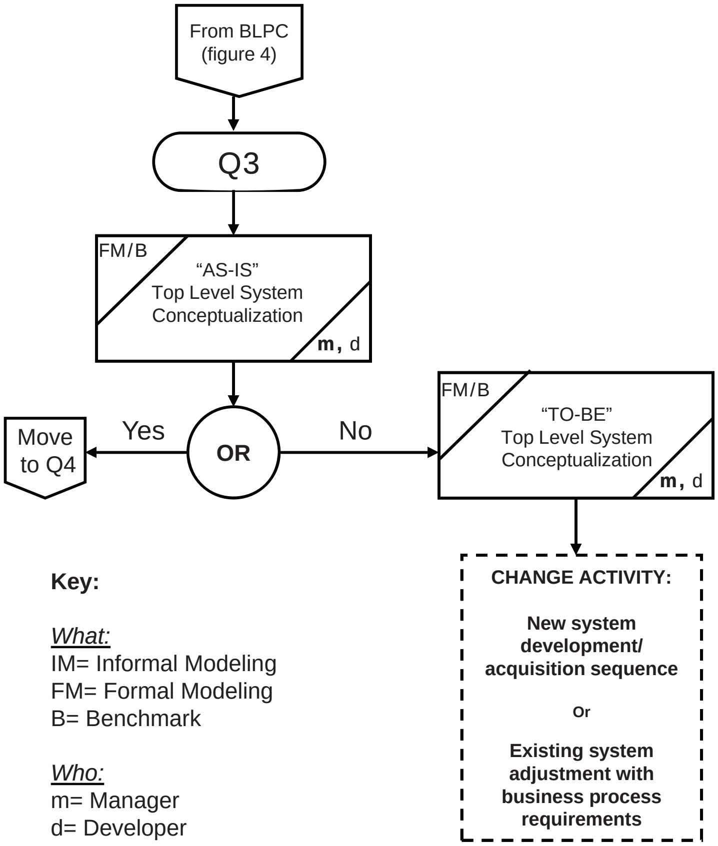
After the processes have been fully examined and redesigned in accordance with the “To-Be” vision, Question 2 should be raised again, accompanied by the examination of the new “As-Is” model of (now improved) processes. This should eventually result in a satisfactory answer and progression to the analysis of information systems in the next stage of the framework. Again, as discussed above, the number of iterations of current process consideration, conceptualization of process improvement and process redesign will vary. The goal of those involved in the effort should be to strike a proper balance. At one extreme, the goal should be to avoid an endless cycle of analysis, resulting in recommendations for concrete implementation action being generated too slowly. Another, potentially more likely extreme is an inclination to simply go through the motions, rubberstamping the current situation as satisfactory and starting the system analysis prematurely.

Figure 5 represents the view of activities motivated by the top-level system conceptualization. The main purpose of this stage is to provide an answer to the question of fit between the processes and systems, as stated in Question 3:

In this phase, the more formal modeling methods may be more appropriate conceptualization tools, with intensive participation by both the IT development staff and management. Another potential conceptualization method that may be used (in addition to, or as an alternative) is benchmarking through the analysis of existing systems as applied in comparable organizations. This is possible if access to main system features and designs is available. The top level abstract model (or other way of achieving a clear vision) of existing systems is used to provide an answer to Question 3 about the adequacy of the existing system in supporting business processes that, at this stage, are aligned with organizational goals. The answer, as in previous stages, can be a full or a partial one. In the case of a fully or partially negative assessment of existing systems at the top level conceptualization, the next step is again to craft a “To-Be” vision of systems that fulfill the goal of properly supporting business processes, based on a formal model and possibly also on a benchmark of systems already in place at other organizations.

The predominantly negative evaluation of this fit may have many causes; some rooted in the way the existing system was adopted in the first place. The realization of the inadequacy of the existing system may actually start to appear during the base level conceptualization of busi-

Figure 5. Top level system conceptualization



ness processes, as conducted in response to Q2, especially if the processes are very dependent on the features and abilities of the current system. For this reason, systems evaluation is followed by the process reconsideration, as shown by the feedback line III in Figures 1 and 2. The process analysis motivated by questions 1 and 2 will be repeated, this time assuming that systems in place are the redesigned systems, based on the "To-Be" top-level systems conceptualization. This approach ensures that processes and systems will not be considered in isolation from each other, but rather through a series of interrelated conceptualization efforts.

The dashed rectangle in Figure 5 represents change activities in response to the predominantly negative evaluation of existing systems as result of "As-Is" high-level system conceptualization. Causes of negative evaluation will vary widely from one case to another, and so will the actions that organizations will undertake in order to address them. In some cases systems may be found to be fundamentally inadequate, with the "To-Be" vision very different from the "As-Is" concept of the existing information systems. In such cases, a probable course of action at this level is the initiation of formal new systems development and design processes, including the evaluation of systems alternatives that exist in the appropriate packaged solutions market.

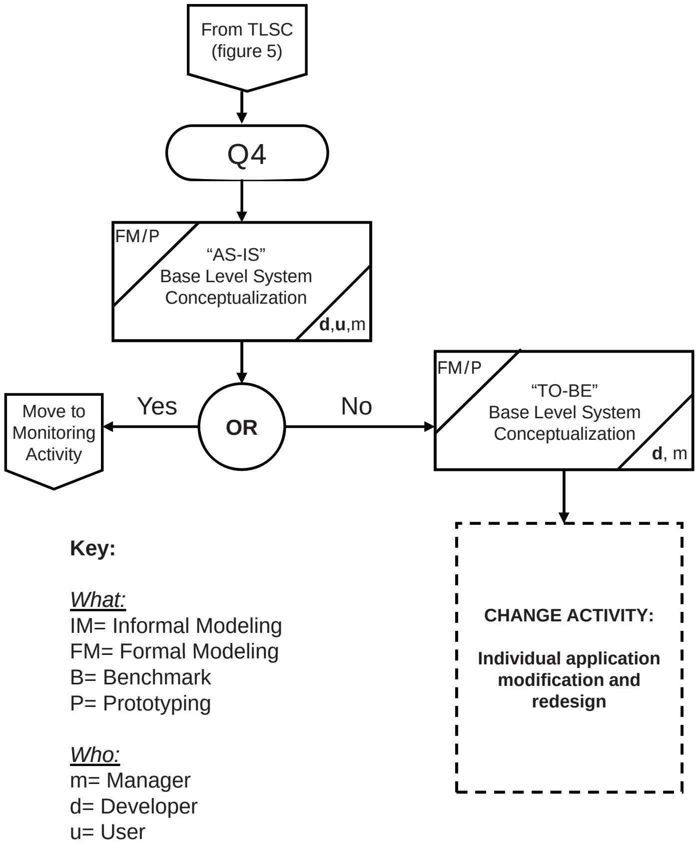
Alternatively, the detected flaws may not be related to the key functional features of existing systems, but rather to the ability to facilitate processes that are enterprise-wide and bridge single systems boundaries. In this case, a possible course of action may include the development of enterprise–wide mechanisms for the successful alignment of different components of the organizational business architecture with existing systems architecture. For example, this may start with the creation of enterprise and supply chain-wide data dictionaries and process semantics. Regardless of scope and complexity, all activities undertaken at this point need to be consistent with the established "To-Be" vision of systems that is again based on the current detailed concept of business processes created in the previous stage.

Figure 6 contains the Base Level System Conceptualization and its resultant activities in response to the Question 4:

The goal here is to achieve further alignment between individual processes and system components through incremental changes at an individual application or application component level. The methods of achieving a clear mental picture at this level may include both formal modeling and prototyping for the purpose of both "As-Is" and especially "To-Be" conceptualizations. In our context, the term "prototyping" means the repeated interaction with each incrementally improved version of the system for the purpose of evaluating its functionalities and support for business processes at the low level of detail. At this stage, the development personnel (or IT evaluation staff if a packaged solution is being considered) will have the highest level of involvement, with active participation by the end user community that may also include management, especially if the system under consideration has a prominent decision support role.

The dashed rectangle in Figure 6 contains the activities that follow low-level base conceptualization of the systems involve modifications and redesign on an individual application level or even lower, constituent object level. This process is most likely to be recursive, with several itera-

Figure 6. Base level system conceptualization



tions between the conceptualization activities and actual development and implementation activities. It is important to keep in mind the complementary roles of abstract modeling and prototyping at this stage. The prototyping approach, at a stage that is close to implementation, provides a very concrete vision of the system component under consideration and facilitates instant user feedback that reveals potential problems and improvement opportunities. The abstract model, on the other hand, is more capable of conveying how an individual application or other system component fits the overall system vision as well as the underlying process vision.

In summary, the diagrams above display a number of conceptualization and conceptualization-driven activities, distributed between high and low level of analysis. The flow of activities is driven by the four fundamental questions posed in the previous section. The emphasis is on considering processes first, in a way that takes into account organizational IT capabilities, as well as other available technologies. The process consideration starts with addressing the fit with organizational goals and then considering possible redesign, followed by understanding the implications for the redesign of underlying systems. In this, our flow model is consistent with the notion voiced by Attaran (2004). While agreeing with Michael Hammer's recommendation to redefine processes first and automate second, Attaran stated that IT capabilities can and should influence all stages of process design. Our framework is consistent with the proactive approach to process and systems planning.

The main purpose of our conceptualization workflow framework is to formalize when and why conceptualization efforts should be undertaken in process and systems planning and design. Its parts are applicable within the standard framework for development of information systems: systems development life cycle, or business process redesign and change sequence, such as those proposed by Davenport (1993), or Champy and Hammer (1993). Our intention was to go a step further beyond general strategy and IT implementation recommendations, especially for the process and system design and configuration stages, encompassing all the planning and decision making stages and pointing out situations where conceptualization is a crucial activity.

Our framework recognizes unique roles of management, developers and users in ensuring the proper alignment of strategy, processes and systems. Its intention is to provide a mechanism that facilitates enterprise wide participation in conceptualization on multiple levels of complexity. This proposed framework envisions that results of conceptualization activities at each level are shared, facilitating the communication between the management, systems analysts and developers. If this is achieved, the result should be the common vision of business goals, processes and applications.

COMPARISON WITH EXISTING APPROACHES

This section will present a comparison of the introduced framework with the existing frameworks that directly or indirectly deal with the issue of change and adoption of corporate information systems. The Open Group Architectural Framework (TOGAF, 2003) is a broad and detailed method and set of supporting tools for developing an enterprise-architecture. It includes a section on architecture change management, which, similarly to our work, recognizes both the technology and business drivers for change and advocates many of the factors (such as the understanding of key organizational strategic goals and the resulting business processes) that we summarized into the concept that we labeled as the Process View. TOGAF even list the steps, such as ongoing monitoring of technology changes and ongoing monitoring of business changes, as the key factors in the architecture-change-management process.

However, TOGAF offers no actual structured and prescriptive method that outlines how to achieve the goals of the Process View during the change process or how and when to undertake the steps during the change process. Instead, the following general advice is given:

There are many valid approaches to change management, and various management techniques and methodologies that can be used to manage change: for example, project management methods, service management methods, management consultancy methods, and many others. An enterprise that already has a change management process in place in a field other than Architecture may well be able to adapt it for use in relation to architecture.

Therefore, organizations must still choose (and then adapt) a method on how to deal with the architecture-change management, which can potentially add to the length and complexity of the change process. On the other hand, the framework based on the four questions that we introduce in this article, presents the users a ready-to-use method specifically designed for the architecture-change process. Our framework not only takes into account alignment between business strategy and business and information system architecture, but it makes it the recurring foundation of all changes in the architecture.

Similarly to TOGAF, Zachman presents in his papers (1987; 2000) a detailed framework for development of enterprise architecture which advocates business process modeling and conceptualization as the integral part of enterprise architecture development, which is also one of the main motivators for Process View. As in TOGAF, there is no specific methodology that details and structures steps for architecture change that would be equivalent or comparable to the detailed framework for architecture-change introduced in this article.

In other words, our framework serves to complement the general frameworks (such as TOGAF or Zachman) with the detailed and structured architecture-change-management component. Constituent parts of the Process View that we describe earlier in this article are not new. In addition to TOGAF and Zachman frameworks, we can find elements of Process View described in detail in other approaches dealing with the process of design and development of managerial information systems, such as OPEN Process Framework (Firesmith 2005). Here, we gathered these elements together under a label of Process View (taking into account our own surveys, as well as sources from various publications referred to in this article) to contrast it with the often inadequate, but quite widespread, practice of System View. What is new in this article is the introduction of the detailed and structured architecture-change framework, whose goal is to facilitate the Process View during the process of change, adaptation and adoption of corporate information systems.

SUMMARY AND CONCLUSION

In this article, we have argued for the importance of proper planning and decision-making during the process of information system change and adoption. We have described two different approaches to information system change; the System View and the Process View, and we argued for, and demonstrated the benefits of, the Process View. We have also shown that a number of other authors have advocated the concepts that we joined in this article under the label Process View. The central part of this article is presentation of a framework that is rooted in the active and conscious usage of various methods of process and system conceptualizations at multiple levels. The framework is designed as a sequential set of activities centered on the questions of fit among organizational goals, processes, and systems. We have motivated this discussion by our classification of motivating factors and outcomes of the change and adoption of new enterprise information systems and/or their components. We have asserted the importance of conceptualization as a means of achieving proper fit between strategic goals and the resultant business processes and systems that support them.

The following question may be posed: is the framework described in this article practical and to what extent would managers and IS professionals be willing to put in the time and effort required to follow the steps of this process approach? As we outlined in this article and illustrated by Figures 1-6, our approach is highly structured and prescriptive, which in itself is practical in the sense that, if this framework is adopted, organizations do not have to spend additional effort and resources on creating their road-maps for the enterprise information system change and adoption. Our framework relies on recursive and continuous "As–Is", and "To-Be" conceptualizations at both high and low levels of process and systems detail. The recursion encourages continuous monitoring of technological and other external (market, regulatory, etc) developments, without which it would be very difficult to make the right decisions during the change and adoption process.

The framework is flexible and adjustable so it can fit a variety of situations and scenarios within enterprises. As show in by Figure 2, many of the recursive steps are optional and, as we discussed earlier in the article, are to be applied only if required by a particular scenario or company policy. Also, a closer look at Figures 3-6 reveals the straightforward and simple nature of each individual step in the framework. For each of the four questions, an "As-Is" conceptualization is recommended as the way to answer the question properly, together with recommendations on which methods (such as informal modeling or prototyping) and people (such as managers, developers or users) to involve. Organizations that adopt the framework essentially commit themselves to considering the four questions and then choosing from the recommendations given in the framework on how to do so. Therefore, any organization that recognizes the need and benefit of conceptualization and is willing to examine its organizational strategy, business processes, and its existing information systems before the actual change and adoption process takes place (i.e., consideration of questions 1 – 4) is, by default, willing to put the time and effort required to follow the steps of the proposed framework.)

Our view is that there is no single conceptualization method uniquely suited for each level, but we do envision the progression from less to more formal techniques as the level of detail and complexity increases. We believe that the first important step is for organizations to be aware of the need for process and system conceptualization at multiple levels. Subsequently, each organization needs to seek a combination of methods that fulfills its specific needs in the most feasible fashion.

Chapter 5.21

Supply Network Planning Models Using Enterprise Resource Planning Systems

Sundar Srinivasan
University of Missouri-Rolla, USA

Scott E. Grasman
University of Missouri-Rolla, USA

ABSTRACT

The advent of the Web as a major means of conducting business transactions and business-to-business communications, coupled with evolving Web-based *supply chain management* (SCM) technology, has resulted in a transition period from “linear” supply chain models to “networked” supply chain models. Various software industry studies indicate that over the next five to seven years, interenterprise business relationships, information structures, and processes will evolve dramatically. Enterprises will blend internal production and supply chain processes with those of their external trading partners. Currently, organizations are finding creative ways to mitigate supply chain costs while maintaining operational efficiency. New approaches, technologies, and methodologies are aiding with these cost-cutting measures to drastically reduce supply chain costs and increase customer satisfaction. This chapter discusses the background of supply chain planning and execution systems, their role in an organization, and how they are aiding in collaboration. The chapter concludes with a case study on how a supply chain management system could help an organization be more effective.

INTRODUCTION TO ERP SYSTEMS

Enterprise resource planning (ERP) systems aim to integrate all business functions and data of an organization into a single integrated system. The main component of an ERP system is the use of a common database. A typical ERP system landscape consists of a variety of hardware and software to help integrate the business functions and data. The goal of an ERP system is to provide a unified scheme to perform and record all the business activities of an organization and ensure organization, classification, and structure of the business processes and data.

An ERP system can be viewed as a group of processes, applications, and technology and consists of the following:

- Databases
- Applications to support business processes
- Network and systems infrastructure
- Middleware (group of software that aid integration of the various components)

This chapter discusses the evolution of ERP systems, provides brief information on the various ERP vendors and details the role and the impact of the integrated business software in manufacturing intelligence.

Evolution of ERP Systems

The concept of ERP has been around since the 1960s, and has its beginning in materials requirements planning (MRP). It was meant to provide an integrated approach to reduce inventory and process times and better manage procurement and production. In the 1970s, ERP systems evolved into manufacturing resource planning (MRP II) to involve financial and human resource planning in a limited capability. MRP and MRP II had their own limitations in terms of handling multiple locations, product aggregations, capacity constraints, and so forth. These limitations resulted in the development of ERP systems.

ERP systems, in the simplest sense, can be considered as a single, integrated database that gathers, stores, and helps analyze the data of an organization. Until the early 1990s ERP products were running on mainframes; however, with the advent of the client-server architecture in the mid-1990s, a majority of the ERP systems run on client-server architectures. The emergence of ERP systems went hand in hand with the idea of concentrating on single enterprises. The primary goal of these systems was to integrate the business processes of a single company. The business process integration capabilities were also very limited even if multiple companies of a conglomerate used the same information system. Among the biggest hurdles for this integration was the cost of technology. However, with significant development in technology over the last 5-7 years, the idea of cross-enterprise integration has become achievable and affordable. This led to the next generation of integrated business software products, commonly referred to as ERP II.

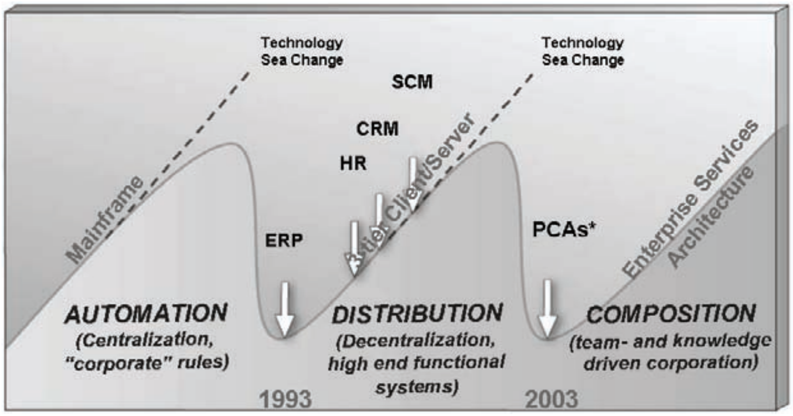
ERP II is the latest evolution that adapts ERP to the e-commerce environment through changes in functionality, technology, and architecture. The most evident change from ERP to ERP II is a change in focus of a business process from enterprise-centric to a collaborative environment. ERP II extends the scope of the business processes from an individual organization to all the stake holders in the supply chain. According to the Gartner Group, ERP II is “a business strategy and set of industry-domain-specific applications that build customer and shareholder community’s value network system by enabling and optimizing enterprise and inter-enterprise collaborative operational and financial processes” (Gartner Group, May 2001).

Table 1 represents the timeframe, industry needs, and the progress of technology of these systems.

Table 1. History of ERP systems

Year	Industry Need	Technology Progress
1970 - 1990	Real-time Automated systems	Automation systems, Transactional systems (OLTP)
Early 1990s	Scalable Integrated business processes	Analytical systems (OLAP), ERP
Late 1990s	Heterogeneous business processes	Integration, Web-services, "e-commerce"
2000s	Packaged composite business processes	ERP II

Figure 1. Paradigm shift in technology (Source: Gartner Group, 2003)



The 1970s through the 1990s saw a significant need for real-time automated systems to enable faster transaction entry. In the early 1990s this expanded by requiring analytical systems to process the transaction data in order to better understand the business. During the late 1990s, the industry requirement further expanded to requiring integration of Web-enabled heterogeneous systems. Organizations used proprietary interfaces to communicate between systems. This approach treats the Web application tier as just another silo, rather than as the integration hub through which all transactions flow, resulting in the need for the development of a technology that could reuse the applications developed. This technology is referred to as packaged composite application software, and the concept is very similar to objects in software development, where applications are built by reusing logic from two or more existing applications to form a new application without having to start from scratch. A composite application consists of functionality drawn from several different sources integrated by a technology platform. The components may be individual Web services, selected functions from within other applications, or entire systems whose outputs have been packaged as Web services.

Figure 1 represents the paradigm shift in technology and the products developed in the respective time frames.

Until the early 1990s, the ERP solutions were hosted on mainframes. With mainframe software architectures all intelligence is within the central host computer, and users interact with the host through a terminal that captures keystrokes and sends that information to the host. A limitation of mainframe software architectures is that they do not easily support graphical user interfaces or access to multiple databases from geographically dispersed sites. As a result of the limitations of file sharing architectures, the client/server architecture emerged in the mid-1990s. This approach introduced a database server to replace the file server. Using a relational database management system, user queries were answered directly. The client/server architecture reduced network traffic by providing a query response rather than total file transfer, improving multiuser updating through a GUI front end to a shared database. This technology evolution resulted in the IT landscape of most organizations being heterogeneous with a variety of enterprise suites, best-of-breed systems, and legacy systems. Also, they have a mixture of hardware platforms, operating systems, and databases.

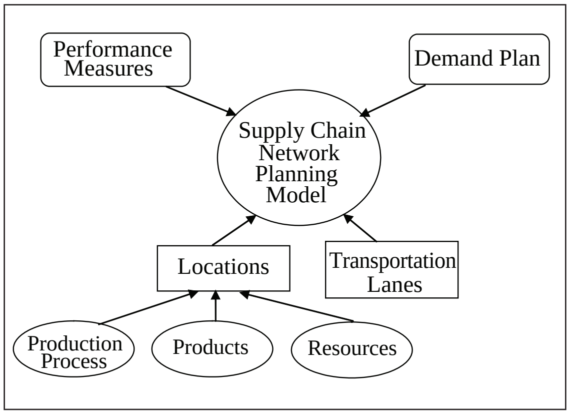
Further complications occur when organizations go through mergers, acquisitions, and divestitures. The traditional applications are designed for efficiency, not reuse, since there is no clear distinction between user interface, logic, and data, and they usually have a high cost of modification. In 2003, the concept of service-oriented architecture (SOA) was developed, which is the underlying structure supporting communications between services. An SOA solution consists of a composite set of business services that realize an end-to-end business process. SOA architecture is an application architecture that is designed to map directly to business requirements and is key to achieving the agility required. SOA, together with the emergence of service-oriented business applications (SOBAs) and service-oriented development of applications (SODA) are among the most significant shifts in IT.

Software is often completely inflexible once deployed, thus changing the nature of software can improve agility. For this to work, packaged business applications need to be broken down into smaller pieces that are easier to change. SOA makes it possible to look at software in pieces. As technology and standards evolve SOA will allow enterprises to mix applications services with others, regardless of the original supplier and the hardware and software platforms they use. We can think of it as separating business functions into subroutines/methods with the subroutines existing in any machine. SOA for an enterprise is usually referred to as the enterprise service architecture (ESA), and is the technology format currently being adopted by all the major ERP vendors in their product development. The evolution of SOA architectures and systems affects all levels, from business-IT alignment to hardware and devices. It will help software developers develop business applications faster and will help users to realize the full potential of integration.

It is important to understand that ERP systems were originally developed as transaction-based systems. With increased competition and shorter product life cycle, there was a significant demand for robust planning systems. It has also become very important for an organization to have near real-time collaboration and integration with all the stakeholders in the supply chain. Organizations have better understood the need for a higher level of information exchange with the vendors to ensure optimized cost and quality (Turban, McLean, & Wetherbe, 2004). Similarly, the impact of increased levels of collaboration with the distributors and the customers has also been recognized (Hitt, Wu, & Zhou, 2002).

The demand for faster and increased levels of information exchange saw the development of functionality-specific planning systems (e.g., supply chain management systems, product life cycle management systems, customer relationship management systems, and supplier relationship management systems, etc.). In addition, the roles

Figure 2. SAP Corporation Product Suite



of planning and execution in a business process are starting to converge. The future integrated business software products will be adaptive in nature, and groups of systems will continuously interact, exchange information, and iteratively plan and execute. For example, Figure 2 represents the product suite from SAP Corporation.

ERP Systems

mySAP ERP serves as the primary transaction processing system, while the rest of the systems are primarily designed for analytical purposes. Netweaver is the technology platform that integrates all these products. mySAP ERP is SAP's latest version of the core ERP software. It is primarily used as an online transaction processing system. Some of the capabilities of mySAP ERP include:

- Streamlining operations and optimizing the use of corporate resources and assets,
- Accelerating time to market and time to value,
- Delivering higher levels of service and more individualized products and services, and
- Enhancing customer satisfaction.

mySAP ERP includes financials (financial and management accounting and financial supply chain management), human capital management (talent management, core HR processes, and workforce deployment), corporate services (managing real estate; enterprise assets; project portfolios; corporate travel, environment, health, and safety [EH&S], quality, and global trade services), and operations (end-to-end procurement and logistics business processes, including discrete and process manufacturing).

ERP systems are the core of an organization's ERP landscape. They have become the primary transaction processing system. The historical transactions are stored in a data warehouse and are diced and sliced by the analytical systems – supply chain, customer relation, supplier relation, and product lifecycle – to help make better business decisions.

Customer Relationship Management Systems

Customer relationship management (CRM) is an information industry term for methodologies, software, and usually Internet capabilities that help an enterprise manage customer relationships in an organized way. For example, an enterprise might build a database about its customers that described relationships in sufficient detail so that management, salespeople, service providers, and perhaps the customer could directly access information, match customer needs with product plans and offerings, remind customers of service requirements, know what other products a customer had purchased, and so forth.

CRM consists of helping an enterprise enable its marketing departments to identify and target their best customers, manage marketing campaigns with clear goals and objectives, and generate quality leads for the sales team. CRM also involves assisting the organization to improve telesales, account, and sales management by optimizing information shared by multiple employees, and streamlining existing processes (e.g., taking orders using mobile devices). Enabling CRM allows the formation of individualized relationships with customers, with the aim of improving customer satisfaction and maximizing profits, and identifying the most valuable customers and providing them the highest level of service. CRM also provides employees with the information and processes necessary to know their customers, understand their needs, and effectively build relationships between the company, its customer base, and distribution partners.

According to the Gartner Group, there are three aspects of CRM, each of which can each be implemented in isolation:

1. **Operational CRM:** Automation or support of customer processes that include a company's sales or service representatives
2. **Collaborative CRM:** Direct communication with customers that does not include a company's sales or service representatives ("self service")
3. **Analytical CRM:** Analysis of customer data for a broad range of purposes

For example, mySAP customer relationship management provides solutions so that organizations can act immediately to improve sales, service, and marketing effectiveness. mySAP CRM provides the functionality to:

- Analyze, plan, develop, and execute all marketing activities.
- Help acquire, grow, and retain profitable.
- Drive service revenue and profitability with support for service sales and marketing.
- Enable e-commerce to increase sales and reduce transaction costs.

CRM systems have gained importance in the last three to four years. For CRM to work, companies must bring together a number of disparate processes, systems, and types of data, regardless of where they reside, to deliver an integrated, unified view of the customer that drives a consistent approach to interactions that is proactive as well as reactive. Adapting an integration technology, like ESA, will help organizations realize system.

Supply Chain Management Systems

Supply chain management (SCM) is the oversight of materials, information, and finances as they move in a process from supplier to manufacturer to wholesaler to retailer to consumer. Supply chain management involves coordinating and integrating these flows both within and among companies. The ultimate goal of any effective supply chain management system is to reduce inventory (with the assumption that products are available when needed). As a solution for successful supply chain management, sophisticated Web-enabled software systems are available.

Supply chain management flows can be divided into three main flows:

- Product flow.
- Information flow.
- Financial flow.

The product flow includes the movement of goods from a supplier to a customer, as well as any customer returns or service needs. The information flow involves transmitting orders and updating the status of delivery, as well as other inventory related data. The financial flow consists of credit terms, payment schedules, and consignment and title ownership arrangements.

There are two main types of SCM software: planning applications and execution applications. Planning applications use advanced algorithms to determine the best way to fill an order. Execution applications track the physical status of goods, the management of materials, and financial information involving all parties. Some SCM applications are based on open data models that support the sharing of data both inside and outside the enterprise (this is called the extended enterprise, and includes key suppliers, manufacturers, and end customers of a specific company). This shared data may reside in diverse database systems, or data warehouses, at several different sites and companies.

By sharing this data "upstream" (with a company's suppliers) and "downstream" (with a company's clients), SCM applications have the potential to improve the time-to-market of products, reduce costs, and allow all parties in the supply chain to better manage current resources and plan for future needs. For example, mySAP supply chain management enables adaptive supply chain networks by providing planning and execution capabilities to manage enterprise operations. mySAP SCM supports supply chain functionality to:

- Model existing supply chain and ensure a profitable match of supply and demand.
- Enable supply chain planning and with distribution, transportation, and logistics integrated into real-time planning processes.
- Provide network-wide visibility across your extended supply chain to perform strategic as well as day-to-day planning.

Supply chain management systems will yield improvements in the areas of cost, time, and quality. A very effectively implemented supply chain management system will help an organization with making processes more transparent and improve flexibility. SCM systems will not only concentrate on the order fulfillment cycle, but also incorporate product design, process recovery, and customer relationship.

Supplier Relationship Management Systems

Supplier relationship management is a comprehensive approach to managing an enterprise's interactions with the organizations that supply the goods and services it uses. The goal of supplier relationship management (SRM) is to streamline and make the processes between an enterprise and its suppliers more effective, just as customer relationship management (CRM) is intended to streamline and make more effective the processes between an enterprise and its customers.

SRM includes both business practices and software and is part of the information flow component of supply chain management (SCM). SRM practices create a common frame of reference to enable effective communication between an enterprise and suppliers who may use quite different business practices and terminology. As a result, SRM increases the efficiency of processes associated with acquiring goods and services, managing inventory, and processing materials.

For example, mySAP supplier relationship management helps simplify and automate procurement, and integrate strategic practices for supplier qualification, negotiation, and contract management more tightly and cost-effectively with other enterprise functions and their suppliers' processes. mySAP SRM supports:

- Supplier qualification, more efficient supplier negotiation, and better contract management.
- Requisitions, orders, goods receipt, and invoice settlement.
- Linking suppliers to purchasing processes and collaborate more effectively.

If correctly put into practice, SRM systems in a firm can enhance supplier selection, improve business interactions, and accelerate purchasing cycle time. SRM systems can definitely be an asset to companies, especially those who are trying to cut down costs.

Product Lifecycle Management Systems

Product lifecycle management (PLM) is a strategic business approach that applies a consistent set of business solutions that support the collaborative creation, management, dissemination, and use of product definition information. PLM supports the extended enterprise (customers, design and supply partners, etc.). PLM spans from concept to end of life of a product or plant and integrates people, processes, business systems, and information.

It is important to note that PLM is not a definition of a piece, or pieces, of technology. It is a definition of a business approach to solving the problem of managing the complete set of product definition information by creating that information, managing it through its life, and disseminating and using it throughout the lifecycle of the product. Three core or fundamental concepts of PLM include universal, secure, managed access, and use of product definition information. PLM helps maintain the integrity of that product definition and related information throughout the life of the product or plant. PLM also helps manage and maintain business processes used to create, manage, disseminate, share, and use the information.

PLM includes management of all product-related information from requirements, through design, manufacturing, and deployment. This information ranges from marketing requirements, product specifications, and test instructions and data to the as-maintained configuration data from the field. The PLM solution links information from many different authoring tools and other systems to the evolving product configuration. At the same time, the lifecycle began to include production-focused attributes and information. Manufacturing and operational process plans are also now viewed as an inherent part of PLM. Processes, and the workflow engines that control them, ensure complete digital feedback to both users and other business systems throughout each lifecycle stage.

The mySAP product lifecycle management application provides an integrated, single source of all product-related information needed for collaborating with business partners and supporting processes including product innovation, design and engineering, quality and maintenance management, and control of environmental issues. mySAP PLM had the functionality to:

- Manage specifications, bills of materials, routing and resource data, project structures, and related technical documentation throughout the product life cycle.
- Helps plan, manage, and control the complete product development process.
- Support collaborative engineering and project management.
- Provide integrated quality management for all industries.
- Coordinate enterprise asset management.
- Monitor, environment, health, and safety.

Enterprises are adopting PLM solutions to meet a variety of challenges. They are increasingly discovering that PLM helps them deal with daunting growth, global operations, and highly competitive market demands. PLM solutions connect people to work collaboratively, and centralize and improve the management of the product data. It streamlines the process steps to create, manufacture, and support products throughout their lifecycle from concept to retirement.

ERP VENDORS

ERP vendors are those organizations that develop, sell, and support ERP systems. The biggest ERP vendors include SAP AG, Oracle Corporation, and Microsoft Corporation. AMR Research expects the enterprise applications market to grow from

$47.8 billion in 2004 to $64.8 billion by 2009 (AMR Research, 2005). Table 2 lists the various enterprise applications, their current market size, and market forecasts until 2009.

Manugistics (recently acquired by JDA) and i2 were among the pioneers in developing supply chain management software. However, the traditional ERP software manufacturers like SAP and Oracle have also been developing supply chain management solutions.

Organizations implementing the entire suite of integrated software solutions have the option of selecting a single integrated system approach or the best-of-breed approach. The single integrated system provides efficient and reliable interfaces between the analytical and transactional systems. Examples of vendors providing a single integrated system include SAP and Oracle. The best-of-breed approach is adopted by organizations that use different "brands" of products for transactional and analytical systems. The best-of-breed approach may provide organizations with better functionality, but lacks the tight integration between the transactional and analytical systems. Historically, the best-of-breed approach has not provided good overall solutions (*Optimize*, September 2006).

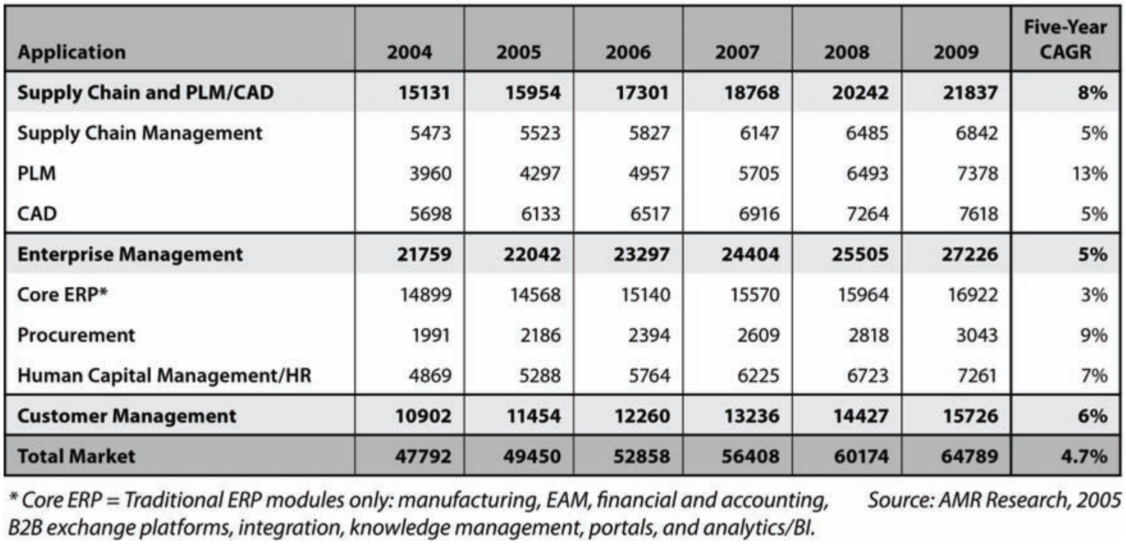
The developments in technology have revolutionized manufacturing processes. The rest of this chapter discusses the impact of the technology and the latest software, and how they have enabled firms to be more profitable.

MANUFACTURING PROCESSES

Traditionally, manufacturing processes included planning and execution. However, with the understanding of the importance of the supply chain and the advances in technology, collaboration has also become an important process in manufacturing.

Until now, most ERP systems performed both strategic and operational level activities, with primary goal being operational activities. The systems performed online transaction processing and online analytical processing. As the planning criteria became complex, the traditional ERP systems were unable to provide accurate planning results. The primary reason is that the data structure of a transaction processing system is very inefficient for analytics purposes. However, with increasing demand for better planning capabilities,

Table 2. Enterprise applications market size and forecasts, 2004-2009



Application	2004	2005	2006	2007	2008	2009	Five-Year CAGR
Supply Chain and PLM/CAD	**15131**	**15954**	**17301**	**18768**	**20242**	**21837**	**8%**

** Core ERP = Traditional ERP modules only: manufacturing, EAM, financial and accounting, B2B exchange platforms, integration, knowledge management, portals, and analytics/BI.*

Source: AMR Research, 2005

ERP vendors have developed products specific for these requirements. These products are referred to as supply chain management systems. The ERP systems have to be tightly integrated with the supply chain management systems to take advantage of its planning capabilities.

Planning

Manufacturing planning requires determining the location, type of product, and the magnitude of the customer demand. The planning results will differ depending on the time frame under analysis. For example, a strategic plan (long-term) may involve determining the product group requirement for a particular region. Tactical (medium-term) and operational (short-term) planning may involve more details about the product, a specific location in the region, and so forth. The first step in manufacturing planning involves calculating the independent requirements based on the forecast values and requirements from the sales information system and costing/profitability analysis. The next step involves the planning of only those items that are critical to the overall process. The final step involves creating the materials requirement planning. The output of MRP is a planned production order, purchase requisition, or a planned purchase order.

Execution

Manufacturing execution involves procurement and supply of goods and services among all the stakeholders in the supply chain. The first step in manufacturing execution is the release of the production order. The next step in this process involves the issues of the materials from the storage location to the work center. After the manufacturing process is complete, goods are received into stock.

Collaboration

Manufacturing companies have increased their productivity and efficiency over time by implementing new strategies like total quality management, lean manufacturing, and Six Sigma. Although these have significantly improved the efficiency, there is an increasing recognition that companies are competing as supply chains, not individual entities. To maintain a competitive advantage, manufacturers must make a significant change in strategy to effectively synchronize activities among functionally and geographically dispersed organizations. All the stakeholders of the supply chain need to collaborate. A collaborative manufacturing strategy would help a company maximize the effectiveness of its value chain and, hence, be more profitable. Collaborative manufacturing strategies will play a crucial role in helping world-class companies increase business value in the emerging global economy. To successfully meet marketplace requirements, manufacturers must create business processes that leverage shared information. ERP solutions provide the perfect platform to aid this collaboration.

A well integrated ERP solution provides all the stakeholders in the supply chain with relevant, real-time information and analysis to be efficient not only as an individual organization, but also as an entire supply chain.

ERP SYSTEMS AND MANUFACTURING PROCESSES

Supply Chain Management Systems

Planning is one of the most important tasks in a supply chain. The software systems that help perform planning are called as supply chain management systems. Advanced planning systems is the generic name for this breed of software.

Advanced planning systems are by no means a replacement to the ERP systems. The aim of an advanced planning system is to address the deficiencies of an ERP system for planning. The two main characteristics of an advanced planning system are:

- **Integral planning:** Plan for the entire supply chain
- **True optimization:** Defining objectives and constraints for every part of the supply chain and solving it

However, it must be acknowledged that it is impossible to plan for the entire supply chain and at the same time perform optimization for every piece of the puzzle. Hence, a new architecture called the hierarchical planning system was developed. Hierarchical planning systems decompose the planning tasks into partial plans based on aggregation and disaggregating capabilities of time, products, resources, and so forth. Hierarchical planning systems provide the feasibility required for addressing integral planning and true optimization at the same time. Advanced planning systems are based on the hierarchical planning architecture, and address the planning requirements for all the four stages of the supply chain (i.e., procurement, production, distribution and sales). They also address planning for all time horizons (i.e., long-term, medium-term and short-term).

Product Lifecycle Management Systems

Product lifecycle management (PLM) systems describes a framework of technology and services that permit manufacturing companies and their partners and customers to collaboratively conceptualize, design, build, and manage products throughout their entire lifecycle. PLM systems enable organizations to create digital product information, and facilitate collaboration during the product development phase. PLM systems also control and automate critical processes such as release to manufacturing, change, and configuration management, throughout the product's lifecycle.

PLM systems have emerged as the primary means by which manufacturing companies can achieve significant improvements in their product development process. PLM systems are unique from other enterprise applications because they manage digital product information and optimize the digital product value chain. PLM systems also act as a document management system throughout the life cycle of a product. PLM systems have to integrate with other enterprise systems including traditional enterprise resource planning (transactional) and supply chain management systems (analytical).

CASE STUDY

Supply chain models give an overview of all elements in the supply chain and their relationship to each other, and are used to describe the strategic view of a supply chain from a planning perspective. There are a lot of models that break down the total supply chain into simpler subsystems and optimize each of them individually; however, optimized subsystems do not necessarily mean the total supply chain is optimized.

Supply network planning models integrates purchasing, production, distribution (of demands), and transportation so that comprehensive mid-term to long-term tactical planning and sourcing decisions can be simulated and performed on the basis of a single, global consistent model.

The case below discusses the methodology to define a supply chain model and suggests techniques for implementation of a supply chain network planning model in an ERP environment. The model, if implemented, would serve as a very valuable tool to enhance learning experience.

Task 1: Defining the Supply Network Planning Model Agents

Supply network planning includes all the processes from the demand plan to the delivery of goods/services to the customer. Definition of the supply network planning process consists of three main subtasks and is represented in Figure 3.

Task 1a: Defining the Supply Chain Model

The supply chain model is a combination of the following agents: production process, locations, products, resources, and transportation lanes. Production process defines the detailed information required for manufacturing a product, and contains the recipe and the routing for the goods/services to be manufactured/rendered. A location is a logical or physical place at which products or resources are managed on a quantity basis. Location includes production plant, distribution centers, customers, and vendors. Resources enable the definition of capacities of equipment, machines, personnel, means of transport, and warehouses. Transportation lanes represent a direct route between two locations that can be used to source and transport products.

A new agent-based supply chain model, as shown in Figure 4, with production process, locations, products, and resources will be created in this research effort.

The location is assigned to the model and the production process, products, and resources are assigned to the location. The supply chain model will be used to synchronize activities and plan the flow of material along the supply chain, thus, creating feasible plans for purchasing, manufacturing, inventory, and transportation, as well as service enterprises.

Task 1b: Analysis of Supply Network Model

For analysis of the supply network model, optimization-based, heuristics-based, and supply/demand propagation-based planning techniques could be investigated to determine their feasibility and appropriateness. Optimization-based planning techniques are typically based on quantitative models aimed at minimizing costs (or maximizing profits) subject to constraints. Heuristics-based

Figure 3. Supply network planning process (Source: SAP AG, 2004.)

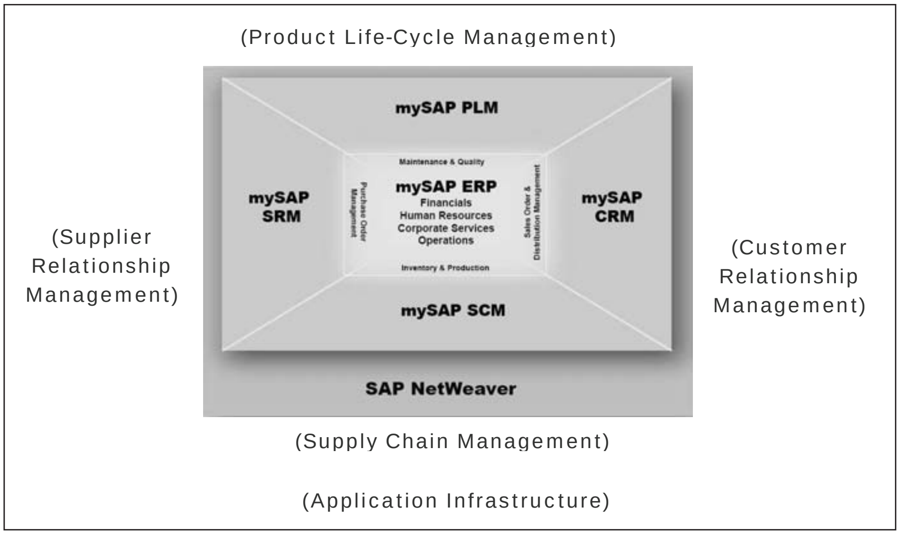

Figure 4. Agent-based supply chain network planning model

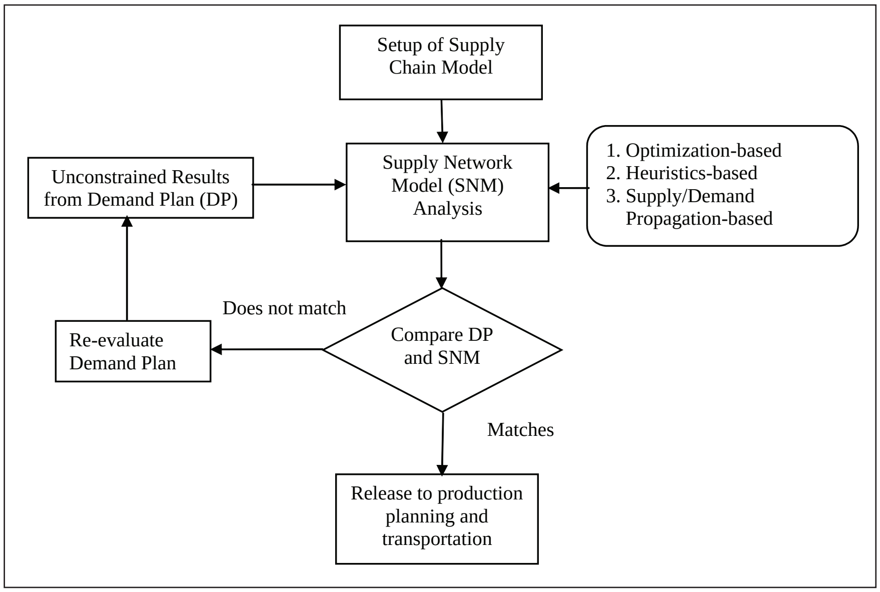

planning techniques work to create feasible (often nonoptimal) plans, and supply/demand-based planning techniques are based on statistical analysis of time series data. Quantitative and qualitative forecasting techniques can be used to develop a demand plan for comparison prior to release of the plan. The results from the demand plan (either real or simulated) are released to the supply network model and they form the basis for the analysis. The results from the demand plan do not include any constraints (e.g., production and distribution).

Task 1c: Validation and Implementation of Supply Network Planning Process

Validation of the model will be based on comparing the results from the constrained supply network model and the unconstrained demand plan. Since the initial model is formulated using an unconstrained demand plan, results may not be feasible when constraints are added, and the model must be modified. For example, available capacity may be less than the planned demand, hence, pricing parameters or resource constraints must be reevaluated.

The agents of the supply chain model represent the enterprise-wide integration, and the analytical agent-based model will be used to determine rules for agent behavior. Once the initial model and rules are developed, they would be evaluated and improved.

Task 2: Model Evaluation and Improvement

Measuring the effectiveness of the supply chain is very important. Successful evaluation and improvement of the agent-based supply chain integration model depends on concentrating on specific key business processes and developing an appropriate set of key performance indicators (KPIs) applicable at the enterprise level to measure the effectiveness of the supply chain. KPIs are quantifiable measurements that reflect the critical success factors of an organization, and depend on the product/service offered by an organization.

Task 2a: Definition of Performance Measures

Five main performance measures could be used for the evaluation of the supply chain models. The performance measures listed below are based on the guidelines from the SCOR model:

- **Supply Chain Delivery Reliability:** The performance of the supply chain in delivering the correct product, to the correct place, at the correct time, in the correct condition and packaging, in the correct quantity, with the correct documentation, to the correct customer.
- **Supply Chain Responsiveness:** The speed at which at which a supply chain provides products to the customer.
- **Supply Chain Flexibility:** The agility of a supply chain in responding to marketplace changes to gain or maintain competitive advantage.
- **Supply Chain Costs:** The costs associated with operating the supply chain.
- **Supply Chain Asset Management Efficiency:** The effectiveness of an organization in managing assets to support demand satisfaction. This includes the management of all assets, fixed and working capital.

Task 2b: Evaluation and Improvement of Performance Measures

The performance measures should be then evaluated for appropriateness for an enterprise-wide model in an ERP environment. Additional performance measures could be developed based on results of the definition and analysis/evaluation of the model. Comparison of the performance of the developed supply chain model with historic data and theoretical results provides an opportunity for benchmarking the performance of the model, as well as continuous improvement. The performance measures defined by SCOR will be studied for their validity and application on an enterprise-wide basis and additional measures will be developed, if necessary.

Task 3: Implementation of Supply Chain Network Planning Model in ERP Environment

Enterprise resource planning (ERP) is a software-driven business management system that integrates all facets of the business, including planning, manufacturing, sales, and marketing. The integrative capability of the ERP software makes it attractive for implementation of the agent-based supply chain integration model presented in this business case.

SAP advanced planner and optimizer (APO) is a component of the mySAP supply chain management solution that is used for planning and optimizing supply chain processes at a strategic, tactical, and operational planning level. APO is used for creating the model agents defined earlier, and assigning agents such as locations, products, resources, and production process models. After the initial assignments are made, agents for transportation lanes are added to link supply to demand locations, allocate products to the transportation lanes, and maintain quota arrangements. The developed model will be capable of tracking and evaluating supply chain agents including products, production process models and material handling, production, storage, and transportation. APO acts as the interface that acts as a top enterprise planning layer covering other planning areas such as manufacturing, demand, distribution, and transportation.

APO supply network planning (SNP) integrates purchasing, manufacturing, distribution, and transportation so that comprehensive tactical planning and sourcing decisions can be simulated and implemented on the basis of a single, globally consistent model. Supply network planning uses advanced optimization techniques based on constraints and penalties to plan product flow along the supply chain. The result is improved purchasing, production, and distribution decisions, reduced order fulfillment times and inventory levels, and improved customer service.

Starting from a demand plan, supply network planning determines a permissible short- to medium-term plan for fulfilling the estimated sales volumes. This plan covers both the quantities that must be transported between two locations (e.g., distribution center to customer or production plant to distribution center), and the quantities to be produced and procured. When making a recommendation, supply network planning compares all logistical activities to the available capacity.

The deployment function determines how and when inventory should be deployed to distribution centers, customers, and vendor-managed inventory accounts. It produces optimized distribution plans based on constraints (i.e., transportation capacities) and business rules (i.e., minimum cost approach, or replenishment strategies). The transport load builder (TLB) function maximizes transport capacities by optimizing load building.

For the implemented scenario, interactive demand planning will be used to create a demand plan, which is released to supply network planning to determine production planning. The process is simulated in APO utilizing planning techniques (cost-optimization, heuristics, and supply/demand propagation). Implementation of the supply chain model in an ERP environment will provide a test bed for validation, benchmarking studies, as well as further research on development and evaluation of analytical supply chain models. As an additional bonus, the implementation provides an infrastructure for creating case studies and exercises utilizing real-world data.

FUTURE RESEARCH DIRECTIONS

Further research in the field of supply chain management should consider analysis to determine the level of implementation of collaborative planning (such as CPFR) and collaborative replenishment (such as CRP) systems in different industries and the effects of this knowledge sharing on the performance of the supply chain. Collaborative planning includes the forecasting aspect of the demand management process, while collaborative replenishment covers the synchronization part of this supply chain process. Research and development of multidecision models which consider the objectives of the different companies will play an important role in these decision and planning systems.

Further research in the field of customer relationship management should try to analyze how different business units can use the same customer data: What specific type of integration alternatives are available for organizations working with rapidly changing CRM and SCM support technologies? Future studies should also develop decision and operations research tools to analyze the large amount of data gathered through the Internet. Further progress in research should be made in order to analyze intraorganizational and interorganizational effects simultaneously.

Further research in the field of order fulfillment needs to address the better use of information and creation of knowledge by using actual and new analytical and decision tools. The access to more data and information will put more emphasis in global optimization along the entire supply chain, instead of the usual models that focus on local optimization. More work considering the global supply chain will appear in this area. Also, more models using multicriteria decision making that reflect the integration and collaboration aspects of the e-fulfillment process will be the subject of future work.

Researchers should develop more decision models that take into account the global aspects of the supply chain to help to improve the manufacturing planning. Significant research is also required to help develop real-time tools, modeling, and decision systems that use real-time data available through the Internet.

CONCLUSION

With the continuous improvement in technology with software and computational capabilities organizations are able to better plan and execute their vision. The role of ERP software in this success cannot be undermined. However, there have also been instances where ERP implementations have resulted in large financial losses, even bankruptcy. It is important for organizations to recognize their core mission and capabilities and understand how ERP software can help achieve better efficiencies at their capabilities. If implemented the right way, ERP software unequivocally can help in the success of an organization.

Chapter 5.22

The Strategic Implications of E-Network Integration and Transformation Paths for Synchronizing Supply Chains

Minjoon Jun
New Mexico State University, USA

Shaohan Cai
Carleton University, Canada

DaeSoo Kim
Korea University Business School, Korea

ABSTRACT

Streamlining information flows across the physical supply chain is crucial for successful supply chain management. This study examines different structures of e-networks (i.e., virtual supply chains linked via electronic information and communication technologies) and their maximum capabilities to gain e-network benefits. Further, this research explores four levels of e-network integration based on a 2x2 e-network technology and transaction integration matrix. Of the four levels, an e-network with high e-technology/high e-transaction integration appears to be most desirable for the companies that aspire to achieve the maximum benefits from their IT investments. Finally, this study identifies three alternative transformation paths toward a powerful high e-technology/high e-transaction integration network and discusses strategic implications of selecting those paths, in terms of e-network structures, availability of financial and technical resources, supply chain members' collaborative planning, e-security mechanisms, and supply chain size.

INTRODUCTION

As competition in the marketplace has increasingly intensified during the past decade, the strategic significance of close collaboration among supply chain members has dramatically increased. This advanced importance of collaborative chain activities is primarily attributable to the change of competitive scenes from a firm vs. a firm to a supply chain vs. a supply chain (Li, Rao, Ragu-Nathan, & Ragu-Nathan, 2005). A supply chain can be defined as encompassing all activities associated with the flow and transformation of goods from the raw material stage through to the end user, as well as the associated information flows (Handfield & Nicholas, 1999).

As this definition implies, a high level of information sharing and collaboration among chain members is an important prerequisite to achieving high performance of the entire supply chain (Li, Ragu-Nathan, Ragu-Nathan, & Rao, 2006; Monczka, Peterson, & Handfield, 1998; Sahin & Robinson, 2005). Many researchers have emphasized this crucial role of inter-organizational information transactions in supply chain management (SCM). They consistently argue that streamlining information flows across the entire chain is one of the critical success factors for gaining maximum SCM benefits, such as lowering product costs, reducing product development cycle time, and increasing responsiveness to customers' changing preferences (e.g., Christiaanse & Kumar, 2000; Cooper & Tracey, 2005; van Hoek, 2001).

However, in reality, lack of information sharing due to inadequate information systems and lack of trust among chain members appear to be serious obstacles to obtaining such SCM benefits (Cooper & Tracey, 2005; Wisner & Tan, 2000). Therefore, to survive in today's fierce competition between supply chains in global markets, the effective use of newly emerged information technologies has already become an important concern for managers who aspire to use an SCM approach as a strategic competitive weapon (Chopra, 2003; Elmuti, 2002). Those information technologies include the Internet, intranet, extranet, wireless technologies like radio frequency identification (RFID), and information integration systems such as enterprise resource planning (ERP), product lifecycle management (PLM), supply chain planning (SCP), supply chain execution (SCE), customer relationship management (CRM), supplier relationship management (SRM), and business process management (BPM).

However, despite the prominent importance of information systems and their integration across the supply chain, most of the previous studies have addressed this issue in the context of a dyadic relationship (e.g., a buyer and a supplier), rather than from the vantage point of an entire supply chain with multiple layers (e.g., a buyer, a buyer's buyer, and a supplier, a supplier's supplier) (Christiaanse & Kumar, 2000). More specifically, relatively little research has addressed such an important issue as "what types of, and in what way, electronic chains (e-networks) should be adopted and implemented to support all the intra- and inter-organizational activities across the supply chain, where the e-network refers to a non-physical, virtual supply chain linked by electronic information and communication technologies?"

Therefore, this study aims at expanding the body of knowledge on e-networks established in the physical supply chain by addressing the following five questions:

1. What types of e-networks exist in practice and what are their key characteristics?
2. What potential benefits can be obtained by an effective e-network management?
3. What measurement schemes can be employed to assess and categorize the various levels of e-network integration?
4. What are the strategic implications of various e-network integration levels and e-network types in gaining e-network benefits?
5. What transformation strategies and their related factors need to be considered in transforming an existing e-network into the most desirable one, which enables chain members to effectively achieve their common SCM goals?

The present study contributes to the literature in three ways. First, this study develops a classification scheme to better represent and understand the diverse and complex nature of e-network structures and their maximum capabilities to gain e-network benefits. Second, this article proposes a 2x2 e-network technology and transaction integration matrix to categorize various levels of e-network integration, and to identify the most desirable level of integration for achieving the maximum benefits from IT investments. Finally, this study introduces three alternative e-network transformation paths toward a powerful high e-technology/high e-transaction integration network and discusses the managerial implications related to those paths.

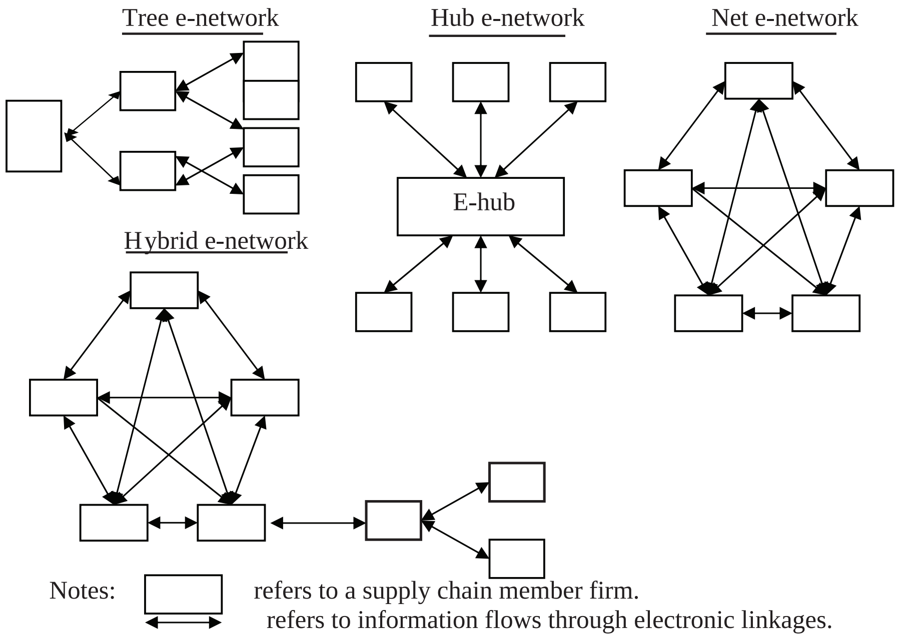
E-NETWORK TYPES AND POTENTIAL BENEFITS

Kumar and van Dissel (1996), from an interdependence view of organizations, have classified electronic data interchange (EDI)-based inter-organizational information systems (IOSs) into three categories: value/supply-chain IOS (enabling sequential transactions among chain members), pooled information resource IOS (sharing common IS/IT resources), and networked IOS (sharing data and supporting collaborative work among members). Building on Kumar and van Dissel's (1996) work, the present study developed a four-type e-network classification scheme to better represent current IOS environments, where Web-based technologies are widely utilized for data sharing and information transmissions. These four types are tree, hub, net, and hybrid e-networks (see Figure 1).

Tree E-Network

The "tree" e-network, similar to Kumar and van Dissel's (1996) value/supply chain IOS, is very close to a typical, physical supply chain in its shape, which has one or more suppliers or buyers in each of its multi-tier stages. This e-network structure usually takes a linear form of electronic linkages, reflecting sequential supplier-buyer relationships

Figure 1. Classification of e-network structures



Notes: refers to a supply chain member firm.
refers to information flows through electronic linkages.

from end suppliers to end customers. Currently, it is commonly found in most industries, including basic apparel, book publishing, computer, and food and beverage.

Hub E-Network

Similar to the pooled information resource IOS, the "hub" e-network, often called "e-hub" or "e-marketplace," is centered on a platform through which both suppliers and buyers are linked to make transactions and/or simultaneously exchange necessary data and information such as order status, shipment schedules, inventory levels, and CAD/CAM data with one another (Kaplan & Sawhney, 2000; Sharifi, Kehoe, & Hopkins, 2006; Zeng & Pathak, 2003). This nonlinear intermediary, often called infomediary, is further classified into vertical and horizontal exchanges, aggregation, and auction and reverse auction hubs (Kaplan & Sawhney, 2000; Zeng & Pathak, 2003). Vertical exchange hubs (e.g., eSteel.com, PaperExchange.com, FloraFlex.com) provide deep domain-specific content and relationships, typically by automating and hosting procurement process for an industry-specific vertical market, while horizontal exchange hubs (e.g., SupplyCore.com, Employease.com, Citadon.com) focus on providing the same functions, such as procurement, benefit administration, and project management, or automating the same business process scalable across multiple vertical markets (Jennings, 1999; Kaplan & Sawhney, 2000).

Next, aggregators serve as hubs in one-way B2C networks (e.g., AOL, Yahoo!, Tavelocity.com, Buy.com) to function as one-stop shopping places for smaller purchasers or operate as hubs in two-way B2B networks (e.g., PlasticsNet.com) that mediate between buyers and sellers and create benefits for both sides with domain expertise. Finally, auction (e.g., eBay, FreeMarkets) or reverse auction (e.g., uBid, Priceline.com) hubs create value by spatial matching of buyers and sellers for a specific bid event for unique non-standard or perishable products. Recently, more companies act as reverse auction hubs, but not as intermediaries, by increasingly sharing material specifications with suppliers, selecting and pre-qualifying them, and running bidding events (e.g., GE's Source-Bid Events). Furthermore, some hubs in the automotive, consumer packaged goods (CPG), logistics service, and business solution system industries (e.g., Transora.com, Transplace.com, mySAP.com) are providing some or all of the aforementioned services.

Net E-Network

The "net" e-network, similar to the networked IOS, refers to the structure in which chain members have direct electronic linkages with one another in a networked supply chain (or a supply network) (Kehoe & Boughton, 2001). For example, in the construction industry, each firm involved in a specific construction project needs to have a direct access to other participants, even though they may not have an explicit or a direct contracting relationship (Cheng, Li, Love, & Irani, 2001). Although these virtual nonlinear net e-networks are rarely found in practice, this type of e-network is increasingly emerging in some industries as evidenced by the interviews of managers in electronic, mechanics, and paper industries (Kemppainen & Vepsalainen, 2003).

Hybrid E-Network

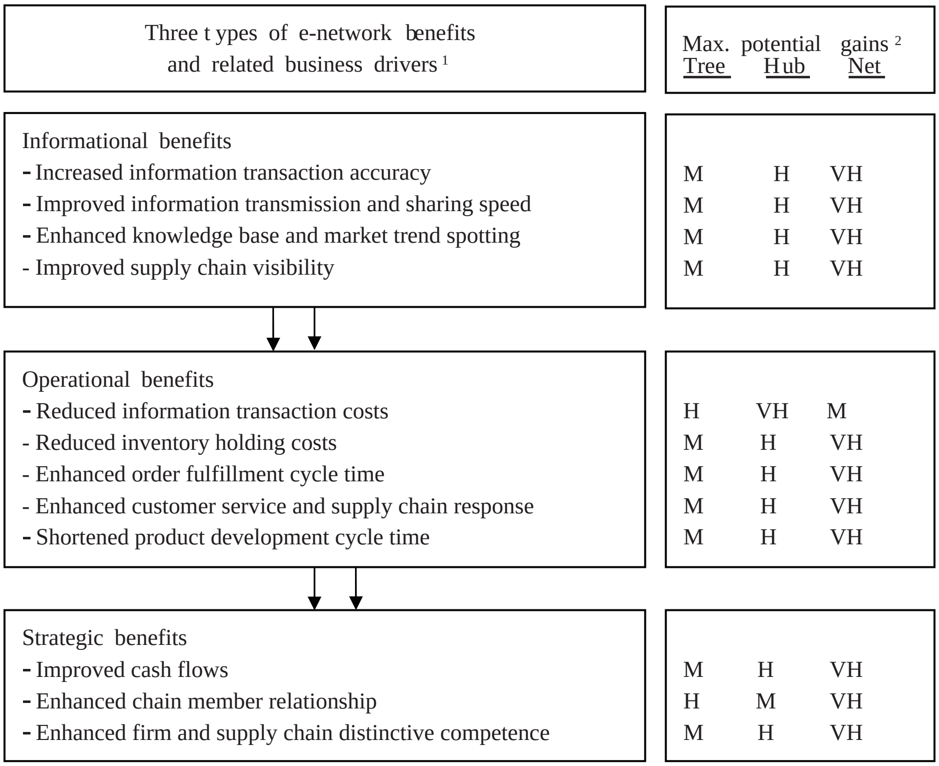
The "hybrid" e-network takes a combined form of the previously mentioned e-network structures, for example, a tree-hub e-network or a tree-net e-network. In practice, many large-sized firms, such as Ford, GM, GE, and Cisco, often employ this complex type of e-networks for managing their supply chains.

Potential E-Network Benefits and E-Network Type

A review of the relevant literature (e.g., Bauer, Poirier, Lapide, & Bermudez, 2001; Edwards, Peters, & Sharman, 2001; Heinrich, 2003; Hendon, Nath, & Hendon, 1998; Iacovou, Benbasat, & Dexter, 1995; Jennings, 1999; Kaplan & Sawhney, 2000; Ovalle & Marquez, 2003; Phan & Stata, 2002; Poirier & Bauer, 2001; Sharifi et al., 2006; Turban, Lee, King, & Turban, 2000) has revealed a variety of potential e-network benefits and varying degrees of the benefits that can be realized by each e-network type. Figure 2 summarizes the key points of benefits and capabilities.

There are three categories of potential e-network benefits: informational, operational, and strategic. First, informational benefits pertain to the effects of e-networks on intra- and inter-organizational information transactions: increased information transaction accuracy, improved information transmission and sharing speed, enhanced market knowledge base and trend spotting, and improved supply chain visibility (Iacovou et al., 1995; Ovalle & Marquez, 2003; Sharifi et al., 2006; Turban et al., 2000). Second, operational benefits refer to the impacts of e-networks on the efficiency of the intra- and inter-organizational business processes: reduced information transaction costs and inventory holding costs, enhanced order fulfillment cycle time, customer service

Figure 2. E-network benefits and maximum potential gains by e-network type



Three types of e-network benefits and related business drivers [1]	Max. potential gains [2] Tree	Hub	Net
Informational benefits			
- Increased information transaction accuracy	M	H	VH
- Improved information transmission and sharing speed	M	H	VH
- Enhanced knowledge base and market trend spotting	M	H	VH
- Improved supply chain visibility	M	H	VH
Operational benefits			
- Reduced information transaction costs	H	VH	M
- Reduced inventory holding costs	M	H	VH
- Enhanced order fulfillment cycle time	M	H	VH
- Enhanced customer service and supply chain response	M	H	VH
- Shortened product development cycle time	M	H	VH
Strategic benefits			
- Improved cash flows	M	H	VH
- Enhanced chain member relationship	H	M	VH
- Enhanced firm and supply chain distinctive competence	M	H	VH

Notes:

1. *Three types of e-network benefits and their related business drivers are partly adapted and compiled from Bauer et al. (2001), Edward et al. (2001), Heinrich (2003), Hendon et al. (1998), Iacovou et al. (1995), Jennings (Jennings, 1999), Kaplan and Sawhney (2000), Phan and Stata (Li et al., 2006; Monczka et al., 1998; , 2002), Ovalle and Marquez (2003), Poirier and Bauer (2001), Sharifi(2006), and Turban et al. (2000).*
2. *Maximum potential gains by e-network type: M = Moderate, H = High, VH = Very High.*

and supply chain response time, and shortened product development cycle time (Hendon et al., 1998; Iacovou et al., 1995; Sharifi et al., 2006). Finally, strategic benefits relate to the effects of e-networks on the competitive position of the entire supply chain in the marketplace: improved cash flows, enhanced chain member relationships, and enhanced distinctive competence of member firms and the entire supply chain (Edwards et al., 2001; Iacovou et al., 1995; Phan & Stata, 2002).

It should be noted that the informational benefits achieved by a highly effective e-network can help chain members obtain a wide range of operational and, in turn, strategic benefits. For example, accurate real-time information transactions across the e-network can enable members to reduce their inventory holding costs and improve their customer service, which in turn could improve their cash flows and enhance distinctive competence of the supply chain as a whole. Moreover, in principle, the net and hub e-networks have a greater potential in gaining maximum e-network benefits than the tree e-network, because the net and hub e-networks enable their members to communicate simultaneously with one another through direct connections (net type) or indirect connections via a platform (hub type), rather than transferring necessary information in a sequential fashion (tree type).

The overall magnitude of informational, operational, and strategic benefits that can be obtained tends to increase as the e-network structure changes from tree to hub to net. However, compared to tree e-networks, hub and net e-networks might have some constraints in gaining substantial cost savings on information transactions as one of the key informational benefits and improving chain partner long-term relationships as one of the key strategic benefits, because of the inherent nature of the hub and net e-networks—that is, multilateral and simultaneous communications among chain members and low switching costs to reconfigure the e-network after changing some of its partner firms. Furthermore, the actual realization of e-network benefits across the supply chain, in reality, is still highly dependent upon the chain members' planning and execution of their e-network efforts. It should also be noted that the aforementioned operational and strategic benefits could also be achieved by other initiatives, such as eliminating non-value-added activities across the supply chain and carefully selecting and retaining competent chain members.

E-NETWORK INTEGRATION MEASUREMENT FRAMEWORK

Successful e-network implementation—seamlessly automating the information transaction processes across organizational boundaries via information and communication technologies—helps all of the chain members achieve maximum e-network benefits and in turn can enhance their competitiveness. Specifically, the types and magnitude of e-network benefits that a supply chain obtains can be primarily determined by how well an e-network is integrated among members. In addition, different e-network structures and supply chain sizes may moderate the effects of e-network integration levels on the e-network benefits that are actually realized.

Measurements of E-Network Integration

Prior studies have proposed various measurements to assess the integration level of inter- and intra-organizational electronic communication. In the context of EDI, Premkumar and Ramamurthy (1995) suggest three key dimensions of EDI utilization: extent of adaptation (the extent of using EDI for generating purchasing order and sales invoice for trading partners), internal diffusion (extent to which EDI is integrated to systems such as shipping/distribution and inventory control), and external connectivity (the extent to which customers are linked by EDI, and the amount of transactions conducted through EDI). Similarly, Massetti and Zmud (1996) propose a four-facet measurement of EDI usage. They are: (1) volume, which represents the extent to which an organization's document exchanges are handled through EDI connections; (2) diversity, which refers to the number of distinct document types that an organization handles via EDI; (3) depth, which refers to the degree of electronic consolidation that has been established between the business processes of two or more trading partners; and (4) breadth, which represents the extent to which an organization has established EDI connections with external organizations such as suppliers, customers, government agencies, and financial institutions.

Later, Shore and Venkatachalam (2003) attempted to measure supply chain information sharing capability in terms of information technology infrastructure (infrastructure capability) and capability of communication collaboration activities (collaboration capability). Recently, in the context of Internet communication, Cai, Jun, and Yang (2006) measured inter-organizational Internet communication in terms of frequency, diversity, and formality dimensions.

It should be noted that all the dimensions identified by the aforementioned studies could be broadly categorized into two groups: e-technology integration (the extent to which electronic linkages are established among chain members) and e-transaction integration (the extent to which electronic linkages are utilized to share information by chain members). Considering the characteristics of the two groups of integration, the following two dimensions of e-network integration are proposed in this study: *e-network information technology (e-technology) integration* and *e-network information transaction (e-transaction) integration*.

The *e-technology* integration dimension, similar to Shore and Venkatachalam's (2003) concept of infrastructure capability, measures the extent to which business processes are electronically consolidated via ICT within and between members in a supply chain. The degree of e-technology integration is heavily influenced by the chain members' willingness to participate in the e-network integration efforts, as well as the connectivity and compatibility of their IS infrastructure (Byrd & Turner, 2001). Connectivity (or breadth) refers to the ability of chain members' IS infrastructure to link to any other IS within and between organizations (adapted from Duncan, 1995; Massetti & Zmud, 1996). On the other hand, compatibility (or depth) means the ability of chain members' IS infrastructure to automatically exchange and handle any type of information (e.g., text, video, image, and audio) across any technology components (regardless of manufacturer, make, or type) in the chain (adapted from Duncan, 1995; Massetti & Zmud, 1996). Thus, high e-technology integration refers to the ideal situation where all chain members' information systems are not only linked internally and externally across the chain (high connectivity), but also able to automatically share information among themselves (high compatibility). Conversely, low e-technology integration pertains to situations where most chain members' ISs are not linked either internally or externally across the chain (low connectivity) and/or are unable to automatically share information among themselves (low compatibility).

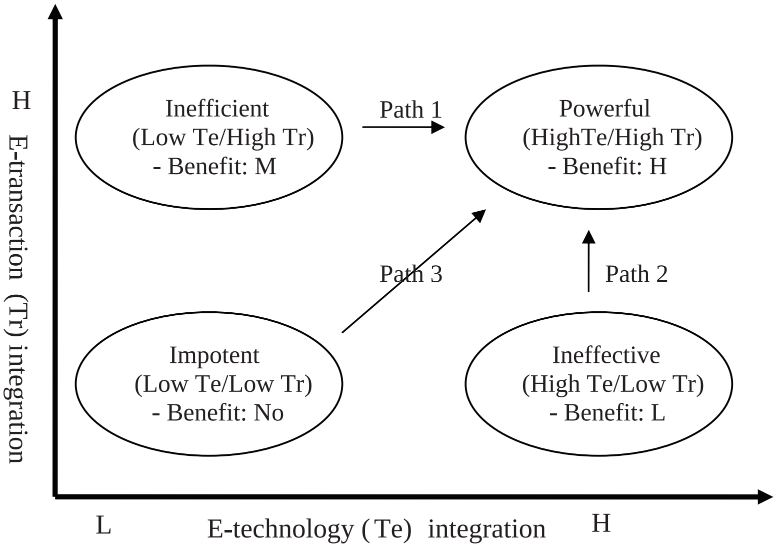
The *e-transaction* integration dimension, similar to Shore and Venkatachalam's (2003) concept of collaboration capability, represents the extent to how much (volume) and what types of documents (diversity) are transmitted via electronic linkages among members within a supply chain (adapted from Massetti & Zmud, 1996). The chain-wide electronic transaction volume can be determined by dividing the total number of documents transmitted through *electronic linkages* in a given time period within a supply chain by the total number of documents transmitted through electronic linkages or other communication means such as mail in the same time period within the supply chain. The chain-wide electronic transaction diversity can be measured by the total number of different document types transmitted through electronic linkages in a given time period within a supply chain. Consequently, the e-transaction integration should reach a certain level for individual members to benefit from their IT investments. This constraint often makes some chain members reluctant to participate in the chain-wide efforts of tightening e-technology integration. Many firms in the consumer packaged goods industry often face this economic feasibility constraint in adopting collaborative planning, forecasting, and replenishment (CPFR) practices.

However, it should be noted that there are some differences between the present study's two measurements and Shore and Venkatachalam's (2003) counterparts. First, while Shore and Venkatachalam's (2003) information technology infrastructure dimension focuses on assessing downstream *individual* suppliers' integration capabilities, the present study's e-technology integration dimension concentrates on measuring both upstream buyers' and downstream suppliers' IS integration (i.e., dual-direction communication). Next, while Shore and Venkatachalam's (2003) collaboration capability dimension focuses on assessing suppliers' ability and willingness to share a variety of information with buyers, the present study's e-transaction integration dimension concentrates on measuring the extent of actual information sharing between upstream buyers and downstream suppliers throughout the supply chain.

E-Network Technology-Transaction Integration Matrix

Based on the two dimensions of e-network integration discussed earlier, the authors developed a 2x2 matrix with vertical and horizontal axes representing the high–low levels of e-technology integration and e-transaction integration, respectively. Figure 3 presents four groups of e-networks classified by the two e-network integration dimensions. The four groups are: powerful e-networks (high e-technology/high e-transaction integration), inefficient e-networks (low e-technology/high e-transaction integration), ineffective e-networks (high e-technology/low e-transaction integration), and impotent e-networks (low e-technology/low e-transaction integration).

Figure 3. E-network technology-transaction integration matrix and transformation paths



Powerful E-Network: High E-Technology/High E-Transaction Integration

In the high e-technology and high e-transaction e-network, a variety and large volume of information is transmitted between members through highly automated (or high-depth) electronic linkages like computer system-to-computer system connections. For example, the members of this powerful e-network can communicate real-time information with one another through SCM solution systems or other inter-organizational systems that are integrated with their respective internal ERP systems, thereby ensuring the visibility or transparency of supply chain business processes. A typical example would be the Cisco Systems' virtual manufacturing system. The system included 37 factories, which are linked to Cisco via the Internet. Approximately 80% of Cisco's purchase orders were automatically released via the Internet to its members. By using this virtual system, Cisco's partners manufactured all the components, performed 90% of the subassembly work, and conducted 55% of the final assembly. Furthermore, the system allowed Cisco to speed time-to-market of its products through collaboration with its suppliers and customers (Ansley, 2000). In other words, through the virtual manufacturing system, Cisco was able to create the right design in a shorter time frame by sharing information seamlessly with its partners in the process of new product development, including prototyping, design change, and quality testing.

The potential benefits that can be realized by this powerful e-network are not greatly affected by e-network type. In the case of advanced hub and net e-networks, the highly automated and integrated electronic linkages enable their members to perform simultaneous, real-time communications with one another directly (net e-networks) or indirectly through a platform (hub e-networks). Even in the less advanced tree e-network, the information and data sent by one member can be rapidly transmitted throughout the e-network without any interruption, because the fully integrated electronic linkages within and between members can automatically handle and deliver electronic documents in a sequential order across the e-network. Therefore, this powerful e-network can eliminate or significantly reduce labors needed for intra- and inter-organizational information exchanges, resulting in eliminating keyed-in errors, lowering information transaction costs, increasing information sharing, and making timely information available to all participants.

In addition, the powerful e-network can help members to eliminate or substantially mitigate so-called "bullwhip effects" in a supply chain. The bullwhip effects can occur when the members make ordering decisions based on the orders only from the next downstream member rather than all the chain members (Lee, Padmanabhan, & Whang, 1997). In this case, each member tends to overestimate the demand of its products to ensure on-time delivery, and order raw materials and components based on the inflated forecasting. The overestimated order variability is then amplified across the supply chain, resulting in high inventory, poor customer service, lost revenues, misguided capacity plans, ineffective transportation, and missed production schedules (Lee et al., 1997). Therefore, in order to reduce the bullwhip effects and improve the total supply chain performance, the extent of information sharing needs to increase in a supply chain (Yu, Yan, & Cheng, 2001). All firms within such a powerful e-network are most likely to achieve a wide range of informational, operational, and strategic e-network benefits to the maximum. Further, the high level of information transactions across the chain can warrant its partners' IT investments.

Inefficient E-Network: Low E-Technology/High E-Transaction Integration

In the low e-technology and high e-transaction integration e-network, active information transactions occur between members, mostly through inefficient low-depth electronic linkages, such as file-to-file connections (e.g., e-mail exchanges between trading partners), since many members have not yet integrated their own internal IS with an IOS, such as Web-EDI, extranets, and SCM solution systems. Some chain partners may not even have any electronic connections with other members, and may rely on traditional communication media like fax and phone for their inter-firm communication needs.

Therefore, this type of e-network usually employs numerous employees to manually handle a large volume and variety of information transmission; such human intervention may result in slow and inaccurate information transactions and/or less information sharing between members. Consequently, those firms are likely to incur "opportunity costs" and fail to gain the maximum potential of IT benefits by additional investment on their IS infrastructure.

One typical example of such inefficient network could be found in the case of one of the Komatsu America Corp.-Peoria Manufacturing Operations (KAC-PMO). The company is a world-leading producer of special, heavy mining equipment, which has approximately 350 direct materials suppliers. Although KAC-PMO had its own ERP system in place and made various types of data, such as sales forecasts and an e-catalog electronically available to its key suppliers through the system, both the company and its suppliers had to utilize mostly traditional communication channels to exchange information, because there was a lack of fully integrated IOSs between them (Versendaal & Brinkkemper, 2003). According to Versendaal and Brinkkemper (2003):

> *[KAC-PMO's] forecast reports and purchase orders were printed and faxed to suppliers. Suppliers keyed-in order data when receiving a purchase order fax. Suppliers provided [order] fulfillment dates to KAC-PMO on paper or by phone. KAC-PMO entered promise dates of supplier fulfillment manually. Purchase order change proposals needed to be approved manually.* (p. 44)

Later, under the heavy pressure of the needs to share a large amount of information with its key suppliers more frequently, KAC-PMO decided to implement an electronic trading exchange system, which enables the company to connect with most of its suppliers electronically.

It is worth noting that when some members form a hub or net e-network in a small segment of this inefficient e-network, the negative impacts of the overall low e-technology integration on the speed, accuracy, and timeliness of information transmission may be restricted only to the remainder of the members linked by low-depth electronic connections. On the other hand, if this inefficient e-network takes the form of a tree e-network and thus all information transmission across the e-network should be performed in a sequential fashion, most of the supply chain members will gain very limited informational benefits because of some "bottleneck" members, which inadvertently make delays or errors in transferring information through their low-depth electronic connections, requiring frequent human interventions.

Ineffective E-Network: High E-Technology/Low E-Transaction Integration

Even though most members in the high e-technology and low e-transaction integration e-network adopt modern IT, they use their highly integrated electronic linkages just to transmit a small volume and few types of documents. Thus, such underutilization of the e-network causes those firms to incur "out-of-pocket costs" and achieve only minimal benefits from their IT investments.

The high e-technology/low e-transaction integration e-network can often be found in a small supply chain or a partial segment of a large supply chain, where a focal company has a dominant position and coerces other members to adopt intra- and inter-organizational IS. In this case, the coerced members tend to be reluctant to share their critical information with the focal company because they fear that the dominant firm would exploit the information to its own advantage, resulting in an ineffective e-network. Mostly, this phenomenon is due to the lack of trust, collaboration, and win-win thinking. The failure of Covisint, a hub e-network in the automotive industry, represents a good example of the gloomy future of the ineffective e-network that fails to transform itself into the powerful e-network and justify its huge IT investment. As a joint venture of Ford, General Motors, and DaimlerChrysler, Covisint promised to bring more suppliers to the table of the OEM giants, lower the cost of transactions, open up the market for suppliers, and create visibility in the chain (Campbell, 2004).

However, while the suppliers of the big three were pushed to adopt Covisint, mistrust between the vehicle manufacturers and their suppliers resulted in the resistance from the suppliers (Koch, 2002). Particularly, the major first tier suppliers were reluctant to utilize Covisint since they wanted to maintain their own data and subcontractors separately from the system (Rosenberg, 2003). Furthermore, many suppliers viewed such a network as a ‘competitive-edge equalizer’. That is, if all parties are using the same technology and process, it is impossible for an individual supplier to build competitive advantage (Campbell, 2004). Thus, although 11,000 auto parts suppliers utilized the Covisint in some fashion, they only occupied 10-15% of the exchange’s revenue, and the big three automotive makers accounted for the majority of the revenue. This fact implies that the Covisint (high e-technology integration) was severely underutilized (low e-transaction integration) by the downstream chain members. Eventually, the Covisint was sold to other firms in early 2004.

Impotent E-Network: Low E-Technology/Low E-Transaction Integration

In the low e-technology and low e-transaction integration e-network, most of the information exchanges between members are handled through low-depth electronic linkages and/or traditional communication media. This rather disintegrated e-network with a low volume and few types of document exchange usually slows down the pace of manufacturing processes across the supply chain, resulting in losses of its competitive edge against competitors.

Such a low e-technology/low e-transaction integration e-network can be observed in a large supply chain, where little or no chain-wide effort has been exerted to build highly integrated communication networks between members. For example, before Hewlett-Packard adopted the SCM software for its supply chain, its chain members had been using various applications with different sophistication levels, ranging from complex ERP programs to simple spreadsheets. Thus, sharing information among the chain members had been limited to passing data only to their adjacent members, and the speed of communication across the supply chain had been very slow. Consequently, this impotent e-network had slowed down the pace of the chain-wide manufacturing process and negatively affected the cash flows of all the chain members (eCompany Now Staff, 2000). In addition, the impotent e-network can often exist in a traditional EDI environment, where a dominant firm in an asymmetric relationship forces its weak trading partner to adopt EDI systems and the reluctant EDI adopters are inclined to use non-integrated, PC-based standalone EDI systems due to the lack of financial and technical resources.

STRATEGIC IMPLICATIONS OF E-NETWORK TRANSFORMATION PATHS

Of the aforementioned four groups of e-network integration, the high e-technology/high e-transaction e-network ideally provides maximum IT benefits to its members and can contribute to the sustainable competitiveness of the entire supply chain. Hence, it can be recommended that firms with e-networks falling into the other three groups (low e-technology/high e-transaction, high e-technology/low e-transaction, and low e-technology/low e-transaction) should consider transforming their e-networks into a powerful e-network (high e-technology/high e-transaction). The following section discusses three alternative transformation paths toward the powerful e-network and strategic considerations involving the transformation process.

Path 1: From Low E-Technology/High E-Transaction to High E-Technology/High E-Transaction

According to the case reported by Kok et al. (2005), Philip Semiconductors (PS) followed Path 1 in its transformation from an inefficient e-network (low e-technology/high e-transaction integration) to a powerful e-network (high e-technology/high e-transaction integration). Before 1999, Philip Semiconductors had a decentralized short-term planning process, which was disconnected from its medium-term planning. All the members of PS's supply chain, including contract manufacturers and customers, had independent weekly planning cycles based on orders from the immediate downstream member (i.e., tree e-network, low e-technology/high e-transaction). These independent processes caused long information latency and strong information distortion by poor visibility of material availability and local optimization, resulting in high bullwhip effects across the supply chain.

Later, PS implemented the collaborative planning process, which calculates the synchronized plan that determines and transmits all orders to be released at all links in the supply chain via a tightly integrated e-network system with a central (or shared) database (i.e., hub e-network; high e-transaction/high e-technology). The e-hub has enabled PS's chain members to virtually guarantee quantities and delivery time, thereby mitigating dramatically the influence of bullwhip effects and saving around US$5 million each year.

When members in an inefficient low e-technology/high e-transaction e-network attempt to fully integrate their ISs across the chain, it is recommended that they pay particular attention to the following three important issues: acquiring needed financial and technical resources, planning collectively for seeking the best software solutions, and adopting Internet-related technologies as communication channels.

First, some members in an inefficient low e-technology/high e-transaction e-network, mostly small firms, may not have sufficient financial and technical resources for integrating ISs internal and external to them. It is thus essential for a focal company to assist its partners in solving diverse and complex problems associated with IS integration.

Second, all members should take a collective planning approach to seeking optimal software solutions for the entire chain, which can avoid or significantly mitigate the adverse impacts by the lack of IS connectivity and compatibility on chain-wide information flows and ultimately reduce total e-network costs. For example, in today's chemical industry, many firms with ERP systems have been experiencing difficulties in connecting their ISs with those of other members, since they purchased the systems from various ERP vendors (e.g., SAP, Oracle) which have set their own standards (Roberts, 2000). Under such circumstances, only collective planning processes can yield a unified software solution to the various connectivity and compatibility problems. Of the three e-network structures, the net e-network is more likely to experience such problems than the tree or hub e-networks, since each member of the net e-network should establish its direct electronic linkages with the rest.

Finally, as argued by Horvath (2001), it is important for the e-network with a low e-technology integration to have the capability of open and low-cost connectivity through broadband Internet connections or virtual private networks. This capability enables small chain members to access a collaborative e-network infrastructure without a major investment in proprietary technology, thereby leading to a high level of e-network integration. In addition, third-party software and systems support for supply chain applications may play a key role in integrating small chain partners into a powerful e-network (Green, 2001; Horvath, 2001).

Path 2: From High E-Technology/Low E-Transaction to High E-Technology/High E-Transaction

Westerman and Cotteleer (1999) report the case of Tektronix Inc., a manufacturer of electronic tools and devices, which has migrated from an ineffective EDI-based net e-network (high e-technology/low e-transaction) to a powerful Internet-based hub e-network (high e-technology/low e-transaction) by following Path 2. In 1992, the company operated seven separate data centers, which were decentralized and segregated by divisions. It had over 460 legacy systems just in the United States, none of which was standardized for global operation. Moreover, each of the company's manufacturers had its own communication protocol. In order to coordinate among these manufacturers, the company had to install multiple lines and protocol converters around its global network. As a result, although the connection between these divisions and manufacturers could be regarded as a high level of integration, the performance of the overall network was still suffering. Due to the sub-optimization of the network by the different divisions, the company could not obtain real-time information of inventory and performance, and could not effectively manage customer account and credit on a global basis. Therefore, the volume and diversity of documents transmitted electronically across the entire supply chain was limited.

To overcome the ineffective use of the information systems, the company initiated a project of network restructure. By 1994, all the members in the network switched from EDI- to Internet-based systems. The company also consolidated its multiple data centers into a single one. A global ERP system was also implemented to integrate all of its business divisions together. With such an Internet-based, fully integrated hub network and improved information flow, the company was able to achieve good inventory visibility, reduce credit approval cycle time, and make better decisions.

The ineffective high e-technology/low e-transaction e-network has technologically the greatest potential to be transformed into a powerful high e-technology/high e-transaction e-network by rapidly increasing the variety and volume of information that transmitted through its already established electronic networks. One major reason for the low information transmission is that the e-network has been optimized only for its certain segment(s), rather than for the entire e-network. This sub-optimized information network discourages members from increasing document variety and volume transmitted throughout the e-network, resulting in an ineffective e-network. Hence, to optimize and standardize IS infrastructure, members should not only adopt advanced electronic linkages, but also exert collective e-network planning efforts.

Another key reason for the e-network underutilization is related to potential security risks and trust issues. There exist various types of potential security threats to the e-network: destruction or unauthorized use of information/resources; corruption or modification of information/resources;

theft, removal, or loss of information/resources; and deception via presentation of false data (Kolluru & Meredith, 2001). Because of such potential security risks and lack of mutual trust, many members might have intentionally restricted the use of their electronic linkages to exchanging just a few routine documents, and avoided adopting advanced applications that enable them to share confidential information, such as CAD/CAM, capacity, and demand data, which are essential for gaining operational and strategic e-network benefits.

Therefore, to utilize their integrated ISs to the full extent, various security technologies, such as authentication, access control, and auditing processes, are needed to ensure the confidentiality of members' critical information. In addition, it is necessary to establish legal and contractual mechanisms that regulate member behaviors and specify policies regarding the deviations from the contract terms. In an effort to establish effective security measures, all members should participate in the process of designing and implementing both technical mechanisms and legal agreements, thereby enhancing mutual trust among them. Over time, however, trust and cooperation need to be generated as a result of a series of interactions between chain members (Chopra & Meindl, 2004).

Path 3: From Low E-Technology/Low E-Transaction to High E-Technology/High E-Transaction

Liu, Zhang, and Hu (2005) report a case of one large Chinese motorcycle corporation, Nanjing Jin Chen Motorcycle, and its suppliers, which have implemented an inter-enterprise supply chain management system to move from an impotent e-network (low e-technology/low e-transaction) to a powerful e-network (high e-technology/low e-transaction), following Path 3. Before the implementation of the e-network, the company and its suppliers generally did not have efficient internally integrated information systems in place, not to mention IOSs (i.e., low e-technology/low e-transaction).

To enhance the work flows between the supply chain members, the motorcycle company initiated a project to integrate its business processes with those of its suppliers through an Internet-based IOS, which allows them to share and exchange information smoothly and quickly. Each of the supply chain members is provided with a workflow support supply chain management system, which comes with an integrated interface that enables seamless information exchange between the supply chain members. The implementation of the systems enables the company and its suppliers to share a variety of real-time information, such as statistical data, manufacturing plan, and inventory information (i.e., high e-technology/low e-transaction).

The impotent low e-technology/low e-transaction e-network is most likely to face the obstacles that both high e-technology/low e-transaction and low e-technology/high e-transaction e-networks often encounter during their transformation process towards a high e-technology/high e-transaction e-network. Thus, members of the impotent e-network should pay attention to the suggestions offered in the two previous sub-sections to increase the levels of both e-technology and e-transaction integration. Further, they may also need to address the following two issues involving the issue of supply chain size.

First, it is conceivable that members of certain segments within a large-scale supply chain have engaged in a so-called "market exchange" relationship. This type of business relationship can be easily observed in the e-marketplace, where firms neither exchange much information with one another nor develop specialized assets to work together (Bensaou, 1999). Since firms in such a relationship, if necessary, want to switch their trading partners at a low cost with minimal damage, they are not strongly motivated to invest substantial funds on the projects for inter-organizational IT integration, thereby resulting in a low e-technology/low e-transaction e-network.

To solve the e-network problems originating from the different types of business relationships among chain members, leading firms in a large-scale supply chain may need to consider a hybrid e-network that consists of multiple e-network structures and/or various levels of electronic linkages. For example, a focal company and its key chain members can establish a private e-hub that allows a large volume of information exchange and close coordination of inter-firm operations. In addition, an e-marketplace, like eSteel.com, can be offered to the firms in the "market exchange" relationship to negotiate, buy, and sell products over the Internet without heavy capital investment in their IS infrastructure.

Next, when multiple focal companies coexist in a large-scale supply chain, and each of those firms has electronic linkages with its close trading partners (e.g., first-tier suppliers or buyers), chain members will encounter various problems arising from the software incompatibility between sub-chains in their endeavor to increase e-technology and e-transaction integration simultaneously (Raupp & Schober, 2000). Thus, these focal companies are well-advised to work together to address such an issue and adopt a common standard and/or flexible technologies such as those enabled by XML (eXtensible markup language) which allow data exchange between different applications for their e-network (Meehan, 2001). Further, a recent RFID initiative by Wal-Mart with its key chain members could be considered a next-generation level of e-technology and e-transaction integration that enables all the chain members to achieve not only informational and operational benefits, but strategic benefits of their e-network.

CONCLUSION AND MANAGERIAL IMPLICATIONS

In recent years, an increasing number of companies have adopted supply chain management (SCM) as a key driver for delivering increased value to customers by focusing on their core competencies, outsourcing non-critical and/or non-competency activities to their upstream suppliers and downstream customers, and integrating all chain members to act as a single entity (Chandrashekar & Schary, 1999). Accordingly, to coordinate and synchronize various business activities at all levels across the supply chain, an effective e-network, along with its associated business process reengineering, should be adopted and implemented (Elmuti, 2002; Kehoe & Boughton, 2001).

In theory, an e-network with high e-technology/high e-transaction integration appears to be the most desirable for the companies that aspire to achieve the maximum benefits from their IT investment and in turn enhance their competitiveness in the marketplace. This fully integrated e-network makes it possible to timely exchange diverse information and data and offer real-time high visibility to all chain partners, thereby eliminating the bullwhip effect across the supply chain. At the same time, the high level of information exchange in such an e-network warrants members' IT investment. In practice, however, such an e-network is not always desirable and feasible. The varying degrees of members' IS infrastructure, competitive pressure in the marketplace, and more importantly, various types of inter-organizational relationships collectively and substantially affect the magnitude of e-network technology and transaction integration.

For example, some firms adopting a total SCM approach may seek to fully integrate chain members' IS for streamlining and synchronizing information flows across the supply chain. However, as time passes, these firms may recognize the need to disintegrate and reconfigure their entire supply chain to sustain their competitive advantages by eliminating non-value-added activities and incompetent chain members, and by utilizing distinctive competence of new members (Markus, 2000). In this case, those firms would have improved their performance by pursuing a "quick integration/

quick disintegration" IS strategy to quickly adapt themselves to changing business environments (Christiaanse & Kumar, 2000; Markus, 2000). Fortunately, the enhanced modularity (which is defined as the ability of the IS infrastructure to add, modify, and remove any software or data components with ease and with no major overall effect; see Duncan, 1995) of current ERP systems (which are mainly used as a means to integrate a firm's internal functions) and the increasing availability of the Internet (which is increasingly used as a major communication channel between firms) enable companies to adopt such a flexible and dynamic e-network strategy.

Next, managers should clearly understand key characteristics of three types of e-networks in terms of information flows control. While the information transmitted across a tree e-network could be easily intercepted or manipulated by any chain members because of its sequential nature of information flows, such a security problem can be eliminated or substantially mitigated in a net e-network, since all members can directly communicate with one another simultaneously. However, in the net e-network, conflicts concerning the ownership of information and accountability of its transactions may arise frequently, since a focal company has almost no control over the information exchange between other chain members (Kumar & van Dissel, 1996). In the case of a hub e-network, a focal company can use the e-hub to monitor all the information transmitted through a central platform. This may pose a threat to other members in that the focal company may exploit the collected information through the platform to seek its own interests rather than those of all chain participants. Another point that should be considered by managers in the adoption of high e-technology/high e-transaction e-networks is that establishing new electronic networks often entails redesigning physical supply networks and restructuring business processes internal and external to all chain members (Barratt, 2004).

Finally, it is often more difficult to manage highly automated electronic linkages in a large supply chain than a small counterpart. As argued by Raupp and Schober (2000), members in a small supply chain are likely to share common norms and attitudes, thereby enhancing their supply chain cohesion and ensuring efficient collaboration. Therefore, to establish a high e-technology/high e-transaction e-network in a small supply chain, the chain members can rely on implicit contractual arrangements to coordinate and regulate their interactions and information sharing through the e-network. In contrast, a large supply chain has such a complex e-network that there is always a probability that some members will have their direct or indirect competitors in the same chain. Consequently, these firms are often reluctant to release their sensitive information to others in the chain. Thus, to maintain a high e-technology/high e-transaction e-network, members should establish tight security mechanisms, mutual trust among members, and right alignment of roles and responsibilities toward common SCM goals, thereby preventing opportunistic behaviors of any member.

Future research, as an extension of the current study, should empirically examine the five research questions mentioned in the introduction section based on the proposed 2x2 e-network technology and transaction integration matrix, and the topology of e-networks. Since the study will explore a relatively new research area, the study of cases is deemed appropriate (Yin, 1994). For this study, multiple data collection methods, such as interviews and on-site observations, should be employed to triangulate the information collected. Interviewees are composed of top managers including IT and SCM directors from focal companies as well as their chain members, who are in charge of the design and/or implementation of e-networks. Several rounds of interviews need to be conducted with each of the interviewees through site visits or telephone calls. The collected data need to be coded and analyzed by following the procedure suggested by Miles and Huberman (1994): conducting within-case analysis (e.g., identifying each participant company's e-network transformation path) and then cross-case analysis (e.g., comparing and contrasting the e-network transformation paths adopted by different participant companies).

ABSTRACT

This study investigated user satisfaction when a new interorganizational information system (green supply chain management system; GSCMS) was introduced to a supplier by a leader in the Taiwan electronic industry. GSCMS providers, according to the requirements of the supplier network leader, trained the representatives of suppliers. All suppliers of two sample vendors (manufacturers of electronic products) were surveyed. Five putative influencing factors were considered: perceived usefulness, perceived ease of use, training, computer anxiety, and computer self-efficacy. We find four factors significantly affect user satisfaction. The results show that the training provided by focal vendors will influence the satisfaction of users. Next, the anxiety and uncertainty experienced by users decreases when they acquire more knowledge about the operation of the new GSCMS. Finally, user satisfaction can be increased by designing the functions and interfaces of a GSCMS in accordance with the user perceptions of usefulness and ease of use,

moreover, implications and suggestions are also discussed.

INTRODUCTION

European Union (EU) RoHS Directive relates to restrictions of the use of certain hazardous substances in electrical and electronic equipment, and states that from July 1, 2006, all electrical and electronic products imported into the EU must be proved not to contain six certain hazardous substances. The Ministry of Economic Affairs of Taiwan assesses that around 44 types of Taiwanese electrical and electronic products (which are exported to the EU) will be impacted by these restrictions. The directive will directly influence over 30,000 companies and annual trade of around NT$ 250 billion in Taiwan (i.e., 2.45% of the GDP), and indirectly influence over NT$ 400 billion annually (Epoch Times International, 2005). In order to facilitate the export of products to Europe, Taiwanese companies that export electrical and electronic products have embarked on implementing green supply chain management systems (GSCMSs) in order to conform to the new requirements.

Park and Krishnan (2005) point out that effective supply chain management can lower development and procurement costs, spur innovation, increase flexibility, and speed up product development. The function of a GSCMS is to ensure that all electrical and electronic products will conform to the relevant environmental controls before they are exported. The implementation of GSCMS by Taiwanese companies that export electrical and electronic products is therefore expected to be an important and necessary weapon to maintain their global competitiveness.

Generally, an electronic product was composed of a large number of raw materials that provided by many different suppliers, the formats of substances examination reports of each raw material may also be different. In the past, to obtain a substances report of an electronic product, manufactures (dominant network vendors) have to contact each raw material supplier individually and ask them to deliver their substance examination reports. Then, the focal vendors integrate all substance examination report of each raw material into a substance report of an electronic product manually. The whole process is complex, time-consuming, and easy to make mistakes to endanger the results. Besides, if there were any tiny changes on substance examination reports, the whole process will be run again.

GSCMS is a Web-based interface, which integrates with the bill of material (BOM) of dominant network vendor. This means that the GSCMS could easy obtain all the raw materials of an electronic product from the BOM. The vendors will set up an account and a password for each supplier that enables them to access the GSCMS. Once the supplier login the GSCMS, they will see a list of all raw material and requirements that they have to provide the substance examination reports and relevant information. The suppliers can upload or manage their substance examination reports online immediately. Besides, they can also search and trace all the substance examination reports status confirmed by the vendor. As long as the substance examination reports are in the valid period, they can be repeatedly used. Furthermore, GSCMS also save every substances examination reports, suppliers can download their former reports, and modify the formats to fit with other dominant network vendors' requirements. After all the substance examination reports of each raw material are entered by their supplier, the vendors can calculate the substance of their electronic products easily and accurately.

Dominant network leaders can use their superior bargaining power in an interorganizational information system to increase their competitive advantage as well as to secure supplier benefits by streamlining interorganizational processes. In Taiwan, a GSCMS is mainly constructed by focal vendors in the electrical and electronic industry, with suppliers generally not being invited to participate in its design and development. Thus, introducing a GSCMS into the supplier network will inevitably cause changes in organizational culture and in the behaviors of managers and data processing users at both the dominant network leaders and supplier sites (Soumi, 1994).

There is literature on supply chain management suggesting that a collaborative relationship is beneficial to achieving long-term competitive advantages (Faisal, Banwet, & Shankar, 2006; Hsu, 2005; Olorunniwo & Hartfield, 2001). Thus, implementing an effective win-win GSCMS requires both dominant network vendors and suppliers to accept and be satisfied with the system. The purpose of this study was to elucidate the satisfaction of suppliers who employ an interorganizational GSCMS under pressure from focal vendors. The influencing factors examined were perceived usefulness, perceived ease of use, training, computer anxiety, and computer self-efficacy. We chose two dominant network vendors (manufacturers of electronic products) and their suppliers' representatives as our research samples. The survey approach and statistical analyses were applied in this study.

The remainder of this article is structured as follows. Section 2 discusses the key factors that may affect user satisfaction with a supplier, and then describes the research model. Section 3 delineates the processes used for data collection, selection, and analysis. Section 4 presents and discusses the results from the study, and finally conclusions are drawn and suggestions for further research are presented in Section 5.

MODEL FACTORS

User satisfaction is an important indicator of the success of an information system. DeLone and McLean (1992) evaluate this through six indicators: the quality of the system, the quality of the information, the system usage, user satisfaction, individual influences, and organizational influences. In 2003 DeLone and McLean reviewed the successful information system models that were implemented during the intervening decade, and reasserted that successful information systems are those that promote user working performance and efficiency.

The parameters used to directly evaluate the success of information systems include the promotion of cost-effectiveness, productivity, accuracy of decision-making, and competitive advantage. However, at the time of the present study, the application of GSCMSs was still in its infancy, and data related to these parameters were difficult to acquire; thus, user satisfaction was chosen as an index to evaluate the success of a GSCMS. Indeed, this is consistent with many studies assessing the success of information systems based on user satisfaction (Igbaria, 1992; Ives, Olson, & Baroudi, 1983; Lee, 1995; Palvia, 1996; Whitten, 2004).

Acceptance behavior is considered to be influenced by a variety of factors, including individual differences, social influences, beliefs and attitudes, situational influences, and managerial interventions (Agarwal, 2000). The subjects in the present study were GSCMS representatives of suppliers, with the focus on the individual user level. Individual user's differences may influence user evaluations of a GSCMS in this environment. Moreover, because the GSCMS was in the introductory stage, system characteristics such as functions and interfaces had significant effects on user satisfaction. Training performances was another possible influencing factor due to the users having been trained by the GSCMS software provider. This study therefore investigated the factors influencing user satisfaction in three dimensions: system, individual differences, and training. The system dimension includes the perceived ease of use and perceived usefulness, and the factors of individual differences include computer self-efficacy and computer anxiety.

Perceived Usefulness and Perceived Ease of Use

At the time of this study, the application of GSCMSs was still in its infancy in Taiwan. At such an early stage, the most important question is what will affect user acceptance of the new type of system. The technology acceptance model (TAM) is frequently applied to predict user acceptance of new systems, where the perceived usefulness is defined as the beliefs of individuals that using a particular technology will enhance their working performance and efficiency (Davis, 1989). Hsu and Chiu (2004) believe that perceived usefulness is a critical factor to determining user satisfaction, because users can evaluate a new system directly after they have applied it. Hsu and Chiu also show that there is a positive relationship between the perceived usefulness and satisfaction of users with electronic information services. Zviran, Pliskin, and Levin (2005) demonstrates the presence of a strong positive correlation between perceived usefulness and user satisfaction, implying that perceived usefulness is one of the critical factors affecting user satisfaction with an electronic data processing system. Moreover, Bhattacherjee (2001) uses expectation confirmation theory to explore the relationship between user perceptions and satisfaction with online bank services, and declares that user satisfaction is influenced by user expectation and perceived usefulness after applying a new system.

GSCMSs represent new integrated systems for examining products that are being employed by suppliers. Before applying such a system, suppliers may assess its usefulness based on the existing processes used to examine products, with this being evaluated after the suppliers have actually used the new system. We believe the evaluation of the usefulness of a new GSCMS will affect user satisfaction. Thus, the first hypothesis is proposed as follows:

H1: *Perceived usefulness is positively related to user satisfaction with a GSCMS.*

In the TAM theory of Davis, perceived ease of use is defined as how little effort it required to use a particular system. Igbaria, Guimaraes, and Davis (1995) believe that the ease of use of an information system determines the user acceptance. Moreover, Mahmood, Burn, Gemoets, and Jacquez (2000) assert from a meta-analysis that the user perception of the value of an information system is positively correlated with its ability to support decision-making. Furthermore, Adamson and Shine (2003) point out that in a mandatory environment, perceived ease of use is the most important factor affecting user satisfaction.

The bargaining power is asymmetric when implementing a GSCMS, in that it is higher for focal vendors than for suppliers. Moreover, a GSCMS is only constructed by focal vendors; that is, without the participation of suppliers. The suppliers can only participate in transactions with focal vendors by adopting a GSCMS, and thus face a mandatory environment in such trading. From the research results mentioned above we can infer that in a mandatory environment, perceived ease of use will be one of the key factors influencing user satisfaction of suppliers who use a GSCMS. This leads to the following second hypothesis:

H2: *Perceived ease of use is positively related to user satisfaction with a GSCMS.*

Training

Amoako-Gyampha and Salam (2004) describe training as the transfer of knowledge about the basic framework and the skills needed to operate the information system to users. The aim of training is to facilitate the correct and smooth operation of an information system by its users. Training has been validated as an essential factor influencing the successful implementation of an information system (Saga & Zmud, 1994; Webster, 1998). The user satisfaction index of Bailey and Pearson (1983) evaluates user satisfaction with an electronic data processing information system, and Palvia (1996) asserts that in small companies training is a significant factor affecting user satisfaction.

Training helps users to familiarize themselves with the system (Saga & Zmud, 1994). In this study, the GSCMS was a new system for those suppliers who did not have the opportunity to participate in its development. Hence, the provision of sufficient training programs by focal vendors to users before implementing a GSCMS might reduce user resistance and increase user satisfaction. The third hypothesis is therefore stated as follows:

H3: *Training is positively related to user satisfaction with a GSCMS.*

Computer Anxiety

Individuals experience anxiety when one or more of their values are threatened, since such values form the foundation of their existence (May, 1996). When faced with a new information system, uncertainty regarding the cost, individual performance, and/or organizational effectiveness may induce anxiety in individuals. Fagan, Neill, and Wooldridge (2003-04) argue that anxiety is an unpleasant emotional reaction experienced by individuals in threatening situations, and the use of a computer appears to provide a fertile environment for such reactions. Heinssen, Glass, and Knight (1987) indicate that computer anxiety is an affective state where an individual feels fear and apprehension about interacting with the computer, and also anticipates negative outcomes from the interaction. Thus, there is a negative relationship between computer anxiety and utilization (Harrison & Rainer, 1996). The fourth hypothesis is thus as follows:

H4: *Computer anxiety is negatively related to user satisfaction with a GSCMS.*

Computer Self-Efficacy

The notion of self-efficacy comes from cognitive psychology, and refers to the perceived ability of an individual to perform a given task, which further affects behaviors and decisions (Bandura, 1986, 1997). When individuals believe that they are able to successfully perform a task, they tend to be satisfied with the outcome of their behavior (Bandura, 1986, 1997; Hsu & Chiu, 2004). Compeau and Higgins (1995) extend the concept of self-efficacy to the field of information technology, and propose the concept of computer self-efficacy that refers to individuals believing they are able to use computers effectively in any situation (Compeau & Higgins, 1995; Marakas, Yi, & Johnson, 1998; Venkatesh, Morris, Davis, & Davis, 2003).

Several studies have revealed that the confidence of individuals in using computers to perform specific tasks influences their acceptance of an information system. For example, Wu (1999) found that the computer self-efficacy and satisfaction with their computer ability were related in students after they had learnt about operating computers. Henry and Stone (1994) assert that computer self-efficacy affects user satisfaction in the use of medical information systems, and Henry and Stone (1995) demonstrate that computer self-efficacy is positively related to performance satisfaction. Hsu, Chiu, and Fu (2004) described how satisfaction with the utilization of the Web, Web self-efficacy, and user expectations determine the continuation of Web usage. Accordingly, computer self-efficacy is also regarded as an important factor for the evaluation of user satisfaction with a GSCMS. Therefore, the fifth hypothesis is as follows:

H5: *Computer self-efficacy is positively related to user satisfaction with a GSCMS.*

RESEARCH METHODOLOGY

Research Model

Drawing on the related concepts of user satisfaction discussed above, we proposed the research model shown in Figure 1 to identify the factors that affect user satisfaction with a GSCMS. The definitions and sources of the six constructs contained in the model are summarized in Table 1.

Instrument

The survey questionnaire contained three parts: (1) general demographic questions, (2) perceptual scales of each construct in the research model, and (3) one open-ended question. The demographic questions were used to collect information about the respondent's sex, age, level of education, working experience, previous experiences of using computers and the Internet, and similar experiences of applying other information systems. In the final part of survey, the respondent was free to write down any ideas about the GSCMS.

To investigate the factors that may affect supplier satisfaction with a GSCMS, the respondents were asked to indicate their degree of agreement with 42 statements, and the user satisfaction was measured by 4 items (see Table 3). The six constructs other than computer self-efficacy were scored on a 7-point Likert scale ranging from strongly disagree (=1) to strongly agree (=7). Computer self-efficacy was measured on a percentage scale comprising 10 increments, ranging from 0% (not at all confident) to 100% (totally confident). The different measurement scale of computer self-efficacy was due to follow its original development format.

Data Collection and Sample Analysis

The sample vendors of this study were two manufacturers of electronic products. The survey was conducted after two GSCMS training programs were run in 2005. The GSCMS adopted by both vendors were the same systems that implemented by a software Corporation. This Corporation is the market leader of GSCMS and holds 55% market share in Taiwan. Thus, it could be a case in point for this investigation. The paper-based questionnaires were distributed to 229 representatives of the suppliers, with the 164 returned questionnaires being examined by 4 researchers. Fourteen questionnaires were discarded due to the presence of many missing values, and hence 150 completed questionnaires were used in statistical analyses, representing a response rate of 65.5%.

Table 2 lists the demographic statistics of the sample. Among the 150 respondents, most of them (*n* = 104, 71.3%) were between 21 and 35 years

Figure 1. Factors affecting user satisfaction with a green supply chain management system, with the associated hypothesis numbers

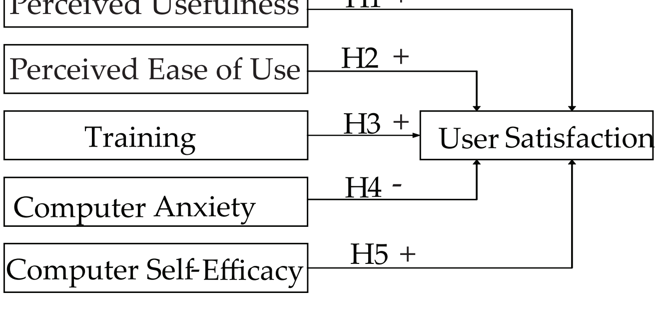

Table 1. Constructs, definitions, and sources

Construct	Definition	Sources
User Satisfaction	Users believe that an information system is able to fulfill their requirements.	Ives et al., 1983; DeLone and McLean, 1992
Perceived Usefulness	Users believe that using the system would enhance their working performance.	Davis, 1989
Perceived Ease of Use	Users believe that using the system would be free of effort.	Davis, 1989
Training	Instructing users to operate the information system correctly and smoothly.	Nelson and Cheney, 1987
Computer Anxiety	Users fear negative outcomes from using computers.	Heinssen et al., 1987; Fagan et al., 2003-04
Computer Self- Efficacy	Users believe that they are able to handle a computer well in any situation.	Compeau and Higgins, 1995; Marakas et al., 1998; Venkatesh et al., 2003

Table 2. Demographic characteristics of the samples (some frequencies do not sum to 150 due to missing data)

Characteristic	Category	Frequency	Percentage (%)
Age (years)	21–30	62	42.5
	31–35	42	28.8
	36–40	19	13.0

	8–10	42	28.6
	>10	59	40.1

continued on following page

Table 2. continued

Characteristic	Category	Frequency	Percentage (%)
Experience of Internet use (years)	<1	2	1.4
	1, 2	7	4.8
	3, 4	25	17.0
	5–7	44	29.9
	8–10	43	29.3
	>10	25	17.0
Experience of using a similar system (years)	Never	68	46.3
	<1	29	19.7
	1, 2	28	19.0
	3, 4	9	6.1
	5–7	3	2.0
	>8	1	0.7
Position	Manager	18	14.17
	Auxiliary Manager	7	5.51
	Chief of Section	17	13.39
	Sales	37	29.13
	Engineer	8	6.30
	Quality Assurance Staff	7	5.51
	Employee	33	25.98

old. The majority (*n* = 124, 84.9%) were educated to the associate's or baccalaureate degree level, and had worked for 1–3 years (*n* = 118, 69.4%). Most of them (*n* = 131, 87.1%) had used computers for at least 5 years, and had at least 5 years of experience using the Internet (*n* = 116, 76.8%). About half of the users had never used a similar information system previously (*n* = 68, 46.3%). In spite of our samples are representatives of suppliers, it is notable that among our samples, about 33% (managers, auxiliary managers and chief of section) were staffs of management level, and 1/3 (quality assurance staffs and employee) were the potential system users. The combination of our research samples was suitable for representing the suppliers' attitude toward the system usage.

DATA ANALYSIS AND DISCUSSION

Construct Validity and Reliability

First, an exploratory factor analysis was used to examine the construct validity. Principal components analysis with varimax rotation revealed that all items loaded on their expected constructs greater than the threshold loading of 0.45 for more than 150 samples (Hair, Anderson, Tatham, & Black, 1998). Cronbach's alpha coefficient was assessed to examine the internal consistency of the items in each construct, and exceeded the threshold of 0.6 recommended by Nunnally and Bernstein (1994) for all six constructs. As indicated in Table 3, all constructs in the model exhibited adequate construct validity and reliability.

Table 3. Reliability, descriptive statistics, and factor loadings

Construct (Sources) (Cronbach's alpha)	Measure	Mean	SD	Factor loading
Perceived Usefulness (Davis, 1989) (0.970)	Using the GSCMS in my job will help me to perform tasks quickly.	4.787	1.207	0.813
	Using the GSCMS will improve my working performance.	4.737	1.173	0.846
	Using the GSCMS in my job will increase productivity.	4.660	1.169	0.880
	Using the GSCMS will enhance my effectiveness in the job.	4.691	1.170	0.894
	Using the GSCMS will assist me to handle my job easily.	4.740	1.184	0.865
	The GSCMS is useful to my job.	4.927	1.136	0.810
Perceived Ease of Use (Davis, 1989) (0.956)	I believe learning how to operate the GSCMS will be easy for me.	4.739	1.028	0.846
	I can operate the GSCMS easily to complete my job.	4.620	1.054	0.879
	Interfaces of the GSCMS are clear and understandable.	4.704	1.067	0.825
	I can use the GSCMS skillfully.	4.507	1.035	0.859
	It is easy for me to become a skillful GSCMS user.	4.844	2.622	0.42
	I consider the GSCMS to be easy to operate.	4.676	1.020	0.812
Training (Amoako-Gyampah & Salam, 2004) (0.931)	The GSCMS training is comprehensive.	4.777	1.073	0.829
	My understanding of the GSCMS improved after receiving training.	4.765	1.083	0.821
	Training assists me to adopt the GSCMS with confidence.	4.698	1.041	0.753
	The length of training is adequate, and includes a detailed introduction to the GSCMS.	4.537	1.162	0.817
	Program instructors have sufficient knowledge to help me to understand the GSCMS.	4.805	1.109	0.816
Computer Anxiety (Heinssen et al., 1987) (0.950)	I am anxious about using computers.	2.704	1.432	0.909
	I am afraid that the computer will destroy my data if I press the wrong key.	2.822	1.409	0.897
	My fear of making irrecoverable mistakes makes me hesitant to use a computer.	2.510	1.423	0.945
	Computers scare me.	2.308	1.415	0.916
Computer Self-Efficacy (Venkatesh et al., 2003) (0.879)	I believe I can use the GSCMS to complete my job even without any instructions.	5.514	1.806	0.701
	With help, I can use the GSCMS to complete my job even when I encounter difficulties.	7.141	1.845	0.869
	I believe I can complete my job by using the GSCMS if I have sufficient time.	7.490	1.686	0.881
	I can complete my job by using the GSCMS if it contained a help systems.	7.280	1.755	0.875

continued on following page

Table 3. continued

Construct (Sources) (Cronbach's alpha)	Measure	Mean	SD	Factor loading
User Satisfaction (Wixom & Todd, 2005; Palvia, 1996) (0.879)	I am satisfied with the information that I receive from the GSCMS.	4.587	0.936	0.672
	I consider the GSCMS a success.	4.615	0.948	0.660
	I am satisfied with the GSCMS.	4.608	0.997	0.651
	I consider that the GSCMS fulfills my expectations.	4.538	0.988	0.633

We also examine the discriminant validity by comparing the square root of the AVEs (Average Variance Extracted) and the interconstruct correlations which indicates that more variance is shared between the construct and its indicators than with other constructs (Fornell & Larcker, 1981). Table 4 shows that the square roots of all the AVEs (i.e., the numbers on the diagonal) are greater than the correlations among constructs (i.e., the off-diagonal numbers), indicating satisfactory discriminant validity of all the constructs.

Hypothesis Testing

Multivariate regression analysis with the stepwise method was used to validate the hypothesized relationships among the research constructs. User satisfaction was set as the dependent variable, and the independent variables were perceived usefulness, perceived ease of use, training, computer self-efficacy, and computer anxiety. Multicollinearity was examined in the regression analysis using the variance inflation factor, which was below the common cutoff threshold of 10 (Hair et al., 1998) for all constructs, indicating the absence of significant multicollinearity.

Four factors, perceived usefulness (H1), perceived ease of use (H2), training (H3), and computer anxiety (H4) were significant ($P < 0.05$), indicating that they affected user satisfaction with the GSCMS. Training explained most variance (53.03%) of user satisfaction, next perceived usefulness explained 9.75% variance, and computer anxiety was negative effect that accounted 1.51%

Table 4. The square root of AVE values

Construct	Training	PU	PEOU	CA	CSE	SA
Training	**0.8857**					
PU	0.6032	**0.9333**				
PEOU	0.4989	0.5307	**0.8496**			
CA	-0.1334	-0.1357	-0.1472	**0.8373**		
CSE	0.1428	0.2218	0.2353	-0.3258	**0.8550**	
SA	0.7304	0.6920	0.5312	0.0109	0.1795	**0.9615**

Note:
1. PU=Perceived Usefulness, PEOU=Perceived Ease of Use, CA=Computer Anxiety, SA=User Satisfaction
2. The diagonal elements (in bold) represent the square root of AVE.

variance, finally perceived ease of use accounted 0.85% variance. However, computer self-efficacy (H5) was not significantly related to user satisfaction. A total of 65.14% of the variance (adjusted R^2) was accounted for user satisfaction. The hypothesis testing results were summarized in Table 5. The analysis results will be discussed in next section.

CONCLUSION AND DISCUSSIONS

This study reveals that perceived usefulness, perceived ease of use, training, and computer anxiety significantly affect user satisfaction with a GSCMS, with training being the most significant factor. GSCMSs are a new type of system for suppliers and not participating in their development. Thus, appropriate training programs can familiarize users with the functions and interface of a GSCMS so as to facilitate their operation of the system. This would also decrease the user perceptions of uncertainty when they encounter a new GSCMS, and lead to positive evaluations of the new system. The investigation by Yasin and Quigley (1994) into the viewpoints of chief executive officers on the effectiveness of information systems revealed that training decreases their anxiety about using information technology and helps them to understand the restrictions and potentiality of information technology. Moreover, William and David (1995) asserted that the training is strongly positively correlated with user satisfaction.

The EU RoHS Directive forces suppliers to search for a suitable new system that helps them to immediately conform to the regulations. The functions and interfaces of such a supply chain management system are expected to operate effectively and efficiently so as to meet the requirements of focal vendors. The results in perceived usefulness and perceived ease of use significantly influences user performance and satisfaction. As discussed earlier, the TAM has been widely and successfully adopted to predict the acceptance and usage of information systems. For example, Lin and Wu (2004) apply the TAM to the influence of end-user computing on small and medium enterprises in Taiwan. Haines and Andrew (1997) employ perceived usefulness and perceived ease of use in an exploration of the factors underpinning successful human resource management systems. Our research results similarly demonstrate the importance of user perceptions of usefulness and ease of use.

Table 5. Results from regression testing

Independent Variable	Dependent Variable (Satisfaction)			
	Standardized Coefficient (Beta)	Significance	Variance Inflation Factor	Correlation
H1: Perceived Usefulness	0.326	0.000 *	1.770	Yes
H2: Perceived Ease of Use	0.127	0.035 *	1.505	Yes
H3: Training	0.468	0.000 *	1.693	Yes
H4: Computer Anxiety	–0.141	0.005 *	1.029	Yes
H5: Computer Self-Efficacy	0.057	0.277	1.180	No
R^2	0.661			
Adjusted R^2	0.651			

*Note: *P < 0.05*, ***indicating correlated factors***

The results also show that computer anxiety is one of the significant factors affecting user satisfaction that employ a GSCMS. When adopting a new system, users will encounter both managerial and procedural changes. People instinctively tend to resist changes due to the associated anxiety. However, in our study we found that the level of suppliers had an average under 2.822 on the 7-point scale. The association between computer anxiety and user satisfaction shows that a lower computer anxiety brings higher supplier satisfaction.

Previous studies have found that computer self-efficacy is positively related to user satisfaction (e.g., Fagan et al., 2003-04), whereas in the present study we found no such relationship. According to Bandura (1997), self-efficacy improves after a new technology has actually been used, even when the users initially doubt their own ability to do this. Guskey and Tschannen-Moran (1988) also suggest that the introduction of a new technology can initially have a negative impact on users, but that their self-efficacy will improve gradually as they become accustomed to the new technology. Although computer self-efficacy did not have a significant effect on user satisfaction in our study, it is thought to affect user satisfaction after sufficient training and practical operation.

The EU is one of the most powerful economic entities in the world, and is also the main export area for Taiwan. Ever-increasing eco-awareness will mean that strict restrictions such as the RoHS Directive will increase the importance of GSCMSs in assisting suppliers. The results from this study also show that training is the most significant factor influencing supplier satisfaction with a GSCMS. Therefore, both the focal vendors and the system designers should provide training that is sufficient to increase user satisfaction of suppliers. Moreover, the results indicate that usefulness and ease of use are fundamental to the success of a system, and hence system designers must understand user requirements and the practical problems that they will encounter. With regard to computer anxiety, previous studies have indicated that people who are familiar with computers show more confidence and feel less anxiety when using computers (Coffin & MacIntyre, 1999; Loyd & Gressard, 1984;). Hence, this study argues that training is essential in order to decrease computer anxiety and promote satisfaction with a GSCMS amongst representatives of suppliers.

Finally, the use of GSCMSs is still in its infancy in Taiwan. The problems or the implications that may occur after their adoption for suppliers are not addressed in present research. Future studies should aim to develop managerial and practical solutions to all the related problems. Besides, the condition and structure of industry in Taiwan may be specific to our study, and it should be careful to generalize the research results to other countries.

Chapter 5.24

SHRM Portals in the 21st Century Organisation

Beverley Lloyd-Walker
Victoria University, Australia

Jan Soutar
Victoria University, Australia

INTRODUCTION

The importance of people to organisational success has been recognised; the implications of this for human resource departments forms the basis for the content of this article. The ways in which information technology has been used to support changes in the human resource function are discussed, leading to an exploration of the role of strategic human resource management portals. The content of strategic human resource management portals is then outlined, and covers the range of information they currently provide and their future role. Finally, issues relating to implementation are addressed. The need for human resource practitioners to develop a greater understanding of technology and its potential benefits is discussed. This article concludes by reiterating the uses made of strategic human resource portals and by acknowledging the need to continue to strive for improvements in the implementation of IT systems.

PEOPLE IN THE 21ST CENTURY ORGANISATION

The resources and capabilities that have the potential to provide an organisation with competitive advantage include financial, physical, and human assets. In this context, human resources include the people and their experience, knowledge, judgement, and wisdom (Barney, 1995). The move to a knowledge and service economy has created a range of changes in organisations; these changes have impacted all areas of the organisation, including the human resource (HR) function. Knowledge work and service provision are highly people-dependent, and hence the importance of people to the success of the organisation has increased with this change. Today's managers rely heavily on people for achievement of their goals; they recognise that people have become their greatest competitive weapon.

Whereas the primary focus of the past has been on managing financial and physical assets, the recognition that staff, and their collective knowledge, have become important assets will require executives to pay more attention to managing people in the coming years (The Boston Consulting Group, 2005). Those entrusted with responsibility for people management within organisations—the HR department which sets the HR strategy and line managers who play a major role in implementing the strategy—now recognise the contribution of HR to organisational performance (Barney & Wright, 1998; Brockbank, 1999; Ramlall, 2003). To add strategic value, HR departments have been asked to develop strategic partnerships (Lawler & Mohrman, 2003), and to become strategically proactive (Brockbank, 1999). This is now happening (Brockbank & Ulrich, 2005).

TECHNOLOGY'S ROLE IN HR MANAGEMENT

Information technology (IT) has an important role to play in strategy formulation and implementation (Powell & Dent-Micallef, 1997), in supporting improved knowledge management processes, in customer relationship management through customer knowledge management (Bueren, Schierholz, Kolbe, & Brenner, 2005), and in organisation-wide financial performance reporting capability. Considerable effort and expense has gone into developing technology-supported financial management systems, client data bases, and data warehouses, with access to a broad range of information provided through purpose-specific portals. The HR function has also been quick to integrate technology into its operations, with the payroll process being one of the first to be automated (Lengnick-Hall & Moritz, 2003).

The HR professional's role is changing in response to changes in the workplace. In the past, the personnel department's role centred on recruiting, selecting, inducting, and paying employees. With the increased importance of people to organisational success, skills shortages as a result of the aging workforce, especially in developed countries, and reduced numbers of young people entering the workforce, HR professionals' services are required for a different range of tasks (Brockbank & Ulrich, 2005). Today's HR staff are involved in organisation-wide strategic planning. Their strategic HR plans no longer merely support achievement of organisational goals set by others; HR practitioners are developing plans to drive organisational success. This strategically proactive approach to HR (Brockbank, 1999) acknowledges that transactional HR activities must still be performed. Staff must be paid, records kept, policies and procedures developed, and HR departments must ensure legal compliance and reporting in relation to income tax, superannuation, and health and safety. But many of these operational tasks are now performed using human resource information systems (HRISs).

Using HRISs to provide employees with the information they require, through an employee self service (ESS) portal, the dependence on HR administrative officers for information provision is reduced. HRISs, especially when part of an enterprise resource planning system (ERP), are being accessed by a range of people for a variety of purposes. HR managers use the information stored within the HRIS, combined with that from other management systems, for strategic planning. HR officers use the system to store records, generate reports, and ensure legal compliance. Supervisors use these systems to track employee and unit performance, to measure their employees' productivity, to compare sick leave figures with industry standards, or to compare performance with that of other units within the organisation.

HR Portals

Strategic human resource management (SHRM) portals, like ESS portals, provide access to information for a specific group of users. SHRM and ESS portals could be seen as two levels of access to HR-related information with some organisations having one HR portal with two or more levels of access. To distinguish between provision of information to employees and access to information for strategic, organisation-wide planning, we have broken HR portals into two types: those providing information to employees (ESS), and those providing a higher, strategic planning level of information to senior and executive level staff (SHRM).

SHRM PORTALS AND ORGANISATIONAL PERFORMANCE

SHRM portals usually form part of an HRIS which, in turn, may be integrated within an ERP of which HRISs have in recent years become a subset. ERPs integrate information from a diverse range of areas and applications within an organisation (Ashbaugh & Miranda, 2002).

SHRM portals support HR managers and others involved in organisation-wide planning within organisations by providing access to information stored in an HRIS, or that contained in an ERP, for strategic planning.

Since the 1990s, it was predicted that improved HR systems would result in improved organisational performance, and this link between HR management practices and organisational performance continues to be acknowledged (Bowen & Ostroff, 2004; Guest, Michie, Conway, & Sheehan, 2003; Wright, Gardner, & Moynihan, 2003), though some suggest more research is required to fully explain this link (Paauwe & Boselie, 2005; van Veldhoven, 2005). Carmeli and Tishler (2004) found that intangible organisational elements, including human capital and culture, are positively associated with organisational performance.

HR activities, or practices which support high performance HR systems, are increasingly being incorporated in SHRM portals; those which support high performance HR systems. ESSs can free HR professionals of operational activities, enabling them to introduce high performance work practices. SHRM portals provide strategic planning information for HR and other senior managers, including line managers to whom an increasingly large range of HR activities have been devolved (Kulik & Bainbridge, 2005). Devolution further frees HR specialists for their more strategic role.

WHAT SHRM PORTALS DO

Portals enable information from multiple sources to be pooled, organised, and distributed through the gateway that the portal provides. SHRM portals enable access by a range of users to information at a variety of predetermined levels. When linked to other organisational information systems, HR information may be combined, for instance, with productivity, sales, and other information to aid high level decision making.

Supporting Devolution of HR Activities to Line

Devolution of HR activities to line means supervisors now conduct many HR activities formerly carried out by HR personnel. Recent research found line managers are now responsible for a range of day-to-day people management activities, such as managing performance, disciplinary action, coaching, and promotion decisions. However, HR's desire to reduce their involvement in a range of HR activities was not matched by line management's enthusiasm for assuming responsibility for these activities (Kulik and Bainbridge, 2005).

While line managers may feel their current role is complex and demanding enough without accepting responsibility for an increasing range of HR activities, research demonstrates that when HR staff are freed from day-to-day people management activities, they are better able to contribute to strategic planning and this, in turn, has been found to lead to improved organisational performance (Lawler & Mohrman, 2003).

Freeing HR Staff for Strategic Planning

There has been a gradual shift toward a more strategic role of HR professionals in the US, and in 2005, Australian HR managers felt they were performing a more strategic role (Sheehan, Holland, & DeCieri, 2005), although as recently as 2002, HR was reported to still be playing an administrative support role in organisations (Michelson & Kramar, 2003). Attempts were being made to devolve administrative tasks to line management using technology to support this process. Many saw IT and its various applications as having the potential to free HR professionals from transactional tasks enabling them to assume the more strategic role (Shrivastava & Shaw, 2003). This automation of transactions using e-HR is seen as the second or higher-level of use of technology to support the HR function because it goes beyond providing only information. It is this level of e-HR that is predicted to transform the HR function by liberating it from its operational role so it may become more strategic. This level of use will lead to nonstrategic HR tasks being performed faster and cheaper, while involving HR staff less in the process (Lengnick-Hall & Moritz, 2003). The study which found Australian HR managers believe they are playing a more strategic role in their organisations did not consider the impact IT may have had on this change. However, when contrasted with Michelson and Kramar's (2003) findings only two years earlier, it is possible that a recent increase in the use of IT to support the HR function has helped bring about this change.

Technology to support initiatives to devolve HR activities is important if organisations are to achieve their goal of increased success through improved people management. As well as reducing HR's transactional tasks, technology can provide line managers with the information they require to perform their increasing range of HR activities through SHRM portals. It is important that line managers can access the information they require to successfully perform their new role.

Strategic Workforce Planning

Skills shortages across developing countries as a result of the aging population present challenges for organisations wishing to succeed in the global marketplace. Strategic workforce planning requires input from a range of sources, something a SHRM portal providing access to HR and other organisational information can provide by linking a diverse range of organisational plans for product changes or service quality improvements to enter new markets, or to compete in new industry sectors.

Information on university enrolments, especially in highly specialised skills areas, is required for good strategic workforce planning. SHRM portals can also be linked to research conducted outside the organisation, which is vital for good planning.

Assisting Cultural Change

A global organisation operating within the automotive, aeronautical systems, space, electronics, and information systems fields, TRW experienced challenges in 2001 as a result of a general downturn in their markets. With two thirds of their business being within the highly competitive/low profit margin automotive industry, turning around their performance was not going to be easy. Pressure to improve shareholder value combined with a change in leadership led to TRW deciding to create systems to support what could be viewed as a cultural revolution within their organisation (Neary, 2002).

TRW developed six company-wide behaviours, to be incorporated in individual performance plans, to enable them to turn around their organisation's performance. To succeed, they needed to develop one uniform method of performance development and review for their almost 100,000 employees (Neary, 2002). The new leadership of TRW put together a team of IT experts, HR staff, and representatives from all business units to develop a Web-based employee performance and development process (EP&DP) to incorporate measurement of the six identified behaviours. The diverse team established guiding principles to ensure that the new system could be in place in just four months.

TRW benefited greatly from the new system. Good design principles ensured the system met the organisation's needs, and being user friendly paid off. Organisation-wide benefits included ensuring the six new behaviours were incorporated in all employees' performance reviews. The EP&DP enabled identification of company talent from around the world, or specific needs such as location of a degree-qualified HR manager with Chinese language skills, in minutes. The system provided wide-ranging and valuable benefits for TRW. In the second year of use, TRW claimed they were more uniformly managing "the day-to-day operations and the long term vitality of the company" (Neary, 2002, p. 498).

An example of IT supported HR systems driving change and improving organisational performance, the EP&DP enabled managers to access information to support cultural change, improve organisational performance, and manage talent. SHRM portals which incorporate access to employee performance data and enable it to be combined with other performance data (e.g., production, sales, or finance) supported change and improved organisational performance.

Supporting Knowledge Sharing

A global communications company, Ericssons, implemented an IT-supported competence management system (CMS) as part of their HR management system. Competence management ensures that both the employees and the organisation have sufficient competencies to support achievement of the organisation's objectives (Nordhaug, 1993). Ericsson's CMS included a register of competence detailing employee qualifications and experience; it enabled identification and mapping of present and future target competence levels and analysis of competence gaps across the organisation. It contained records of the outcome of HR discussions, and stored and tracked competence development actions, including training. It supported Ericsson's knowledge creation efforts by both locating "experts and stimulating emerging communities of knowing" (Hustad & Munkvold, 2005, p. 78).

Ericssons found the design and development of the CMS challenging, but the potential benefits of enabling access to competence resources worldwide, combined with the ability to link experts enabling knowledge sharing to increase innovation and stimulate new learning processes, made the challenge worthwhile. Although Ericssons is a technology savvy organization, it did confront challenges in gaining commitment to the new system and in encouraging the necessary change in employee mindsets to use the system to build individual competence (Hustad & Munkwold, 2005).

HRISs can support improved organisational performance through individual employee performance improvement. The ability to access information stored in the CMS, using the SHRM portal, is a vital element in the success of such a project. The information contained in the CMS and the linking of expertise for organisational learning have the potential to provide considerable benefits if the issues of planning, design, and implementation are managed to deliver a system which will be used to its full potential.

FUTURE ROLE OF SHRM PORTALS

SHRM portals will enable the combination and manipulation of a range of information from across the organisation to support overall organisational planning. By providing direct comparison between performance ratings, career aspirations, training completed, and qualifications and experience, selection of suitable employees for vacancies will be streamlined. Much of the increased use of SHRM portals in the future will involve extending the number of activities performed, increasing the range of information available and expanding the level of integration of HR and other organisational information.

Moving beyond HR-related information to production, financial, sales, logistics and distribution, and even research and development plans, planning for people can be linked to developments across the organisation, all geographic locations, and business units.

Health and Safety

Using the SHRM portal to record and analyse near misses and minor accidents, not just those where injuries or equipment damage are sustained, information will be available to guide the redesign of work processes, to inform changes in OH&S procedures, and to highlight OH&S training needs.

Flexible Work Practices

SHRM portals can combine and analyse information from a broad range of sources. To attract and retain quality staff, SHRM can assist innovative job design. Redesign of managerial roles can design challenging senior positions which are worked part time, perhaps linked to phased retirement. A senior manager may work only four days a week by isolating a range of tasks and responsibilities to be taken over by another member of staff. This increased responsibility may form part of a formal mentoring program, tracked through the HRIS, details of which may be accessed via the SHRM portal. The SHRM portal can provide information to those taking on new roles, and support planning for the flexible work arrangements.

Linking HR and Organisation-Wide Information

Linking HR information to other organisational information will support overall firm and HR specific strategic planning. For good people management, understanding how training, development, coaching, flexible work practices, extended leave programs, and a range of innovative HR initiatives are impacting the wider organisation will be important. Analyses can be made of staff turnover numbers or retention of key staff, absenteeism can be tracked, accident rates monitored, and the impact of changes introduced in response to analysis of near misses evaluated. Changes in employee engagement levels across areas of the organisation can be tracked and productivity and profit linked to the introduction of people management programs.

This information will be made accessible to managers through the SHRM portal.

Implementation

Planning, design, and implementation of SHRMs can be complex and require considerable cooperation and discussion between IT experts, senior HR managers, and executive management to identify the range of information required, uses to be made of the information, and levels of access required. Success will only come after considerable time investment by a range of personnel, making it a costly process, but one which has the potential to bring considerable benefits to the organisation.

Technology Acceptance

HR professionals need to learn how to communicate their needs to IT professionals. In turn, IT professionals have to develop an understanding of the HR function so that they can better communicate with and address the needs of HR staff. User acceptance will present issues to be considered in the design and implementation of sophisticated HRISs and their access points, ESS and SHRM portals. The change of management strategy, including a comprehensive implementation plan, will be required to positively influence portal acceptance across user groups (Ruta, 2005).

The aim of SHRM portals is to provide management with a range of information to guide strategic planning; hence, the SHRM portal will need to support the generation of a range of reports combining data from multiple sources for planning purposes. Benefits will only be gained when users are willing to change the way they have obtained information in the past. Of importance here is the often held view that HR professionals lack technology literacy and will not be able to communicate needs effectively to technology staff to direct the design process. Additionally, the reticence of HR professionals to use IT may influence the level of acceptance by other users because technology use will not be strongly driven by the commissioning department (HR).

HR Professionals

HRM has often been characterised as a “soft” or nontechnical profession (Townsend & Bennett, 2003). Initially, managerial resistance to such initiatives as SHRM portals was based on a fear of becoming displaced by IT. The “taking over” of HR tasks by line managers was also viewed as a threat (Lepak & Snell, 1998). However, these fears have been replaced by an enthusiasm to take on the new strategic role required of HR in today’s organisation.

IT to support the transfer of operational HR processes to technology requires of HR staff a new set of capabilities in order to perform their new role and to carry out parts of their old role in different ways (Lawler & Mohrman, 2003). This change includes the need to have HR professionals who can work with IT specialists to develop appropriate solutions (Ulrich, 2000).

If any investment in IT is to deliver value, the technology must be adopted and properly used. Only some organisations gain the full potential value of their IT investments. This may be for a variety of reasons; users may not have learned how to use technology or it may be because managers have not learned how to manage its benefits. A lack of senior executive use of IT applications means they do not experience first hand the benefits IT offers, and this leads to attitudes remaining unchanged (Pijpers & van Montfort, 2006). Successful implementation of a SHRM portal will include making strategic planners in the organisation aware of the benefits the portal can provide, and conducting training on how to use the portal to advantage. If senior HR managers use the SHRM portal, it will help to create a level of acceptance throughout the organisation.

E-business is creating new roles for HR, as well as offering creative ways of changing its role to provide increased competitive advantage by freeing HR of operational tasks. Using Web-based technologies to support the HR function will require HR and IT to form alliances to develop integrated solutions to business problems. By ensuring IT has the people and processes in place to provide systems to support decision making and service delivery, HR assists IT and IT, in turn, provides HR with “the technological infrastructure to more efficiently and effectively deliver HR” (Ulrich, 2000, p. 20).

This transformation of HR into e-HR will require HR professionals to take on the challenge of developing new skills to take advantage of the opportunities it offers. HR professionals will continue to require behavioural and strategic competencies, but they will need to add to these technological competencies (Hempel, 2004).

CONCLUSION

The increasing involvement of HR managers in the strategic planning team within organisations, and the increased use of HR information by other members of the planning team, requires new and different technology to support the planning process.

By integrating HR information with that in organisation-wide ERPs, SHRM portals support devolution of HR enable transactional HR activities to be conducted via technology, freeing HR staff for strategic planning, and support report generation for strategic planning.

To ensure that the technology delivers the gains desired of it, implementation needs to address issues of technology acceptance and use. With HR departments commonly staffed by people from nontechnology backgrounds, this raises issues which need to be addressed as part of the change program.

SHRM portals will increasingly in the future drive HR strategy implementation within organisations. They will provide information for management and strategic planners. IT/HR partnerships to plan and manage the crucial implementation stage will be required if organisations are to achieve the benefits available from SHRM portals (Ruta, 2005). The benefits that organisations might gain from SHRM portals will be limited by the quality of the planning, design, and implementation stages (Shrivastava & Shaw, 2003).

KEY TERMS

Devolution of HR to Line Management: Handing over the responsibility for the conduct of a range of HR activities to immediate supervisor.

E-HR: Using the Web to deliver HR activities in much the same way as e-business uses the Web to conduct business.

Employee Self Service: A portal which provides access to strategic information from a range of areas in the organisation, including HR, for strategic planning purposes. Using technology to enable employees to gain HR information without consulting HR staff.

Enterprise Resource Planning Systems: Systems which have the capacity to integrate information from a diverse range of areas and applications within an organisation.

Human Resource Information System: An information system designed to support the organisation's HR function. It is used to store and to distribute HR-related information, and to communicate with employees.

Human Resource Portal: A means through which HR information and HR applications can be accessed Strategic HRM portal

Strategic Planning: Devising the way in which an organisation will go about achieving its goals.

This work was previously published in Encyclopedia of Portal Technologies and Applications, edited by A. Tatnall, pp. 927-933, copyright 2007 by Information Science Reference (an imprint of IGI Global).

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of strategic information systems. Particular contributions address firm performance as it relates to IT strategy, the nature of knowledge in the IT workforce, and the effectiveness of strategic implementation. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how strategic information systems can inform their practices and behavior.

Chapter 6.1

IT-Enabled Strategy:
Implications for Firm Performance?

Paul L. Drnevich
Purdue University, USA

ABSTRACT

The rapid evolution of IT has enabled new organizational capabilities to manage knowledge and information. Given this evolution, IT systems for enabling the acquisition, processing and dissemination of knowledge may present unique opportunities, if effectively leveraged, for firm competitive capabilities. This chapter examines some of these uses of IT; offers a framework to view firm activities as knowledge Inflow, Intraflow and Outflow processes; and explores possible performance implications of some potential IT-enabled capabilities. Such IT enablement challenges some existing views of strategic management theory and suggests that theory may need to be reexamined and extended to handle some implications arising from advances in IT systems. We explore potential implications of IT-enabled capability and argue that through adopting, integrating and effectively leveraging these capabilities, firms may have the opportunity to enhance their competitive advantages and performance.

INTRODUCTION

Information processing and knowledge management (KM) systems have seen a significant evolution over the past decade. As management research from a knowledge-base view (KBV) links the competitive advantage of an organization to individual tacit knowledge (Kogut & Zander, 1992; Grant, 1996), what impact has this rapid evolution in IT capabilities, and the resultant increase in organizational abilities to now codify and more effectively acquire, store and transfer knowledge, had on firms and their performance? These changes in management information systems (MIS) capabilities may also provide cause to reexamine some of our theories and accepted views of the bounds of organizational capabilities based upon knowledge. Specifically, if a firm's KM systems are significantly augmented in terms of their capabilities for data acquisition, codification and combinative capabilities, what are the theoretical implications of the sustainability of competitive advantages and firm performance based upon such knowledge? These are the issues and implications explored in this chapter.

In this chapter, we explore IT-enabled means of acquisition of data and information, and systems for conversion of information into actionable knowledge. This is conducted through exploration of the potential impacts of KM technology in combination with variations of IT systems infrastructure. We are specifically interested in exploring the potential implications for firm performance through mediating or moderating relationships of IT resources on firm knowledge flows. We discuss how IT systems may enable organizations to more effectively acquire, codify, aggregate and allocate competitive knowledge. Through this discussion, we review common competency-based perspectives of strategic management. From this theoretical basis, we develop propositions regarding whether IT-enabled knowledge capabilities should lead to increased performance or a corresponding decrease in the firm's ability to sustain competitive advantage on that knowledge. To facilitate this, the chapter provides a brief review of research on related IT applications and platforms in the context of organizational KM processes, and then explores theoretical implications of IT-enabled KM on firm competitive advantage and performance.

ISSUES, CONTROVERSIES, PROBLEMS

The Evolution of IT-Enabled KM Capability

IT knowledge systems have evolved significantly over the past decade. These include a wide variety of approaches, which range from simple e-mail and groupware collaboration tools to extensible markup language (XML)-based workflow management systems, knowledge repository networks and aggregated knowledge portals, to complex Online Analytical Processing (OLAP)-based customer data warehouse (CRM) and data mining/business intelligence (BI) and alerting systems. Regardless of the technical system, common threads exist across IT platforms and applications. Among current and recent generational systems, these include relational database central processes, XML- and Java-based open architectures, and fairly transparent workflow management (WFM) capabilities. These solutions are significantly advanced from previous systems of only a few years ago, and the MIS field has been actively attempting to address limitations of the models underlying these technical systems.

Current generational databases have benefited from extensive theoretical advances in the areas of database design (Dey, Sarkar & De, 1998; ; Storey, Chiang, Dey, Goldstein, & Sundaresan, 1997; Storey & Dey, 2002) and database design cost-benefit considerations (Dey et al., 1998). Further, current-generation databases are more capable of handling entity matching and semantic heterogeneity, which is a key issue facing organizations with both cross-generational legacy technology and in the management of knowledge inflows. Object-oriented database approaches (Dey, Sarkar, & De, 2002), as well as significant advances using decision theoretic (Dey et al., 1998, 2002), and algebraic and probabilistic solutions to these issues (Dey & Sarkar, 1996, 2000) have also been advanced, which may benefit current and future generation databases. Therefore, the existence of prior- or current-generation databases may significantly moderate the effectiveness of current-generation IT, such as CRM systems, on the organization's ability to acquire information and generate knowledge (customer analytics), as well as create knowledge outflows to improve sales (such as sales force automation and targeted marketing campaigns). For example, based on these database system advances, we can assume that CRM systems built upon modern CDW or relational database management systems (RDBMS) systems should be more effective for KM capability than implementations less effectively integrated to online transaction processing (OLTP), or CRM implementations on older non-RDBMS systems.

IT systems also deal with the information and business process workflows that underlie the organization's activities. Advances in this area from the MIS literature include extensive analysis and conceptual introductions of modern workflow management systems (WFMS) (Bussler, 1999; Georgakopoulos, Hornick, & Sheth, 1995), as well as significant improvements in the codification and modeling of workflows (Aalst, 1998; Basu & Blanning, 2000). Of particular interest to management scholars may be findings that inter-firm and cross-organization interactions may also rely heavily on the seamless, transparent and automated exchange of information facilitated through inter-organizational workflow systems that have been advanced in recent MIS literature (Aalst & Kumar, 2003; Klingeman, Wasch, & Aberer, 1998). Additional research indicates that knowledge flows are also dependent upon open-architecture solutions and e-service platforms to facilitate inter- and intra- workflows via the Internet as evidenced through discussions of exchange and XML-based solution propositions in recent literature (Basu & Kumar, 2002; Casati & Shan, 2001).

These IT advances in the workflow area may be quite timely. Inherent uncertainty in the exogenous, real-world environment forces business decisions to be made with uncertain data and incomplete information. IT-enabled knowledge systems, based on these improved databases and workflow systems, may be utilized to provide actionable knowledge to more effectively support managerial decision making under prevalent conditions of uncertainty. These and other advances in database and workflow technology have and will enable an organization's knowledge acquisition, codification, analysis and transfer capabilities. This, in turn, may significantly enable more effective knowledge-based competitive advantages for some organizations. Further, organizations not utilizing such current-generation KM technology may likely have redundant data collection activities, difficulty sharing information between groups within the firm, and difficulty enforcing and standardizing workflows. Therefore, current-generation KM systems may be fairly reliant on the presence of current- or recent-generation WFMS-type systems to facilitate KM capabilities. However, to make more sense of the potential implications of these KM technology advances, we need to first explore the theoretical mechanisms through which they may contribute to the firm.

IT-Enabled Capability and Strategic Management Theory

What impact have these advances in IT capability had on firms' abilities to manage knowledge, and what implications might a continuing advance of IT-enabled knowledge capabilities hold for strategic management theory? Specifically, what are the theoretical implications of a firm's ability to now more effectively acquire, process, store and transfer knowledge on the sustainability of competitive advantages and firm performance based upon such knowledge?

The management field's current theoretical treatment of knowledge may perhaps be best viewed through common competency-based theoretical perspectives, such as the RBV and KBV of the firm (Barney, 1991; Grant, 1996; Kogut & Zander, 1992; Wernerfelt, 1984). In these views, RBV deals with the potential for a firm's resources to generate sustained competitive advantage if the resource is: (1) valuable; (2) rare; (3) imperfectly imitable; and (4) non-substitutable (Barney, 1991). Whereas KBV, as an outgrowth of resource-base view (RBV), treats individual or organizational knowledge as a distinctively unique resource that is the true source of sustained competitive advantage in organizations (Grant, 1996; Kogut & Zander, 1992).

Extensions of KBV have argued that the ability to transfer knowledge within the firm is a critical component of an organization's ability to build competitive advantage and appropriate rents from internal knowledge resources (Szulanski, 1996). While such competencies and/or knowledge are ideally imperfectly imitable by a firm's competitors, they are also then by nature difficult to imitate internally, and may therefore represent a limiting factor on a firm's competitive advantage if methods of effective intra-firm knowledge transfer are not institutionalized or technically enhanced. Therefore, increased adoption of modern IT-enabled KM systems could facilitate an increase in organizational knowledge flow. Further, organizations adopting these IT-enabled knowledge systems could, therefore, potentially experience increased performance. However, where, when and how should IT systems align with an organization's knowledge processes to potentially result in such IT-enabled capabilities?

SOLUTIONS AND RECOMMENDATIONS

A wide body of literature from various academic disciplines has attempted to explore and address issues of knowledge acquisition and learning processes within organizations. Some common historical perspectives may treat knowledge as a specific static construct that must be uniquely constructed. More recent research advocates examining KM from an organizational capabilities perspective (Gold, Malhotra, & Segars, 2001). This suggests that knowledge infrastructure should consist of technology as well as a supportive organizational structure and culture to effectively facilitate acquiring, processing, applying and protecting knowledge (Gold et al., 2001).

Along these lines, we suggest that one possible solution approach to better understand how IT may enhance or enable organization capabilities may be to adopt the perspective utilized in the KBV (Grant, 1996; Kogut & Zander, 1992). This perspective views knowledge as more of a complex creation evolving from data and information. KBV perspectives of KM focus on issues of how knowledge is acquired, where knowledge is stored, how learning takes place and how knowledge is transferred. Despite extensive work on knowledge and organizational capability topics, few studies have specifically or effectively addressed knowledge acquisition and transfer processes within an organization in terms of their effects on organizational performance metrics.

Organizational KM Processes

As recent work (Argote, 2000) rationalizes that technical systems may be one of the most effective means of acquiring, storing and transferring knowledge between individuals and organizations, this chapter addresses this gap by examining firm performance implications of organizational knowledge processes supported through such systems. To facilitate this approach, we design a simplified taxonomy to group organizational knowledge processes and their related IT systems into three categories based on the type of knowledge process. This simple typology is applicable to either information or knowledge flows through the organization. It consists of knowledge flows into the organization (*Inflows*), knowledge flows within the organization (*Intraflow*) and knowledge flowing out of the organization (*Outflows*). The knowledge flow typology is depicted in Table 1.

Organizational Knowledge Inflows

Organizational knowledge inflows consist of data and information entering the organization from multiple external sources and channels, which the organization can convert to actionable knowledge.

Table 1. Knowledge flow typology

	Inflows	**Intraflows**	**Outflows**
Knowledge Management Process	Knowledge search and acquisition	Knowledge codification, aggregation, recombination and intra-firm transfer	Knowledge allocation, deployment, inter-firm transfers and leakage
Information Source and Flow	External information and new hires	Internal existing data and employees	Organization
Technical System Support Applications	External databases, CRM, OLTP, open and proprietary Internet, extranets and CI systems	Internal databases, OLAP, WFMS, ERP, ELS, BI tools, Intranets, collaboration tools, e-mail/exchange systems	INET, B2B and business-to-consumer (B2C) exchanges, hubs, information security, cross-organizational WFMS and extranets

Inflows can also consist of external knowledge entering the organization through the acquisition of new individuals or interactions with individuals external to the organization.

IT systems supporting knowledge and information search and acquisition activities include external open and proprietary Internet resources and databases, online transaction processing systems for the collection of customer data, CRM systems for the analysis and handling of customer information flows to the organization, and competitive intelligence (CI) tools for acquiring and analyzing competitive information. While these systems tend to be more current, the presence of previous-generation workflow management systems as well as legacy databases and related OLTP systems in the organization may complement the effectiveness of these systems.

Therefore, leveraging a KBV perspective of treating acquired information or knowledge as a resource, and utilizing such enabling technologies to enhance the knowledge acquisition (*inflow*) processes, we make the following proposition:

Proposition #1: *Firms utilizing IT-enabled information and knowledge acquisition capabilities, in conjunction with complementary supporting technology and processes, will experience increased knowledge inflows and the benefits corresponding to these knowledge flows, compared to firms not utilizing IT-enabled information and knowledge acquisition capabilities.*

Organizational Knowledge Intraflows

Internal information flows deal with the processes of codifying, aggregating and recombining internalized information and knowledge for transfer within the organization. Complex knowledge may require IT systems for its effective codification and deployment. Knowledge requiring high internal transferability should greatly enhance organizational performance when flows are facilitated through technical systems. However, much of the valuable knowledge is usually tacit by nature, and historically has been difficult or impossible to codify until the recent advances of modern KM technologies. Further, once codified, if the knowledge is proprietary or strategic to the firm, it must also be protected and secured to avoid its potential loss and possible resulting harm to the firm. Therefore, trade-offs must be evaluated if the organization also depends on the internal transferability of strategic and proprietary knowledge.

IT systems that support internal knowledge processes include current RDBMS and prior-generation internal databases, as well as RDBMS-based customer-centric data warehouses, OLAP systems and analytical CRM/data mining/BI analysis tools. Further, intranets, knowledge repositories, collaboration tools and e-mail systems may also facilitate the intraorganizational exchange of information and knowledge. WFMS may also be employed to manage and reengineer the information system processes that underlie business activities. WFMS-type application platforms, such as Enterprise Learning Systems (ELS), are also utilized to store and manage the flow of organizational and external knowledge to and among individuals in much the same manner as enterprise resource planning (ERP) systems manage resource flows, production processes and personnel within organizations.

While it is often evidenced in system integration projects that cross-generational intra-firm legacy technology may likely serve as a constraint preventing the effective integration or full utilization of current-generation systems capabilities, some generational technology mixes may actually support intra-firm knowledge flows. For example, cross-generational technology may complement modern *intraflow* technologies by providing both a data source and repository from legacy data warehouses and WFMS-type ELS and ERP platforms for modern analytical CRM (eCRM) and analytic tools to interact with and to search, recombine and deploy intraorganizational knowledge.

Therefore, leveraging KBV perspectives on the role of generating and transferring knowledge within the organization as a means of increasing firm performance, and given technology's ability to enhance these activities, we make the following proposition regarding IT-enabled (*intraflow*) processes and firm performance:

Proposition #2: *Firms utilizing IT-enabled information and knowledge analysis and processing capabilities, in the presence of some technology combinations and supportive organizational processes, will experience increased intra-firm knowledge flows and knowledge generation benefits, compared to firms not utilizing IT-enabled information and knowledge analysis and processing capabilities, or firms utilizing it in non-supportive technological environments.*

Organizational Knowledge Outflows

Knowledge outflows consist of the firm's efforts to organize, recombine and deploy knowledge assets to create and support revenue-generating activities and opportunities for the organization. These processes may involve the exploitation of opportunities; strategic communication and positioning activities; and interactions with customers, partners, suppliers and competitors in the external environment.

IT systems supporting these activities include business to business (B2B), business to consumer (B2C) and business-to-government (B2G), public and private exchanges, Internet sales channels, cross-organizational workflow platforms and extranets. The control and protection of such flows from unwanted extra-firm knowledge transfers and leakage may also be moderated or deterred to some extent through the use of information security (INFOSEC). The existence of high degrees of IT cross-generational heterogeneity and/or extensive use of legacy-generation technology may present substantial constraints to desired knowledge outflows (limited capabilities and managed control of outflows) while challenging current-generation information security and facilitating unwanted extra-firm knowledge flows (leakage).

Therefore, based upon the KBV-motivated perspective that codified or partially codified tacit knowledge and information leakage will undermine firm sustainable competitive advantage (Grant, 1996; Kogut & Zander, 1992), as well as RBV motivations on the importance of resource rareness, value, inimitability and cost to substitute (Barney, 1991), and the technology's ability to facilitate as well as deter leakage, we make the following proposition regarding IT-enabled *outflow* processes and firm performance:

Proposition #3: *Firms utilizing IT-enabled information and knowledge dissemination capabilities, in the presence of some technology combinations* *and supportive organizational processes, should experience increased productive knowledge outflows. If unwanted extra-firm knowledge outflows (leakage) are minimized, these firms should experience greater performance compared to firms not utilizing IT-enabled knowledge capabilities, firms using unsupportive IT combinations or processes and/or firms not utilizing effective information security.*

IMPLICATIONS AND FUTURE TRENDS

So why might the issues raised in this chapter be important to future research in strategic management and information systems? Firm theory based upon the KBV accepts tacit knowledge as the source of sustainable competitive advantage within the firm (Grant, 1996; Kogut & Zander, 1992). Further, many scholars extend the RBVof the firm to include knowledge as a resource from which competitive advantage may derive (Eisenhardt & Santos, 2002). As proponents of KBV argue that once knowledge is codified, competitive advantage is subsequently unsustainable, what issues will the evolving codification capabilities of IT systems pose to this view? So, the main implications for organizational knowledge and the management of such knowledge rely in the internal structure of the firm and its support mechanisms (Grant, 1996). Further, the organizational capability to transfer and aggregate knowledge is also a key determinant of the organization's ability to grow and sustain competitive performance. Therefore, if we are to assume that organizational growth and performance are moderated by the firm's ability to manage and internally transfer and allocate organizational knowledge, and that knowledge capable of sustaining competitive advantage tends to be tacit by nature, then a firm's effectiveness at acquiring, generating and managing strategic, proprietary and complex competitive tacit knowledge should be positively related to firm growth and performance (Grant, 1996; Kogut & Zander, 1992). Thus, IT systems enabling these activities should theoretically have the potential to contribute to a firm's performance.

KBV holds that while improved knowledge flows may increase organizational performance, once competitive knowledge is codified, it can no longer be a source of sustainable competitive advantage, since replication, transfer and application of the knowledge can facilitate imitation by competitors (Grant, 1996; Kogut & Zander, 1992). Therefore, KBV predicts conflicting outcomes from technically enhanced knowledge capability: (1) A positive relationship with performance from IT-enabled capability in the short- to near-term; but (2) theoretical destruction of a firm's basis of sustaining competitive advantage in the long-term from the codification, replication and transfer of tacit knowledge. However, RBV further confounds this dichotomous theoretical prediction through its central premise that the competitive advantage derived from a resource may be sustainable as long as the resource is valuable, sufficiently protected from external leakage and unwanted outflow, and imperfectly imitable (Barney, 1991).

Regarding our propositions, given this apparent conflict between RBV and KBV, we are unsure of what assumptions to make regarding implications of IT-enabled capability on long-term performance. However, careful consideration could suggest an RBV argument that increased IT-enabled knowledge flow would not necessarily lead to a loss of long-term sustainable competitive advantage, under some conditions. Therefore, we propose that IT-enabled knowledge capability should not, in and of itself, lead to a corresponding decrease in a firm's ability to sustain competitive advantage on that knowledge in the long term. Based on these theoretical arguments from RBV and KBV, we feel that IT-enabled knowledge capabilities will facilitate opportunities for increased firm performance. However, significant further work is needed to develop and model the implications of this for strategic management theory, as well as to test these proposed implications empirically.

CONCLUSION

This chapter offered an exploration of the evolution of IT-enabled KM capabilities, and a comparison of RBV and KBV suggested implications of these advances on firm performance and sustainable competitive advantage. We argued that IT resources may enable new KM capabilities, which may, in turn, affect firm performance. However, codification and potential leakage of valuable tacit knowledge has the potential to undermine longer-term sustainable competitive advantage. Based on RBV assumptions, and the arguments put forth in this chapter, we feel that this rigid KBV argument is likely not supportable under some circumstances.

Conversely, following an RBV premise, we argue that codified tacit knowledge may be a sustainable source of competitive advantage if knowledge remains valuable, sufficiently rare (protected), imperfectly imitable (uncodifiable components) and non-substitutable. If the codified competitive knowledge is sufficiently protected/deterred from unwanted extra-firm knowledge transfers and leakage, IT-enabled KM may significantly enhance an organization’s ability to transfer intra-firm knowledge and, hence, improve competitive advantage and subsequent resulting firm performance.

However, these arguments shouldn’t necessarily limit aspects of a KBV perspective, and conversely, may point to KBV’s continued relevance by highlighting areas for extension and further refinement. Recent work advocates that the real value of KBV may be in the processes for knowledge sourcing, transferring and integration within and across organizations (Eisenhardt & Santos, 2002). In concurrence with Grant (1996) and Eisenhardt and Santos (2002), theory extension of KBV may require a more comprehensive competency-based view of the firm, which should embrace IT-enabled knowledge capabilities.

Finally, this chapter provided a starting point for examining the relationships among IT-enabled knowledge capability, firm performance and longer-term sustainable competitive advantage. We argue that through the adoption and integration of evolving IT-enabled KM, organizations may have the opportunity to significantly expand their knowledge-based capabilities. Such capability enhancement may serve as cause for reexamination of strategic management theory and its possible extension to handle these implications arising from advances in MIS research and related IT systems.

ACKNOWLEDGMENTS

We would like to thank Kent Miller, Tom Brush and Mark Shanley for their helpful comments on multiple drafts of this project throughout its development. Likewise, we’d like to thank Prabuddha De, Alok Chaturvedi, Roberto Mejias, Jungpil Hahn, Jackie Rees and Karthik Kannan of the MIS group at the Krannert School for their insights to the MIS field and its perspectives. Additionally, we’d like to thank Oana Branzei of the Schulich School at York University for her views and insights on the IT/strategy relationship and assistance with this project. Finally, we’d like to thank three anonymous reviewers from the Academy of Management 2003 conference, and the participants at our presentation and subsequent discussion for their helpful comments on an early version of this project.

Chapter 6.2

Building the IT Workforce of the Future:

The Demand for More Complex, Abstract, and Strategic Knowledge

ABSTRACT

The software development process has undergone a considerable amount of change from the early days of spaghetti code to the present state of the art of development using strategic patterns. This has caused not only changes in the toolkits that developers use, but also a change in their mindset—the way that they approach and think about software development. This study uses revealed causal mapping techniques to examine the change in mindset that occurs across the procedural to OO development transition, and lays the foundation for future studies of the OO/pattern cognitive transition. The results indicate that there is not only increasing complexity in the cognitive maps of the OO developers, but also that there is a need for the developer to shift from routine, assembly line coding to more abstract thought processes.

INTRODUCTION

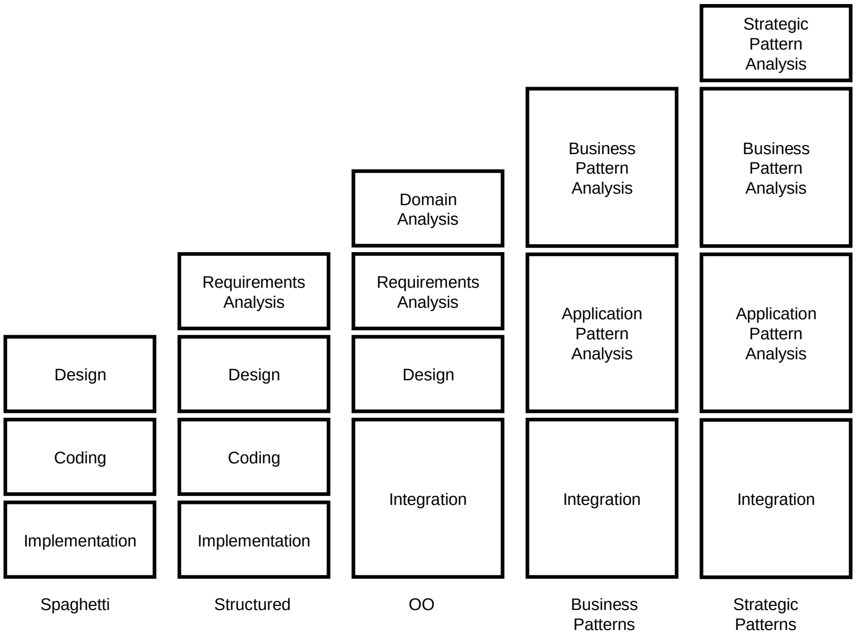
No one doubts that the software development process has undergone a profound transformation. Twenty years ago, the state of the art was the waterfall model of the systems development life cycle. The project planning and feasibility study steps were followed by systems analysis and requirements gathering, system design, coding, integration and testing, and finally installation and maintenance. The waterfall model fit very nicely within the rigid hierarchical organizational structures of the time. Functional silos and economies of scale drove software development. Systems analysts created data flow diagrams and ER diagrams and passed these to the designers. Designers would create functional decomposition diagrams and relational data models and pass these to the coders. Finally, the coders rendered all these into COBOL, FORTRAN, or a number of other procedural programming languages and database management systems. The constant translation from model to model enforced a sequence on the development process (Coad & Yourdon, 1991), with the side effect of keeping each different kind of developer in his or her place. Expert coders could not easily transition to the more abstract world of the designer and the analyst (Crowder, 1976).

The software development revolution of the 1990s began with the need for easier modeling, increased code reuse, higher quality, and easier to maintain software (Johnson, Hardgrave, & Doke, 1999). The structured programming paradigm focused on simplifying and controlling the development process (Martin & McClure, 1988) as well as increasing the efficiency and effectiveness of the development team. Where the design, code, and implementation steps of the "spaghetti code era" was replaced with a structured software engineering approach, the object oriented (OO) programming methods focus more on reuse of tested software, flexibility, and ease of maintenance with a more seamless integration of the analysis, design, and implementation development steps. This results in a development process that is incremental, concurrent, iterative, and evolutionary (Xing & Stroulia, 2005). The changes in the development process from spaghetti to structured to OO and beyond are shown in Figure 1.

The blurring of the boundaries and the smooth iteration between analysis and design in OO combined with the iterative, if not concurrent, performance of these activities has led to a cognitive blurring as well. While coders had to move to the more abstract world of analysis and design, designers had to become more analytical. Analysts, in turn, needed to move from relatively limited requirements analysis to the much more extensive domain analysis and the development of organizational information architectures (Evernden, 1996). Further, the breakdown of the barriers between the analyst and the designer and the use of models that span the lifecycle (for example, UML, Booch, Rumbaugh, & Jacobson, 1999) has created the need for more extensive project management skills. The shift from "doing analysis" then "doing design" structured by the different models in use has been replaced by an iterative and seamless development life cycle. However, just as coders have difficulty transitioning to the more abstract world of analysis, expert analysts have difficulty transitioning to the strategic world of the project planner (Nelson & Nelson, 2003).

This trend is continuing with the beginning of another software development revolution. One of the causes of recent technology project failures is the disconnect between organizational strategy and technology (Luftman & Brier, 1999; Luftman, 1996). An example of this disconnect can be found in the implementation of enterprise resource planning (ERP) systems. ERPs were sold as strategic enterprise solutions, even though at their core is a set of integrated, somewhat standardized business processes (Lee, Siau, & Hong, 2003). This approach to product development had virtually no strategic intent, and therefore ERPs, while sometimes solving process level problems,

Figure 1. The shift to the more abstract and the more strategic



often create more strategic problems than they solve (Davenport, 2000; Ezingeard & Chandler-Wilde, 1999).

The new revolution is shifting the balance of technological power from the technologists that create the technology to the managerial organizations that use technology. This revolution is creating methods for developing emerging technologies, written in a language that business decision makers understand and can control. By articulating business technology needs through understandable and consistent strategy-oriented methods (patterns), business will start to drive competitive needs down to the technologists to configure, rather than attempting to "mate" with what the technologists present to them.

A pattern-oriented development process has considerable advantages over traditional structured or OO development processes. For example, an organization encounters many problems in its day-to-day operations and in its strategic positioning against other organizations. These problems occur repeatedly in slightly different forms but with the same fundamental characteristics. A pattern is a "core of the solution" to these common problems (Alexander, Ishikawa, Silverstein, Jacobson, & Angel, 1977). Recognizing that a problem has been seen before and applying a semi-customized solution pattern to it allows faster reaction times and it "enables efficiency in both the communication and the implementation of software design, based on a common vocabulary and reference" (Adams, Koushik, Vasudeva, & Galambos, 2001).

Figure 1 shows this continuing trend. The OO revolution shifted the development process as a whole to the more abstract. The pattern revolution has again shifted the development process, first to a more organized higher-level form, then to the more strategic. While the effect on developers was well documented in the structured revolution and research is continuing on the cognitive effects of the OO revolution, the pattern-based approach to development has so far had an unknown effect on the analysts who must transition from abstract technical to abstract strategic thinking.

This article is the first step in a two-step research program that explores the cognitive differences across the OO revolution and the pattern revolution. Revealed causal mapping (RCM) techniques are used to explore how expert procedural programmers and expert OO developers exhibit expertise in their internal cognitive structures and examine the similarities and differences between the two programming paradigms. While there are general models of IS expertise (Batra, 1992; Koubek, Salvendy, Dunsmore, & LeBold, 1989; Nelson, Nadkarni, Narayanan, & Ghods, 2000), little is known about the cognitive structures of expertise that expert procedural developers and expert OO developers have and use during the software development process. Insights from this "cognitive lens" allow us to understand the differences between the two paradigms and add insight into how an individual thinks, learns, and reasons, and how his or her cognition relates to the quantity of knowledge and relationships among knowledge elements (Kraiger, Ford, & Salas, 1993). Understanding the underlying cognitive differences between the procedural and OO approaches is a first step in understanding the learning difficulties and in subsequently designing more effective relearning methods.

The second, future study examines the cognitive differences between expert OO developers and expert pattern developers to anticipate differences that may be encountered across this new revolution.

The remainder of the article is organized as follows: The second section provides an overview of prior research in software development expertise. The third section discusses the research methods used, and the fourth section provides the results. Finally, the fifth section discusses the implications of the study and suggests future areas for research.

BACKGROUND

Software development is knowledge work where the most important resource is expertise (Faraj & Sproull, 2000). There are many definitions of expertise from a cognitive perspective: the possession of a large body of knowledge and procedural skills (Bedard, 1991); an organized body of conceptual and procedural knowledge that an individual can readily access and use (Glaser & Chi, 1988); and the combination of knowledge and ability as well as the capability to use knowledge to achieve results (Nelson et al., 2000). Common to all these definitions is the idea that expertise *is a body of organized knowledge used to achieve results*. The expertise identified in this study was focused on procedural and OO software development. Procedural software development uses a set of principles in which top down design is used to develop a process-oriented, functional, modular program structure (Richardson, Butler, & Tomlinson, 1980). On the other hand, OO software development uses a set of principles where information (data) and processing (behavior) is manipulated in a manner similar to real-world objects (Brown, 1977).

The implementation phase of OO development is a cognitively incremental change from the implementation phase of procedural development (Sircar, Nerur, & Mahapatra, 2001). For example, when looking at programming in the small, an OO *method* is similar to a procedural *function*. While OO programming may appear to be simply an evolutionary development of procedural programming, it does represent a considerably different mindset for analysts (Agarwal, Sinha, & Tanniru, 1996; Boehn-Davis & Ross, 1992; Lee & Pennington, 1994). During the analysis and design phases, OO development represents a more revolutionary change from procedural development (Fichman & Kemerer, 1992; Sircar et al., 2001). The seamlessness of the models, the data-based object oriented viewpoint rather than the process-oriented viewpoint, and the shift to more abstract thinking represents a departure from procedural programming methods. Therefore, to get a holistic picture of the differences in mindsets between procedural and OO experts, this study utilized experts in all phases of the development process rather than simply one phase.

Most studies of expertise focus on the differences between novices and experts within the same software development mindset, such as the differences between novice and expert procedural programmers. In those studies, novices typically are "true novices" with little or no previous software development experience. Novices tend to form a more concrete representation of program function during software analysis, whereas experts tend to form more abstract representations (Adelson, 1981; McKeithen, Reitman, Rueter, & Hirtle, 1981; Vitalari, 1985). As a developer becomes more experienced he or she not only stops thinking in the concrete and begins thinking in the abstract, but also develops larger and larger chunks of information to represent important functional units or structures. It appears that expertise is not just a volume of knowledge, but also a way of thinking about the problem based on how that knowledge is organized (Vitalari, 1985).

From a cognitive perspective, the chasm between the procedural and OO approaches appears vast. To successfully develop software using OO requires a divergence from the procedural approach, especially during the initial phases of development. A review of the literature suggests that a systematic identification of the major constructs of procedural and OO software development expertise and the organization of those constructs has yet to receive significant attention. The studies by Sheetz and Teagarden (Sheetz, 2002; Sheetz & Teagarden, 2001) are the only ones found that explored OO developer cognitive structures; and those focused only on specific components of the OO approach. To understand the cognitive differences between expertise in procedural development and expertise in OO development we examine three key questions:

- What are the concepts that constitute expertise in procedural and OO software development knowledge?
- How are these concepts organized into cognitive structures?
- What are the similarities and differences in cognitive representations between the two software development approaches?

The answers to these questions will increase the understanding of the structural differences in the two approaches and aid the development of effective methods for retraining expert procedural developers in the OO approach.

METHOD

The purpose of this study was to understand what knowledge expert procedural and OO software developers possess and how that knowledge was organized, in essence to understand their cognitive structures. These structures are programming language-independent and relate to the conceptual, high-level abstractions that define each mindset. In order to understand these internal cognitive structures, the individuals' external cognitive representations must be examined (Pennington, 1987). With few theories in this domain available to guide the research, an exploratory approach was deemed appropriate for this study (Nelson et al., 2000).

Causal mapping, a collection of techniques used to elicit and analyze the structure and content of cognition (Axelrod, 1976; Fiol & Huff, 1992) is a qualitative research method that is suited for capturing cognitive structures and causal assertions. To understand the expert cognitive representations, *revealed* causal mapping (RCM) (Narayanan & Fahey, 1990) was used because what was captured in the maps were the concepts and causal connections that the developer revealed during the interview. RCMs are consistent with an exploratory research setting, can be used to elicit group level cognition (Bougon, Weick, & Binkhorst, 1977; Eden, Jones, Sims, & Smithin, 1981; Fiol & Huff, 1992; Narayanan & Fahey, 1990), and have been successfully used in a software development context (Nelson et al., 2000).
